- An opportunistic invasive fungal infection caused by *Fusarium* species, affecting predominantly immunocompromised patients, particularly those with prolonged neutropenia or hematological malignancies. It causes disseminated infection with skin lesions, bloodstream infection, and involvement of multiple organs. It is resistant to many antifungal agents, requiring voriconazole or amphotericin B. Mortality is high. **Gartner duct cyst**

- A benign cyst arising from remnants of the mesonephric (Wolffian) duct along the lateral wall of the vagina or uterus. They are typically asymptomatic and discovered incidentally on pelvic examination or imaging. Most require no treatment unless symptomatic, in which case surgical excision is performed. They are distinguished from other vaginal cysts by their location along the anterolateral vaginal wall.

Gaucher's disease

- See [Storage Diseases](#). **Giant right atrium**
- Marked dilatation of the right atrium, most commonly caused by chronic severe tricuspid regurgitation, Ebstein anomaly, or long-standing atrial fibrillation with right heart failure. The enlarged atrium may cause compression of adjacent structures, arrhythmias, and thrombus formation. Diagnosis is by echocardiography or cardiac imaging. Treatment targets the underlying cause.

Glucose-6-phosphate dehydrogenase deficiency

- An X-linked enzymopathy affecting approximately 400 million people worldwide, causing episodes of hemolytic anemia triggered by oxidative stress from infections, certain drugs including primaquine and sulfonamides, and fava beans. G6PD is essential for generating NADPH to protect red blood cells from oxidative damage. Diagnosis is by quantitative G6PD assay. Management is avoidance of triggers.

Harlequin color change

- A transient, benign skin color change in newborns where one half of the body becomes flushed while the other half remains pale, due to asymmetric vasomotor tone. It occurs in up to 10 percent of healthy neonates, typically when the infant is

placed on their side. The color difference is sharply demarcated at the midline and resolves spontaneously within minutes. **Herpes vegetans**

- A rare, chronic, verrucous or vegetative form of herpes simplex virus infection occurring in immunocompromised patients, particularly those with HIV/AIDS. It presents as exophytic, proliferative, ulcerative plaques on the genital or perianal skin, often refractory to standard antiviral therapy. Diagnosis is by viral culture, PCR, or biopsy showing characteristic intranuclear inclusions. Treatment requires prolonged systemic antivirals. **Hydatid cyst**

- A cyst caused by the larval stage of *Echinococcus granulosus*, a tapeworm transmitted from dogs to humans through ingestion of contaminated food. The liver is the most commonly affected organ, followed by the lungs. Cysts grow slowly and may become symptomatic from mass effect or rupture, causing anaphylaxis. Diagnosis is by imaging and serology. Treatment includes surgical excision or PAIR procedure with albendazole.

Hypercholesterolemia

- Elevated serum total cholesterol and LDL cholesterol levels, a major modifiable risk factor for atherosclerotic cardiovascular disease. It may be primary, due to familial hypercholesterolemia from LDL receptor mutations, or secondary to diet, obesity, hypothyroidism, or nephrotic syndrome. Treatment includes lifestyle modification, statins, ezetimibe, and PCSK9 inhibitors.

Hypertriglyceridemia

- Elevated serum triglyceride levels, classified as mild at 150 to 499 mg per dL, moderate at 500 to 999, and severe above 1000. Severe hypertriglyceridemia increases the risk of acute pancreatitis. Causes include obesity, diabetes, alcohol use, and genetic disorders of lipoprotein metabolism. Treatment includes dietary modification, omega-3 fatty acids, fibrates, and insulin in acute pancreatitis. **Hypocalcemia, hypophosphatemia, and hyperkalemia**

- The classic electrolyte triad of acute hypoparathyroidism, most commonly occurring

after thyroid or parathyroid surgery from inadvertent removal or devascularization of the parathyroid glands. Hypocalcemia causes tetany, paresthesias, and Chvostek and Trousseau signs.

Hypophosphatemia results from loss of PTH-mediated renal phosphate reabsorption.

Hyperkalemia results from PTH deficiency. **IgG and complement deposition at the dermis-epidermis junction**

- A pathognomonic immunofluorescence finding in systemic lupus erythematosus, where immune complexes of IgG and complement components deposit at the basement membrane zone in a continuous, linear pattern. This finding, demonstrated by direct immunofluorescence biopsy of uninvolved skin, is the lupus band test and helps confirm the diagnosis of SLE. **IgG4-related disease arteritis**

- A form of IgG4-related disease affecting large and medium-sized arteries, characterized by transmural inflammation with abundant IgG4-positive plasma cells, storiform fibrosis, and obliterative phlebitis. It may involve the aorta and its branches, causing stenosis or aneurysm formation. It is distinguished from other vasculitides by serology and histopathology. Treatment is corticosteroids with rituximab for refractory cases. **Infant harlequin syndrome**

- A transient, benign cutaneous vascular phenomenon in neonates characterized by asymmetric flushing of one half of the body with sharp midline demarcation, caused by transient asymmetric sympathetic tone. The affected side is red and warm while the contralateral side is pale. It resolves spontaneously within minutes to hours and requires no treatment. **Insect bite**

- A cutaneous reaction resulting from the injection of salivary contents from an insect during feeding, causing a localized or systemic hypersensitivity response. Common presentations include a pruritic papule or wheal with surrounding erythema. Severe reactions may include anaphylaxis, particularly with Hymenoptera stings. Treatment includes topical corticosteroids, antihistamines, and epinephrine for severe reactions.

Insulin-induced lipohypertrophy

- A common complication of subcutaneous insulin therapy characterized by localized accumulation of adipose tissue at injection sites, caused by the lipogenic effect of insulin on subcutaneous fat. It presents as firm, rubbery, non-tender subcutaneous nodules that can cause unpredictable insulin absorption and glycemic variability. Prevention requires regular injection site rotation. **Insulin lipohypertrophy**

- See [Insulin-induced lipohypertrophy](#).

Intrathoracic localized obstruction

- A focal blockage within the thoracic cavity affecting the airways, esophagus, or great vessels, leading to localized symptoms depending on the structure involved. Causes include endobronchial tumors, foreign bodies, esophageal strictures, or vascular anomalies. Diagnosis is by imaging and endoscopy. Treatment depends on the underlying cause and may include endoscopic intervention or surgery. **Iron deficiency**
- The most common nutritional deficiency worldwide, resulting from inadequate iron intake, impaired absorption, or chronic blood loss, leading to reduced hemoglobin synthesis and microcytic hypochromic anemia. Clinical features include fatigue, pallor, koilonychia, pica, and angular cheilitis. Diagnosis is by low serum ferritin, low transferrin saturation, and elevated red cell distribution width. Treatment is oral or parenteral iron supplementation. **JAK2**
- Janus kinase 2 is a tyrosine kinase essential for hematopoietic cell signaling. The JAK2 V617F mutation, found in over 95 percent of polycythemia vera cases and approximately 50 percent of essential thrombocythemia and primary myelofibrosis cases, causes constitutive activation of the JAK-STAT signaling pathway, leading to uncontrolled hematopoietic proliferation. Testing for this mutation is a key diagnostic step in myeloproliferative neoplasms. **Kawasaki's disease**
- An acute, self-limited systemic vasculitis of childhood, also known as mucocutaneous lymph node syndrome, primarily affecting medium-sized arteries with a predilection for the coronary

arteries. It presents with fever lasting at least five days, bilateral nonexudative conjunctivitis, oral mucosal changes, extremity changes, rash, and cervical lymphadenopathy. The most serious complication is coronary artery aneurysm.

Treatment is intravenous immunoglobulin and aspirin. **Knife-cut ulcers from Crohn's disease**

- Deep, linear, serpiginous ulcerations of the intestinal mucosa in Crohn disease, resembling cuts made by a knife. These longitudinal ulcers with heaped-up margins are characteristic of Crohn disease and help distinguish it from ulcerative colitis on endoscopy. They may cause strictures, fistulae, and bleeding. They indicate active, transmural inflammatory disease. **Left testicular torsion**
- Acute rotation of the left testis on its spermatic cord, obstructing blood flow and causing ischemia. It is a urological emergency presenting with sudden severe left scrotal pain, nausea, vomiting, and a high-riding, horizontally oriented testis with absent cremasteric reflex. Diagnosis is by color Doppler ultrasound showing reduced blood flow. Surgical detorsion within six hours is critical to salvage the testis. **Legg–Calvé–Perthes disease**
- Idiopathic avascular necrosis of the femoral head in children, typically between ages two and twelve, resulting from disrupted blood supply to the capital femoral epiphysis. It presents with insidious onset of hip pain, limp, and restricted range of motion. The disease progresses through stages of necrosis, fragmentation, reossification, and remodeling. Treatment depends on the stage and extent of involvement. **Lentigo maligna**
- A melanoma in situ that occurs on chronically sun-damaged skin, most commonly on the face of elderly individuals. It presents as a large, irregularly pigmented, slow-growing macule with variegated shades of brown and black. The radial growth phase may persist for years before invasion occurs. Treatment is surgical excision with clear margins. **Leukemic infiltration of the gingiva**
- Gingival enlargement caused by infiltration of leukemic cells, most commonly in acute myeloid

leukemia, particularly the monocytic subtype. The gingiva becomes swollen, erythematous, friable, and may bleed spontaneously. It results from leukemic cell proliferation within the gingival connective tissue. Treatment is systemic chemotherapy directed at the underlying leukemia.

Lipoatrophy

– Loss of subcutaneous adipose tissue at specific sites, most commonly caused by repeated subcutaneous injections of insulin or other medications, or associated with autoimmune conditions and HIV lipodystrophy. It presents as visible depressions in the subcutaneous tissue at injection sites, causing cosmetic concerns and unpredictable drug absorption. Prevention requires injection site rotation. **Lipodystrophy**

– See **Lipoatrophy**. **Lipomatosis**

– A rare condition characterized by the diffuse, symmetric, non-encapsulated proliferation of mature adipose tissue, most commonly affecting the pelvis and lower extremities. Unlike simple lipomas, lipomatosis involves infiltration of fat into surrounding structures without encapsulation, making surgical excision difficult. It may cause pain, nerve compression, and functional impairment. Treatment is surgical debulking when symptomatic. **Loa loa**

– The African eye worm, a filarial nematode transmitted by Chrysops deer flies, endemic to the rainforests of West and Central Africa. Adult worms migrate subcutaneously, causing Calabar swellings, and may cross the subconjunctiva of the eye, causing visible worm migration. Microfilariae are detected in daytime peripheral blood. Treatment is diethylcarbamazine or surgical worm extraction. **Ménétrier's disease**

– A rare acquired gastropathy characterized by massive hypertrophy of the gastric mucosal folds, particularly in the body and fundus, with foveolar hyperplasia, cystic dilation of gastric glands, and glandular atrophy. It presents with epigastric pain, nausea, vomiting, weight loss, and protein-losing enteropathy causing hypoalbuminemia. It is associated with overexpression of epidermal growth factor receptor. Treatment is supportive; gastrectomy for refractory cases. **Miliaria**

crystallina

– A benign, asymptomatic eruption of small, clear, superficial vesicles caused by obstruction of eccrine sweat ducts in the stratum corneum, occurring in hot, humid environments or during high fevers. The vesicles resemble dewdrops on the skin and rupture easily, leaving fine scales. No treatment is necessary; lesions resolve spontaneously with cooling. **Monosodium urate**

– The crystalline salt that precipitates in tissues when serum uric acid levels exceed the saturation point, forming needle-shaped, negatively birefringent crystals under polarized light microscopy. It is the pathological hallmark of gout, depositing in joints, soft tissues, and kidneys. Identification of monosodium urate crystals in synovial fluid aspirate is the gold standard for diagnosing gout. **Multiple bacterial abscesses**

– Numerous circumscribed collections of pus within an organ or tissue, caused by hematogenous seeding or direct extension of bacterial infection. They appear as multiple, low-attenuation lesions on imaging, often with peripheral enhancement. Common sites include the liver, brain, and kidneys. Treatment requires prolonged antimicrobial therapy and possibly percutaneous or surgical drainage. **Multiple biliary hamartomas**

– Benign, congenital malformations of the intrahepatic bile ducts appearing as multiple, small, well-defined cystic lesions scattered throughout the liver parenchyma on imaging. They are typically asymptomatic and discovered incidentally. They must be distinguished from metastatic disease and Caroli disease. No treatment is necessary as they are benign and do not undergo malignant transformation. **Multiple endocrine neoplasia type 2B**

– An autosomal dominant syndrome caused by RET proto-oncogene mutations, characterized by medullary thyroid carcinoma, pheochromocytoma, mucosal neuromas of the lips and tongue, and a marfanoid habitus. Medullary thyroid carcinoma in MEN 2B is aggressive and occurs at an early age. Prophylactic thyroidectomy is recommended in infancy. Genetic testing identifies at-risk family

members. **Necrobiosis lipoidica diabeticorum**

- A chronic granulomatous skin disorder most commonly associated with diabetes mellitus, presenting as well-demarcated, atrophic, yellow-brown plaques with telangiectasia, typically on the pretibial area. The plaques have a waxy, glazed appearance with a violaceous border. Ulceration occurs in approximately 35 percent of cases. Treatment includes topical corticosteroids and management of underlying diabetes.

Neonatal herpes simplex virus

- A severe neonatal infection caused by herpes simplex virus, typically acquired during passage through the birth canal, presenting within the first month of life as skin, eye, and mouth disease, central nervous system disease, or disseminated disease with multiorgan involvement. Disseminated disease carries a mortality rate exceeding 80 percent without treatment. Intravenous acyclovir is the standard of care. **Neutrophilic eccrine hidradenitis**

- A neutrophilic dermatosis characterized by neutrophilic infiltration of the eccrine glands and surrounding dermis, typically occurring in patients receiving chemotherapy, particularly cytarabine. It presents with painful, erythematous plaques or nodules, most commonly on the trunk and extremities. It is self-limited and resolves without specific treatment after discontinuation of the offending agent. **Nodular lymphoid hyperplasia**

- Benign aggregates of lymphoid tissue occurring in the gastrointestinal tract, most commonly in the small intestine, presenting as multiple small nodules on endoscopy or imaging. It may be associated with immunodeficiency states, particularly common variable immunodeficiency, and *Giardia lamblia* infection. It must be distinguished from intestinal lymphoma. Treatment targets the underlying condition.

Nummular eczema

- A chronic inflammatory dermatosis presenting as coin-shaped, well-demarcated, erythematous, vesicular, or crusted plaques, typically on the extremities. The lesions are intensely pruritic and

may be triggered by dry skin, skin trauma, or allergic contact dermatitis. It is more common in adults with atopic predisposition. Treatment includes topical corticosteroids and emollients.

Obstructive parotitis

- Inflammation of the parotid gland resulting from obstruction of the parotid duct, most commonly by sialolithiasis, presenting with painful glandular swelling that worsens with meals. The obstruction leads to stasis, secondary bacterial infection, and recurrent episodes of swelling and tenderness. Treatment includes sialogogues, antibiotics for acute infection, and surgical removal of the obstructing stone. **Odontogenic cutaneous fistula**

- An abnormal tract connecting the skin surface to a periapical dental infection, typically presenting as a draining sinus tract on the chin, cheek, or submandibular region. It results from chronic dental infection eroding through the bone and soft tissue to the skin surface. Treatment is dental extraction or endodontic therapy of the offending tooth, which leads to spontaneous fistula closure.

Ogilvie's syndrome

- Acute colonic pseudo-obstruction characterized by massive dilation of the colon, particularly the cecum and right colon, without mechanical obstruction. It occurs in hospitalized patients with serious medical or surgical conditions, often postoperatively, and results from autonomic nervous system imbalance. It carries a risk of cecal perforation. Treatment includes positional changes, neostigmine, and colonoscopic decompression.

Osborn wave

- A positive deflection at the junction of the QRS complex and ST segment on electrocardiography, also known as a J wave. It is classically associated with hypothermia, where its amplitude correlates with the degree of cooling. Osborn waves are also seen in hypercalcemia, Brugada syndrome, subarachnoid hemorrhage, and certain genetic channelopathies. Treatment is directed at the underlying cause. **Paraneoplastic disorder**

- A systemic syndrome caused by a malignancy through mechanisms other than direct invasion,

metastasis, or metabolic effects of the tumor. Paraneoplastic syndromes result from hormone production, immune-mediated mechanisms, or cytokine release by the tumor, affecting distant organs. Common examples include Lambert-Eaton myasthenic syndrome in small cell lung cancer, Cushing syndrome in ectopic ACTH production, and hypercalcemia in squamous cell carcinomas. Treatment targets the underlying malignancy.

Paternal uniparental disomy 14 (UDP 14 pat) thoracic dysplasia

– A rare genetic condition resulting from inheritance of both copies of chromosome 14 from the father, leading to dysregulated expression of imprinted genes on chromosome 14. It presents with severe thoracic hypoplasia, pulmonary hypoplasia, and characteristic facial features. It is a lethal condition in most cases. Diagnosis is by chromosomal microarray analysis. **Pelvic spleen**

– An ectopic or wandering spleen that has descended into the pelvic cavity, resulting from laxity or absence of the normal ligamentous attachments that fix the spleen in the left upper quadrant. It may present as a palpable pelvic mass, with risk of torsion, infarction, or rupture. Diagnosis is by CT or ultrasound. Treatment is surgical splenectomy to prevent torsion.

Pemberton's sign

– A clinical sign elicited by asking the patient to raise both arms above the head for one minute, causing facial plethora, cyanosis, and distended neck veins in patients with a substernal goiter or mediastinal mass compressing the thoracic inlet. A positive sign indicates venous obstruction and helps identify patients requiring further imaging and potential surgical intervention.

Periungual fibroma

– Benign, flesh-colored or pink fibrous tumors arising from the nail fold or nail bed, presenting as firm, exophytic nodules that may distort the nail plate. They occur sporadically or in association with tuberous sclerosis complex. When multiple periungual fibromas are present, they raise suspicion for tuberous sclerosis. Treatment is surgical excision for symptomatic lesions.

Peutz-Jeghers's syndrome

– An autosomal dominant condition caused by STK11 gene mutations, characterized by hamartomatous polyps throughout the gastrointestinal tract and mucocutaneous hyperpigmented macules on the lips, buccal mucosa, and digits. The polyps may cause gastrointestinal bleeding, intussusception, and obstruction. Patients have an increased lifetime risk of gastrointestinal and other cancers. Surveillance colonoscopy and endoscopy are recommended.

Pigmentary mosaicism

– A pattern of alternating hyperpigmented and hypopigmented skin patches arranged in a linear, segmental, or blaschkoid distribution, caused by genetic mosaicism from post-zygotic mutations affecting melanocyte development. It is a cosmetic condition without systemic involvement. It must be distinguished from inflammatory or nevoid conditions. No treatment is necessary unless cosmetically concerning. **Plombage**

– An obsolete surgical technique for treating pulmonary tuberculosis in which material was placed in the extrapleural space to compress the diseased lung and promote collapse therapy. Various materials including paraffin wax, lucite balls, and oil were used. It has been abandoned since the development of effective antituberculous chemotherapy but may be seen as a historical finding on imaging. **Prevertebral air**

– Gas in the prevertebral soft tissues on lateral cervical spine radiograph, indicating a breach in the aerodigestive tract. It may result from esophageal perforation, tracheal injury, retropharyngeal abscess with gas-forming organisms, or trauma. This is an urgent finding requiring immediate clinical correlation and further imaging to identify the source of the air leak.

Primary hyperoxaluria

– A group of autosomal recessive metabolic disorders characterized by overproduction of oxalate by the liver, leading to calcium oxalate deposition in the kidneys and other organs. Type 1 is caused by alanine-glyoxylate aminotransferase deficiency. It presents with recurrent nephrolithiasis, nephrocalcinosis, and progressive

renal failure. Treatment includes pyridoxine, high fluid intake, and combined liver-kidney transplantation in severe cases.

Prolactinoma

- A benign prolactin-secreting pituitary adenoma, the most common functional pituitary tumor, presenting with galactorrhea, amenorrhea, infertility, and hypogonadism in women, and decreased libido, erectile dysfunction, and visual field defects in men. Prolactin levels are markedly elevated, often above 200 ng per mL. Treatment is with dopamine agonists such as cabergoline, which normalize prolactin and shrink the tumor.

Prolapse of orbital fat

- Herniation of intraorbital fat through a dehiscence in the orbital septum, most commonly presenting as a painless, soft, reducible mass in the upper eyelid or lower eyelid. It is often age-related and may be confused with a lipoma or dermoid cyst. It is benign and requires no treatment unless cosmetically bothersome, in which case surgical excision is performed.

Protease inhibitor

- A class of antiretroviral drugs that block the viral protease enzyme responsible for cleaving polyprotein precursors into functional proteins during HIV replication, preventing the formation of mature, infectious virions. Used in combination antiretroviral therapy for HIV infection. Common side effects include gastrointestinal disturbance, lipodystrophy, and metabolic abnormalities including hyperglycemia and hyperlipidemia.

Pseudoclubbing

- Broadening and flattening of the nail tips without the complete loss of the angle between the nail and nail fold that characterizes true clubbing. It is seen in conditions such as hyperparathyroidism, rheumatoid arthritis, and psoriasis. Unlike true clubbing, pseudoclubbing does not involve fluctuation of the nail bed or loss of the Lovibond angle. Treatment addresses the underlying condition.

Pthirus pubis

- The pubic louse, a parasitic insect that infests the pubic hair and occasionally other coarse body hair, causing pediculosis pubis. Transmission is primarily through sexual contact. It causes intense pruritus and may transmit *Borrelia recurrentis*

causing relapsing fever. Diagnosis is by visual identification of the louse or nits. Treatment is topical permethrin or malathion.

Pyostomatitis vegetans

- A rare, chronic, inflammatory oral mucosal condition characterized by multiple, soft, yellowish, vegetative pustules on an erythematous base, predominantly affecting the buccal mucosa and gingiva. It is strongly associated with inflammatory bowel disease, particularly ulcerative colitis, and may precede gastrointestinal symptoms. Treatment includes systemic corticosteroids and management of the underlying bowel disease.

Radiation recall

- An inflammatory reaction that occurs in previously irradiated skin or mucosa after administration of certain chemotherapeutic agents, particularly antimetabolites and anthracyclines. It manifests as erythema, desquamation, or mucositis in the previously irradiated field, mimicking acute radiation dermatitis. Treatment is supportive with corticosteroids and topical care, and the offending chemotherapy may need to be discontinued.

Rat bite fever

- A systemic bacterial infection caused by *Streptobacillus moniliformis* or *Spirillum minus*, transmitted through rat bites or contact with rat-contaminated food or water. It presents with relapsing fever, rash, polyarthritides, and lymphadenopathy. The characteristic rash is petechial or maculopapular on the extremities. Diagnosis is by culture, which requires anaerobic conditions. Treatment is penicillin or doxycycline.

Scrofula

- Tuberculous lymphadenitis, most commonly affecting the cervical and submandibular lymph nodes, caused by *Mycobacterium tuberculosis* or atypical mycobacteria. It presents as chronic, painless, matted lymphadenopathy that may develop into cold abscesses with draining sinuses. Diagnosis is by fine needle aspiration or biopsy showing caseating granulomas, with acid-fast bacilli staining and culture. Treatment is antituberculous chemotherapy.

Seborrheic keratoses

- Common, benign, epidermal skin tumors presenting as waxy, stuck-on, pigmented plaques

with a rough, verrucous surface, typically appearing on the trunk and face of middle-aged and older adults. They are the most common benign skin neoplasm and are caused by keratinocyte proliferation. They are clinically insignificant but may be confused with melanoma. Treatment is cryotherapy or excision if symptomatic or cosmetically concerning. **Sister Mary Joseph's nodule**

- A firm, hard nodule in the umbilicus resulting from metastatic malignancy, most commonly from intra-abdominal or pelvic cancers including gastric, ovarian, and colorectal carcinoma. It indicates advanced, disseminated disease with a poor prognosis. Diagnosis is by fine needle aspiration biopsy. Treatment is directed at the underlying malignancy. **Situs inversus totalis**

- A congenital condition in which the major visceral organs are mirrored from their normal positions, with the liver on the left, heart on the right, and other viscera similarly reversed. It occurs in approximately 1 in 10,000 individuals and is often associated with primary ciliary dyskinesia (Kartagener syndrome), which includes situs inversus, bronchiectasis, and chronic sinusitis. Most individuals are asymptomatic and the condition is discovered incidentally. **Sjögren's syndrome**

- A chronic autoimmune disorder characterized by lymphocytic infiltration and destruction of exocrine glands, primarily the salivary and lacrimal glands, resulting in dry eyes (keratoconjunctivitis sicca) and dry mouth (xerostomia). It may be primary or secondary to other autoimmune diseases, particularly rheumatoid arthritis and systemic lupus erythematosus. Anti-Ro and anti-La antibodies are characteristic. Treatment is symptomatic with artificial tears and sialagogues.

Somatotropic pituitary adenoma

- A benign neoplasm of the anterior pituitary arising from growth hormone-secreting cells, causing acromegaly in adults and gigantism in children if occurring before epiphyseal closure. Patients present with coarsening of facial features, enlarged hands and feet, prognathism, soft tissue swelling, and systemic complications including diabetes, hypertension, and cardiomyopathy.

Diagnosis is by elevated IGF-1 and failure of GH suppression on oral glucose tolerance test.

Treatment is transsphenoidal surgery. **Spider angioma**

- A benign vascular lesion consisting of a central arteriole with radiating small vessels, resembling a spider, most commonly found on the face, neck, and upper trunk. They are associated with hyperestrogenic states including pregnancy, oral contraceptive use, and chronic liver disease, particularly cirrhosis. They are clinically insignificant in isolation but may indicate underlying hepatic dysfunction when numerous.

Spider bite

- A cutaneous envenomation resulting from the bite of a spider, ranging from minor local reactions to severe systemic envenomation. The brown recluse spider may cause loxoscelism with necrotic skin lesions, while the black widow spider may cause latrodectism with muscle cramps, hypertension, and autonomic dysfunction. Treatment is supportive; antivenom is available for black widow bites. **Splenic cyst**

- A fluid-filled lesion within the spleen, classified as true cysts with an epithelial lining, including congenital, epidermoid, and dermoid cysts, or pseudocysts without a lining, typically resulting from trauma, infection, or pancreatitis. Most are asymptomatic and discovered incidentally on imaging. Large or symptomatic cysts may require surgical excision or splenectomy. **Substernal goiter**

- Extension of thyroid tissue into the mediastinum, typically arising from the thyroid gland in the neck and growing downward through the thoracic inlet. It may cause compressive symptoms including dyspnea, dysphagia, and superior vena cava syndrome. Most are multinodular goiters.

Diagnosis is by CT or MRI. Surgical resection is indicated for symptomatic or rapidly enlarging lesions. **Sweet's syndrome**

- Acute febrile neutrophilic dermatosis, characterized by fever, neutrophilia, and painful, erythematous plaques or nodules on the skin, histologically showing dense neutrophilic infiltration of the dermis. It may be idiopathic,

drug-induced, or associated with malignancy, particularly hematological cancers. It responds dramatically to systemic corticosteroids.

Recurrence is common. **Synovial chondromatosis**

– A benign, metaplastic condition characterized by the formation of multiple cartilaginous loose bodies within joint synovium, bursae, or tendon sheaths. It presents with joint pain, swelling, locking, and restricted range of motion, most commonly affecting the knee, hip, and elbow. Radiographs show multiple calcified intra-articular bodies. Treatment is surgical synovectomy with removal of loose bodies. **Syphilitic gumma**

– A destructive, granulomatous lesion occurring in tertiary syphilis, characterized by a center of necrotic tissue surrounded by plasma cells, lymphocytes, and fibroblasts. Gummas may affect any organ, most commonly the skin, bones, liver, and central nervous system. They present as painless, firm nodules that may ulcerate.

Treatment is penicillin G, which typically leads to resolution of the lesion. **Tickborne relapsing fever**

– A vector-borne illness caused by *Borrelia hermsii* and related species, transmitted by *Ornithodoros* ticks. It presents with recurrent episodes of fever, headache, myalgia, and arthralgia, separated by afebrile intervals. The relapsing pattern results from antigenic variation of the spirochete's surface lipoproteins. Diagnosis is by thin blood smear during febrile episodes. Treatment is doxycycline or tetracycline. **Tissue plasminogen activator-associated angioedema**

– Angioedema occurring as a complication of tissue plasminogen activator therapy for acute ischemic stroke or myocardial infarction, affecting approximately 1 to 5 percent of patients. It typically involves the face, tongue, and upper airway and may be life-threatening. The mechanism involves bradykinin accumulation from plasmin-mediated activation of the kinin system. Treatment is fresh frozen plasma, icatibant, or C1 esterase inhibitor concentrate. **Tophaceous gout**

– Chronic tophaceous gout represents advanced gout

with deposition of large, visible tophi consisting of monosodium urate crystals surrounded by granulomatous inflammation. Tophi typically develop after years of inadequately treated gout and occur on the ears, fingers, toes, and olecranon bursa. They can cause joint destruction, deformity, and nerve compression. Treatment is urate-lowering therapy with allopurinol or febuxostat. **Torus mandibularis**

– A bony outgrowth arising from the lingual surface of the mandible, typically bilateral and located in the premolar region above the mylohyoid ridge. It is a common, asymptomatic developmental anomaly, more prevalent in women and certain ethnic populations. It rarely requires treatment unless it interferes with denture fitting or causes ulceration. **Torus palatinus**

– A bony exostosis arising from the midline of the hard palate, typically presenting as a slow-growing, asymptomatic, hard, bony protuberance discovered incidentally. It is more common in women and certain ethnic groups. It is a benign developmental anomaly that rarely requires treatment unless it interferes with denture fitting or causes discomfort.

Type III hypersensitivity reaction

– See [Hypersensitivity Type III](#). **Vernal conjunctivitis**

– A bilateral, recurrent, allergic conjunctivitis affecting children and young adults, typically occurring in spring and summer. It presents with intense ocular itching, tearing, photophobia, and mucous discharge. Palpable cobblestone papillae on the upper tarsal conjunctiva are characteristic. It is associated with atopy and elevated IgE. Treatment includes topical mast cell stabilizers, antihistamines, and corticosteroids for severe cases. **Vernal keratoconjunctivitis**

– See [Vernal conjunctivitis](#). **Vitamin A deficiency**

– A nutritional disorder resulting from inadequate intake or absorption of retinol, causing xerophthalmia, night blindness, follicular hyperkeratosis, and impaired immunity. Severe deficiency leads to corneal ulceration and blindness, and is a leading cause of preventable childhood blindness worldwide. It also increases susceptibility

to measles and diarrheal diseases. Treatment is vitamin A supplementation. **Waldenström's macroglobulinemia**

- An indolent B-cell lymphoplasmacytic lymphoma characterized by the production of a monoclonal IgM paraprotein, causing hyperviscosity syndrome with visual disturbances, bleeding, and neurological symptoms. It typically affects elderly patients and involves the bone marrow, lymph nodes, spleen, and liver. Diagnosis is by serum protein electrophoresis, bone marrow biopsy, and MYD88 mutation testing. Treatment includes rituximab-based chemotherapy.

Waldenström's macroglobulinemia

- See [Waldenström's macroglobulinemia](#).

Wilson's disease

- An autosomal recessive disorder of copper metabolism caused by mutations in the ATP7B gene, leading to impaired biliary copper excretion and toxic copper accumulation in the liver, brain, cornea, and other organs. It presents with hepatic disease, neuropsychiatric manifestations including tremor and personality changes, and Kayser-Fleischer rings on slit-lamp examination. Diagnosis is by low ceruloplasmin, elevated 24-hour urine copper, and liver biopsy. Treatment is penicillamine or trientine with zinc supplementation. **Yellow-nail syndrome**

- A rare triad of yellow, thickened, slow-growing nails, lymphedema, and chronic respiratory disease including bronchiectasis and pleural effusions. The nail changes result from impaired lymphatic drainage affecting nail growth. It typically affects middle-aged adults. Treatment is symptomatic, including nail care, compression garments for lymphedema, and management of respiratory complications.

Calcification

- See [Dystrophic Calcification](#) and [Metastatic Calcification](#).

Dermoid Cyst

- See [Dermoid](#).

Hypoplasia

- Incomplete or underdevelopment of a tissue, organ, or body structure, resulting in reduced size or functional capacity. It may be congenital, developmental, genetic, or acquired and ranges from a mild

anatomical variant to severe organ dysfunction.

Malacoplakia

- A chronic granulomatous inflammatory reaction characterized by macrophages containing basophilic Michaelis-Gutmann bodies. It most often affects the urinary or gastrointestinal tract and may form mass-like lesions that mimic malignancy.

Chapter 30

Pediatrics

Hypotonia

- Abnormally reduced muscle tone, causing decreased resistance to passive movement and a floppy or poorly supported posture. It may result from muscle, peripheral nerve, neuromuscular-junction, spinal-cord, brain, genetic, or metabolic disorders and requires evaluation when persistent or associated with weakness or developmental delay.

Microcephaly

- A head size substantially smaller than expected for age and sex, usually defined by an occipitofrontal circumference below the third percentile or more than two standard deviations below the mean. Causes include genetic disorders, congenital infections, brain injury, malnutrition, and impaired brain development.

Bilirubin Encephalopathy

- Neurologic injury caused by deposition of unconjugated bilirubin in the brain, especially the basal ganglia. Severe neonatal hyperbilirubinemia can produce acute lethargy, abnormal tone, feeding difficulty, seizures, and permanent kernicterus.

Ganglioneuroblastoma

- A pediatric tumor of the sympathetic nervous system containing both neuroblastic and ganglion-cell elements. It most often arises in the adrenal or paraspinal region and may present with an abdominal mass, pain, hypertension, or systemic symptoms.

Natal Teeth

- Teeth present at birth, most often involving the lower central incisors. They may be loose, interfere with feeding, or injure the infant's tongue and require dental assessment.

Neonatal Conjunctivitis

- Inflammation of the conjunctiva during the first

month of life, caused by chemical irritation, bacteria, or viruses acquired during delivery. Purulent discharge, eyelid swelling, and corneal involvement require urgent evaluation.

Infant Botulism

- A neuromuscular illness caused by intestinal colonization with *Clostridium botulinum* and production of botulinum neurotoxin in infants. It causes constipation, poor feeding, weak cry, hypotonia, facial weakness, and descending paralysis.

Encopresis

- Recurrent passage of stool in inappropriate places by a child who is developmentally old enough for bowel control. It is commonly associated with chronic constipation and fecal retention, with overflow soiling around impacted stool.

Intestinal Malrotation

- Congenital failure of normal midgut rotation and fixation, predisposing to a narrow mesenteric base, volvulus, and duodenal obstruction. Infants may present with bilious vomiting, abdominal distension, or bowel ischemia; sudden symptoms require emergency assessment. Upper gastrointestinal contrast imaging or ultrasound supports diagnosis, and symptomatic malrotation is treated surgically.

Acne

- A chronic inflammatory disorder of the pilosebaceous unit, extremely common during adolescence. Pathogenesis involves sebum production, follicular hyperkeratinization, *Cutibacterium acnes* colonization, and inflammation. Grading: comedonal, papulopustular, nodulocystic. Treatment: topical retinoids, benzoyl peroxide, and antibiotics for mild to moderate; isotretinoin for severe or refractory disease. Early treatment prevents scarring.

Acute Otitis Media

– Infection of the middle ear space with acute onset of symptoms and signs of middle ear inflammation. Diagnosis requires middle ear effusion plus acute symptoms (ear pain, fever, irritability) or signs (bulging tympanic membrane, erythema). Most common pathogen: *Streptococcus pneumoniae*. Treatment: amoxicillin for 10 days; amoxicillin-clavulanate for treatment failure or concurrent sinusitis.

ADHD

– Attention deficit hyperactivity disorder: a neurodevelopmental disorder with inattention, hyperactivity, and impulsivity inappropriate for age, affecting function in school/home; onset before 12 years, persistence ≥ 6 months in ≥ 2 settings. Subtypes: inattentive, hyperactive-impulsive, combined. Comorbidities: learning disorders, anxiety, depression, ODD, tics. Diagnosis: clinical (DSM-5 criteria), rating scales (Conners, Vanderbilt), history from parents/teachers; exclude hearing/vision, sleep, anxiety, and trauma. Management: behavioral/parent training first (preschool), stimulants (methylphenidate) or non-stimulants (atomoxetine, guanfacine) for school-age, structured environment, and educational support; monitor growth and side effects.

Adolescent Health

– The health and wellbeing of young people (10-19 years), addressing the physical, psychological, and social transitions of puberty and adolescence. Key issues: growth/development (puberty, menarche), nutrition (obesity, eating disorders), mental health (depression, anxiety, suicide—leading causes of morbidity), sexual health (contraception, STIs, pregnancy), substance use (tobacco, alcohol, drugs), injuries/violence, and preventive care (immunizations—HPV, Tdap; screening). Confidentially provided care, HEADSSS assessment (Home, Education, Activities, Drugs, Sexuality, Suicide, Safety), and a non-judgmental approach are essential. Early identification and intervention improve long-term outcomes.

Alagille Syndrome

– An autosomal dominant disorder caused by mutations in *JAG1* (95%) or *NOTCH2* ($<5\%$), affecting the Notch signaling pathway. Features: chronic

cholestasis from paucity of intrahepatic bile ducts (90-100%), cardiac anomalies (peripheral pulmonary stenosis most common, also tetralogy of Fallot), butterfly vertebrae (50%), posterior embryotoxon (a ring in the anterior chamber of the eye, 90%), and characteristic facies (broad forehead, deep-set eyes, pointed chin, 90-95%). Presents in infancy with prolonged jaundice, pruritus, and failure to thrive. Other findings: renal anomalies (30-50%), hypercholesterolemia, and coagulopathy from fat malabsorption. Diagnosis: clinical criteria (Alagille score) and *JAG1*/*NOTCH2* genetic testing. Management: ursodeoxycholic acid for cholestasis, fat-soluble vitamin supplementation, nutritional support, cardiac repair as needed, and liver transplantation for end-stage liver disease (15-20%).

Angelman Syndrome

– A genetic disorder caused by loss of function of the *UBE3A* gene on chromosome 15 (maternal deletion or paternal uniparental disomy). Features: severe intellectual disability, absent speech, seizures, ataxia, and frequent laughter. Characteristic happy demeanor with hand-flapping movements. Management: seizure control, physical therapy, and communication support.

Annular Pancreas

– A congenital anomaly where a ring of pancreatic tissue completely or partially encircles the second portion of the duodenum, causing duodenal obstruction. It results from failure of the ventral pancreatic bud to completely rotate around the duodenum during embryogenesis. Associated with Down syndrome, duodenal atresia (coexisting in 50%), and other GI anomalies. Presents in the newborn period with bilious or non-bilious vomiting (depending on the position relative to the ampulla) and polyhydramnios (prenatal). In adults, may present with recurrent pancreatitis or peptic ulcer disease. Diagnosis: upper GI series shows a narrowed, eccentric duodenum with obstructive findings; CT or MRCP demonstrates the pancreatic tissue ring encasing the duodenum. Treatment: surgical bypass (duodeno-duodenostomy or duodeno-jejunostomy) without resection of the annular tissue (risk of pancreatitis and fistula). Prognosis: excellent after surgical repair.

Anorectal Malformation

– A spectrum of congenital anomalies involving the anus and rectum, classified by the location of the rectal pouch relative to the puborectalis sling: Low (passes through the levator muscle, good prognosis) — perineal fistula, vestibular fistula, or covered anus. High (ends above the levator muscle, poor prognosis, 60%) — rectourethral fistula (boys), rectovaginal fistula (girls), or rectobladder neck fistula. Cloaca (girls): a single common channel for the urethra, vagina, and rectum. Presents with absence of a normal anal opening on perineal examination and failure to pass meconium within 24 hours. Associated anomalies (VACTERL workup): vertebral, cardiac (VSD), tracheoesophageal, renal (VUR, renal agenesis), and limb. Diagnosis: invertogram (Wangensteen-Rice X-ray) and cross-table lateral X-ray to determine the level. MRI for complex cases. Treatment: low lesions — primary perineal anoplasty. High lesions — colostomy in the newborn period, followed by posterior sagittal anorectoplasty (PSARP, deVries-Peña procedure) at 3-6 months. Prognosis: low lesions — excellent bowel control. High lesions — variable fecal continence, requiring bowel management programs (enemas, laxatives, antegrade continence enema).

Anorexia Nervosa

– An eating disorder characterized by restriction of energy intake, intense fear of weight gain, and distorted body image. Highest mortality of any psychiatric disorder. Features: emaciation, lanugo, bradycardia, hypotension, amenorrhea, and electrolyte abnormalities. Diagnosis by DSM-5 criteria. Treatment: nutritional rehabilitation, cognitive behavioral therapy, and family-based therapy. Medical stabilization when severely malnourished.

Apert Syndrome

– An autosomal dominant craniosynostosis syndrome caused by FGFR2 mutations (most commonly Ser252Trp or Pro253Arg). Features: craniosynostosis (bilateral coronal, resulting in turri-brachycephaly — tower-shaped skull), midface hypoplasia, proptosis, hypertelorism, and syndactyly of the hands and feet (mitten or spade-like hands, complete fusion of digits). Cleft palate occurs in 30%. May have intellectual disability (variable). Other associations: cervical spine fusion, congen-

ital heart disease, and hydrocephalus. Diagnosis: clinical and genetic testing. Management: staged surgical reconstruction — cranial vault remodeling (3-6 months), midface advancement (Le Fort III, 6-12 years), and syndactyly release (6-18 months). Lifelong neurosurgical and dental monitoring.

Apgar Score

– Rapid clinical assessment of newborn well-being performed at 1 and 5 minutes after birth. Five criteria scored 0-2 each: Appearance (skin color), Pulse (heart rate), Grimace (reflex irritability), Activity (muscle tone), and Respiration. Total score 0-10. Score 7-10 normal; 4-6 moderately depressed; 0-3 severely depressed. Determines need for immediate resuscitation. May extend to 10 and 20 minutes in severely depressed infants.

Apnea of Prematurity

– Cessation of breathing for more than 20 seconds or shorter episodes with bradycardia or desaturation in infants less than 34-37 weeks gestation. Three types: central (no respiratory effort), obstructive (airway collapse), and mixed. Treatment: caffeine citrate (first-line), continuous positive airway pressure, and methylxanthine therapy. Monitor with cardiorespiratory monitors. Most resolve by 34-44 weeks corrected gestational age.

Brief Resolved Unexplained Event (BRUE)

– A sudden, brief, and now-resolved episode in an infant involving abnormal breathing, skin color, muscle tone, or responsiveness, with no explanation after the initial evaluation. Risk assessment is based on age, history, examination findings, and recurrence; higher-risk events require targeted investigation.

Argininosuccinic Aciduria

– Autosomal recessive urea cycle disorder caused by deficiency of argininosuccinate lyase (ASL gene, 7cen-q11.2). Biochemical hallmark: accumulation of argininosuccinic acid in blood, urine, and CSF with hyperammonemia, low citrulline, and elevated argininosuccinic acid. Neonatal form presents within days of birth with poor feeding, vomiting, lethargy, tachypnea, seizures, and progressing to coma; milder late-onset forms present later with developmental delay, intellectual disability, hepatic dysfunction, and brittle hair (trichorrhexis nodosa).

Diagnosis: plasma amino acids (elevated citrulline, argininosuccinic acid), urine orotic acid, enzyme assay in erythrocytes, and ASL genetic testing. Treatment: ammonia scavenging (sodium benzoate, sodium phenylbutyrate, glycerol phenylbutyrate), arginine supplementation (provides an alternative excretion route via argininosuccinate in urine), low-protein diet, and liver transplantation in severe cases.

Arnold-Chiari Malformation

- Herniation of cerebellar tonsils through the foramen magnum into the upper cervical spinal canal. Type II (myelomeningocele-associated) is the most common form in pediatrics. Associated with hydrocephalus, syringomyelia, and spinal cord dysfunction. Symptoms include headache, neck pain, and lower cranial nerve palsies. Treatment: posterior fossa decompression with duraplasty. Often coexists with myelomeningocele requiring concurrent repair.

Babinski Reflex

- An extensor plantar response present from birth to approximately 2 years. When the lateral sole is stroked, the great toe dorsiflexes and other toes fan outward. Disappears as the corticospinal tract myelinates. Persistence beyond age 2 may indicate neurologic abnormality. Pathologic in older children and adults, suggesting upper motor neuron lesion. One of the primitive reflexes assessed in infants.

Bacterial Meningitis

- Infection of the meninges by bacteria, a medical emergency. In neonates: Group B Streptococcus, *E. coli*, *Listeria*. In older children: *Neisseria meningitidis*, *Streptococcus pneumoniae*. Presents with fever, headache, neck stiffness, altered consciousness, and Kernig/Brudzinski signs. Diagnosis by lumbar puncture. Treatment: immediate empiric antibiotics (ceftriaxone and vancomycin) without delaying for imaging.

Ballard Score

- Clinical assessment of gestational age in newborns using 6 physical and 6 neuromuscular maturity criteria. Physical parameters: skin texture, ear form and recoil, eye appearance, breast tissue, and genitalia. Neuromuscular: posture, arm and leg recoil, popliteal angle, scarf sign, and heel-to-ear. Each scored 0-5; total converted to gestational age in

weeks. Most accurate near term; used when prenatal dating is uncertain.

Beckwith-Wiedemann Syndrome

- An overgrowth disorder associated with 11p15.5 imprinting defects. Features: macrosomia, macroglossia, omphalocele, visceromegaly, and neonatal hypoglycemia. Increased risk of embryonal tumors (Wilms tumor, hepatoblastoma). Management: glucose monitoring, tumor surveillance with abdominal ultrasound and AFP levels, and surgical correction of structural anomalies.

Bilious Vomiting

- Vomiting of green/yellow, bilious material in the newborn or infant, defined as emerald green or yellow vomitus that contains bile. In neonates (first days to weeks), it is a surgical emergency until proven otherwise, often indicating intestinal obstruction at or below the ampulla of Vater: differential includes duodenal atresia (Down syndrome, polyhydramnios, "double bubble" radiograph, bilious vomiting on day 1), malrotation with midgut volvulus (true emergency, "corkscrew" upper GI series, Ladd procedure), jejunoileal atresia (distension, bilious vomitus, intraperitoneal calcifications on radiograph), meconium ileus (cystic fibrosis), Hirschsprung disease, and necrotizing enterocolitis. In older children: gastroenteritis, intussusception (currant-jelly stool), appendicitis, post-treatment vomiting due to pyloric stenosis (typically NON-bilious). Workup: abdominal X-ray, contrast upper GI series, ultrasound, electrolyte/fluid resuscitation, NPO, NG decompression, surgical consultation.

Binge Eating Disorder

- Recurrent episodes of eating large quantities of food with a sense of lack of control, without regular compensatory behavior. Associated with obesity, depression, and anxiety. Diagnosis by DSM-5 criteria. Treatment: cognitive behavioral therapy, interpersonal therapy, and SSRIs. Weight management with dietary counseling and exercise.

Biotinidase Deficiency

- An autosomal recessive inborn error of biotin recycling caused by BTM gene mutations, resulting in inability to cleave biotin from biocytin (proteolytic degradation product of biotin-dependent carboxylases). This leads to multiple carboxylase de-

iciency affecting four biotin-dependent enzymes: pyruvate carboxylase, propionyl-CoA carboxylase, 3-methylcrotonyl-CoA carboxylase, and acetyl-CoA carboxylase. Presents between 1 week and 10 years of age (mean 3 months). Features: neurological — seizures (myoclonic, infantile spasms), hypotonia, ataxia, hearing loss, and optic atrophy; cutaneous — periorificial dermatitis, alopecia, and candidal infections; metabolic — metabolic acidosis, ketolactic acidosis, and organic aciduria (3-hydroxyisovalerate, 3-methylcrotonylglycine, lactate, propionate). Diagnosis: biotinidase enzyme assay in serum and BTD genetic testing. Included in newborn screening in many countries. Treatment: oral biotin (5-20 mg/day) — a dramatically effective and inexpensive therapy. Starting biotin promptly reverses most symptoms except sensorineural hearing loss and optic atrophy, which may be irreversible if delayed.

Blue Baby

– Generic term for an infant with cyanosis (bluish skin, lips, nail beds) from arterial oxygen desaturation. Differential: cyanotic congenital heart disease (right-to-left shunting; classic "5 T's" of Fallot, transposition of the great arteries, tricuspid atresia, truncus arteriosus, total anomalous pulmonary venous connection; plus hypoplastic left heart syndrome, pulmonary atresia), persistent pulmonary hypertension of the newborn, respiratory disorders (respiratory distress syndrome, meconium aspiration, congenital diaphragmatic hernia), methemoglobinemia (reduced hemoglobin cannot bind O₂), polycythemia, and sepsis. Differentiate central cyanosis (warm, blue tongue/lips from low arterial O₂) from peripheral (cold, acrocyanosis, normal O₂ saturation). Workup: hyperoxia test (100% FiO₂ for 10 min; PaO₂ > 150 mmHg suggests pulmonary cause; < 100 mmHg suggests cyanotic CHD), pre/post-ductal saturations, chest X-ray, echocardiography, ABG/anion gap, sepsis workup. Emergency management: prostaglandin E₁ infusion to maintain ductus arteriosus in duct-dependent lesions, transfer to cardiac center.

Bochdalek Hernia

– A congenital diaphragmatic hernia (CDH) occurring through the posterolateral foramen of Bochdalek, resulting from failure of the pleuroperitoneal membrane to close by the 8th week of gesta-

tion. The left side is affected in 85% of cases (the right pleuroperitoneal canal closes earlier). Abdominal organs (stomach, spleen, small intestine, colon, and sometimes the left lobe of the liver) herniate into the chest, causing pulmonary hypoplasia and pulmonary hypertension. Presents at birth with severe respiratory distress, cyanosis, scaphoid abdomen, and decreased breath sounds on the affected side with bowel sounds heard in the chest. Diagnosis: prenatal ultrasound (polyhydramnios, mediastinal shift, herniated organs), postnatal chest X-ray shows abdominal organs in the thorax. Treatment: endotracheal intubation (avoid bag-mask ventilation — distends the stomach), nasogastric decompression, and surgical repair via an abdominal approach once pulmonary hypertension is managed. Delayed surgical repair after physiologic stabilization improves outcomes. High-frequency ventilation, inhaled nitric oxide, and ECMO for severe pulmonary hypertension. Prognosis depends on the degree of pulmonary hypoplasia; LHR (lung-to-head ratio) is the best prenatal predictor.

Brachial Plexus Injury

– Damage to the brachial plexus nerves during birth, most commonly from shoulder dystocia or excessive traction. Erb's palsy (C5-C6) presents with waiter's tip position (arm adducted, elbow extended, forearm pronated). Klumpke's palsy (C8-T1) affects the hand and may cause Horner syndrome. Most cases resolve spontaneously. Physical therapy initiated early; surgical exploration considered if no recovery by 3-6 months.

Bradycardia of Prematurity

– Heart rate less than 100 beats per minute in a premature infant, often associated with apnea and oxygen desaturation. May be caused by vagal stimulation, reflux, or immaturity of the cardiac conduction system. Treatment: gentle stimulation, caffeine, and addressing underlying causes. Usually self-limited and resolves as the infant matures. Monitoring with continuous cardiorespiratory monitoring.

Branchial Cleft Cyst

– Congenital cystic mass arising from incomplete obliteration of branchial cleft apparatus during embryogenesis. Most are second branchial cleft (95%),

presenting in childhood or adolescence as a painless, fluctuant anterior neck mass along the anterior border of the sternocleidomastoid (typically at the junction of upper and middle thirds), inferior to the angle of the mandible; may enlarge with upper respiratory infections; fistula to skin can discharge; tract passes between internal and external carotid arteries to the tonsillar fossa. First branchial cleft cysts (type I or II) occur near the ear or angle of mandible, and may present with otorrhea. Third/fourth branchial anomalies present as left thyroid or pyriform sinus fistulas. Diagnosis: ultrasound, contrast fistulography, CT, MRI. Treatment: complete surgical excision of cyst and tract (after acute infection resolves); incomplete excision risks recurrence.

Breast Engorgement

- See obstetrics and gynecology.

Breath-Holding Spells

- A benign paroxysmal phenomenon in young children (6 months to 6 years), provoked by frustration, pain, or fear. Cyanotic type (more common): child cries, forcefully exhales, becomes cyanotic, and may lose consciousness briefly. Pallid type: triggered by sudden pain/fright, child becomes pale and limp, may have brief seizure-like activity due to reflex anoxic seizure. Pathophysiology: autonomic dysregulation, vagal overactivity. Diagnosis: clinical; EEG normal (distinguishing from epilepsy). Treatment: parental reassurance, management of triggers, iron supplementation if anemic. Spells resolve spontaneously by age 6. No increased risk of epilepsy or other neurological problems.

Bronchiolitis

- Lower respiratory tract infection causing inflammation and obstruction of small airways. Most common cause is respiratory syncytial virus. Affects infants under 12 months. Presents with wheezing, tachypnea, nasal flaring, and retractions. Diagnosis is clinical. Treatment: supportive care with nasal suctioning, supplemental oxygen, and respiratory support. Severe cases may require CPAP or mechanical ventilation. No effective antiviral therapy.

Bronchopulmonary Dysplasia

- A chronic lung disease of premature infants, resulting from lung injury from mechanical ventila-

tion, oxygen toxicity, and inflammation. Most commonly occurs in infants born at less than 28 weeks gestation with birth weight less than 1500 grams. Pathophysiology involves arrested alveolar and vascular development with simplified alveolar structures, decreased alveolar number, and pulmonary vascular remodeling. The National Institutes of Health consensus definition classifies severity at 36 weeks postmenstrual age or at discharge: mild (no supplemental oxygen), moderate (oxygen less than 30%), or severe (oxygen at least 30% or positive pressure ventilation). Pathogenesis is multifactorial: ventilator-induced lung injury, oxygen toxicity, infection, patent ductus arteriosus, and fluid overload. Management: lung-protective ventilation strategies, judicious oxygen therapy targeting saturations 90-95%, fluid restriction, diuretics, caffeine, and systemic corticosteroids for severe cases not weaning from ventilation. Nutritional support with high-calorie formulas to promote lung growth. Long-term complications include pulmonary hypertension, reactive airway disease, and neurodevelopmental impairment. Most infants improve with lung growth, but pulmonary function abnormalities may persist into adulthood.

Bulimia Nervosa

- An eating disorder characterized by recurrent episodes of binge eating followed by compensatory behaviors (purging, laxatives, excessive exercise). Self-esteem overly influenced by body shape and weight. Complications: electrolyte abnormalities (hypokalemia, metabolic alkalosis), dental erosion, esophageal tears, and parotid gland enlargement. Treatment: cognitive behavioral therapy and SSRIs (fluoxetine).

Caput Succedaneum

- Edema of the scalp presenting as a soft, boggy swelling that crosses suture lines. Caused by pressure of the vaginal walls on the fetal head during labor. Resolves within hours to days. Differentiated from cephalohematoma (subperiosteal, does not cross suture lines) and subgaleal hemorrhage (life-threatening, crosses suture lines). No treatment required; spontaneous resolution.

Cerebral Palsy

- A group of permanent disorders of movement and

posture development causing activity limitation, attributed to non-progressive disturbances occurring in the developing fetal or infant brain. It is the most common motor disability in childhood, affecting approximately 1 in 500 live births. Classification by motor type: spastic (80 percent, most common, includes hemiplegia, diplegia, and quadriplegia), dyskinetic (athetoid, choreoathetoid, dystonic), ataxic, hypotonic, and mixed. Spastic cerebral palsy is subclassified by distribution: hemiplegia (unilateral arm and leg), diplegia (lower limbs more affected, common in premature infants with periventricular leukomalacia), and quadriplegia (all four limbs, often with intellectual disability and seizures). Causes: prematurity, intrauterine infection, perinatal hypoxia-ischemia, intracranial hemorrhage, and genetic abnormalities. Diagnosis is clinical, based on delayed motor milestones, abnormal muscle tone, and persistent primitive reflexes. Management is multidisciplinary: physical therapy, occupational therapy, speech therapy, orthotics, spasticity management (botulinum toxin, oral baclofen, intrathecal baclofen pump), orthopaedic surgery for contractures, and management of associated conditions including epilepsy, feeding difficulties, and learning disabilities. Prognosis depends on severity and associated impairments; most children survive to adulthood with appropriate support.

CHARGE Syndrome

– A genetic disorder caused by CHD7 gene mutations (autosomal dominant, most cases de novo) affecting multiple organ systems. The mnemonic CHARGE describes: Coloboma (coloboma of the eye, 80-90%), Heart defects (tetralogy of Fallot, VSD, ASD, PDA, 75-85%), Atresia choanae (choanal atresia/stenosis, 50-60%), Retarded growth and development (growth hormone deficiency, intellectual disability), Genital hypoplasia (cryptorchidism, micropenis, 50-60% in males), and Ear anomalies (characteristic cup-shaped ears with prominent antihelix, hearing loss, 90-95%). Presents with life-threatening respiratory distress at birth from choanal atresia. Other common features: facial palsy, cleft lip/palate, and feeding difficulties. Diagnosis: clinical criteria (Verloes or Blake) and CHD7 genetic testing. Management: multidisciplinary — airway management, cardiac repair, hearing aids/cochlear implants, growth hor-

mone therapy, and developmental support.

Chickenpox

– Primary infection with Varicella-Zoster Virus, characterized by pruritic, vesicular rash in different stages (macules, papules, vesicles, crusts). Highly contagious via respiratory droplets and contact with lesions. Incubation 10-21 days. Complications include secondary bacterial infection, pneumonia, encephalitis, and Reye syndrome. Prevention by varicella vaccine. Treatment: supportive care; acyclovir for severe cases.

Child Abuse

– Physical, sexual, or emotional harm or neglect of a child by a caregiver. Recognized by inconsistent histories, injury patterns inconsistent with mechanism, and behavioral indicators. Types: physical abuse, sexual abuse, neglect, and emotional abuse. Mandatory reporting requirements for healthcare providers. Evaluation includes full skeletal survey for suspected physical abuse, laboratory tests, and social work involvement.

Child Neglect

– The failure of a caregiver to provide adequate food, shelter, clothing, supervision, education, or medical care. The most common form of child maltreatment. Types: physical neglect, educational neglect, emotional neglect, and medical neglect. May result in failure to thrive, developmental delay, and chronic illness. Identified through failure to attend appointments, untreated medical conditions, and inadequate living conditions.

Chlamydia

– The most common reportable bacterial STI, caused by *Chlamydia trachomatis*. Often asymptomatic in women, causing cervicitis, urethritis, and pelvic inflammatory disease. Complications include tubal factor infertility and ectopic pregnancy. Diagnosis by nucleic acid amplification test. Treatment: azithromycin or doxycycline. Partner treatment essential to prevent reinfection. Screening recommended for all sexually active women under 25.

Choanal Atresia

– A congenital obstruction of the posterior nasal passage (choana) due to failure of the bucconasal membrane to rupture during embryogenesis. Bilateral choanal atresia presents as a respiratory emergency

in the newborn, who is an obligate nasal breather — cyclic cyanosis that improves with crying. Unilateral atresia presents later with persistent unilateral nasal discharge and obstruction. 70% are bony, 30% are membranous. Associated with CHARGE syndrome (coloboma, heart defects, choanal atresia, retardation, genital hypoplasia, ear anomalies) and other anomalies. Diagnosis: inability to pass a nasogastric tube through the nose, confirmed by CT. Treatment: immediate airway management (oral airway, McGovern nipple), followed by surgical repair via transnasal endoscopic choanoplasty with stenting. Unilateral cases are repaired electively.

Clavicle Fracture

– The most common birth-related fracture, occurring in approximately 1-2% of vaginal deliveries. Risk factors include shoulder dystocia, macrosomia, and breech presentation. Presents with asymmetric arm movements, palpable crepitus, and reluctance to move the affected arm. Diagnosis by X-ray. Treatment: arm immobilization against the body (pinned diaper or arm sling). Heals rapidly in newborns with excellent prognosis.

Cleft Lip

– A congenital malformation: incomplete fusion of the lip (and often palate) during embryologic development, causing a facial cleft; cleft lip and/or cleft palate are the most common craniofacial birth defects. Features: cleft lip (unilateral/bilateral) and/or cleft palate (hard/soft); feeding difficulties, speech problems, recurrent otitis media/hearing loss, dental anomalies, and psychosocial impact; associated with syndromes (Pierre Robin, Van der Woude, trisomy 13/18). Diagnosis: prenatal ultrasound; clinical at birth. Management: multidisciplinary team—feeding support (special nipples), surgical repair (lip 3-6 months, palate 9-18 months), speech therapy, audiology/ENT, dental/orthodontics, and psychologic support.

Cloacal Exstrophy

– The most severe congenital anomaly of the ventral abdominal wall, also called the OEIS complex (Omphalocele, Exstrophy of the bladder, Imperforate anus, Spinal defects). Incidence 1 in 200,000-400,000 births. Features: an exstrophic central bowel segment (cecum, between two hemi-bladders),

omphalocele, imperforate anus, and spinal anomalies (myelomeningocele, tethered cord). Girls have a duplicated vagina and uterus; boys have an epispadiac, short phallus. There is near-universal association with Chiari malformation and hydrocephalus. Diagnosis: prenatal ultrasound shows a large midline abdominal wall defect with cystic structures (hemi-bladders) and spinal abnormalities. Treatment: staged surgical reconstruction — immediate bowel coverage (silo), separation of bowel from bladder, closure of the abdominal wall; later — bladder closure, genital reconstruction, and spinal cord repair. Prognosis: survival >90% with modern care. Bowel and bladder function outcomes are guarded; most require intermittent catheterization and bowel management.

Colic

– See [Infantile Colic](#).

Congenital CMV

– Cytomegalovirus infection acquired in utero, the most common congenital viral infection. Maternal primary infection poses highest risk of fetal transmission and disease. Can cause microcephaly, sensorineural hearing loss, chorioretinitis, hepatosplenomegaly, and petechiae. Diagnosis by CMV PCR in urine or saliva. Treatment: ganciclovir (IV) or valganciclovir (oral) for 6 months for symptomatic congenital CMV. Long-term sequelae include hearing loss and developmental delay.

Congenital Diaphragmatic Hernia

– A defect in the diaphragm allowing abdominal organs to herniate into the thoracic cavity, causing pulmonary hypoplasia and respiratory distress at birth. Most commonly a posterolateral (Bochdalek) defect on the left side. Presents with cyanosis, scaphoid abdomen, and bowel sounds in the chest. Treatment: intubation, nasogastric decompression, stabilization, and surgical repair once pulmonary hypertension is controlled. See also [Bochdalek Hernia](#) (the most common specific type).

Congenital Heart Disease

– Structural heart defects present at birth, the most common congenital anomaly (1% of live births). Common defects: ventricular septal defect (VSD, 30%), atrial septal defect (ASD), patent ductus arteriosus (PDA), tetralogy of Fallot (TOF), transpo-

sition of great arteries (TGA), coarctation of aorta, and hypoplastic left heart syndrome. Presentation depends on shunt direction and severity: cyanotic (TOF, TGA, tricuspid atresia) vs. acyanotic (VSD, ASD, PDA). Cyanotic: blue spells, clubbing, polycythemia. Acyanotic: heart murmur, heart failure, failure to thrive. Detected by prenatal ultrasound, newborn pulse oximetry screening, or clinical signs. Diagnosis: echocardiography. Treatment: surgical repair or palliation, catheter-based interventions for selected defects.

Congenital Heart Murmur

- A heart murmur detected in the newborn period, present in approximately 50-60% of healthy newborns. Most are innocent (functional) murmurs that disappear by 6 months of age. Pathologic murmurs may indicate congenital heart defects. Differentiation based on murmur characteristics, timing, and associated findings. Echocardiography recommended for pathologic murmurs. Innocent murmurs require no treatment.

Congenital Hip Dislocation

- See [Hip Dysplasia](#).

Congenital Pneumonia

- Lung infection acquired in utero, often from ascending chorioamnionitis. Presents with respiratory distress, fever or hypothermia, and sepsis. Common organisms include Group B Streptococcus, *E. coli*, and *Ureaplasma*. Diagnosis by chest X-ray showing infiltrates and blood culture. Treatment: broad-spectrum IV antibiotics (ampicillin and gentamicin) plus respiratory support.

Congenital Rubella Syndrome

- Fetal infection with rubella virus, particularly dangerous in the first trimester. Classic triad: congenital heart disease (patent ductus arteriosus, pulmonary stenosis), cataracts, and sensorineural hearing loss. Also causes hepatosplenomegaly, thrombocytopenia, and blueberry muffin rash. Prevention by maternal vaccination before pregnancy. No specific antiviral treatment; supportive care.

Congenital Syphilis

- *Treponema pallidum* infection acquired transplacentally. Can cause stillbirth, prematurity, hepatosplenomegaly, rash, snuffles, osteochondritis, and Hutchinson teeth. Diagnosed by darkfield mi-

croscopy, VDRL/RPR in neonatal serum, or PCR. Treatment: IV penicillin G—asymptomatic congenital syphilis: 10 days; symptomatic or CNS involvement: 10-14 days. Prevention through maternal screening and treatment during pregnancy.

Congenital Zika Syndrome

- Fetal brain infection with Zika virus, causing microcephaly, brain abnormalities, eye defects, hearing loss, and limb contractures. Transmission occurs via mosquito bite or sexual contact. Diagnosis by Zika virus PCR in maternal serum or amniotic fluid. No specific treatment. Prevention by avoiding endemic areas during pregnancy. Surveillance and developmental monitoring recommended for exposed infants.

Contraception for Adolescents

- Methods to prevent unintended pregnancy. Options: combined oral contraceptives, progestin-only pills, depot medroxyprogesterone acetate, contraceptive implant (Nexplanon), intrauterine devices (IUDs), condoms, and abstinence. Long-acting reversible contraceptives (LARC) such as IUDs and implants have highest efficacy and are first-line recommendations. Dual protection against STIs requires barrier methods.

Cornelia de Lange Syndrome

- A genetic disorder caused by mutations in genes of the cohesin complex (NIPBL 60%, SMC1A, SMC3, RAD21, HDAC8). Features: characteristic facies — synophrys (confluent eyebrows), long eyelashes, low-set ears, depressed nasal bridge with anteverted nares, thin lips, and micrognathia; prenatal and postnatal growth restriction; hirsutism; microcephaly; limb defects (oligodactyly, ectrodactyly, phocomelia, 30%); and congenital heart disease (VSD, ASD). Intellectual disability ranges from moderate to severe. Gastroesophageal reflux and feeding difficulties are near-universal. Diagnosis: clinical and genetic testing. Management: growth and feeding support (gastrostomy tube often required), antireflux therapy, developmental therapies, and surveillance for hearing loss, vision problems, and scoliosis.

Craniosynostosis

- Premature fusion of one or more cranial sutures, restricting skull growth perpendicular to the af-

fectured suture. Presents with abnormal head shape (scaphocephaly from sagittal fusion, plagiocephaly from coronal fusion). May increase intracranial pressure. Diagnosis by physical examination and CT with 3D reconstruction. Treatment: surgical cranioplasty to release fused suture and allow normal brain growth, typically between 3-12 months of age.

Cri-du-Chat Syndrome

- A genetic disorder caused by a deletion of the short arm of chromosome 5 (5p-), with the size of the deletion correlating with severity. Incidence 1 in 15,000-50,000. Features: a characteristic high-pitched, cat-like cry in infancy (due to laryngeal hypoplasia), microcephaly, round face, hypertelorism, epicanthal folds, micrognathia, and hypotonia. Intellectual disability ranges from moderate to severe. Other findings: congenital heart disease (VSD, PDA), scoliosis, and hearing loss. Diagnosis: karyotype, FISH, or chromosomal microarray showing 5p deletion. Management: early intervention programs, speech therapy, physical therapy, and treatment of associated anomalies. Patients have a characteristic friendly, sociable personality. Life expectancy is near normal for mild cases.

Croup

- Acute laryngotracheobronchitis, most commonly caused by parainfluenza virus. Affects children 6 months to 3 years. Presents with barking cough, stridor, hoarseness, and inspiratory distress, worse at night. Diagnosis is clinical; X-ray shows subglottic narrowing (steeple sign). Treatment: single dose of oral dexamethasone and nebulized epinephrine for moderate to severe cases. Self-limited; resolves in 3-7 days.

Crouzon Syndrome

- An autosomal dominant craniosynostosis syndrome caused by mutations in the FGFR2 or FGFR3 genes, leading to premature fusion of multiple cranial sutures. Features: brachycephaly (short, broad head from bilateral coronal synostosis), proptosis (shallow orbits), hypertelorism, midface hypoplasia, beaked nose, and Class III malocclusion. Unlike Apert syndrome, there are no hand or foot anomalies. Intelligence is typically normal. Increased intracranial pressure can occur from progressive synostosis. Diagnosis: clinical and genetic testing; CT for cran-

iosynostosis confirmation. Management: multidisciplinary — cranial vault remodeling surgery for craniosynostosis (3-6 months), midface advancement (Le Fort III osteotomy, 6-12 years), and orthognathic surgery for malocclusion. Lifelong monitoring for elevated ICP, sleep apnea, and vision changes.

Cystic Hygroma

- Congenital lymphatic malformation composed of thin-walled lymphatic cysts, manifesting as a soft, fluid-filled, painless, translucent (transilluminates brilliantly) mass, typically in the posterior triangle of the neck (75%, left-sided), axilla (20%), mediastinum, retroperitoneum, or groin. Most appear at birth or in early childhood; size ranges from a few cm to massive cystic masses. Histologic: dilated endothelial-lined lymphatic channels without communication to normal lymphatics. Etiology: congenital malformation of the lymphatic venous system, often from sequestration of lymphatic tissue that fails to drain into venous system, occurring during embryogenesis (9 weeks); also reported in Turner syndrome (~ 50% of prenatally detected cystic hygroma), Noonan syndrome, Trisomy 21, 18, 13. Diagnosis: prenatal ultrasound (nuchal translucency > 3.5 mm or septated cystic mass), fetal MRI, fetal echocardiography; karyotype and chromosomal microarray. Postnatal: physical exam, ultrasound, MRI for extent, airway assessment (cyst may compromise airway). Treatment: prenatal intervention for severe cases (sclerotherapy in utero); postnatal surgical excision (treatment of choice; complete excision if possible) preserving facial nerve, vessels, vital structures; sclerotherapy (picibanil OK-432, doxycycline, ethanol, bleomycin) for inoperable or recurrent cases; tracheostomy for airway compromise; multi-disciplinary management. Prognosis: depends on size, location, and associated anomalies; mortality high for large fetal hygroma (80% with hydrops); isolated small postnatal lesions surgical cure rate excellent.

Developmental Milestones

- Skills and abilities that children typically acquire at predictable ages. Examples: social smile at 2 months, rolling over at 4-6 months, sitting independently at 6-8 months, walking at 12 months, and speaking two-word phrases at 2 years. Delays in reaching milestones may indicate developmental de-

lay, autism, or neurologic impairment. Screening at each well-child visit using age-appropriate tools.

DiGeorge Syndrome

- 22q11.2 deletion syndrome. See immunology.

Diphtheria Vaccine

- Toxoid vaccine containing formalin-inactivated diphtheria toxin, providing immunity against the exotoxin produced by *Corynebacterium diphtheriae* rather than the bacterium itself. Administered as part of combination vaccines: DTaP (pediatric, 2, 4, 6, 15-18 months, 4-6 years), Tdap (adolescent booster at 11-12 years, and during each pregnancy at 27-36 weeks), and Td (adult booster every 10 years). The toxoid is adsorbed onto an aluminium salt adjuvant to enhance immunogenicity. Antibody levels wane over 10-15 years, necessitating periodic boosters. Diphtheria toxoid is also combined with tetanus and pertussis antigens in Tdap and DTaP, and with inactivated polio vaccine in DTaP-IPV formulations. Efficacy exceeds 95 percent after a complete primary series. Before widespread vaccination, diphtheria was a leading cause of childhood mortality from respiratory obstruction and myocarditis. In India and many low- and middle-income countries, diphtheria toxoid is delivered as part of the pentavalent vaccine (DPT+HepB+Hib), using whole-cell rather than acellular pertussis, with booster doses of DPT given at 16-24 months and 5-6 years. See [Pentavalent Vaccine](#), [India Immunization Schedule](#), and [Diphtheria](#) in infectious disease for disease details.

Down Syndrome

- Trisomy 21, most common viable trisomy. See genetics.

DTaP Vaccine

- Diphtheria, Tetanus, and acellular Pertussis vaccine given at 2, 4, 6, and 15-18 months, and 4-6 years. Protects against three serious bacterial diseases. Diphtheria causes respiratory and cardiac complications. Tetanus causes lockjaw and muscle rigidity. Pertussis causes whooping cough, most severe in young infants. Acellular formulation reduces side effects compared to whole-cell pertussis vaccine.

Ductal-Dependent Lesions

- Congenital heart defects that require the ductus

arteriosus to remain patent for adequate systemic or pulmonary blood flow. Includes pulmonary atresia, critical aortic stenosis, coarctation, hypoplastic left heart syndrome, and transposition of the great arteries. Present with cyanosis or shock when the ductus closes (typically within 24-48 hours). Treatment: prostaglandin E1 to maintain ductal patency until surgical intervention.

Duodenal Atresia

- A congenital obstruction of the duodenum caused by failure of recanalization during the 8th-10th week of gestation. Associated with Down syndrome (30%), polyhydramnios (due to impaired fetal swallowing of amniotic fluid), and other anomalies (VACTERL, congenital heart disease, annular pancreas, malrotation). Presents within hours of birth with bilious vomiting (90%, if distal to the ampulla of Vater), epigastric distension, and failure to pass meconium. The classic X-ray finding is the double bubble sign (air in the stomach and proximal duodenum, with no distal gas). Diagnosis: prenatal ultrasound (polyhydramnios, dilated stomach and duodenum), postnatal abdominal X-ray, and upper GI series to confirm and exclude malrotation. Treatment: nasogastric decompression, IV fluids, and surgical duodeno-duodenostomy (diamond-shaped anastomosis, Kimura technique). Prognosis: excellent with surgical repair (>95% survival), but depends on associated anomalies.

Dyslexia

- A specific learning disorder with neurobiological origin, characterized by difficulties with accurate and fluent word recognition, spelling, and decoding ability, despite adequate intelligence, motivation, and educational opportunity. Affects approximately 5-10% of the population. The underlying cause involves impaired phonological processing (difficulty recognizing and manipulating the sounds of spoken language) and deficits in rapid automatized naming. Functional neuroimaging shows reduced left temporoparietal and occipitotemporal activation during reading. Diagnosis: comprehensive educational assessment evaluating reading accuracy, fluency, comprehension, and phonological processing. Management: structured, explicit, multisensory phonics-based reading instruction (Orton-Gillingham, Wilson Reading System, Barton), assistive technology,

and educational accommodations.

Edwards Syndrome

– Trisomy 18, the second most common autosomal trisomy in live births (1 in 5,000). Caused by complete trisomy 18 (94%), mosaicism, or partial trisomy (translocation). Features: severe intrauterine growth restriction, clenched fists with overlapping fingers (index over middle, fifth over fourth), rocker-bottom feet, low-set malformed ears, micrognathia, prominent occiput, and congenital heart defects (VSD, PDA, polyvalvular disease, 90-95%). Other findings: horseshoe kidney, esophageal atresia, omphalocele, and neural tube defects. Diagnosis: prenatal screening (low PAPP-A, low hCG, high inhibin A), NIPT, and karyotype/CMA. Management: comfort care is the standard (median survival 5-15 days; 5-10% survive to 1 year). Surgical intervention for life-threatening anomalies is controversial. Survivors have severe intellectual disability.

Ehlers-Danlos Syndrome

– A group of hereditary connective tissue disorders caused by defects in collagen synthesis or processing. The most common types: Classic (COL5A1, COL5A2) — skin hyperextensibility, atrophic scarring, and joint hypermobility; Hypermobile (hEDS, unknown genetic cause, most common) — generalized joint hypermobility, chronic pain, and easy bruising; Vascular (COL3A1, most dangerous) — thin translucent skin, easy bruising, arterial rupture (carotid, aortic, visceral), uterine rupture, and sigmoid colon perforation; Kyphoscoliotic (PLOD1) — congenital hypotonia, scoliosis, and joint laxity; and Arthrochalasia (COL1A1, COL1A2) — severe joint hypermobility and congenital hip dislocation. Diagnosis: clinical (Beighton score for hypermobility), collagen typing on skin biopsy (vascular type), and genetic testing. Management: activity modification and joint protection, vascular surveillance for vascular EDS (carotid duplex, aortic imaging, avoidance of invasive procedures), high-dose vitamin C, and genetic counseling. No cure; management is symptomatic and preventive.

Emergency Contraception

– Postcoital contraception to prevent pregnancy after unprotected intercourse or contraceptive failure. Levonorgestrel (Plan B): effective within 72 hours,

available over the counter. Ulipristal acetate (Ella): effective within 120 hours, prescription only. Copper IUD: most effective emergency contraception, placed within 5 days. Not abortifacients; prevent or delay ovulation.

Enuresis (Bedwetting)

– Involuntary urination during sleep in a child aged 5 years or older, affecting approximately 5–10% of 7-year-olds. Primary enuresis: the child has never achieved sustained nighttime dryness. Secondary enuresis: wetting recurs after at least 6 months of dryness, often triggered by psychosocial stress, urinary tract infection, or diabetes. Pathophysiology involves a mismatch between nocturnal bladder capacity, nighttime urine production (lack of circadian ADH rhythm), and inability to arouse from sleep in response to bladder fullness. Evaluation: history (wetting pattern, fluid intake, constipation), urinalysis (glucose, infection). Management: behavioral (timed voiding, reward systems, fluid restriction before bed), enuresis alarm (first-line, 70% success), and pharmacotherapy (desmopressin—synthetic ADH—reduces nighttime urine production).

Epiglottitis

– Inflammation of the epiglottis, a life-threatening emergency. Most commonly caused by *Haemophilus influenzae* type b (now rare due to vaccination). Presents with high fever, drooling, dysphagia, tripod position, and rapid progression to airway obstruction. Do not examine the throat. Treatment: secure airway in operating room, IV antibiotics (ceftriaxone). Requires immediate airway management; mortality high if untreated.

Epispadias

– A congenital anomaly where the urethral meatus opens on the dorsal (top) surface of the penis in boys or in a split, open position on the clitoral hood in girls. Caused by abnormal development of the genital tubercle and cloacal membrane. In boys, the opening may be at the glans (glandular, mildest), penile shaft, or penopubic (most severe, associated with bladder exstrophy). In girls, the urethra is short with a bifid clitoris and separated labia. Epispadias presents as part of the exstrophy-epispadias complex spectrum. The penis is short, wide, and up-

wardly curved (dorsal chordee). Diagnosis: clinical. Treatment: surgical repair (Mitchell or Cantwell-Ransley technique) between 6-12 months — urethral reconstruction, penile straightening, and urethroplasty. Prognosis: urinary continence is achieved in 70-80% with repaired epispadias.

Erb's Palsy

– Upper brachial plexus injury (C5-C6) causing weakness or paralysis of the shoulder and arm muscles. Presents with the characteristic waiter's tip position: arm adducted, elbow extended, forearm pronated, wrist flexed. Most commonly caused by shoulder dystocia during delivery. See also [Brachial Plexus Injury](#).

Esophageal Atresia

– A congenital anomaly where the esophagus ends in a blind pouch, often with a tracheoesophageal fistula connecting the distal esophagus to the trachea. Presents with drooling, inability to pass a nasogastric tube, and choking with feedings. The 3 Es association: Esophageal atresia, Esophageal anomalies, and Extremity anomalies. Treatment: surgical ligation of fistula and esophageal anastomosis.

Exchange Transfusion

– Emergent procedure to rapidly lower severe hyperbilirubinemia by removing small volumes of the infant's blood and replacing with compatible donor blood. Used when phototherapy fails or bilirubin approaches toxic levels (greater than 25 mg/dL in term infants or above exchange threshold on Bhutani curve). Risks include infection, electrolyte imbalances, and air embolism. Double-volume exchange (160-200 mL/kg) replaces approximately 85% of circulating red blood cells.

Failure to Thrive

– Inadequate growth in children, defined as weight below the 5th percentile or crossing two major percentile lines on growth charts. Causes include caloric insufficiency (neglect, poor feeding), organic disease (congenital heart disease, renal disease), and psychosocial factors. Evaluation includes comprehensive history, physical examination, laboratory studies, and calorie counts. Treatment addresses underlying cause and nutritional rehabilitation.

Fanconi Anemia

– An autosomal recessive (or X-linked) bone marrow

failure syndrome caused by mutations in at least 22 FANC genes involved in DNA repair (the FA/BRCA pathway). Features: progressive pancytopenia (onset typically at 5-10 years), radial ray anomalies (thumb hypoplasia or aplasia, radial club hand), microcephaly, short stature, café-au-lait spots, and renal anomalies. Increased risk of myelodysplastic syndrome, acute myeloid leukemia, and solid tumors (head and neck squamous cell carcinoma, gynecological cancer). Diagnosis: chromosomal breakage test (diepoxybutane or mitomycin C — increased chromosome breaks) and FANC gene sequencing. Management: androgens (oxymetholone) for cytopenias, hematopoietic stem cell transplant for bone marrow failure (with reduced-intensity conditioning), and lifelong cancer surveillance.

Febrile Seizures

– Seizures occurring in children 6 months to 5 years triggered by fever (temperature greater than 38 degrees Celsius), without intracranial infection or defined cause. Occurs in 2-5% of children. Simple: generalized, single seizure lasting less than 15 minutes, no recurrence within 24 hours. Complex: focal, prolonged (greater than 15 minutes), or recurrent within 24 hours. Diagnosis of exclusion after ruling out meningitis and intracranial infection. In simple febrile seizures, there is no increased risk of epilepsy. Management: parental education on seizure first aid, antipyretics for comfort (do not prevent recurrence), and reassurance. No routine antiepileptic medication is indicated. Lumbar puncture should be considered when meningeal signs are present or in infants under 12 months with incomplete vaccination.

Fetal Distress

– Abnormal fetal status during labor, indicated by abnormal fetal heart rate patterns (late or prolonged decelerations, minimal variability, absent accelerations). May indicate fetal hypoxia, cord compression, or placental insufficiency. Management includes intrauterine resuscitation: change maternal position, stop oxytocin, give IV fluids and oxygen, and amnioinfusion. If persistent, emergent delivery by cesarean or operative vaginal delivery.

Fifth Disease

– Erythema infectiosum caused by Parvovirus B19.

Characterized by bright red cheeks (slapped cheek appearance) followed by a lacy, reticulated rash on the trunk and extremities. Mild febrile illness in children. Concern in pregnancy (hydrops fetalis risk) and immunocompromised patients (pure red cell aplasia). Diagnosis by serology. Self-limited; no specific treatment.

Fine Motor Skills

- The ability to use small muscles (hands/fingers) for precise movements, developing with age: reaching (3-4 months), grasping (5-6 months), pincer grasp (9-12 months), self-feeding (12-18 months), building towers/scribbling (18-24 months), drawing shapes and using utensils (3-5 years), and handwriting. Delays relate to neuromotor conditions (cerebral palsy, developmental delay), visual problems, and autism (with other signs). Assessed at well-child visits; early referral for occupational therapy improves function. Monitor bimanual use, hand dominance, and age-appropriate play skills.

Fontanelle

- Soft membranous spaces between skull bones that allow brain growth and skull molding during delivery. Anterior fontanelle diamond-shaped, closes by 12-18 months. Posterior fontanelle triangular, closes by 2-3 months. Bulging fontanelle suggests increased intracranial pressure; sunken fontanelle indicates dehydration. Palpation is part of the routine infant physical examination.

Formula Feeding

- Alternative to breastfeeding using commercially prepared infant formula. Types include cow's milk-based, soy-based, hydrolyzed protein, and amino acid-based formulas. Iron-fortified formulas standard to prevent iron deficiency anemia. Preparation requires clean water and proper sterilization of bottles. Feeding on demand approximately every 3-4 hours. Provides adequate nutrition when breastfeeding is not possible or desired.

Fragile X Syndrome

- X-linked dominant disorder caused by CGG trinucleotide repeat expansion in the FMR1 gene. Most common inherited cause of intellectual disability. Features: long face, prominent ears, macroorchidism in post-pubertal males, and behavioral problems including autism spectrum features. Diagnosis by

DNA testing for CGG repeat expansion. No cure; behavioral and educational interventions.

Functional Asplenia

- Loss of splenic function due to sickling and infarction in sickle cell disease, typically by age 5 years. Increases risk of overwhelming bacterial infection, particularly from encapsulated organisms (*Streptococcus pneumoniae*, *Haemophilus influenzae*). Management: prophylactic penicillin, pneumococcal vaccines, and parental education about fever as a medical emergency.

Galactoceles

- See obstetrics and gynecology.

Galant Reflex

- A primitive reflex present from birth to 4 months, elicited by stroking the skin along the side of the infant's back. The infant curves toward the stimulated side. Assessed by running a finger from the lateral back toward the hip while the infant is in ventral suspension. Absence may indicate neurologic abnormality. One of the trunk reflexes evaluated during newborn neurologic examination.

Gastroschisis

- A full-thickness abdominal wall defect, usually to the right of the umbilicus, through which bowel herniates without a covering membrane. Not associated with chromosomal abnormalities. Presents at birth with exposed bowel loops that may be edematous, thickened, and discolored from amniotic fluid exposure. Management: immediate coverage with saline-moistened dressings, nasogastric decompression, and surgical repair (primary closure or staged reduction).

German Measles (Rubella)

- See infectious disease.

Glandular Fever (Infectious Mononucleosis)

- See infectious disease.

Glycogen Storage Disease

- A group of inherited metabolic disorders caused by defects in glycogen synthesis, breakdown, or regulation, resulting in abnormal glycogen accumulation in tissues. Major types: Type I (von Gierke, G6PC deficiency) — fasting hypoglycemia, lactic acidosis, hepatomegaly, hyperuricemia, and hypertriglyc-

eridemia. Type II (Pompe disease, GAA deficiency) — infantile form: hypertrophic cardiomyopathy, hypotonia, and death by 1 year; late-onset: proximal myopathy and respiratory weakness. Type III (Cori disease, AGL deficiency) — hypoglycemia, hepatomegaly, and myopathy. Type IV (Andersen disease, GBE1 deficiency) — liver failure, cirrhosis, and cardiomyopathy. Type V (McArdle disease, PYGM deficiency) — exercise intolerance, myoglobinuria, and second-wind phenomenon. Type VI (Hers disease, PYGL deficiency) — mild fasting hypoglycemia and hepatomegaly. Type VII (Tarui disease, PFKM deficiency) — exercise intolerance similar to McArdle with hemolytic anemia. Diagnosis depends on the type: enzyme assay in liver or muscle biopsy, genetic testing, and newborn screening for Pompe. Treatment varies by type: Type I — continuous glucose therapy (cornstarch), allopurinol, and lipid-lowering agents. Type II (Pompe) — enzyme replacement therapy (alglucosidase alfa). Types III, VI — high-protein diet. Types V, VII — exercise modification and creatine supplementation.

Goldenhar Syndrome

— A variant of hemifacial microsomia characterized by the triad: epibulbar dermoids (benign conjunctival tumors), preauricular skin tags or sinuses, and vertebral anomalies (hemivertebrae, fused vertebrae, scoliosis). Also involves facial asymmetry, microtia, conductive hearing loss, and macrostomia. Other associations: congenital heart disease (VSD, tetralogy of Fallot), renal anomalies, and cleft lip/palate. Most cases are sporadic. Diagnosis: clinical and imaging (CT for skeletal anomalies, echocardiogram, renal ultrasound). Management: multidisciplinary — ophthalmology (epibulbar dermoid excision), audiology (hearing aids), plastic surgery (auricular reconstruction, mandibular distraction), and orthopedic monitoring for scoliosis.

Gonorrhea

— See infectious disease.

Gross Motor Skills

— The ability to use large muscle groups for movement and posture, developing in a predictable sequence in infancy/childhood: head control (3 months), sitting (6 months), crawling (9 months), standing (10-12 months), walking (12-18 months), running/jumping

(2-3 years), hopping and balance (3-5 years). Delays warrant assessment: cerebral palsy, muscular dystrophy, developmental delay, hypotonia, and environmental factors. Milestone monitoring at well-child visits (screening—ASQ) and early intervention improve outcomes; gross motor regression is always concerning. Encourage tummy time and active play.

Group B Strep

— Group B Streptococcus (GBS, *Streptococcus agalactiae*): a gram-positive coccus colonizing the GI and genitourinary tract in 10-30 percent of women; major cause of neonatal sepsis and meningitis. Neonatal disease: early-onset (<7 days—vertical transmission during delivery: sepsis, pneumonia, meningitis) and late-onset (7 days-3 months—sepsis, meningitis, osteomyelitis). Risk: maternal GBS carriage, preterm, prolonged rupture of membranes, intrapartum fever, and previous GBS-affected infant. Prevention: universal screening (35-37 weeks) and intrapartum antibiotic prophylaxis (penicillin) for carriers. Diagnosis: blood/CSF culture, PCR. Management: empiric antibiotics (penicillin/ampicillin + gentamicin), supportive care; also causes UTI and chorioamnionitis in pregnancy.

Growing Pains

— Recurrent, bilateral leg pain in children ages 3-12, typically occurring in the late afternoon or evening and resolving by morning. Pain is deep, aching in the calves, shins, and thighs (not joints). No limping, fever, swelling, or functional impairment. Etiology unclear: may relate to increased activity, musculoskeletal overuse, or decreased pain threshold. Diagnosis: clinical (diagnosis of exclusion). Red flags suggesting pathology: unilateral pain, joint involvement, morning stiffness, limping, fever, night sweats, nocturnal pain waking the child. Treatment: reassurance, massage, stretching, warm baths, and acetaminophen/ibuprofen as needed. Benign and self-limited.

Growth Chart

— A graphical representation of growth (weight, height/length, head circumference, BMI) plotted against age, standardized by population (WHO growth standards 0-5 years; CDC growth charts 2-20 years; percentiles/z-scores). Used to monitor normal

growth, detect growth disorders (failure to thrive, short stature, obesity, microcephaly/macrocephaly), and assess nutritional status. Interpretation: track crossing of percentiles (crossing downward—poor growth; upward—overfeeding/obesity), symmetry, and parental heights (target height). Regular plotting at well-child visits identifies deviations early, prompting evaluation (nutrition, endocrine, chronic disease, genetic).

Gynecomastia

- Enlargement of breast tissue in males, often bilateral, occurring physiologically in neonates, during puberty (40-60% of boys), and in aging men. Pathologic causes include Klinefelter syndrome, testicular tumors, medications (spironolactone, cannabis), and liver disease. Persistent or asymmetric gynecomastia warrants evaluation. Management: observation for physiologic cases; treatment of underlying cause; mastectomy for severe persistent cases.

Hand Foot and Mouth Disease

- A common viral illness (mostly children <10 years) caused by coxsackievirus A16 (and enterovirus 71), transmitted by fecal-oral/respiratory. Features: fever, sore throat, and a vesicular rash on the hands, feet, and mouth (ulcers on buccal mucosa, tongue, palate; vesicles on palms/soles); enterovirus 71 may cause severe CNS disease (meningoencephalitis, polio-like paralysis) and cardiorespiratory failure. Diagnosis: clinical. Management: supportive—hydration, analgesia, and antipyretics; watch for dehydration; severe/neurologic cases (EV71) require hospital care. Highly contagious; hygiene and isolation. Usually self-limiting in 7-10 days.

Head Circumference

- Measured at the largest circumference above the ears and eyebrows, reflecting brain growth. Plotted on growth charts to detect microcephaly (below 3rd percentile) or macrocephaly (above 98th percentile). Rapid increase may indicate hydrocephalus or intracranial hemorrhage; failure to grow may indicate microcephaly or brain atrophy. Measured at each well-child visit until age 2.

Head lice

- An infestation of the scalp by the obligate human ectoparasite *Pediculus humanus capitis*, a wingless, blood-sucking insect that feeds on human blood,

most common in children aged 3-12. It is extremely common, especially in school-aged children aged 3-11 years, with an estimated 6-12 million infestations annually in the United States. Transmission is primarily through direct head-to-head contact (the most common route), and less commonly through shared combs, brushes, hats, headphones, pillows, or other personal items. Lice do not jump or fly; they crawl. Diagnosis is confirmed by finding live lice or nits attached to hair shafts within 1 cm of the scalp using a fine-toothed detection comb. Treatment: topical pediculicides containing permethrin 1% or dimeticone; oral ivermectin for treatment-resistant cases; wet combing (bug busting) as a non-insecticidal alternative. Bedding and clothing should be washed in hot water (60 degrees Celsius) and non-washable items sealed in a plastic bag for 2 weeks. Prophylactic treatment of household contacts is not recommended. School exclusion policies vary; the American Academy of Pediatrics and the UK National Institute for Health and Care Excellence recommend children remain in school after first treatment, as no-nit policies are unnecessary and promote stigma.

Hearing Screening

- Newborn hearing screening (universal): otoacoustic emissions (OAE) and/or automated auditory brainstem response (AABR) before discharge; referral for comprehensive audiology if failed. Early detection (<6 months) of congenital hearing loss (1-3/1000) allows early intervention (hearing aids, cochlear implants, early communication) with vastly improved language outcomes. Risk factors: family history, prematurity, low birth weight, infections (CMV, meningitis), ototoxic drugs, and jaundice. Ongoing surveillance: behavioral screening and audiometry at well-child visits and school; signs of delayed speech/response to sound prompt referral. Follow-up and documentation are critical.

Hemifacial Microsomia

- A congenital craniofacial disorder involving asymmetric hypoplasia of the structures derived from the first and second branchial arches, most commonly affecting the mandible, ear, and soft tissues on one side. Also known as craniofacial microsomia or Goldenhar syndrome when epibulbar dermoids and vertebral anomalies are present. Presents with

asymmetry: mandibular hypoplasia (Pruzansky-Kaban classification I-III), microtia (small or absent pinna), preauricular tags or sinuses, conductive hearing loss, and macrostomia (enlarged oral commissure). Severity ranges from mild asymmetry to severe facial deformity. Diagnosis: clinical, CT for skeletal assessment, and audiometry. Management: reconstructive surgery (mandibular distraction, costochondral graft, or orthognathic surgery), auricular reconstruction, hearing rehabilitation, and speech therapy.

Henoch-Schonlein Purpura

– See [IgA Vasculitis](#).

Hepatitis B Vaccine

– Recombinant vaccine given at birth, 1-2 months, and 6-18 months. Protects against hepatitis B virus, which can cause chronic liver disease, cirrhosis, and hepatocellular carcinoma. Also prevents perinatal transmission when given to infants of HBsAg-positive mothers within 12 hours of birth, plus hepatitis B immune globulin.

Hib

– *Haemophilus influenzae* type b: an encapsulated gram-negative bacterium causing serious invasive disease in unvaccinated children—meningitis, epiglottitis, pneumonia, septic arthritis, cellulitis, and sepsis. Highly prevented by the Hib conjugate vaccine (given in infancy, part of routine schedule). Invasive Hib disease in vaccinated populations is rare. Diagnosis: culture/PCR (blood, CSF). Management: antibiotics (third-generation cephalosporin—ceftriaxone), and respiratory/droplet precautions; treatment of close contacts with rifampin chemoprophylaxis (household/school, especially with young children); monitor for complications (meningitis—deafness). Epiglottitis is an airway emergency.

Hip Dysplasia

– Developmental dysplasia of the hip (DDH): abnormal development of the acetabulum/femoral head causing instability, subluxation, or dislocation. Risk factors: female, breech presentation, family history, firstborn, and tight swaddling. Features: asymmetric skin creases, limited abduction, Ortolani (relocation) and Barlow (dislocation) tests in the newborn; later—gait limp, leg length discrepancy, Trendelen-

burg. Diagnosis: ultrasound (age <6 months), X-ray (older). Management: early—Pavlik harness (success >90 percent); late—closed reduction/casting or surgery. Screening (clinical ± selective ultrasound) and early referral prevent long-term arthritis and disability.

Holt-Oram Syndrome

– An autosomal dominant disorder caused by TBX5 gene mutations, characterized by congenital heart disease and upper limb malformations. Cardiac anomalies: atrial septal defect (most common), VSD, and conduction abnormalities (heart block, atrial fibrillation). Limb defects are bilateral and asymmetric: thumb anomalies (absent, hypoplastic, triphalangeal, or finger-like thumb, 100%), radial dysplasia (radial club hand), and phocomelia. Diagnosis: clinical (heart defect + preaxial radial ray anomaly) and TBX5 genetic testing. Management: cardiac repair (ASD/VSD closure, pacemaker for heart block), reconstructive hand surgery (pollicization for absent thumb, centralization for radial club hand), and genetic counseling.

Homocystinuria

– An autosomal recessive inborn error of methionine metabolism caused most commonly by deficiency of cystathionine beta-synthase (CBS), leading to accumulation of homocysteine and methionine. Features (develop in childhood if untreated): ectopia lentis (lens dislocation, typically downward, differentiating from Marfan syndrome), severe myopia, intellectual disability, thromboembolism (the major cause of morbidity/mortality, affecting arteries and veins), osteoporosis, and a Marfanoid habitus (tall stature, pectus deformities, arachnodactyly). Diagnosis: elevated plasma homocysteine and methionine, homocystinuria, and CBS gene sequencing. Newborn screening includes homocystinuria in expanded panels. Treatment: pyridoxine (vitamin B6) responsiveness testing (approximately 50% are responsive), betaine (to remethylate homocysteine to methionine), methionine-restricted diet (especially for non-responders), and anticoagulation (aspirin for thromboprophylaxis). Lifelong monitoring for thromboembolism and lens dislocation.

Horseshoe Kidney

– The most common renal fusion anomaly (1 in 400-

500), where the lower poles of both kidneys are fused across the midline by an isthmus of renal parenchyma or fibrous tissue. The fused kidney is located lower in the abdomen than normal (at L3-L5, anterior to the aorta and IVC) due to the isthmus being trapped under the inferior mesenteric artery during ascent. Associated with Turner syndrome, Edwards syndrome, Patau syndrome, and other urogenital anomalies. Often asymptomatic and discovered incidentally. May present (30%) with hydronephrosis from UPJ obstruction (the ureter passes anterior to the isthmus, causing kinking), recurrent UTIs, nephrolithiasis, and increased risk of Wilms tumor. Diagnosis: ultrasound, CT, or IV pyelogram. Treatment: surgical management of complications (pyeloplasty for UPJ obstruction, and nephrolithotomy for stones). Surveillance imaging for Wilms tumor is controversial.

HPV Vaccine

- Human Papillomavirus vaccine given at 11-12 years (can start at 9), with series completion by 15 years. Two-dose series if started before 15; three-dose series if started at 15 or older. Protects against HPV types causing cervical cancer, oropharyngeal cancer, and genital warts. Gardasil 9 covers nine HPV types. Expected to prevent over 90% of HPV-associated cancers.

Human Papillomavirus

- The most common STI, with over 100 types. High-risk types (16, 18) cause cervical, oropharyngeal, anal, and genital cancers. Low-risk types (6, 11) cause genital warts. Prevention: HPV vaccine (Gardasil 9) protects against 9 HPV types. Screening: Pap smear and HPV testing for cervical cancer prevention. Most infections clear spontaneously.

Inactivated Polio Vaccine (IPV)

- Salk vaccine, a formalin-inactivated preparation containing all three poliovirus serotypes (1, 2, and 3), administered by intramuscular injection. The only polio vaccine used in the United States since 2000, and the recommended vaccine for immunocompromised individuals and pregnant women worldwide. The current CDC schedule specifies doses at 2 months, 4 months, 6-18 months, and a booster at 4-6 years. Unlike oral polio vaccine (OPV), IPV does not carry the risk of vaccine-associated para-

lytic polio (VAPP) or circulating vaccine-derived poliovirus (cVDPV), because the inactivated virus cannot replicate in the gut. However, IPV generates weaker intestinal mucosal immunity than OPV, meaning vaccinated individuals can still harbour and transmit wild poliovirus in the gut. IPV is included in combination vaccines such as DTaP-IPV and DTaP-IPV-Hib. Post-2016, the type 2 component was removed from both IPV (now bIPV) and OPV in response to the global eradication of wild poliovirus type 2. Efficacy exceeds 99 percent after a complete primary series. In India, IPV is given as fractional doses (fIPV) rather than full intramuscular doses. See [Fractional IPV \(fIPV\)](#), [Polio](#), and [Poliomyelitis](#) in infectious disease.

Fractional IPV (fIPV)

- A reduced-dose schedule of inactivated polio vaccine used in the WHO and India Universal Immunization Schedule, where one-fifth of the standard intramuscular IPV dose (0.1 mL instead of 0.5 mL) is given by intradermal injection at each of two deltoid sites (total 0.2 mL per fractional dose), rather than the full 0.5 mL intramuscular dose. The schedule comprises two fractional doses at 6 weeks and 14 weeks, with a third full intramuscular IPV dose at 9-12 months. This approach was adopted to address global IPV supply constraints while maintaining adequate seroconversion rates (greater than 90 percent for all three serotypes after three doses). Intradermal delivery targets the antigen-rich dermal layer, enhancing immune stimulation per microgram of antigen. Seroconversion rates with fractional IPV are comparable to full-dose IPV after three doses, though antibody titres may be slightly lower after two fractional doses alone. India adopted fIPV in 2016 as part of its dual polio vaccination strategy combining OPV and IPV. The approach is endorsed by the WHO Strategic Advisory Group of Experts on Immunization (SAGE).

Hunter Syndrome

- Mucopolysaccharidosis type II (MPS II), an X-linked recessive lysosomal storage disorder caused by iduronate-2-sulfatase deficiency (IDS gene mutations). Accumulation of dermatan sulfate and heparan sulfate (same as Hurler). Two forms: severe (neuronopathic, 2/3 of cases) — progressive intellectual disability, neurodegeneration, and

death by 10-15 years; attenuated (no or minimal neurologic involvement) — survival into adulthood. Features: coarse facies, corneal clouding (less prominent than Hurler), hepatosplenomegaly, recurrent hernias, dysostosis multiplex, joint stiffness, short stature, and cardiac valvular disease. A characteristic feature is the pebbled, ivory-white skin lesions (papules) over the back and shoulders (pathognomonic). Diagnosis: urine GAG analysis, iduronate-2-sulfatase enzyme assay, and IDS gene sequencing. Treatment: enzyme replacement therapy (idursulfase, Elaprase) improves somatic features, and intrathecal idursulfase is under investigation for neurologic disease. HSCT is less effective than in MPS I.

Japanese Encephalitis (JE) Vaccine

– An inactivated (SA 14-14-2 strain, widely used) or live attenuated vaccine protecting against Japanese encephalitis, the most common cause of viral encephalitis in Asia, transmitted by *Culex* mosquitoes in rural rice-growing and pig-farming areas. Most infections are subclinical or cause mild febrile illness, but symptomatic disease carries a case fatality rate of 20-30 percent and neurological sequelae in 30-50 percent of survivors. In India's Universal Immunization Schedule, JE vaccine is given in districts with high JE burden: the first dose at 9-12 months and a second dose at 16-24 months, administered by subcutaneous injection. The vaccine is also part of pre-travel recommendations for long-term travellers to endemic areas (multiple doses required). Adverse effects are generally mild: injection site pain, fever, and headache. The WHO recommends JE vaccination for all children living in or travelling to endemic areas.

Hurler Syndrome

– Mucopolysaccharidosis type I (MPS I), the severe form, an autosomal recessive lysosomal storage disorder caused by alpha-L-iduronidase deficiency (IDUA gene mutations). Accumulation of dermatan sulfate and heparan sulfate leads to progressive multisystem involvement. Features: coarse facies (gargoyle-like appearance), corneal clouding, hepatosplenomegaly, recurrent hernias, dysostosis multiplex (kyphoscoliosis, J-shaped sella, paddle ribs, claw-hand deformity, hip dysplasia), aortic valve

disease, and severe intellectual disability. Hearing loss, obstructive airway disease, and hydrocephalus (communicating) are common. Diagnosis: urine glycosaminoglycan (GAG) analysis (elevated dermatan and heparan sulfate) and IDUA enzyme assay in leukocytes. Newborn screening is available. Treatment: hematopoietic stem cell transplant (HSCT) performed early (<2.5 years) preserves cognitive function and improves somatic features but does not fully correct skeletal or corneal disease. Enzyme replacement therapy (laronidase, iduronidase) improves somatic features but does not cross the blood-brain barrier. Prognosis: untreated, death by 6-10 years from cardiorespiratory failure.

Hydrocephalus

– Abnormal accumulation of cerebrospinal fluid (CSF) within the ventricles of the brain, leading to increased intracranial pressure. See neurology.

Hypertelorism

– Increased distance between the orbits (the bony eye sockets), measured as an increased interorbital distance on imaging. Can result from premature fusion of the cranial sutures (craniosynostosis syndromes), frontonasal dysplasia, facial clefting, or can be associated with genetic syndromes (Apert, Crouzon, Noonan, 22q11.2 deletion, and CHARGE). Presents with widely spaced eyes (telecanthus). Diagnosis: clinical measurement of the intercanthal distance and orbital imaging (CT or MRI) to confirm increased interorbital distance. Management: surgical correction by orbital box osteotomy or facial bipartition for severe cases; treatment of the underlying syndrome. Not typically a functional concern.

IgA Vasculitis (Henoch-Schonlein Purpura)

– The most common systemic vasculitis in children (peak age 2-8 years), characterized by IgA1-containing immune complex deposition in small vessels. Often preceded by an upper respiratory tract infection (e.g., group A *Streptococcus*). Classic clinical tetrad: 1) Palpable purpura (non-thrombocytopenic) on lower extremities and buttocks, 2) Arthralgia/arthritis (knees, ankles), 3) Abdominal pain (colicky, risk of intussusception), and 4) Renal involvement (hematuria, proteinuria,

IgA nephropathy). Lab workup: normal platelet count, elevated serum IgA, normal complement levels. Management: supportive care, NSAIDs for joint pain; systemic corticosteroids for severe abdominal pain or crescentic glomerulonephritis. Excellent prognosis with >90% spontaneous resolution.

Immune Thrombocytopenic Purpura

- Autoimmune destruction of platelets by antiplatelet antibodies, causing isolated thrombocytopenia. Most common in children 2-6 years, often following viral infection. Presents with petechiae, purpura, and mucosal bleeding. Diagnosis of exclusion. Treatment: observation for mild cases; IVIG or corticosteroids for severe thrombocytopenia or active bleeding. Spontaneous resolution in 80% within 6 months.

Imperforate Anus

- A congenital anomaly where the anus is completely absent or fails to open at the perineum. Classified as low (distal to the levator ani complex) or high (proximal to the levator ani). Often associated with other anomalies including vertebral, anal, cardiac, tracheoesophageal, renal, and limb defects. Presents with absence of anal opening on physical examination. Management: colostomy for high lesions; perineal anoplasty for low lesions.

Impetigo

- A superficial bacterial skin infection, most commonly caused by *Staphylococcus aureus* or Group A *Streptococcus*. Presents with honey-colored crusted lesions (nonbullous) or fluid-filled blisters (bullous). Common in children. Diagnosis is clinical. Treatment: topical mupirocin for localized disease; oral antibiotics for extensive disease. Prevention by good hand hygiene and avoiding sharing personal items.

Infantile Colic

- A behavioral syndrome in healthy infants characterized by episodes of excessive, inconsolable crying for >3 hours per day, >3 days per week, for >3 weeks (Wessel criteria). Onset typically at 2-3 weeks, peaks at 6-8 weeks, and resolves by 3-4 months of age. Etiology poorly understood: possible GI (gas, gut microbiota, cow milk protein intolerance), neurodevelopmental, or behavioral. Diagnosis: clinical; must rule out organic causes (intussusception,

GERD, infection, hair tourniquet, corneal abrasion, testicular torsion). Treatment: parental reassurance, carrying/rocking, white noise, and swaddling. Probiotics, simethicone, and hypoallergenic formula may help some infants. Prognosis: excellent, self-limited.

Influenza Vaccine

- Inactivated influenza vaccine given annually starting at 6 months of age. Two doses needed in the first season for children under 9. Live attenuated nasal spray vaccine (FluMist) available for children over 2. Updated annually to match circulating strains. Reduces influenza complications, hospitalizations, and deaths. Recommended for all children.

Intestinal Atresia

- A congenital obstruction of the small intestine (jejunum or ileum) caused by an intrauterine vascular accident (mesenteric ischemia) leading to aseptic necrosis and resorption of a segment of bowel. In contrast to duodenal atresia, it is not associated with Down syndrome. Presents in the first 24-48 hours with bilious vomiting and progressive abdominal distension. Failure to pass meconium is universal with distal atresia. Classification (Grosfeld): Type I — mucosal web with intact bowel wall; Type II — blind ends connected by a fibrous cord; Type IIIa — complete separation of blind ends with a V-shaped mesenteric defect; Type IIIb — apple-peel or Christmas-tree deformity (extensive atresia with a spiral-shaped distal bowel); Type IV — multiple atresias. Diagnosis: abdominal X-ray shows dilated proximal bowel loops (number indicates level of atresia) with no distal gas; contrast enema shows an unused microcolon. Treatment: primary anastomosis after resection of the dilated proximal segment; tapering enteroplasty may be needed for severe proximal dilation. Prognosis: excellent for Type I-IIIa; guarded for IIIb and IV.

Intraventricular Hemorrhage

- Bleeding into the germinal matrix and ventricular system, primarily in premature infants less than 32 weeks gestation. Graded I-IV by severity on cranial ultrasound. Grade I (germinal matrix only) and Grade II (intraventricular without dilation) have good prognosis. Grade III (with ventricular dilation) and Grade IV (parenchymal involvement) risk

neurodevelopmental impairment. Prevention: antenatal corticosteroids, avoiding rapid fluid shifts.

Jaundice in newborns

– See [Neonatal Jaundice \(Jaundice of the Newborn\)](#).

Juvenile Idiopathic Arthritis (JIA)

– A heterogeneous group of autoimmune and inflammatory conditions causing persistent arthritis (joint swelling, pain, limited range of motion) in children aged <16 years, lasting >6 weeks. Classification: oligoarticular (most common, 50%, <5 joints, high risk of uveitis), polyarticular (RF-positive or RF-negative, 30%), systemic-onset (Still disease, high spiking fevers, salmon-pink evanescent rash, serositis, hepatosplenomegaly), enthesitis-related (enthesitis, sacroiliitis, HLA-B27 association), and psoriatic arthritis. etiology: complex genetic predisposition (HLA class II associations) plus environmental triggers. Management: NSAIDs (first-line), intra-articular corticosteroid injections, methotrexate (first-line DMARD), biologic agents (anti-TNF—etanercept, adalimumab; anti-IL-6—tocilizumab for systemic JIA; anti-IL-1—anakinra). Uveitis screening is essential (slit-lamp every 3-4 months) as most cases are asymptomatic and can cause blindness.

Kawasaki Disease

– An acute vasculitis of childhood affecting medium-sized arteries, particularly coronary arteries. Diagnosis requires fever greater than 5 days plus 4 of 5 criteria: bilateral conjunctivitis, oral mucosal changes, cervical lymphadenopathy, extremity changes, and polymorphous rash. Complications include coronary artery aneurysms. Treatment: IV immunoglobulin (IVIG) 2 g/kg as a single infusion within the first 10 days of illness, plus aspirin—high-dose (80-100 mg/kg/day in 4 divided doses) during the acute febrile phase, then low-dose (3-5 mg/kg/day for 6-8 weeks, or longer if coronary aneurysm present). Coronary artery aneurysms occur in 15-25 percent of untreated cases; IVIG reduces this to less than 5 percent. Most common acquired heart disease in children in developed countries.

Kernicterus

– Bilirubin encephalopathy resulting from severe unconjugated hyperbilirubinemia (typically greater than 25 mg/dL in term infants). Bilirubin deposits in the basal ganglia, hippocampus, and brainstem

nuclei. Presents with lethargy, poor feeding, high-pitched cry, opisthotonus, seizures, and choreoathetosis. May cause permanent neurologic damage including hearing loss, cerebral palsy, and intellectual disability. Prevention by treating severe jaundice with phototherapy or exchange transfusion.

Klippel-Trenaunay Syndrome

– A congenital vascular disorder characterized by the triad: capillary malformations (port-wine stains), venous malformations (varicose veins, persistent embryonic veins), and soft tissue or bone hypertrophy of the affected limb (typically a lower extremity). Caused by a somatic activating mutation in PIK3CA (part of the PIK3CA-related overgrowth spectrum). The hypertrophy is disproportionate, involving bone (increased length and girth) and soft tissues. Present at birth; progresses with growth. Complications: chronic venous insufficiency, cellulitis, deep vein thrombosis, pulmonary embolism (from anomalous veins), and life-threatening bleeding from pelvic or abdominal venous malformations. Diagnosis: clinical and MRI/MRV of the affected limb (shows abnormal venous anatomy and hypertrophy). Treatment: compression stockings for venous insufficiency; epiphyseal stapling or surgical debulking for limb overgrowth; sclerotherapy or surgical excision for symptomatic venous malformations. Anticoagulation for thromboembolic events. Differentiated from Parkes Weber syndrome by the absence of arteriovenous fistulas.

Legg-Calve-Perthes Disease

– Idiopathic avascular necrosis of the femoral head in children, typically ages 4-8 years. More common in boys (4:1) and Caucasian children. Presents with limping (antalgic gait), hip/knee pain, and limited hip range of motion (especially abduction and internal rotation). Etiology: temporary disruption of blood supply to the femoral head. Diagnosis: hip X-ray shows fragmentation, flattening, and collapse of the femoral head (staging: Waldenstrom). MRI for early diagnosis. Prognosis: better in younger children (<6), with preservation of femoral head sphericity. Treatment: observation for mild cases; containment therapy (Petrie cast, abduction brace, or femoral/pelvic osteotomy) for moderate to severe.

Low Birth Weight

- Birth weight <2500 g, often due to prematurity and/or intrauterine growth restriction; further classified: very low (<1500 g), extremely low (<1000 g), and small for gestational age. Risks: increased neonatal mortality, hypothermia, hypoglycemia, respiratory distress, infection, feeding difficulties, and long-term growth and neurodevelopmental problems. Causes: preterm birth, placental insufficiency, maternal hypertension/preeclampsia, smoking, malnutrition, multiple pregnancy, infection, and congenital anomalies. Management: specialized neonatal care (thermal, nutritional—breast milk/fortified feeds, infection prevention), monitoring for complications, catch-up growth, and long-term follow-up. Prevention: antenatal care and treatment of maternal conditions.

Malrotation

- See [Intestinal Malrotation](#).

Maple Syrup Urine Disease

- An autosomal recessive inborn error of branched-chain amino acid metabolism caused by deficiency of the branched-chain alpha-ketoacid dehydrogenase complex (BCKDC) — mutations in BCKDHA, BCKDHB, DBT, or DLD. Results in accumulation of leucine, isoleucine, and valine (and their ketoacids) in the blood, giving a characteristic maple syrup (burnt sugar) odor to urine and cerumen. The classic neonatal form presents at 3-5 days of life with poor feeding, vomiting, lethargy, hypertonicity (opisthotonus), seizures, and cerebral edema progressing to coma and death if untreated. Diagnosis: plasma amino acid analysis (elevated leucine, isoleucine, valine, and alloisoleucine — pathognomonic) and BCKDHA/B gene testing. Newborn screening detects MSUD in most developed countries. Treatment: acute crises — rapid removal of branched-chain amino acids via hemodialysis or hemofiltration, IV glucose, insulin, and supplementation with isoleucine and valine to promote protein synthesis. Chronic management: strict dietary restriction of leucine, isoleucine, and valine (specialized medical formulas), thiamine supplementation (thiamine-responsive forms, 5%), and metabolic monitoring. Liver transplantation can be curative.

Marfanoid Habitus

- A body habitus characterized by tall stature, long limbs, long fingers (arachnodactyly), and joint laxity. Seen in Marfan syndrome, but also in other connective tissue disorders and homocystinuria. Differentiated from Marfan syndrome by absence of aortic root dilation and lens subluxation. Requires cardiac evaluation to rule out aortic pathology.

Measles

- A highly contagious viral illness caused by Morbillivirus, transmitted by respiratory droplets. Prodrome of fever, coryza, cough, and conjunctivitis, followed by Koplik spots (white buccal mucosal lesions) and maculopapular rash spreading cephalocaudally. Complications: pneumonia, encephalitis, and subacute sclerosing panencephalitis. Prevention by MMR vaccination. Highly contagious with R0 of 12-18.

Meconium Aspiration Syndrome

- Respiratory distress in newborns born through meconium-stained amniotic fluid, caused by aspiration of meconium into the airways. Presents with respiratory distress, barrel-shaped chest, and coarse crackles. Meconium is thick, greenish-black fetal stool passed in utero. Risk factors include post-term pregnancy and fetal distress. Management: airway suctioning, mechanical ventilation, and treatment of complications including pneumothorax.

Meconium-Stained Amniotic Fluid

- Greenish or yellowish discoloration of amniotic fluid due to fetal meconium passage in utero. Associated with fetal distress, post-term pregnancy, and fetal growth restriction. Thick meconium increases risk of meconium aspiration syndrome. Management of non-vigorous newborns: tracheal suctioning before positive pressure ventilation. Vigorous newborns: routine care with close monitoring.

Meningococcal Vaccine

- Conjugate vaccine (MenACWY) and serogroup B vaccine (MenB) given at 11-12 years with booster at 16 years. Protects against *Neisseria meningitidis*, causing meningitis and septicemia. MenACWY booster at 16 years covers the high-risk period for serogroup C and Y disease. MenB given based on shared clinical decision-making or during outbreaks. One of the most devastating pediatric infections.

Menkes Disease

– An X-linked recessive disorder of copper metabolism caused by ATP7A mutations, resulting in impaired intestinal copper absorption and defective copper transport across the blood-brain barrier. Copper accumulates in intestinal and renal cells but is deficient in the liver and brain. Presents at 2-3 months with progressive neurologic deterioration, seizures, and characteristic hair abnormalities — stubby, white, brittle, and twisted (pili torti, pathognomonic on microscopy). Other features: hypotonia, failure to thrive, metaphyseal spurring (bladder-like metaphyses), wormian skull bones, and arterial tortuosity (cerebral and femoral arteries, prone to thrombosis and aneurysms). Diagnosis: low serum copper and ceruloplasmin (after 6-8 weeks of age), elevated copper in cultured fibroblasts, and ATP7A sequencing. Treatment: early parenteral copper-histidine supplementation (before symptoms) can improve neurologic outcomes. Established neurologic disease is irreversible. Prognosis: severe neurodegeneration and death by 3 years without treatment.

Metaphyseal Corner Fractures

– Bucket-handle or corner fractures at the metaphysis of long bones, characteristic of child abuse. Caused by twisting or pulling forces on extremities. Most common in the knee, ankle, and elbow. Seen on skeletal survey; may not be visible initially. Highly specific for non-accidental trauma in infants. Orthopedic consultation and full skeletal survey recommended.

Micrognathia

– A condition where the mandible is abnormally small, resulting in a retruded chin and decreased size of the oral cavity. May be isolated or syndromic (Pierre Robin sequence, Treacher Collins, Nager syndrome, Stickler syndrome). Presents at birth with potential airway obstruction (glossoptosis) and feeding difficulties. The severity depends on the degree of mandibular hypoplasia and tongue position. Diagnosis: clinical examination and cephalometric analysis. Management: prone positioning or lateral positioning for mild cases (gravity helps keep the tongue forward), nasopharyngeal airway for moderate obstruction, and mandibular distraction osteogenesis for severe obstruction. Most cases

show significant mandibular catch-up growth during childhood.

MMR Vaccine

– Measles, Mumps, and Rubella live attenuated vaccine given at 12-15 months and 4-6 years. Two doses provide 97% protection against measles and mumps, and 98% against rubella. Contraindicated in pregnancy and immunocompromised individuals. Post-exposure prophylaxis within 72 hours. Measles remains a global health threat; outbreaks occur in under-vaccinated communities.

Measles-Rubella (MR) Vaccine

– A combined live attenuated vaccine containing measles and rubella antigens without the mumps component, widely used in countries where mumps is not a significant public health burden, including India's Universal Immunization Schedule. The WHO-prequalified MR vaccine (e.g., Serum Institute of India) is administered as two doses: the first at 9 months (alongside or shortly after BCG) and the second between 16-24 months. In India, the first dose is given at 9-12 months and the second at 16-24 months. Two doses provide greater than 95 percent protection against both measles and rubella. Measles remains a leading cause of vaccine-preventable childhood mortality globally, and rubella infection in pregnancy causes congenital rubella syndrome (deafness, cataracts, cardiac defects). The MR vaccine replaces the separate monovalent measles and rubella doses used in earlier schedules. Contraindicated in pregnancy and severely immunocompromised individuals. Post-exposure prophylaxis within 72 hours. See also [MMR Vaccine](#) for the mumps-containing formulation.

Morgagni Hernia

– A congenital diaphragmatic hernia occurring through the anterior retrosternal foramen of Morgagni (space of Larrey), resulting from failure of the sternal and costal portions of the diaphragm to fuse. The right side is affected in 90% of cases (the hernia sac is present in 90%). Abdominal contents (typically omentum, transverse colon, and liver) herniate into the anterior mediastinum. Often asymptomatic and incidentally discovered on chest X-ray (seen as a right cardiophrenic angle mass). Presents

later in life than Bochdalek hernias (childhood to adulthood) with recurrent chest infections, dyspnea, or abdominal pain. Associated with obesity and trauma (increases intra-abdominal pressure). Diagnosis: chest X-ray shows a well-defined opacity in the right cardiophrenic angle; CT confirms the hernia, the contents, and the defect. Treatment: surgical repair (laparoscopic or open) with reduction of hernia contents and primary closure of the defect with or without mesh. Prognosis: excellent, with low recurrence rates.

Moro Reflex

- A primitive reflex present from birth to 3-6 months, elicited by suddenly startling the infant (loud noise, head drop). The infant extends both arms outward with fingers spread, then draws arms inward as if embracing. Absence at birth suggests central nervous system injury or brachial plexus palsy. Asymmetric response may indicate clavicle fracture or Erb palsy. Used as a marker of neurologic integrity.

Multicystic Dysplastic Kidney

- A congenital renal anomaly where one or both kidneys are replaced by multiple non-communicating cysts of varying sizes, with no functioning renal parenchyma. The most common cause of an abdominal mass in a newborn (unilateral). The ureter is typically atretic. The contralateral kidney may have VUR (20%) or UPJ obstruction (10%). Bilateral MCDK is incompatible with life (Potter syndrome). Most unilateral cases are asymptomatic and discovered on prenatal ultrasound. Diagnosis: postnatal ultrasound shows multiple non-communicating cysts of varying sizes, no identifiable renal sinus, and a reniform shape may be lost. A DMSA renal scan shows no function in the affected kidney. Treatment: observation is standard — most MCDKs involute (shrink) spontaneously over years. Blood pressure monitoring and urinalysis annually. Nephrectomy is rarely indicated (hypertension, recurrent UTI, or mass effect). Contralateral kidney evaluation (VCUG) for VUR and (US) for UPJ obstruction is essential.

Mumps

- Paramyxovirus infection causing bilateral parotitis, fever, and headache. Complications include orchitis (rarely causing infertility), meningitis, pancreatitis,

and sensorineural hearing loss. Prevention by MMR vaccination. Outbreaks occur in unvaccinated populations. Diagnosis by serology or RT-PCR from saliva. Supportive treatment; no specific antiviral therapy.

Myelomeningocele

- The most severe form of spina bifida, where the spinal cord and meninges herniate through a vertebral defect into a sac on the back. Presents with a visible, fluid-filled sac at birth. Associated with hydrocephalus, Arnold-Chiari malformation, and lower extremity paralysis. Management: surgical closure within 24-48 hours, CSF drainage if hydrocephalus develops, and long-term rehabilitation for mobility and bowel/bladder function.

Necrotizing Enterocolitis

- An acquired necrotic inflammatory disease of the intestine, primarily affecting premature infants. Risk factors include prematurity, enteral feeding, and bacterial colonization. Presents with abdominal distension, bloody stools, bilious vomiting, and feeding intolerance. Pneumatosis intestinalis on X-ray is pathognomonic. Management: NPO, nasogastric decompression, IV antibiotics, and supportive care. Complications include perforation, peritonitis, and stricture formation.

Neglect

- A form of child maltreatment: the failure to provide for a child's basic needs—physical (food, clothing, shelter, medical care), educational, or emotional—causing harm or risk of harm. Features: failure to thrive, poor hygiene, untreated illness/injury, missed healthcare appointments, inadequate supervision, and developmental delay. Risk: parental mental illness, substance use, poverty, and domestic violence. Diagnosis: high index of suspicion, history, physical exam, growth assessment, and documentation. Management: safeguarding—report to child protection services, multidisciplinary assessment, support for the family (parenting programs, social services), and child safety planning; hospitalization for severe cases. Prevention: home visiting and family support.

Neonatal Abstinence Syndrome

- A withdrawal syndrome in neonates following in utero exposure to opioids (most common) or other

substances (benzodiazepines, SSRIs, alcohol). Onset within 24-72 hours of birth (varies by half-life of substance). Presents with CNS hyperirritability (high-pitched crying, tremors, irritability, hyper-tonia, seizures), autonomic dysfunction (sweating, fever, tachypnea), and GI symptoms (poor feeding, vomiting, diarrhea). Diagnosis: Finnegan Neonatal Abstinence Scoring System quantifies severity. Treatment: non-pharmacologic (swaddling, low stimulation, skin-to-skin contact, breastfeeding if no contraindications) and pharmacologic for moderate-severe (morphine or methadone weaning protocol). Adjunctive: clonidine, phenobarbital. Prognosis: most recover fully with appropriate management.

Neonatal Cephalohematoma

– A subperiosteal hematoma of the skull, occurring in approximately 1-2% of births, usually from forceps or vacuum delivery. Presents as a boggy, fluctuant swelling over the skull that does not cross suture lines (differentiating from caput succedaneum). Resolves spontaneously over weeks to months. Complications include hyperbilirubinemia, anemia, and calcification. No treatment required in most cases.

Neonatal Herpes Simplex

– Herpes simplex virus infection in the first 28 days of life, usually HSV-2 from maternal genital infection. Three forms: skin, eye, and mouth disease; CNS disease; and disseminated disease. Disseminated form mimics sepsis with high mortality. Diagnosis by viral PCR, culture, or Tzanck smear. Treatment: IV acyclovir for 14-21 days. Cesarean delivery recommended for active genital lesions near term.

Neonatal Hypoglycemia

– Blood glucose less than 40-45 mg/dL in term infants or less than 25 mg/dL in preterm infants. Risk factors include prematurity, small for gestational age, large for gestational age, and maternal diabetes. Presents with jitteriness, lethargy, poor feeding, and seizures. Treatment: early feeding, IV dextrose infusion, and monitoring. Persistent hypoglycemia may require glucagon or hydrocortisone.

Neonatal Hypothermia

– Core body temperature below 36.5 degrees Celsius in a newborn. Classified as mild (36-36.4), moderate (32-35.9), or severe (below 32). Occurs due to rapid heat loss through evaporation, convection,

conduction, and radiation. Prevention: skin-to-skin contact, drying, warm environment, and delayed bathing. Treatment: warming methods appropriate to severity; monitor glucose and electrolytes.

Neonatal Jaundice

– See Neonatal Jaundice (Jaundice of the Newborn).

Neonatal Jaundice (Jaundice of the Newborn)

– Yellowish discolouration of the skin and sclerae in newborn infants due to elevated unconjugated bilirubin. Occurs in 60% of term infants and 80% of preterm infants. Physiological jaundice: appears after 24 hours of life, peaks at day 3-5 in term infants (day 5-7 in preterm), resolves by 2 weeks. Caused by: increased RBC mass, shorter RBC lifespan (70-90 days), immature hepatic conjugation (decreased UGT activity), increased enterohepatic circulation. Pathological jaundice: appears within 24 hours, bilirubin rising >85 micromol/L/day, or persisting >14 days (term) or >21 days (preterm). Causes: hemolytic (ABO incompatibility, Rh incompatibility, G6PD deficiency, hereditary spherocytosis), bruising/cephalhaematoma, polycythaemia, sepsis, biliary atresia, galactosaemia, Crigler-Najjar syndrome, Gilbert syndrome. Complications: acute bilirubin encephalopathy (lethargy, poor feeding, hypotonia, high-pitched cry, opisthotonos, seizures) and kernicterus (chronic, irreversible choreoathetoid cerebral palsy, upward gaze palsy, sensorineural hearing loss, enamel dysplasia). Management: phototherapy (most effective, blue light 460-490 nm, converts bilirubin to water-soluble isomers excreted without conjugation), exchange transfusion (for severe hyperbilirubinaemia failing phototherapy), and treatment of underlying cause. NICE and AAP guidelines provide phototherapy and exchange transfusion thresholds based on gestational age, birth weight, and risk factors.

Neonatal Sepsis

– Systemic bacterial infection in the first 28 days of life, classified as early-onset (within 72 hours, usually from vertical transmission) or late-onset (after 72 hours, often nosocomial). Common organisms: Group B Streptococcus, E. coli, Listeria. Presents with non-specific symptoms: poor feeding, lethargy, temperature instability, tachycardia, and respira-

tory distress. Diagnosis by blood culture; treatment with empiric IV antibiotics (ampicillin and gentamicin).

Neonatologist

– A pediatrician who specializes in the medical care of newborn infants, particularly premature and critically ill neonates. Neonatologists manage conditions including respiratory distress syndrome, bronchopulmonary dysplasia, intraventricular hemorrhage, necrotizing enterocolitis, neonatal sepsis, hypoxic-ischemic encephalopathy (therapeutic hypothermia), congenital anomalies, and extreme prematurity. They work in neonatal intensive care units (NICU), lead resuscitation teams at high-risk deliveries, and coordinate care with pediatric surgeons, cardiologists, and geneticists. Training: pediatric residency + 3-year neonatal-perinatal medicine fellowship.

Neural Tube Defects

– Congenital malformations resulting from failure of the neural tube to close during the third to fourth week of gestation. Include anencephaly (incomplete cranial closure), encephalocele (herniation through skull defect), and spina bifida (incomplete spinal closure). Spina bifida ranges from occulta (mild, asymptomatic) to myelomeningocele (severe, with neural tissue protrusion). Prevention with folic acid supplementation before and during pregnancy.

Neurofibromatosis Type 2

– An autosomal dominant disorder caused by NF2 gene mutation on chromosome 22. Characterized by bilateral vestibular schwannomas (acoustic neuromas), meningiomas, and ependymomas. Features: hearing loss, tinnitus, and balance problems. Diagnosis: MRI showing bilateral vestibular schwannomas. Management: hearing preservation surgery, radiation therapy, and surveillance imaging.

Newborn Circumcision

– Surgical removal of the foreskin from the penis, typically performed within the first few days of life. Medical benefits include reduced risk of urinary tract infections, sexually transmitted infections, and penile cancer. Complications include bleeding, infection, and meatal stenosis. Techniques include Plastibell, Gomco clamp, and Mogen clamp. Performed with parental informed consent. Not uni-

versally recommended; benefits versus risks should be discussed.

Niemann-Pick Disease

– A group of autosomal recessive lysosomal storage disorders caused by sphingomyelinase deficiency (ASM, types A and B, SMPD1 mutations) or NPC1/NPC2 cholesterol transport defects (type C). Type A (infantile neuropathic): severe, presents at 3-6 months with hepatosplenomegaly, cherry-red macula (50%), developmental regression, neurodegeneration, and death by 2-3 years. Type B (chronic visceral): later onset, hepatosplenomegaly, pulmonary infiltrates (foam cells in alveoli), thrombocytopenia, and dyslipidemia — no or minimal neurologic involvement; survival into adulthood. Type C: variable onset (infantile to adult) with neurologic features: vertical supranuclear gaze palsy (pathognomonic), ataxia, dystonia, seizures, dementia, and cataplexy. Diagnosis: types A/B — acid sphingomyelinase enzyme assay in leukocytes. Type C — filipin staining for cholesterol accumulation in fibroblasts and NPC1/NPC2 sequencing. Treatment: types A/B — olipudase alfa (enzyme replacement therapy, FDA-approved for type A/B non-neurologic). Type C — miglustat (substrate reduction therapy). Supportive care for neurological symptoms.

Non-Accidental Trauma

– Injuries inflicted on a child, suspected when history and examination findings are inconsistent with the reported mechanism. Red flags: multiple fractures at different stages of healing, posterior rib fractures, metaphyseal corner fractures, and retinal hemorrhages. Requires comprehensive evaluation including skeletal survey, CT head, ophthalmologic exam, and laboratory workup. Social work and child protective services involvement mandatory.

Noonan Syndrome

– An autosomal dominant multisystem disorder caused by mutations in the RAS-MAPK pathway genes (PTPN11 50%, SOS1 10-15%, RAF1 5-10%, RIT1, KRAS). Features: characteristic facies (hypertelorism, downslanting palpebral fissures, low-set posteriorly rotated ears, webbed neck, ptosis), short stature, congenital heart disease (pulmonary stenosis 50-60%, hypertrophic cardiomyopathy 20-30%),

pectus deformities, and cryptorchidism. Coagulation defects (factor XI deficiency, von Willebrand disease) are common. Intelligence is usually normal, though learning disabilities and speech delays are common. Diagnosis: clinical criteria (van der Burgt) and genetic testing. Management: growth hormone therapy for short stature, cardiology follow-up (pulmonary stenosis balloon valvuloplasty, HCM monitoring), and developmental support.

Omphalitis

– Infection of the umbilical stump in neonates, typically occurring within the first 1–2 weeks of life. Omphalitis is a potentially serious condition requiring prompt treatment due to the risk of spread to the liver (portal vein thrombosis, portal hypertension) and peritoneum via the umbilical vessels. Risk factors: home delivery with unsterile cord care, low birth weight, prolonged rupture of membranes (>18 hours), umbilical catheterisation, and immunocompromised state. Presentation: periumbilical erythema, edema, tenderness, purulent or foul-smelling discharge from the umbilicus. Signs of systemic infection (fever, lethargy, poor feeding, tachycardia, hypotension) indicate severe disease. Pathogens: *Staphylococcus aureus*, Group A *Streptococcus*, *Escherichia coli*, *Klebsiella*, and anaerobes (*Bacteroides fragilis*). Diagnosis is clinical; wound culture, blood culture, and ultrasound (assess for abscess, thrombophlebitis, necrotising fasciitis) in severe cases. Treatment: IV antibiotics covering Gram-positive, Gram-negative, and anaerobic organisms (flucloxacillin plus gentamicin plus metronidazole). Surgical debridement for necrotising fasciitis or abscess drainage. Complications: necrotising fasciitis (abdominal wall cellulitis with crepitus, high mortality), portal vein thrombosis, peritonitis, and neonatal sepsis. Prevention: chlorhexidine cord care (reduces omphalitis in high-mortality settings per WHO recommendation).

Omphalocele

– A congenital abdominal wall defect where abdominal organs herniate into the base of the umbilical cord, covered by a peritoneal-amniotic membrane. Associated with chromosomal abnormalities (trisomies 13, 18) and other anomalies. Differentiated from gastroschisis by membrane coverage and midline location. Small omphaloceles may be repaired

primarily; large defects require staged closure with silastic silo and gradual reduction.

Oral Polio Vaccine (OPV-O)

– Sabin vaccine, a live attenuated preparation of poliovirus administered orally, historically the primary tool for global polio eradication. The bivalent formulation (bOPV) contains attenuated types 1 and 3 only; the type 2 component was withdrawn from routine use in April 2016 following the certified eradication of wild poliovirus type 2. OPV replicates in the intestinal mucosa, inducing both humoral (serum IgG) and robust mucosal (secretory IgA) immunity, which interrupts person-to-person fecal-oral transmission—a critical advantage over inactivated polio vaccine (IPV) for eradication campaigns. Advantages include low cost, ease of administration (no needles), cold-chain flexibility, and secondary immunisation of close contacts through shedding of attenuated virus. The World Health Organization and Global Polio Eradication Initiative continue to use bOPV in mass vaccination campaigns in endemic and at-risk regions. Risks include vaccine-associated paralytic polio (VAPP, approximately 1 case per 2.7 million first doses, caused by reversion of attenuated virus to neurovirulent form) and circulating vaccine-derived poliovirus (cVDPV), which emerges in under-immunised populations where the attenuated virus circulates and reverts. OPV is contraindicated in immunocompromised individuals. The United States exclusively uses IPV since 2000. In India's Universal Immunization Schedule, OPV-0 is given at birth, followed by OPV 1-3 at 6, 10, and 14 weeks, and a booster at 16-24 months, alongside fractional IPV for enhanced protection. See [India Immunization Schedule](#), [Polio](#), and [Poliomyelitis](#) in infectious disease.

Osteogenesis Imperfecta

– A connective tissue disorder caused by collagen type I mutations, ranging from mild to lethal. Features: fractures with minimal trauma, blue sclerae, dental abnormalities, and hearing loss. Severe forms (type II) cause multiple fractures in utero and perinatal death. Diagnosis: clinical features, genetic testing, and bone biopsy. Management: bisphosphonates, physical therapy, and surgical correction of deformities.

Otitis Media

– Middle ear infection, the most common childhood illness after the common cold. Peak incidence between 6-15 months. Risk factors include secondhand smoke, daycare attendance, formula feeding, and anatomy. Presents with ear pain, fever, irritability, and hearing loss. Diagnosis by otoscopic exam showing erythema, bulging tympanic membrane, or effusion. Treatment: antibiotics (amoxicillin first-line) for acute otitis media. See also [Acute Otitis Media](#).

Palmar Grasp Reflex

– A primitive reflex present from birth to 5-6 months, elicited by placing a finger in the infant's palm. The infant grips tightly, strong enough to support the infant's weight briefly. Bilateral symmetry assessed; asymmetry may indicate birth injury. Disappears as voluntary grasping develops around 3-4 months. Used as a neurologic marker in the newborn examination.

Parvovirus B19

– Human parvovirus B19: a small DNA virus causing erythema infectiosum ('fifth disease') in children, transmitted by respiratory droplets. Features: 'slapped cheek' rash (bright red cheeks) followed by a lace-like (reticular) rash on the trunk/limbs, mild fever; in adults: arthropathy; in chronic hemolytic states (sickle cell): transient aplastic crisis (severe anemia); in pregnancy: fetal hydrops (anemia) and fetal loss; in immunocompromised: chronic anemia. Diagnosis: clinical; serology (IgM/IgG), PCR (aplastic crisis/fetus). Management: supportive—transfusion for aplastic crisis, intrauterine transfusion for severe fetal anemia; no vaccine; respiratory precautions; reassure about benign course in immunocompetent children.

Patau Syndrome

– Trisomy 13, affecting 1 in 10,000-20,000 live births. Features: holoprosencephaly (most characteristic, incomplete forebrain division), microcephaly, microphthalmia or anophthalmia, cleft lip and palate, polydactyly (postaxial), clenched fists with overlapping fingers, and congenital heart defects (VSD, PDA, dextrocardia, 80%). Other findings: cutis aplasia (scalp defect, particularly the occipital scalp), omphalocele, and renal anomalies (polycys-

tic kidneys). Diagnosis: prenatal screening (abnormal first-trimester ultrasound with increased nuchal translucency), NIPT, and karyotype/CMA. Management: comfort care (median survival 7-10 days; <10% survive to 1 year). Survivors have profound intellectual disability and severe growth restriction.

Patent Ductus Arteriosus

– PDA: failure of the ductus arteriosus (fetal connection between pulmonary artery and aorta) to close after birth, causing a left-to-right shunt. Common in preterm infants; term—often small. Features: continuous 'machinery' murmur, bounding pulses, wide pulse pressure; large shunt—heart failure, failure to thrive, pulmonary hypertension (Eisenmenger if long-standing). Diagnosis: echocardiography. Management: preterm—indomethacin/ibuprofen (cyclooxygenase inhibitors) or paracetamol, and surgical ligation if refractory; term/older—transcatheter closure (coil/device) or surgery; small asymptomatic PDAs—monitoring/elective closure; prevention of endocarditis historically. Closure prevents complications.

Pectus Carinatum

– A congenital chest wall deformity characterized by anterior protrusion of the sternum (pigeon chest), caused by excessive growth of the costal cartilages pushing the sternum forward. Less common than pectus excavatum. Associated with congenital heart disease, Marfan syndrome, Noonan syndrome, and homocystinuria. Presents in childhood and progresses during the adolescent growth spurt. Symptoms are predominantly cosmetic, but some children experience chest pain, exercise intolerance, or psychosocial distress. Diagnosis: clinical examination and CT or X-ray to evaluate symmetry and severity. Treatment: orthotic bracing (dynamic chest compressor, effective for flexible deformities in younger children) is first-line, worn 12-23 hours daily for 6-12 months. Surgical correction (Ravitch-type sternal osteotomy with costal cartilage resection) for severe or rigid deformities or bracing failure. Outcomes are excellent with both methods.

Pectus Excavatum

– The most common congenital chest wall deformity, characterized by depression of the sternum (funnel chest), caused by excessive growth of the

costal cartilages that push the sternum inward. Typically sporadic, but associated with Marfan syndrome, Ehlers-Danlos syndrome, Noonan syndrome, and Poland syndrome. Presents in early childhood and progresses during the adolescent growth spurt. Symptoms are usually cosmetic, but severe cases can cause cardiopulmonary impairment (reduced stroke volume, dyspnea on exertion, exercise intolerance). The Haller index (CT ratio of transverse chest diameter to anterior-posterior diameter, >3.25 is severe) quantifies severity. Diagnosis: clinical (the depression is obvious) and CT chest for Haller index. Treatment: observation for mild cases. Surgical correction: Nuss procedure (minimally invasive, pectus bar placed retrosternally under thoracoscopic guidance, removed after 2-4 years) for moderate to severe cases. Modified Ravitch procedure (open resection of costal cartilages and sternal osteotomy) for older patients or failed Nuss. Outcomes: excellent cosmetic and functional results.

Pediatric Diabetic Ketoacidosis

– A life-threatening complication of type 1 diabetes characterized by hyperglycemia, metabolic acidosis, and ketosis. Presents with polyuria, polydipsia, vomiting, abdominal pain, Kussmaul respirations, and fruity breath odor. Diagnosis: blood glucose greater than 250 mg/dL, pH less than 7.3, bicarbonate less than 15 mEq/L, and positive ketones. Treatment: IV fluids, insulin infusion, and electrolyte replacement with careful potassium monitoring.

Pediatric Health

– Pediatric health encompasses the physical, cognitive, emotional, and social development of children from infancy through adolescence, with emphasis on preventive care, developmental surveillance, and age-appropriate management of acute and chronic conditions. Well-child care follows a schedule: immunizations (per CDC/ACIP: DTaP, IPV, MMR, varicella, HPV, meningococcal, influenza, COVID-19), developmental screening (Ages and Stages Questionnaire, M-CHAT for autism at 18 and 24 months), growth monitoring (WHO/CDC growth charts), vision/hearing screening, and anticipatory guidance (injury prevention, nutrition, sleep, media use, substance use prevention). Common pediatric conditions: otitis media, asthma, atopic dermatitis, allergic rhinitis, ADHD (prevalence 9%), autism spectrum disorder (prevalence 2.8%), anxiety/depression, obesity (affecting 20% of US children), infectious diseases (RSV, croup, gastroenteritis), and congenital anomalies. Adolescent health addresses puberty, sexual health (STI prevention, contraception), mental health (leading cause of disability in teens), substance use, and transition to adult care. Family-centered care and trauma-informed approaches improve outcomes.

– Inflammation of the meninges in children, bacterial forms being the most dangerous. Presents with fever, headache, neck stiffness, photophobia, altered mental status, and petechial rash (meningococcal). Infants may present with irritability, poor feeding, bulging fontanelle, and high-pitched cry. Diagnosis by lumbar puncture showing elevated WBC, elevated protein, low glucose, and positive Gram stain/culture. Treatment: empiric ceftriaxone and vancomycin.

Pediatric Meningitis

– A medical doctor who specializes in the health and medical care of children from birth through adolescence (typically up to age 16-18). Pediatricians focus on: growth and development, preventive care (immunizations, developmental screening, anticipatory guidance), acute illness (infections, injuries), chronic disease management (asthma, diabetes, epilepsy, allergies), and behavioral/mental health. Subspecialties: neonatology, pediatric cardiology, pediatric oncology, pediatric gastroenterology, pediatric emergency medicine, pediatric intensive care, pediatric endocrinology, pediatric neurology, and developmental pediatrics. Training: medical school + 2 years foundation training (UK) or 3 years pediatrics residency (US) + subspecialty fellowship.

Pediatrician

– The branch of medicine concerned with the health and medical care of infants, children, and adolescents from birth to age 18 (or up to age 16 in the UK). Pediatric care encompasses: well-child visits (growth monitoring, developmental screening, immunisations, anticipatory guidance), management of acute illness (infections, injuries), management of chronic conditions (asthma, diabetes, epilepsy, cystic fibrosis, congenital heart disease), and be-

Pediatrics

– The branch of medicine concerned with the health and medical care of infants, children, and adolescents from birth to age 18 (or up to age 16 in the UK). Pediatric care encompasses: well-child visits (growth monitoring, developmental screening, immunisations, anticipatory guidance), management of acute illness (infections, injuries), management of chronic conditions (asthma, diabetes, epilepsy, cystic fibrosis, congenital heart disease), and be-

havioural/mental health (ADHD, autism, anxiety, depression). Subspecialties: neonatology, pediatric cardiology, pediatric oncology, pediatric gastroenterology, pediatric pulmonology, pediatric neurology, pediatric nephrology, pediatric endocrinology, pediatric rheumatology, pediatric infectious disease, pediatric emergency medicine, pediatric intensive care, developmental pediatrics, and pediatric surgery. Preventive care: the childhood immunisation schedule (UK: 2, 3, 4 months; 12–13 months; 3 years 4 months; 12–14 years—boosters for tetanus, diphtheria, polio, HPV, MenACWY). The UK has a comprehensive child health surveillance programme (health visitor reviews, school entry checks).

Periventricular Leukomalacia

– Ischemic white matter injury in the premature infant brain, a major cause of cerebral palsy. Risk factors include prematurity, hypotension, and inflammation. Diagnosis by cranial ultrasound showing periventricular echodensities or cystic changes. Prevention: avoiding hypotension, maintaining normothermia, and managing infection. Long-term sequelae include spastic diplegia, cognitive impairment, and visual disturbances.

Pertussis

– A highly contagious bacterial infection caused by *Bordetella pertussis*, producing characteristic paroxysmal cough with whooping inspiratory sound. Three stages: catarrhal (1–2 weeks of URI symptoms), paroxysmal (weeks to months of violent coughing spells), and convalescent. Most dangerous in infants under 6 months. Treatment: macrolide antibiotics (azithromycin). Prevention: DTaP vaccination.

Pentavalent Vaccine

– A WHO-prequalified five-in-one combination vaccine containing Diphtheria toxoid, Tetanus toxoid, whole-cell Pertussis antigen, Hepatitis B (HBsAg), and *Haemophilus influenzae* type b (Hib) conjugate, administered as a single intramuscular injection. The pentavalent formulation replaces separate DTaP, HepB, and Hib injections, reducing the number of injections and improving coverage in resource-limited settings. India's Universal Immunization Schedule uses pentavalent vaccine at 6, 10, and 14 weeks of age (three primary doses). The

whole-cell pertussis component (as opposed to the acellular pertussis in US DTaP) provides broader protection but may cause more local reactions and fever. Common adverse effects include injection site swelling, redness, and pain, and transient fever (managed with paracetamol). The pentavalent vaccine is a cornerstone of the Expanded Programme on Immunization (EPI) in over 100 countries. Alternative formulations include DPT-HepB (without Hib) where Hib conjugate is supplied separately. DPT booster doses are given at 16–24 months and 5–6 years as part of India's Universal Immunization Schedule. See [India Immunization Schedule](#).

Pfeiffer Syndrome

– An autosomal dominant craniosynostosis syndrome caused by FGFR1 or FGFR2 mutations. Features: craniosynostosis (bilateral coronal), midface hypoplasia, proptosis, hypertelorism, broad thumbs and great toes (medial deviation), and variable syndactyly. Three clinical types: Type 1 (classic, milder, normal intelligence, good prognosis with surgery), Type 2 (cloverleaf skull, severe proptosis, elbow ankylosis, poor prognosis), and Type 3 (similar to Type 2 without cloverleaf skull, severe neurological impairment). Types 2 and 3 have significant mortality. Diagnosis: clinical and genetic testing. Management: staged cranial vault and midface surgery for Type 1; palliative management for Types 2 and 3.

Pierre Robin Sequence

– A congenital anomaly triad: micrognathia (small mandible), glossoptosis (posteriorly displaced tongue causing airway obstruction), and U-shaped cleft palate. The sequence arises from early mandibular hypoplasia, which prevents the tongue from descending, thereby impairing palatal shelf fusion. Presents at birth with respiratory distress (stridor, retractions, cyanosis, worse supine) and feeding difficulties. Diagnosis: clinical examination and polysomnography to assess obstructive sleep apnea severity. Management: prone positioning (first-line, 70% improve), nasopharyngeal airway, and surgical intervention for severe cases (tongue-lip adhesion, mandibular distraction osteogenesis, or tracheostomy). Cleft palate repair is typically performed at 9–18 months.

Pneumococcal Conjugate Vaccine

– PCV13 and PCV15 vaccines given at 2, 4, 6, and 12-15 months. Protects against *Streptococcus pneumoniae* serotypes causing invasive disease, pneumonia, and otitis media. PCV20 now recommended for older children and adults. Has dramatically reduced rates of invasive pneumococcal disease in children since universal vaccination.

Poland Syndrome

– A congenital anomaly characterized by unilateral absence or hypoplasia of the pectoralis major muscle (specifically the sternocostal head) and ipsilateral hand anomalies (syndactyly, most commonly; also brachydactyly, ectrodactyly, or radial club hand). The right side is affected in 60-75% of cases. Males are affected 2-3 times more frequently. Associated findings: rib defects (aplasia or hypoplasia of the second to fifth ribs), chest wall depression, breast and nipple hypoplasia or absence (in females), axillary hair loss, and vertebral anomalies. The cause is thought to be an interruption of the subclavian artery blood supply during the sixth week of gestation. Diagnosis: clinical with ultrasound or CT for chest wall evaluation. Treatment: hand surgery for syndactyly release; breast reconstruction with implants or autologous tissue for females; chest wall reconstruction for severe rib defects.

Post-Term Pregnancy

– Pregnancy continuing beyond 42 weeks gestation (294 days from LMP). Risk factors include prior post-term pregnancy, nulliparity, and genetic factors. Complications include macrosomia, oligohydramnios, meconium aspiration, placental insufficiency, and stillbirth. Management: antenatal surveillance with NST and biophysical profile starting at 41 weeks. Induction of labor recommended by 41-42 weeks.

Posterior Urethral Valves

– The most common cause of lower urinary tract obstruction in male infants, caused by congenital mucosal folds (valves) in the posterior urethra (prostatic urethra) that obstruct urine outflow. Presents prenatally with oligohydramnios, bilateral hydronephrosis, and a distended, thick-walled bladder, and postnatally with poor urinary stream, urinary retention, and abdominal distension. Severe

cases present with the prune belly sequence (deficient abdominal wall musculature from massive bladder distension) and Potter sequence (pulmonary hypoplasia from oligohydramnios). Diagnosis: prenatal ultrasound, postnatal voiding cystourethrogram (VCUG) shows a dilated posterior urethra with a sharp cutoff. Treatment: immediate bladder decompression (urethral catheter), endoscopic valve ablation (transurethral incision of the valves, first-line). Temporary vesicostomy for small or premature infants. Prognosis: depends on the degree of renal impairment at presentation. Even with successful valve ablation, 25-30% develop end-stage renal disease in childhood or adolescence due to preexisting renal dysplasia.

Potter Syndrome

– A sequence of anomalies resulting from severe oligohydramnios (low amniotic fluid volume), most commonly caused by bilateral renal agenesis, but also from autosomal recessive polycystic kidney disease, posterior urethral valves, or chronic amniotic fluid leak. Features: pulmonary hypoplasia (the most critical, incompatible with life), Potter facies (low-set, flattened ears, recessed chin, prominent epicanthal folds, flattened nose), limb deformities (clubfoot, hip dislocation, flexion contractures), and amnion nodosum (nodules on the amnion). Presents at birth with severe respiratory distress, inability to oxygenate, and typical facies. Diagnosis: prenatal ultrasound shows anhydramnios/oligohydramnios and absent or abnormal kidneys. Chest X-ray shows small lung volumes. Prognosis: uniformly fatal in the newborn period due to pulmonary hypoplasia. Management: perinatal palliative care.

Prader-Willi Syndrome

– A genetic disorder caused by loss of function of genes on chromosome 15 (paternal deletion or maternal uniparental disomy). Features: neonatal hypotonia and failure to thrive, followed by hyperphagia and obesity in childhood. Intellectual disability, short stature, hypogonadism, and behavioral problems. Management: controlled diet, growth hormone therapy, and behavioral interventions.

Preterm Infant

– An infant born before 37 completed weeks of gestation; classified by gestational age (late preterm

34-36, moderate 32-33, very preterm <32, extremely <28 weeks) and by birth weight. Causes: preterm labor, PPROM, preeclampsia, multiple pregnancy, infection, and iatrogenic. Complications: respiratory distress syndrome (surfactant deficiency), apnea, intraventricular hemorrhage, necrotizing enterocolitis, infection/sepsis, hypoglycemia, jaundice, thermoregulation difficulty, patent ductus arteriosus, and retinopathy of prematurity; long-term: neurodevelopmental and growth concerns. Management: neonatal intensive care (surfactant, respiratory support, thermal care, nutrition—breast milk, kangaroo care), prevention (progesterone, cervical cerclage), antenatal corticosteroids and magnesium for lung maturity/neuroprotection, and developmental follow-up.

Prune Belly Syndrome

– A congenital syndrome comprising the triad: deficient abdominal wall musculature (wrinkled, prune-like appearance), bilateral cryptorchidism (undescended testes), and urinary tract anomalies (dilated ureters, dilated and trabeculated bladder, and posterior urethral valves or urethral atresia). Almost exclusively affects boys. Other associations: pulmonary hypoplasia from oligohydramnios, orthopedic anomalies (clubfoot, hip dislocation), and cardiac anomalies. The severity ranges from the lethal form (severe oligohydramnios, pulmonary hypoplasia, and renal dysplasia) to the mild form (preserved renal function and mild abdominal wall laxity). Diagnosis: prenatal ultrasound shows a distended bladder with thickened walls and oligohydramnios. Postnatal diagnosis is clinical. Treatment: depends on severity — mild cases: observation and orchiopexy. Moderate-severe: urinary tract reconstruction (reduction cystoplasty, ureteral reimplantation, and abdominoplasty). Renal transplantation for end-stage renal disease. All patients require lifelong urologic and nephrologic surveillance.

Reflux

– Gastroesophageal reflux in infants: effortless regurgitation of gastric contents, very common (physiologic ‘spitting up’) and usually benign, resolving by 12 months with maturation of the lower esophageal sphincter. Pathologic GERD: poor weight gain, irritability, feeding refusal, arching (Sandifer syndrome), apnea/bradycardia, recurrent pneumonia

(aspiration), and esophagitis. Diagnosis: clinical; endoscopy/PH-impedance for complications. Management: reassurance and feeding modifications (thickened feeds, frequent small feeds, upright positioning after feeds) for physiologic reflux; GERD—thickened feeds, alginate, and PPI (omeprazole) for significant disease; alarm signs (hematemesis, bilious vomiting, failure to thrive) require evaluation.

Renal Agenesis

– Congenital absence of one (unilateral, 1 in 1,000) or both (bilateral, 1 in 4,000) kidneys. Unilateral renal agenesis: usually asymptomatic, discovered incidentally — the solitary kidney undergoes compensatory hypertrophy. The contralateral kidney may have VUR, UPJ obstruction, or ectopia. Associated with VACTERL, Mayer-Rokitansky-Kuster-Hauser syndrome (Müllerian agenesis), and other GU anomalies. Bilateral renal agenesis (Potter syndrome): incompatible with life — causes severe oligohydramnios, leading to Potter sequence: pulmonary hypoplasia (the proximal cause of death), limb deformities (clubfoot, contractures), characteristic Potter facies (low-set ears, flat nose, epicanthal folds), and amnion nodosum. Diagnosis: prenatal ultrasound (absent renal tissue, empty renal fossa, severe oligohydramnios). Bilateral renal agenesis is uniformly fatal in the newborn period from pulmonary hypoplasia. Unilateral: annual blood pressure monitoring, urinalysis, and renal function surveillance.

Respiratory Distress Syndrome

– A condition primarily affecting premature infants caused by pulmonary surfactant deficiency, leading to alveolar collapse and respiratory failure. Presents with tachypnea, grunting, nasal flaring, retractions, and cyanosis. Chest X-ray shows diffuse ground-glass opacity. Treatment: surfactant replacement therapy, mechanical ventilation, and continuous positive airway pressure. Prevention with antenatal corticosteroids when preterm delivery anticipated.

Respiratory Syncytial Virus

– A paramyxovirus and the most common cause of bronchiolitis and pneumonia in infants and young children. Seasonal outbreaks in fall, winter, and spring. Transmission by respiratory droplets and

fomites. Mild in older children and adults; can be severe or fatal in infants, premature infants, and those with chronic lung or heart disease. Prevention with palivizumab (Synagis) or nirsevimab (Beyfortus) in high-risk infants during RSV season. Nirsevimab is now the preferred RSV prophylaxis for all infants in many guidelines (CDC/ACIP), providing passive protection with a single dose.

Retinal Hemorrhages

- Bleeding within the retina, a hallmark finding in abusive head trauma (shaken baby syndrome). Found on dilated fundoscopic examination, often bilateral and multi-layered. Also seen in severe accidental trauma, bleeding disorders, and increased intracranial pressure. In the context of suspected abuse, strongly suggestive of non-accidental injury. Ophthalmologic consultation essential for documentation.

Retinopathy of Prematurity

- Abnormal vascularization of the retina in premature infants, a leading cause of childhood blindness. Affects infants less than 32 weeks gestation and less than 1500 grams. Stages range from mild (avascular retina) to severe (retinal detachment). Screening began at 31-33 weeks corrected gestational age or 4 weeks chronological age. Treatment: laser photocoagulation or anti-VEGF injection for type 1 ROP.

Rett Syndrome

- An X-linked dominant neurodevelopmental disorder affecting almost exclusively females, caused by mutations in the MECP2 gene. Normal development for the first 6-18 months, followed by regression with loss of acquired language and motor skills, stereotypical hand-wringing movements, deceleration of head growth (acquired microcephaly), seizures, and gait ataxia. Autonomic dysfunction causes breathing irregularities (hyperventilation, breath-holding), cold extremities, and bruxism. Diagnosis: clinical criteria (Neul 2010) and MECP2 genetic testing. Treatment: symptom management — antiepileptic drugs for seizures, physical/occupational therapy, nutritional support, and scoliosis monitoring. Trofinetide is FDA-approved for Rett syndrome in adults and children >2 years.

Rheumatic Fever

- A nonsuppurative inflammatory complication of Group A Streptococcal pharyngitis, occurring 2-4 weeks after infection. Diagnosed by Jones criteria: major manifestations (carditis, polyarthritides, chorea, erythema marginatum, subcutaneous nodules) plus evidence of prior streptococcal infection. Major criterion plus two minor criteria. Treatment: anti-inflammatory agents and antibiotics. Prevention: prompt treatment of strep throat.

Rooting Reflex

- A primitive reflex present from birth to 3-4 months, triggered by stroking the infant's cheek or corner of the mouth. The infant turns toward the stimulus and opens the mouth, searching for the nipple. Facilitates breastfeeding. Absence may indicate neurologic impairment. Disappears as voluntary feeding develops. One of several primitive reflexes assessed in the newborn period to evaluate neurologic function.

Roseola

- See [Roseola Infantum](#).

Roseola Infantum

- A viral illness caused by Human Herpesvirus 6 (HHV-6), affecting children 6 months to 2 years. Characterized by high fever (39-40.5 degrees Celsius) for 3-5 days followed by defervescence and appearance of a maculopapular rash starting on the trunk and spreading outward. Rash appears as fever resolves. Diagnosis is clinical. Self-limited; treatment is supportive.

Rotavirus Vaccine

- Oral live attenuated vaccine given at 2, 4, and 6 months (RV1) or at 2, 4, and 8 months (RV5). Protects against rotavirus gastroenteritis, a leading cause of severe diarrhea in infants. Reduced rotavirus hospitalizations by over 80% since introduction. Mild side effects include fever and diarrhea. Contraindicated in infants with severe combined immunodeficiency.

RSV

- Respiratory syncytial virus: the most common cause of bronchiolitis and viral pneumonia in infants and young children, transmitted by droplets/fomites; seasonal (winter). Features:

coryza, cough, wheeze, tachypnea, and respiratory distress; apnea in young infants; risk factors for severe disease: prematurity, congenital heart disease, chronic lung disease, and immunodeficiency. Diagnosis: clinical; nasopharyngeal PCR/antigen. Management: supportive—oxygen, hydration/nasal suctioning, and respiratory support; no routine antiviral; palivizumab (monoclonal antibody) prophylaxis for high-risk infants; new vaccines/monoclonals (nirsevimab) emerging; prevention: hand hygiene, and avoid sick contacts.

Rubella

- German measles caused by Rubivirus. Mild illness with fever, rash, and lymphadenopathy in children. Dangerous in pregnancy due to congenital rubella syndrome (cataracts, heart defects, deafness). Rash similar to measles but milder, with postauricular and suboccipital lymphadenopathy. Prevention by MMR vaccination. Eradicated in the Americas since 2015.

Rubinstein-Taybi Syndrome

- A genetic disorder caused by mutations in CREBBP (50-60%) or EP300 (3-8%), encoding histone acetyltransferases involved in transcriptional regulation. Features: characteristic facies — downslanting palpebral fissures, broad nasal bridge, beaked nose, high-arched palate, and low-set ears; broad thumbs and halluces (pathognomonic, 100%); short stature; microcephaly; and moderate to severe intellectual disability. Other findings: congenital heart disease (PDA, ASD, VSD, 30-35%), cryptorchidism, renal anomalies, and increased risk of tumors (benign: meningioma, pilomatixoma; malignant: leukemia). Diagnosis: clinical and genetic testing. Management: multidisciplinary — cardiac evaluation, developmental therapies, physical therapy for joint laxity, and tumor surveillance. Anesthesia risk: difficult airway from micrognathia and potential malignant hyperthermia.

Scarlatina

- A toxin-mediated illness caused by Group A Streptococcus producing erythrogenic toxin. See [Scarlet Fever](#).

Scarlet Fever

- A toxin-mediated illness caused by Group A Streptococcus producing erythrogenic toxin. Presents

with fever, pharyngitis, and a characteristic diffuse, erythematous, sandpaper-textured rash that blanches with pressure. Circumoral pallor, Pastia lines (linear petechiae in skin folds), and strawberry tongue are classic findings. Treatment: penicillin or amoxicillin for 10 days. Prevents rheumatic fever complications.

Shaken Baby Syndrome

- A form of abusive head trauma caused by violent shaking, typically in infants under 1 year. The triad: subdural hemorrhage, retinal hemorrhages, and encephalopathy. May present with irritability, lethargy, vomiting, seizures, and apnea. CT shows subdural hematoma; MRI shows diffuse axonal injury. Ophthalmologic exam reveals retinal hemorrhages. High mortality and long-term neurodevelopmental impairment.

Sickle Cell Anemia

- The most severe form of sickle cell disease (HbSS), causing chronic hemolytic anemia and vaso-occlusive crises. Features: jaundice, splenomegaly (infancy), pain crises, acute chest syndrome, stroke, and increased infection risk from functional asplenia. Diagnosis: hemoglobin electrophoresis showing HbS. Management: penicillin prophylaxis, hydroxyurea, pneumococcal vaccines, and folic acid supplementation.

SIDS

- See [Sudden Infant Death Syndrome](#).

Skeletal Survey

- A series of radiographs obtained when child abuse is suspected. Includes AP and lateral views of the skull, chest (including oblique views), abdomen, spine, and bilateral upper and lower extremities. Identifies fractures of varying ages, which is highly suggestive of non-accidental trauma. Initial survey may be negative; repeat at 2 weeks may reveal healing fractures. Interpretation by pediatric radiologist recommended.

Slipped Capital Femoral Epiphysis

- Displacement of the femoral head relative to the femoral neck through the growth plate (physis) in adolescents. Most common hip disorder in adolescents (10-16 years). Risk factors: obesity, male sex, African American, and endocrine disorders (hypothyroidism, growth hormone deficiency). Presents

with hip, groin, or knee pain with limping (antalgic gait). On examination: limited internal rotation and obligatory external rotation with hip flexion. Diagnosis: bilateral hip X-ray (AP and frog-leg lateral) shows femoral head displaced posteriorly and medially relative to the neck (Klein line). Treatment: surgical stabilization with in situ screw fixation of the affected and contralateral hip. Urgent: non-weight-bearing to prevent further slippage.

Smith-Lemli-Opitz Syndrome

- An autosomal recessive disorder of cholesterol metabolism caused by mutations in *DHCR7*, encoding 7-dehydrocholesterol reductase, the final enzyme in the cholesterol biosynthetic pathway. Features: microcephaly, characteristic facies (ptosis, anteverted nares, micrognathia, low-set ears), intellectual disability (mild to profound), syndactyly of the second and third toes (pathognomonic, 95%), postaxial polydactyly, cleft palate, hypospadias (ambiguous genitalia in males), and congenital heart disease. Diagnosis: elevated serum 7-dehydrocholesterol levels and *DHCR7* genetic testing. Treatment: dietary cholesterol supplementation (improves growth and behavior), and symptomatic management of associated anomalies. Prognosis correlates with severity of malformations and cholesterol levels.

Speech Delay

- A delay in language development compared to peers: by 12 months—no single words; 18 months—<10-20 words/no word combinations by 24 months; or regression. Causes: hearing impairment (must exclude—audiology), global developmental delay, autism spectrum disorder (with social communication deficits), expressive language disorder, psychosocial/environmental deprivation, and prematurity. Bilingualism does not cause delay. Evaluation: hearing test (essential), developmental assessment, speech-language evaluation, and screening for autism. Management: early intervention—speech therapy, parent training, treat underlying cause; monitor progress; red flags (loss of skills, poor response to name) prompt urgent referral.

Spina Bifida

- A neural tube defect: incomplete closure of the neural tube (days 22-28), causing spinal cord/meningeal malformation. Types: spina bifida occulta (hid-

den—no protrusion, often asymptomatic, hairy patch/hemangioma over defect), meningocele (meninges protrude), and myelomeningocele (cord + meninges protrude—most severe, neurologic deficits below the lesion: paralysis, sensory loss, bladder/bowel dysfunction, hydrocephalus, Chiari II malformation). Associated with folate deficiency; prevention: periconceptional folic acid. Prenatal: AFP (elevated), ultrasound. Management: multidisciplinary—surgical closure, VP shunt for hydrocephalus, urologic/orthopedic care, and rehabilitation.

Spina Bifida Occulta

- The mildest form of spina bifida, characterized by incomplete closure of the vertebral arch without herniation of neural elements. Often asymptomatic; may be detected by skin findings (dimple, hair tuft, lipoma) over the lower spine. Incidence approximately 1-2% of the population. Usually requires no treatment unless associated with tethered cord or spinal cord symptoms.

Stepping Reflex

- A primitive reflex present from birth to 2 months, elicited by holding the infant upright with feet touching a flat surface. The infant makes stepping-like movements as if walking. Disappears by 2 months as voluntary motor control develops. Reappears around 9-10 months as voluntary walking emerges. Assessed during newborn and early infant neurologic examination.

Stickler Syndrome

- An autosomal dominant connective tissue disorder caused by mutations in collagen genes (*COL2A1* most common, also *COL11A1*, *COL11A2*, *COL9A1*). Features: Pierre Robin sequence (micrognathia, glossoptosis, cleft palate, 30%), high myopia (present in 90% by 10 years), retinal detachment (highest risk of any pediatric syndrome), sensorineural hearing loss, and early-onset osteoarthritis with mild epiphyseal dysplasia. Pierre Robin sequence in Stickler syndrome mandates ophthalmologic screening. Diagnosis: clinical criteria (major: Pierre Robin-associated cleft palate, high myopia, retinal detachment, hearing loss, family history) and genetic testing. Management: ophthalmology — annual dilated fundus exams, retinal detachment

prevention; audiology — hearing aids; orthopedics — joint protection and pain management; dental palatal repair; avoidance of contact sports.

Strep Throat

– Acute streptococcal pharyngitis caused by group A *Streptococcus* (*S. pyogenes*), most common in children 5-15 years. Features: sudden sore throat, fever, tonsillar exudate, palatal petechiae, anterior cervical lymphadenopathy, and headache/abdominal pain; cough, coryza, and oral ulcers suggest viral. Diagnosis: rapid antigen test or throat culture (confirmatory); clinical criteria (Centor/McIsaac). Complications: suppurative (peritonsillar abscess, otitis) and nonsuppurative (acute rheumatic fever, post-streptococcal glomerulonephritis). Management: antibiotics within 9 days to prevent rheumatic fever—penicillin (or amoxicillin), macrolide if allergic; analgesia and supportive care.

Sturge-Weber Syndrome

– A neurocutaneous syndrome (phakomatosis) characterized by a facial capillary malformation (port-wine stain) in the V1 distribution of the trigeminal nerve (forehead and upper eyelid) and ipsilateral leptomeningeal angiomas (venous malformations of the pia mater). Caused by a somatic activating mutation in *GNAQ*. Presents in infancy with the port-wine stain, which is the visible marker. Neurologic features: seizures (75-90%, often focal or infantile spasms, typically starting in the first year), hemiparesis (contralateral to the angioma, 30-50%), developmental delay, and intellectual disability. Ocular features: glaucoma (30-70%, can be congenital or develop later, ipsilateral to the angioma), and choroidal hemangioma. Diagnosis: clinical with contrast-enhanced brain MRI (leptomeningeal enhancement, cerebral atrophy, gyriform calcification, and choroid plexus enlargement). Skull X-ray may show tram-track calcifications. Treatment: anti-convulsants for seizures; early hemispherectomy or corpus callosotomy for refractory epilepsy. Regular ophthalmologic monitoring for glaucoma (lifelong). Laser therapy for the port-wine stain. Surveillance: developmental assessments and neuroimaging.

Subgaleal Hemorrhage

– A life-threatening accumulation of blood in the subgaleal space (between the periosteum and the

epicranial aponeurosis). Can contain up to 50% of the infant's blood volume. Risk factors include vacuum-assisted delivery. Presents with rapidly enlarging, boggy scalp swelling that crosses suture lines, associated with anemia and hemodynamic instability. Requires urgent evaluation, blood transfusion, and resuscitation.

Sucking Reflex

– A primitive reflex present from birth, elicited by placing an object in the infant's mouth. The infant rhythmically sucks on the object. Coordinated sucking and swallowing typically develop by 34-36 weeks gestational age. Premature infants may lack coordinated suck-swallow, requiring gavage feeding. Absence in a term infant may indicate neurologic impairment. Important for successful breastfeeding and oral feeding.

Sudden Infant Death Syndrome

– SIDS: the sudden, unexplained death of an infant <1 year (peak 2-4 months) that remains unexplained after a thorough investigation (autopsy, scene examination, and review of clinical history). Risk factors: prone sleep, bed-sharing, soft bedding, overheating, maternal smoking, prematurity/low birth weight, and co-sleeping. Protective factors: supine sleep ('Back to Sleep'), firm mattress, room-sharing without bed-sharing, breastfeeding, pacifier, and no smoke exposure. Diagnosis is by exclusion after comprehensive investigation. Prevention: safe sleep education is the cornerstone. Grief support and counseling for families; differentiate from accidental suffocation and child abuse.

Sudden Infant Death Syndrome (SIDS)

– See [Sudden Infant Death Syndrome](#).

Surfactant

– A phospholipid-protein complex produced by type II pneumocytes that reduces alveolar surface tension, preventing atelectasis. Deficiency causes respiratory distress syndrome in premature infants. Exogenous surfactant (beractant, poractant alfa) administered via endotracheal tube. Natural surfactant contains phosphatidylcholine, phosphatidylglycerol, and surfactant proteins A, B, C, and D. Production begins at approximately 24-28 weeks gestation.

Syphilis

– A bacterial STI caused by *Treponema pallidum*. Primary: chancre at inoculation site. Secondary: rash, mucous patches, condylomata lata. Latent: asymptomatic. Tertiary: gummas, cardiovascular, neurosyphilis. Diagnosis: non-treponemal tests (RPR/VDRL) confirmed by treponemal tests. Treatment: penicillin G benzathine IM. Congenital syphilis preventable with maternal screening and treatment.

Tanner Staging

– A scale for assessing sexual maturity during puberty. Stage 1: prepubertal. Stage 2: breast buds (girls), testicular enlargement (boys). Stage 3: breast enlargement, pubic hair. Stage 4: areolar development, more pubic hair. Stage 5: adult breasts and genitalia, adult hair pattern. Used to track pubertal progression and identify precocious or delayed puberty.

Tdap Vaccine

– Tetanus, Diphtheria, and acellular Pertussis booster given at 11-12 years and during each pregnancy (27-36 weeks gestation). Replaces one dose of Td. Important for pertussis protection, particularly for protecting newborns through maternal antibody transfer. Also given to adolescents and adults to maintain tetanus and diphtheria immunity.

Teenage Pregnancy

– Pregnancy in adolescents (usually 10-19 years), associated with higher maternal and fetal risks: preterm birth, low birth weight, preeclampsia, anemia, and increased neonatal mortality; also socioeconomic and educational consequences. Causes: unprotected intercourse, lack of contraception/education, poverty, and peer/family factors. Management: comprehensive antenatal care (nutrition, folate), psychosocial support, education continuation, and safe delivery; counseling on contraception postpartum to prevent recurrence. Prevention: sex education, access to contraception, and youth-friendly services. Multidisciplinary support (medical, social, educational) improves outcomes.

Teething

– The eruption of primary (deciduous) teeth, usually starting around 6 months (range 3-12), with lower central incisors first; 20 teeth by 2-3 years. Features:

irritability, drooling, gum swelling/tenderness, biting/chewing, disrupted sleep, mild low-grade fever; NOT a cause of high fever, diarrhea, or serious illness (which warrant evaluation). Management: teething rings, gum massage, cool (not frozen) items, acetaminophen/ibuprofen for discomfort; avoid topical benzocaine (risk). Emergence of permanent teeth continues through childhood (6-12 years). Differentiate from infections when fever is significant.

Tetralogy of Fallot

– The most common cyanotic congenital heart defect, accounting for 7-10% of congenital cardiac anomalies. Characterized by four anatomical features: 1) Subpulmonary infundibular stenosis (right ventricular outflow tract obstruction — primary defect), 2) Ventricular septal defect (VSD), 3) Overriding aorta, and 4) Right ventricular hypertrophy (RVH). Associated with chromosome 22q11.2 deletion (DiGeorge syndrome). Clinical presentation: cyanosis ("blue baby") appearing in early infancy; hypercyanotic "tet spells" (triggered by crying, feeding, or exertion; managed by squatting or knee-to-chest position, which increases SVR and reduces right-to-left shunt). Physical exam: harsh holosystolic ejection murmur at upper left sternal border; single S2. Diagnostic imaging: chest X-ray shows classic "boot-shaped heart" (coeur en sabot) with decreased pulmonary vascular markings; echocardiogram confirms 4 defects. Treatment: surgical repair (VSD closure and RVOT relief) typically performed at 3-6 months of age.

Thalassemia Major

– Beta-thalassemia, an autosomal recessive hemoglobin disorder with absent or minimal beta-globin chain production. Presents in infancy with severe anemia, failure to thrive, hepatosplenomegaly, and skeletal deformities. Diagnosis by hemoglobin electrophoresis showing absent HbA and elevated HbF and HbA2. Treatment: chronic blood transfusions, iron chelation, and hematopoietic stem cell transplant.

Tonic Neck Reflex

– A primitive reflex present from birth to 6 months, also called fencer's pose. When the head is turned to one side, the arm on that side extends while the opposite arm flexes. Present in both directions.

Asymmetry may indicate neurologic injury. Disappears as voluntary head control develops. One of several posture-related reflexes assessed in the newborn period.

Toxoplasmosis

- See infectious disease.

Tracheoesophageal Fistula

- An abnormal connection between the trachea and esophagus, often associated with esophageal atresia. Presents with recurrent aspiration, coughing with feedings, and cyanosis during meals. The H-type fistula may present later in infancy with chronic aspiration and failure to thrive. Diagnosis by esophagram or bronchoscopy. Treatment: surgical ligation and division of the fistula.

Transfusion of Neonate

- Administration of packed red blood cells to neonates for symptomatic anemia or hematocrit below transfusion threshold. Indications include acute blood loss, severe anemia (hematocrit less than 20%), and respiratory distress. Volume: 10-20 mL/kg over 2-4 hours. Blood products must be CMV-negative, irradiated, and crossmatched. Complications include volume overload, infection, and transfusion reactions.

Transposition of the Great Arteries

- A cyanotic congenital heart defect where the aorta arises from the right ventricle and the pulmonary artery arises from the left ventricle (ventriculoarterial discordance). The result: two parallel circulations (systemic and pulmonary) with no mixing. Survival depends on associated shunts (ASD, VSD, PDA) to allow mixing of oxygenated and deoxygenated blood. Presents in the first days of life with severe cyanosis, tachypnea, and profound hypoxemia. Classic chest X-ray: egg-on-side appearance (narrow superior mediastinum). Treatment: immediate PGE1 infusion to maintain PDA patency, balloon atrial septostomy (Rashkind procedure) to improve mixing, and ultimately arterial switch operation (Jatene procedure) within the first 2 weeks of life.

Treacher Collins Syndrome

- An autosomal dominant craniofacial disorder caused by mutations in TCOF1 (most common),

POLR1C, or POLR1D genes, encoding ribosomal RNA transcription factors. Bilateral, symmetric craniofacial anomalies: zygomatic hypoplasia (malar flattening), micrognathia, downward-slanting palpebral fissures, coloboma of the lower eyelid, microtia (small, malformed pinna), and conductive hearing loss (from middle ear anomalies). Intelligence is typically normal. Diagnosis: clinical and genetic testing. Management: multidisciplinary — airway assessment (possible tracheostomy for severe micrognathia), hearing aids or bone-anchored hearing aids for hearing loss, and staged reconstructive surgery (zygomatic and mandibular distraction, eyelid reconstruction, and external ear reconstruction).

Tricuspid Atresia

- Absence of the tricuspid valve, resulting in no direct communication between the right atrium and right ventricle. Blood flow depends on an atrial septal defect and ventricular septal defect for mixing. Presents with cyanosis. Staged surgical repair: modified Blalock-Taussig shunt in infancy, followed by Fontan procedure in early childhood. Oxygen and prostaglandin E1 used for stabilization.

Trisomy 21

- Down syndrome: the most common chromosomal disorder, caused by an extra chromosome 21 (trisomy 21; 95 percent meiotic nondisjunction, mosaicism, translocation). Features: intellectual disability, characteristic facial features (flat facies, upslanting palpebral fissures, epicanthic folds, macroglossia), hypotonia, congenital heart disease (50 percent—AVSD, VSD), GI anomalies (duodenal atresia), hypothyroidism, hearing/vision problems, and increased risk of leukemia and Alzheimer disease. Antenatal screening (NIPT, quad test) and diagnosis (amniocentesis/CVS). Management: multidisciplinary—cardiac repair, thyroid monitoring, audiology/ophthalmology, early intervention, education, and adult care; life expectancy now 60 years.

Truncus Arteriosus

- A congenital heart defect where a single large vessel arises from both ventricles, receiving a mixed blood supply. Associated with a large ventricular septal defect and abnormal semilunar valve. Presents with cyanosis and heart failure early in life. Requires surgical repair in the neonatal period, involving

VSD closure and placement of a right ventricle-to-pulmonary artery conduit.

Tuberculin Skin Test

– Intradermal injection of purified protein derivative (PPD) to test for *Mycobacterium tuberculosis* infection. Read at 48-72 hours measuring induration (not erythema). Positive: greater than 5 mm in HIV or close contacts; greater than 10 mm in high-risk groups; greater than 15 mm in low-risk populations. Does not differentiate latent from active infection. False positives from BCG vaccination.

Tuberculosis in Children

– Infection with *Mycobacterium tuberculosis*, often from household contacts. Latent TB infection (LTBI) positive tuberculin skin test or interferon-gamma release assay with no symptoms or radiographic findings. Active TB presents with cough, fever, weight loss, and lymphadenopathy. Diagnosis by PPD, chest X-ray, and sputum culture. Treatment: isoniazid, rifampin, pyrazinamide, and ethambutol for active disease.

Tuberous Sclerosis Complex

– An autosomal dominant genetic disorder caused by mutations in *TSC1* (hamartin) or *TSC2* (tuberin) genes, leading to mTOR pathway activation. See neurology.

Tympanostomy Tubes

– Small tubes inserted through the tympanic membrane to ventilate the middle ear and prevent fluid accumulation. Indicated for recurrent acute otitis media (3 episodes in 6 months or 4 in 12 months) or persistent otitis media with effusion greater than 3 months with hearing loss. Performed as outpatient procedure under general anesthesia. Most tubes extrude spontaneously within 6-18 months.

Tyrosinemia

– An autosomal recessive inborn error of tyrosine metabolism. Type I (fumarylacetoacetate hydroxylase deficiency, FAH mutations) is the most severe: presents in infancy with liver failure, renal tubular dysfunction (Fanconi syndrome — hypophosphatemic rickets), neurologic crises (painful paresthesias, autonomic instability, porphyria-like symptoms from succinylacetone accumulation), and hepatocellular carcinoma risk. Type II (tyrosine aminotransferase deficiency, TAT muta-

tions): oculocutaneous tyrosinemia with painful palmar/plantar hyperkeratosis and corneal ulcers; no liver or kidney disease. Type III (4-hydroxyphenylpyruvate dioxygenase deficiency, HPD mutations): rare, mild intellectual disability and ataxia. Newborn screening shows elevated tyrosine and succinylacetone (pathognomonic for Type I). Diagnosis: urine succinylacetone (Type I), plasma amino acids, and FAH/TAT/HPD genetic testing. Treatment: Type I — nitisone (NTBC, 2-(2-nitro-4-trifluoromethylbenzoyl)-1,3-cyclohexanedione) blocks tyrosine catabolism upstream of FAH, preventing toxic metabolite accumulation, combined with a tyrosine- and phenylalanine-restricted diet. Liver transplantation for refractory liver disease or HCC. Type II — dietary restriction of tyrosine and phenylalanine.

Undescended Testis

– Cryptorchidism: failure of one or both testes to descend into the scrotum, the most common congenital male genital anomaly (preterm 30 percent, term 3-4 percent); often descends spontaneously in the first months. Complications: impaired fertility, increased risk of testicular cancer, torsion, and hernia. Diagnosis: clinical (absent testis in the scrotum—exclude retractile); imaging rarely needed; bilaterally impalpable—hormone/ultrasound evaluation. Management: surgical orchidopexy recommended at 6-12 (ideally 6-18) months to preserve fertility and allow surveillance; if bilateral and hypogonadism—hormonal evaluation. Monitor for malignancy with regular examination after surgery.

Urea Cycle Disorder

– A group of inborn errors of ammonia metabolism caused by deficiency of any of the six enzymes or two transporters in the urea cycle. X-linked: ornithine transcarbamylase deficiency (OTC, most common, 50%). Autosomal recessive: N-acetylglutamate synthase (NAGS), carbamoyl phosphate synthetase I (CPS1), argininosuccinate synthetase (citrullinemia), argininosuccinate lyase (argininosuccinic aciduria), and arginase 1 (argininemia). Presents with hyperammonemic encephalopathy: poor feeding, vomiting, lethargy, tachypnea/respiratory alkalosis (from central hyperventilation), ataxia, seizures, and coma. Onset varies from neonatal (complete deficiency) to late-onset (partial defi-

ciency). Diagnosis: plasma ammonia (elevated $>150 \mu\text{mol/L}$ in neonates is symptomatic), quantitative plasma amino acids (citrulline, arginine, glutamine, alanine), urine orotic acid, and genetic testing. Treatment: acute hyperammonemia — IV sodium phenylacetate/sodium benzoate (Ammonul), IV arginine, nitrogen-free IV fluids, and hemodialysis for severe ($>500 \mu\text{mol/L}$). Chronic management — low-protein diet, ammonia-scavenging drugs (sodium phenylbutyrate, glycerol phenylbutyrate, arginine or citrulline supplementation), and liver transplantation for severe OTC deficiency. NAGS deficiency is uniquely treatable with oral N-carbamylglutamate.

Vaccination Schedule

– The recommended immunization schedule for infants, children, and adolescents (e.g., WHO/CDC): birth—HepB; 2 months—DTaP, IPV, Hib, PCV13, RV; 4 months—same; 6 months—HepB, IPV, PCV, RV, influenza (seasonal); 12 months—MMR, varicella, Hib, PCV; 18 months—DTaP, HepA; 4-6 years—DTaP, IPV, MMR, varicella; 9-16 years—HPV; 11-12 years—Tdap, meningococcal (MenACWY); annual influenza. Catch-up schedules for missed doses. Timing ensures protection at vulnerable ages; vaccines are safe and effective; document and counsel on side effects. School entry requirements often enforce immunization. See also [India Immunization Schedule](#).

India Immunization Schedule

– The Universal Immunization Schedule (UIP) of the Government of India, providing free vaccines to all children, adolescents, and pregnant women through the public health system. The childhood schedule: at birth—BCG (single dose, intradermal, upper arm, against tuberculosis), OPV-0 (zero dose, oral, against poliovirus), and Hepatitis B birth dose (injection); 6 weeks—OPV-1, Pentavalent-1 (DPT+HepB+Hib, injection), Rotavirus Vaccine-1 (oral), Pneumococcal Conjugate Vaccine-1 (PCV, injection), and fractional IPV-1 (fIPV, intradermal); 10 weeks—OPV-2, Pentavalent-2, Rotavirus-2; 14 weeks—OPV-3, Pentavalent-3, Rotavirus-3, PCV-2, and fIPV-2; 9-12 months—Measles-Rubella-1 (MR-1, injection), Japanese Encephalitis-1 (JE-1, in endemic districts, injection), PCV booster, and fIPV-3 (full intramuscular dose); 16-24 months—

MR-2, JE-2, DPT booster-1, and OPV booster. The adolescent schedule: 5-6 years—DPT booster-2; 10 years—Td (Tetanus and adult Diphtheria); 16 years—Td booster. The maternal schedule: Td-1 as early as possible in pregnancy, Td-2 at least 4 weeks later (one booster dose sufficient if two Td doses received within the preceding 3 years). India uses the bivalent oral polio vaccine (bOPV, types 1 and 3) and fractional IPV (0.1 mL intradermal at 6 and 14 weeks) to optimise polio immunity while managing vaccine supply. The pentavalent vaccine reduces the number of injections from five to one at each visit. Japanese encephalitis vaccine is given only in districts with high JE burden. The schedule aligns with WHO recommendations and has contributed to India achieving polio-free certification in 2014.

VACTERL Association

– A non-random association of congenital anomalies, diagnosed when at least three of the following are present: Vertebral anomalies (hemivertebrae, fused vertebrae, scoliosis, 70%), Anorectal malformations (imperforate anus, 80%), Cardiac defects (VSD, tetralogy of Fallot, 50-80%), Tracheo-Esophageal fistula (with or without esophageal atresia, 70%), Renal anomalies (renal agenesis, horseshoe kidney, hydronephrosis, 60%), and Limb defects (radial dysplasia, thumb anomalies, polydactyly, 50-70%). The acronym also includes non-VACTERL findings: single umbilical artery and rib anomalies. The cause is unknown; most cases are sporadic. Diagnosis: clinical with systematic evaluation of involved organ systems. Management: staged surgical repair (imperforate anus colostomy, TEF repair, cardiac surgery), and long-term follow-up for renal function, growth, and development.

Varicella Vaccine

– Live attenuated vaccine given at 12-15 months and 4-6 years. Protects against chickenpox (varicella-zoster virus). Two doses provide greater than 90% protection. Contraindicated in immunocompromised and pregnant individuals. Also reduces risk of herpes zoster later in life. Universal vaccination significantly reduced varicella incidence and complications.

Viral Meningitis

- Inflammation of the meninges caused by viruses, usually Enteroviruses. Presents similarly to bacterial meningitis but generally less severe. CSF shows lymphocytic pleocytosis, normal glucose, and mildly elevated protein. Self-limited in most cases; supportive treatment. Differentiated from bacterial meningitis by CSF analysis to prevent unnecessary prolonged antibiotic therapy.

Vision Screening

- Screening for visual problems in children: newborn—red reflex examination (cataract, retinoblastoma); 3-5 years—visual acuity, strabismus screening (cover test, photostrengthening), and amblyopia risk factors. Goals: detect amblyopia ('lazy eye'), strabismus, and refractive errors early (before 5-7 years, the critical period), since treatment (patching, glasses) is most effective early. Risk factors: prematurity, family history, syndromes. Referral criteria: acuity below age norms, significant refractive error, strabismus, or abnormal red reflex. Regular screening at well-child visits and school entry; early referral to pediatric ophthalmology prevents permanent vision loss.

Whooping Cough

- A highly contagious bacterial infection caused by *Bordetella pertussis*, producing characteristic paroxysmal cough with whooping inspiratory sound. See [Pertussis](#).

Williams Syndrome

- A microdeletion syndrome involving the elastin gene on chromosome 7q11.23. Features: elfin facies, supravalvular aortic stenosis, hypercalcemia, intellectual disability with strong verbal skills, and overly friendly personality. Often associated with connective tissue abnormalities. Management: cardiac monitoring, calcium management, and educational support.

Wilms' tumor (Nephroblastoma)

- The most common renal malignancy in children, accounting for 95% of pediatric renal tumors (peak incidence 2-5 years). It is an embryonal tumor arising from metanephric blastemal cells. Associated syndromes: WAGR (Wilms, Aniridia, Genitourinary anomalies, Intellectual Disability (formerly mental retardation)) — WT1 deletion on

11p13), Beckwith-Wiedemann syndrome (hemihypertrophy, macroglossia, omphalocele — WT2 locus 11p15), and Denys-Drash syndrome (WT1 mutation, male pseudohermaphroditism, nephrotic syndrome). Pathology: triphasic histology (blastemal, stromal, epithelial components). Anaplastic histology (focal or diffuse) confers a worse prognosis. Presents with a large, asymptomatic abdominal mass (often noted by parent while bathing the child), abdominal pain, haematuria (microscopic or gross), and hypertension (from renin secretion by the tumor or renal artery compression). Workup: abdominal ultrasound (distinguishes solid tumor from hydronephrosis, cystic lesions, neuroblastoma) and CT abdomen (staging: tumor extent, lymph node involvement, bilateral disease, IVC thrombus). Staging: Stage I (limited to kidney, capsule intact, completely resected), Stage II (extends beyond kidney, completely resected), Stage III (gross residual disease, positive lymph nodes, tumor spillage), Stage IV (haematogenous metastases — lung, liver, bone, brain), Stage V (bilateral renal involvement). Treatment: multimodal therapy based on staging and histology. Surgery: radical nephrectomy (transperitoneal approach, remove kidney + Gerota fascia + ipsilateral ureter + lymph node sampling). Chemotherapy: regimen depends on stage and histology (favourable vs. anaplastic) — vincristine, dactinomycin, doxorubicin. Radiation: for high-stage disease (Stage III-IV, anaplastic histology). Bilateral Wilms: neoadjuvant chemotherapy followed by nephron-sparing surgery. Prognosis: overall cure rate exceeds 90% (favourable histology). Anaplastic histology and metastatic disease have lower survival rates (50-70%). Long-term follow-up for renal function, cardiac function (doxorubicin), and second malignancies.

Corrected Age

- The age of a preterm infant calculated by subtracting the number of weeks born before 40 weeks of gestation from chronological age. Corrected age helps interpret growth and developmental milestones during early childhood, commonly until about 2 years of age.

Developmental Surveillance

- The ongoing process of eliciting caregiver concerns, observing the child, documenting developmental history, and monitoring milestones during routine

care. It differs from formal developmental screening, which uses standardized instruments at specified ages.

Developmental Regression

- Loss of previously acquired developmental skills. Regression is a neurologic red flag requiring prompt evaluation for genetic, metabolic, neurodegenerative, epileptic, infectious, or structural causes.

Precocious Puberty

- Onset of secondary sexual characteristics earlier than the accepted age threshold, commonly before 8 years in girls or 9 years in boys. It may be central from early activation of the hypothalamic-pituitary-gonadal axis or peripheral from excess sex steroids.

Delayed Puberty

- Failure to begin or progress through puberty by the expected age, such as absence of breast development by 13 years in girls or testicular enlargement by 14 years in boys. Causes include constitutional delay, chronic disease, gonadal failure, and hypothalamic or pituitary disorders.

Dehydration in Children

- A deficit of total body water, usually caused by gastrointestinal losses, inadequate intake, fever, or renal losses. Clinical assessment includes mental status, heart rate, mucous membranes, tears, capillary refill, urine output, weight change, and perfusion rather than a single sign.

Pediatric Shock

- Inadequate tissue oxygen delivery or utilization in a child, most often caused by hypovolemia, distributive disease, cardiogenic dysfunction, or obstruction. Children may maintain blood pressure until late; tachycardia, abnormal perfusion, altered mental status, and oliguria are important early warning signs.

Intussusception

- Telescoping of one segment of intestine into an adjacent segment, causing intermittent obstruction and impaired venous drainage. It commonly presents in infants with episodic colicky pain, vomiting, lethargy, and sometimes currant-jelly stool; ultrasound and pneumatic or hydrostatic reduction are standard approaches when appropriate.

Hypertrophic Pyloric Stenosis

- Hypertrophy and hyperplasia of the pyloric mus-

cle causing gastric outlet obstruction, typically in young infants. Progressive nonbilious projectile vomiting, hunger after vomiting, dehydration, and hypochloremic hypokalemic metabolic alkalosis may occur.

Foreign-Body Aspiration

- Entry of an object into the larynx, trachea, or bronchi, most often in toddlers. Sudden cough, choking, unilateral wheeze, or focal air trapping may occur; complete airway obstruction is an immediate emergency and requires age-appropriate resuscitation.

Pediatric Appendicitis

- Acute inflammation of the vermiform appendix, usually caused by luminal obstruction. Children may have evolving periumbilical-to-right-lower-quadrant pain, anorexia, vomiting, fever, and guarding, but presentation can be atypical in young children; timely surgical and antimicrobial assessment reduces perforation risk.

Congenital Hypothyroidism

- Insufficient thyroid hormone present at birth, caused by thyroid dysgenesis, dyshormonogenesis, or central disease. Early screening and treatment with levothyroxine prevent severe neurodevelopmental impairment.

Phenylketonuria (PKU)

- An inherited disorder, usually due to phenylalanine hydroxylase deficiency, causing accumulation of phenylalanine and reduced tyrosine availability. Untreated disease can cause intellectual disability, seizures, eczema, and a musty odor; newborn screening and dietary treatment are effective.

Neonatal Hypoxic-Ischemic Encephalopathy (HIE)

- Brain dysfunction in a newborn caused by inadequate oxygenation and/or cerebral blood flow around the time of birth. Moderate or severe HIE may produce altered consciousness, abnormal tone, seizures, and multiorgan injury; selected term or near-term infants may benefit from early therapeutic hypothermia.

Phototherapy

- Treatment of neonatal unconjugated hyperbilirubinemia using light wavelengths that convert bilirubin

bin into water-soluble photoisomers excreted without hepatic conjugation. Indications depend on gestational age, postnatal age, bilirubin level, and neurotoxicity risk factors.

Catch-Up Immunization

- Vaccination of a person who is behind the recommended schedule using age- and risk-appropriate intervals. Doses generally do not need to be restarted because of delay, but minimum ages and intervals must be respected.

Sentinel Injury

- A minor but potentially significant injury in a non-mobile infant, such as unexplained bruising, oral injury, or a fracture, that may precede more severe abuse. It warrants careful history, complete examination, safeguarding assessment, and documentation.

Abusive Head Trauma

- Injury to an infant or child caused by inflicted blunt force, shaking, impact, or a combination of mechanisms. Findings may include subdural hemorrhage, retinal hemorrhages, encephalopathy, seizures, and fractures; suspected cases require urgent medical stabilization and safeguarding evaluation.

Sudden Unexpected Infant Death (SUID)

- The sudden and unexpected death of an infant younger than 1 year, whether or not the cause is known before investigation. Sudden infant death syndrome is the unexplained subtype after complete scene, history, and autopsy evaluation.

Fencer's Pose

- See [Tonic Neck Reflex](#).

Pediculosis Capitis

- See [Head lice](#).

Growth Retardation

- Abnormally slow physical growth or failure to reach expected height or weight for age and developmental stage. Causes include inadequate nutrition, chronic systemic disease, endocrine or genetic disorders, malabsorption, psychosocial deprivation, and constitutional variation; assessment uses growth charts and clinical context.

Enuresis

- Repeated involuntary urination, usually during

sleep in a child who is developmentally expected to remain dry. It may be primary or secondary and requires assessment for constipation, urinary infection, diabetes, sleep or developmental disorders, psychosocial stressors, and lower-urinary-tract dysfunction when clinically indicated.

Iniiencephaly

- A rare, usually lethal neural-tube defect characterized by occipital bone defect, severe retroflexion of the head, and marked shortening or distortion of the cervical and thoracic spine. It is often identified prenatally and may occur with other congenital anomalies.

Otocephaly

- A severe congenital craniofacial malformation characterized by absent or markedly underdeveloped mandible, ventral displacement or fusion of the ears, and associated facial and airway abnormalities. It is usually lethal because of profound impairment of breathing and feeding.

Bedwetting

- Involuntary urination during sleep after the age at which nighttime bladder control is usually established. It may be primary or secondary to urinary infection, constipation, diabetes, sleep disorders, stress, or other medical conditions and should be assessed when persistent, new, or accompanied by daytime symptoms.

Chapter 31

Pharmacology

Agonist

- A substance that binds to a receptor and activates it, producing a biological response. A full agonist can produce the receptor's maximum response, whereas a partial agonist produces a lower maximum response even when it occupies all available receptors. An inverse agonist reduces constitutive receptor activity, while an antagonist binds without activating the receptor and blocks agonist effects.

Antiemetic

- A medication that prevents or treats nausea and vomiting. Classes target different pathways and receptors: 5-HT₃ receptor antagonists (ondansetron, granisetron) — block serotonin receptors in the chemoreceptor trigger zone and GI tract, first-line for chemotherapy-induced nausea and vomiting; NK₁ receptor antagonists (aprepitant, fosaprepitant) — block substance P/neurokinin-1 receptors in the vomiting center, used for highly emetogenic chemotherapy; dopamine D₂ antagonists (metoclopramide, prochlorperazine, droperidol) — block dopamine receptors in the CTZ, used for migraine and postoperative nausea; antihistamines (dimenhydrinate, meclizine) — block H₁ receptors, effective for motion sickness; anticholinergics (scopolamine) — block muscarinic receptors, used for motion sickness; and corticosteroids (dexamethasone) — mechanism unclear, used for chemotherapy-induced nausea and postoperative nausea.

Antiemetics

- Medications that prevent or treat nausea and vomiting. Classes and mechanisms: 5-HT₃ antagonists (ondansetron — block serotonin receptors in CTZ and gut, effective for chemotherapy and postoperative nausea), dopamine antagonists (metoclopramide, prochlorperazine — block D₂ receptors in

CTZ, prokinetic effect), antihistamines (cyclizine, promethazine — block H₁ receptors, effective for motion sickness), anticholinergics (hyoscine — motion sickness), neurokinin-1 antagonists (aprepitant — chemotherapy), and cannabinoids (nabilone). The cause of vomiting dictates drug choice.

Antihistamines

- Medications that block histamine receptors, primarily H₁ and H₂ receptors, used to treat allergic conditions and other histamine-mediated disorders. H₁ antihistamines are classified as first-generation (sedating, with significant anticholinergic effects) and second-generation (non-sedating, with minimal anticholinergic activity). First-generation H₁ antihistamines include diphenhydramine, chlorpheniramine, hydroxyzine, and doxylamine; they cross the blood-brain barrier, causing sedation, cognitive impairment, and anticholinergic side effects including dry mouth, urinary retention, and constipation; second-generation H₁ antihistamines include loratadine, cetirizine, and fexofenadine, which are preferred for long-term use due to their favourable safety profile.

Antiparkinson

- A class of medications used to manage Parkinson disease symptoms by restoring dopaminergic activity or modulating other neurotransmitter systems. Dopaminergic agents: levodopa (combined with carbidopa to prevent peripheral decarboxylation) — the most effective symptomatic treatment, converted to dopamine in the brain; dopamine agonists (pramipexole, ropinirole, rotigotine patch) — directly stimulate dopamine receptors; MAO-B inhibitors (selegiline, rasagiline) — inhibit dopamine breakdown; COMT inhibitors (entacapone, tolcapone) — inhibit peripheral levodopa metabolism,

extending its half-life. Anticholinergic agents (benztropine, trihexyphenidyl) — reduce tremor by blocking muscarinic receptors. Amantadine — increases dopamine release and reduces dyskinesias.

Antispasmodic

– A medication that reduces smooth muscle spasm, primarily in the gastrointestinal tract. Anticholinergic agents: hyoscyamine, dicyclomine, atropine — block muscarinic M3 receptors on GI smooth muscle, reducing contractions and peristalsis, used for irritable bowel syndrome and functional dyspepsia. Direct smooth muscle relaxants: mebeverine, papaverine, peppermint oil — act directly on smooth muscle cells without anticholinergic effects, providing relief from GI spasms. Urinary antispasmodics: oxybutynin, tolterodine, solifenacin — block M3 receptors on detrusor muscle in the bladder wall, reducing overactive bladder symptoms.

Antithyroid

– A class of medications that reduce thyroid hormone synthesis, used to treat hyperthyroidism (Graves disease, toxic nodular goiter). Thioamide derivatives: methimazole (propylthiouracil as second-line) — inhibit thyroid peroxidase, blocking iodination of tyrosine residues and coupling of iodotyrosines, reducing production of T3 and T4. PTU also inhibits peripheral conversion of T4 to T3. Methimazole is first-line due to better tolerability and once-daily dosing. Adverse effects: agranulocytosis (0.3-0.5%, the most serious, presenting with fever and sore throat), hepatotoxicity (rare with methimazole, more common with PTU), rash, arthralgia, and cholestatic jaundice. Treatment monitoring: thyroid function tests every 4-6 weeks during dose titration. Beta-blockers (propranolol, atenolol) are used adjunctively to control adrenergic symptoms (tachycardia, tremor) until euthyroid.

Anxiolytic

– A medication that reduces anxiety without producing excessive sedation. First-line for generalized anxiety disorder: SSRIs (escitalopram, paroxetine, sertraline) and SNRIs (venlafaxine, duloxetine) — increase serotonin/norepinephrine activity, require 2-4 weeks for therapeutic effect, first-line for chronic anxiety disorders. Buspirone — a 5-HT_{1A} partial agonist, effective for GAD, no sedation, no depen-

dence, requires 2-4 weeks for effect. Benzodiazepines (alprazolam, lorazepam, diazepam, clonazepam) — enhance GABA-A receptor activity, rapid onset (minutes to hours), effective for acute anxiety and panic attacks, limited to short-term use (2-4 weeks) due to tolerance, dependence, and withdrawal risks. Beta-blockers (propranolol) — reduce somatic symptoms of performance anxiety (tachycardia, tremor) through peripheral beta-blockade.

Atypical Antipsychotics

– A class of modern psychiatric medications used to treat schizophrenia and bipolar disorder. They work by balancing dopamine and serotonin levels in the brain, which helps reduce symptoms like hallucinations and delusions with fewer movement-related side effects than older antipsychotics.

Cardioselective Beta-Blockers

– Cardioselective beta-blockers selectively block beta-1 adrenergic receptors, which are predominant in the heart, while having minimal effects on beta-2 receptors in the bronchial smooth muscle and peripheral vasculature at therapeutic doses. Common cardioselective beta-blockers include metoprolol, atenolol, bisoprolol, and nebivolol. At low to moderate doses, these agents produce cardiac effects including decreased heart rate, reduced myocardial contractility, and decreased cardiac output without significant bronchospasm, making them preferred in patients with asthma or COPD, though cardioselectivity is dose-dependent and may be lost at higher doses.

Cholinesterase Inhibitor

– A class of medications that inhibit acetylcholinesterase, the enzyme that breaks down acetylcholine in the synaptic cleft, thereby increasing cholinergic neurotransmission in the central nervous system and peripheral tissues. Centrally acting cholinesterase inhibitors: donepezil, rivastigmine, and galantamine — used for symptomatic treatment of Alzheimer disease and other dementias by enhancing central cholinergic activity, providing modest cognitive and functional benefit (typically 6-12 months of stabilization before decline resumes). Rivastigmine is also approved for Parkinson disease dementia. Peripherally acting: neostigmine, pyridostigmine — used for myasthenia gravis to increase neuromuscular junction acetylcholine lev-

els; and physostigmine — used as an antidote for anticholinergic poisoning. Adverse effects: GI symptoms (nausea, vomiting, diarrhea, most common), bradycardia, increased gastric acid secretion, muscle cramps, and insomnia.

Decongestants

– Medications that reduce nasal congestion by constricting blood vessels in the nasal mucosa, decreasing swelling and mucus production. Systemic decongestants: pseudoephedrine and phenylephrine (oral), which stimulate alpha-adrenergic receptors causing vasoconstriction. Topical decongestants: oxymetazoline, xylometazoline, naphazoline, phenylephrine (nasal sprays)—more potent and rapid-acting but risk of rhinitis medicamentosa (rebound congestion) with use beyond 3–5 days. Indications: nasal congestion from allergic rhinitis, common cold, sinusitis. Contraindications: uncontrolled hypertension, severe coronary artery disease, narrow-angle glaucoma, and MAOI use.

Dopamine Agonist

– A class of medications that stimulate dopamine receptors (D1-D5), mimicking the effects of endogenous dopamine. Used primarily in Parkinson disease: pramipexole and ropinirole (non-ergot dopamine agonists) are effective for early and advanced PD, delaying levodopa initiation and reducing motor fluctuations; rotigotine is available as a transdermal patch providing continuous delivery. Apomorphine is a potent, rapid-acting injectable dopamine agonist used for acute rescue in refractory motor fluctuations and off episodes. Adverse effects: impulse control disorders (pathological gambling, hypersexuality, compulsive shopping, binge eating — unique to dopamine agonists, occurring in 15-25%), nausea, orthostatic hypotension, hallucinations, and daytime somnolence (sudden sleep attacks). Ergot-derived dopamine agonists (bromocriptine, cabergoline) are rarely used due to risk of pulmonary and retroperitoneal fibrosis.

Drug Antagonism

– An interaction where one drug blocks or decreases the effectiveness of another, such as when an antidote blocks a poison.

Epinephrin (Adrenaline)

– Alternate spelling of epinephrine (adrenaline). See

Epinephrine (Adrenaline).

Epinephrine (Adrenaline)

– A catecholamine hormone and neurotransmitter produced by the adrenal medulla and sympathetic nerve terminals, acting on alpha-1, alpha-2, beta-1, beta-2, and beta-3 adrenergic receptors. Effects: alpha-1: vasoconstriction (increases blood pressure), mydriasis; beta-1: increased heart rate and contractility; beta-2: bronchodilation, vasodilation in skeletal muscle, glycogenolysis. Clinical uses: first-line treatment for anaphylaxis (0.3–0.5 mg IM, repeat every 5–15 minutes), cardiac arrest (1 mg IV every 3–5 minutes during ACLS), severe asthma exacerbation (subcutaneous or IV), septic shock (IV infusion), and local vasoconstriction (combined with local anesthetics to prolong duration and reduce bleeding). Side effects: hypertension, tachycardia, arrhythmias, tremor, anxiety, hyperglycemia. Auto-injectors (EpiPen) are prescribed for patients with severe allergies.

Ganglionic Blocker

– A class of drugs that block nicotinic acetylcholine receptors at autonomic ganglia (both sympathetic and parasympathetic), inhibiting neurotransmission in both divisions of the autonomic nervous system. Due to their non-selective blockade of all autonomic ganglia, they produce widespread and unpredictable effects including severe orthostatic hypotension, blurred vision (cycloplegia), dry mouth, constipation, urinary retention, and impotence. Prototype: hexamethonium. Clinical use: historically used for hypertensive emergencies before the development of safer agents. Currently used rarely, primarily for inducing controlled hypotension during surgery (trimethaphan). Ganglionic blockers are of more pharmacological than clinical importance, serving as tools for understanding autonomic physiology.

Inverse Agonist

– A type of drug that binds to a cell receptor and actively produces the opposite biological effect of an agonist, effectively turning down the receptor's baseline activity.

MAOIs

– Monoamine oxidase inhibitors are a class of antidepressant drugs that inhibit the enzyme

monoamine oxidase, which breaks down serotonin, norepinephrine, and dopamine in the brain. By inhibiting this enzyme, MAOIs increase the levels of these neurotransmitters in the synaptic cleft. There are two forms of MAO: MAO-A preferentially metabolizes serotonin and norepinephrine, while MAO-B preferentially metabolizes dopamine and tyramine. Non-selective MAOIs including phenelzine and tranylcypromine inhibit both MAO-A and MAO-B, while selective MAO-B inhibitors such as selegiline are used in Parkinson disease. MAOIs have significant potential for drug interactions and require dietary restriction of tyramine-containing foods due to the risk of hypertensive crisis.

Neuroleptic Malignant Syndrome

– A rare but life-threatening idiosyncratic reaction to dopamine receptor-blocking agents, typically antipsychotics, characterized by hyperthermia, severe muscle rigidity, altered mental status, and autonomic dysfunction. The pathogenesis involves sudden blockade of dopamine D2 receptors in the hypothalamus causing thermoregulatory dysfunction, in the nigrostriatal pathway causing extrapyramidal symptoms, and in the mesocortical pathway causing altered mental status; treatment involves immediate discontinuation of the causative agent, supportive care, and pharmacological therapy including dantrolene (a direct-acting muscle relaxant that inhibits calcium release from the sarcoplasmic reticulum), bromocriptine (a dopamine agonist), and benzodiazepines for agitation and muscle rigidity, with careful monitoring of vital signs in an intensive care setting.

Nonselective Beta-Blockers

– Nonselective beta-adrenergic blocking agents block both beta-1 and beta-2 adrenergic receptors, reducing heart rate, myocardial contractility, and cardiac output through beta-1 blockade, while also blocking beta-2 receptors in the bronchial smooth muscle and peripheral vasculature. Common nonselective beta-blockers include propranolol, nadolol, timolol, and pindolol. Propranolol is the prototype agent, with lipophilic properties allowing good CNS penetration, making it useful for performance anxiety and essential tremor, though this property also increases the risk of CNS side effects including fatigue, depression, and sleep disturbances.

Over-the-Counter (OTC) Medications

– Nonprescription drugs approved as safe and effective for self-management of common symptoms, available at pharmacies and retail stores without a prescription. Major categories: analgesics/antipyretics (acetaminophen—max 3000–4000 mg/day, hepatotoxicity risk with overdose; NSAIDs—ibuprofen, naproxen—GI bleeding and cardiovascular risk with chronic use), cough and cold preparations (decongestants—pseudoephedrine, phenylephrine; antihistamines—diphenhydramine, cetirizine; dextromethorphan for cough), gastrointestinal (PPIs/omeprazole, H2 blockers/famotidine for GERD; antacids; loperamide for diarrhea; psyllium, polyethylene glycol for constipation; bismuth subsalicylate for dyspepsia), allergy (oral/loratadine, cetirizine; intranasal corticosteroids, cromolyn), dermatologic (hydrocortisone, antifungals—clotrimazole, terbinafine), and sleep aids (diphenhydramine, doxylamine, melatonin). Risks: drug–drug interactions (NSAIDs with anticoagulants, antacids with antibiotics), unintentional overdose (especially combination products with acetaminophen), and delayed diagnosis of serious conditions. Pharmacist counseling improves safe OTC selection.

Parasympatholytic

– A drug that blocks muscarinic (cholinergic) receptors, inhibiting parasympathetic nervous system activity. Agents: atropine (bradycardia, organophosphate poisoning), ipratropium/tiotropium (COPD/asthma—bronchodilation), scopolamine (motion sickness), oxybutynin/tolterodine (overactive bladder), and glycopyrrolate. Effects: mydriasis, cycloplegia, tachycardia, dry mouth, urinary retention, constipation, and bronchodilation. Adverse effects: confusion (elderly), heat intolerance, and glaucoma precipitation. Reversed by physostigmine.

Parasympathomimetic

– A drug that mimics or enhances parasympathetic (cholinergic) activity. Direct agonists: muscarinic (pilocarpine—glaucoma, dry mouth) and nicotinic agonists. Indirect (acetylcholinesterase inhibitors): neostigmine (myasthenia gravis, postoperative ileus/urinary retention), physostigmine

(anticholinergic poisoning), donepezil/rivastigmine (Alzheimer disease). Effects: miosis, bradycardia, bronchoconstriction, salivation, lacrimation, GI stimulation, and bladder contraction. Adverse effects: bradycardia, bronchospasm, diarrhea, and sweating; reversed by atropine.

Placebo Effect

- A psychological and physiological phenomenon where a patient experiences a real improvement in health or symptoms after receiving an inactive treatment (like a sugar pill) due to their expectations of healing.

Receptor Downregulation

- A decrease in the number or sensitivity of receptors in response to chronic receptor stimulation by agonists. When receptors are chronically activated, the cells compensate by internalizing and degrading receptors, reducing receptor density on the cell surface, and decreasing receptor responsiveness. This process contributes to drug tolerance, where increasing doses are needed to achieve the same therapeutic effect. Chronic use of beta-agonists such as albuterol for asthma leads to reduced bronchodilator response, and tolerance to opioid analgesics develops through downregulation of mu-opioid receptors in the central nervous system.

Receptor Upregulation

- An increase in the number or sensitivity of receptors in response to chronic receptor blockade or decreased neurotransmitter activity. When receptors are chronically blocked by antagonists, the cells compensate by synthesizing more receptors to maintain homeostatic signaling, leading to increased sensitivity to agonists. This phenomenon contributes to drug tolerance, where increasing doses are needed to achieve the same effect, and to withdrawal syndromes when the blockdrug is discontinued; well-recognized examples include the upregulation of beta-adrenergic receptors following chronic beta-blocker therapy, causing rebound tachycardia and hypertension upon abrupt withdrawal, and the upregulation of histamine H₂ receptors after chronic proton pump inhibitor use, leading to rebound acid hypersecretion.

Salbutamol (Albuterol)

- A selective beta-2 adrenergic agonist bronchodila-

tor used for acute relief and prevention of bronchospasm in asthma and COPD. Relaxes airway smooth muscle; short-acting (SABA), onset 5-15 minutes, duration 4-6 hours via inhaler or nebulizer. Adverse effects: tremor, tachycardia, palpitations, hypokalemia, and headache. First-line rescue therapy; overuse signals poor control. Levalbuterol is the R-enantiomer. Salmeterol and formoterol are long-acting (LABAs, not for acute relief).

Sedatives

- A class of drugs that produce a calming or drowsy effect by depressing the central nervous system. Sedatives reduce anxiety, promote sleep, and induce relaxation. Classes: (1) Benzodiazepines—enhance GABA_A receptor activity (diazepam, lorazepam, midazolam, temazepam). Used for anxiety, insomnia, seizures, muscle relaxation, procedural sedation, and alcohol withdrawal. (2) Z-drugs—non-benzodiazepine hypnotics (zolpidem, zopiclone, zaleplon)—selective for GABA_A $\alpha 1$ subunit, primarily for insomnia. (3) Barbiturates—enhance GABA_A activity but with a narrower therapeutic index (phenobarbital, thiopental)—now rarely used except for refractory epilepsy and anesthetic induction. (4) Antihistamines—H₁ antagonists with sedative properties (diphenhydramine, hydroxyzine, promethazine)—mild sedation. (5) Antipsychotics—low-dose quetiapine, olanzapine—used as sedatives off-label. (6) Melatonin receptor agonists (ramelteon, prolonged-release melatonin)—regulate circadian rhythm. (7) Orexin receptor antagonists (suvorexant, daridorexant)—promote sleep by blocking wake-promoting orexin signalling. (8) $\alpha 2$ -adrenergic agonists (clonidine, dexmedetomidine)—sedation without respiratory depression. Adverse effects: drowsiness, daytime sedation, cognitive impairment, impaired coordination, falls (especially elderly), tolerance, dependence, and withdrawal. Respiratory depression (especially with alcohol, opioids). Long-term use of benzodiazepines is discouraged (dependence, tolerance, cognitive decline, increased dementia risk—controversial).

Serotonin Syndrome

- A potentially life-threatening condition caused by excessive serotonergic activity in the central and peripheral nervous systems, typically resulting from drug interactions or overdose involving serotonergic

medications. The classic triad includes neuromuscular hyperactivity with tremor, clonus, rigidity, and hyperreflexia; autonomic dysfunction with hyperthermia, diaphoresis, tachycardia, and hypertension; and altered mental status with agitation, confusion, and delirium. Severe cases may progress to hyperpyrexia, rhabdomyolysis, multi-organ failure, and death. Treatment involves immediate discontinuation of all serotonergic agents, supportive care with intravenous fluids and cooling, and administration of cyproheptadine, a serotonin antagonist, for moderate to severe cases.

Skeletal Muscle Relaxant

- A medication that reduces muscle spasm, spasticity, and associated pain. Centrally acting muscle relaxants: baclofen — GABA-B agonist that reduces spinal reflex activity, first-line for spasticity in cerebral palsy, multiple sclerosis, and spinal cord injury; tizanidine — alpha-2 adrenergic agonist that inhibits spinal motor neuron activity; diazepam — enhances GABA-A activity, effective for acute muscle spasm; cyclobenzaprine — structurally related to tricyclic antidepressants, reduces brainstem descending noradrenergic activity; methocarbamol and carisoprodol — centrally acting, mechanism less defined. Peripherally acting: dantrolene — inhibits calcium release from the sarcoplasmic reticulum by blocking ryanodine receptors, used for malignant hyperthermia and chronic spasticity. Botulinum toxin — blocks acetylcholine release at the neuromuscular junction, used for focal spasticity and dystonia.

SNRIs

- Serotonin-norepinephrine reuptake inhibitors are a class of antidepressant drugs that inhibit the reuptake of both serotonin and norepinephrine from the synaptic cleft, increasing both serotonergic and noradrenergic neurotransmission. Common SNRIs include venlafaxine, duloxetine, desvenlafaxine, and levomilnacipran. They are used for major depressive disorder, generalized anxiety disorder, panic disorder, social anxiety disorder, and chronic pain conditions. Duloxetine is also approved for diabetic peripheral neuropathy, fibromyalgia, and chronic musculoskeletal pain. Common adverse effects include nausea, dry mouth, insomnia, sweating, and sexual dysfunction; discontinuation syndrome with dizziness and paresthesias may occur with

abrupt cessation, requiring gradual tapering.

Tachyphylaxis

- A rapid, acute decrease in response to a drug after repeated administration over a short period, distinct from tolerance which develops more gradually. Tachyphylaxis results from rapid depletion of neurotransmitter stores, receptor desensitization, or receptor downregulation. A classic example is the rapid development of tachyphylaxis to ephedrine, where repeated doses lead to depletion of norepinephrine stores in nerve terminals, reducing the sympathomimetic effect. Nicotine also demonstrates tachyphylaxis, and this phenomenon contributes to the need for dose escalation during the first few days of therapy. Tachyphylaxis is distinct from tolerance, which develops more slowly, and from desensitization, which results from reduced receptor responsiveness.

TCAs

- Tricyclic antidepressants are a class of drugs that inhibit the reuptake of serotonin and norepinephrine, similar to SNRIs, but also block histamine H1 receptors, muscarinic acetylcholine receptors, and alpha-1 adrenergic receptors, producing numerous side effects. Common TCAs include amitriptyline, nortriptyline, imipramine, and clomipramine. They are effective antidepressants but are now used less frequently for depression due to their side effect profile and toxicity in overdose. TCAs are used for a range of other conditions including neuropathic pain (amitriptyline, nortriptyline), migraine prophylaxis (amitriptyline), chronic pain syndromes, enuresis, and insomnia (doxepin, trimipramine). Their anticholinergic effects cause dry mouth, blurred vision, constipation, urinary retention, and cognitive impairment in elderly patients; cardiotoxicity in overdose manifests as QT prolongation, conduction abnormalities, and potentially fatal arrhythmias, limiting their use in patients with cardiac disease or at risk of suicide.

Tocolytics

- Medications used to suppress preterm labor (contractions before 37 weeks gestation), to delay delivery for corticosteroid administration (fetal lung maturity) and in utero transport to a tertiary care center. First-line: calcium channel blockers (nifedipine)

ine) — inhibit smooth muscle contraction by blocking voltage-gated calcium channels, oral administration, fewer side effects than other tocolytics. Beta-2 adrenergic agonists (terbutaline, ritodrine) — activate beta-2 receptors on uterine smooth muscle, causing relaxation via increased intracellular cAMP, side effects include maternal tachycardia, pulmonary edema, and hypokalemia. NSAIDs (indomethacin) — inhibit prostaglandin synthesis by COX inhibition, effective for short-term tocolysis (<48 hours), side effects include oligohydramnios and premature closure of the fetal ductus arteriosus with prolonged use. Magnesium sulfate — blocks calcium entry into smooth muscle cells, used for neuroprotection in preterm infants (<32 weeks) and seizure prophylaxis in preeclampsia, but has marginal tocolytic efficacy.

Typical Antipsychotics

– Typical antipsychotics, also known as first-generation antipsychotics, primarily block dopamine D2 receptors in the mesolimbic pathway, reducing positive symptoms of schizophrenia including hallucinations, delusions, and disorganized thinking. They are classified by potency: high-potency agents including haloperidol and fluphenazine require lower doses and have more extrapyramidal side effects; low-potency agents including chlorpromazine and thioridazine require higher doses and have more anticholinergic side effects including sedation, dry mouth, constipation, and postural hypotension; all typical antipsychotics carry a risk of tardive dyskinesia, a potentially irreversible movement disorder characterized by involuntary, repetitive movements of the face, mouth, and extremities, with higher potency agents posing a greater risk.

Uterotonic

– A medication that stimulates uterine contraction, used for induction/augmentation of labor, prevention and treatment of postpartum hemorrhage, and medical termination of pregnancy. Oxytocin — a synthetic analog of the endogenous hormone, stimulates oxytocin receptors on uterine smooth muscle, producing rhythmic contractions, administered IV for labor induction/augmentation; also used IV or IM for active management of the third stage of labor to prevent postpartum hemorrhage. Ergot alkaloids (ergometrine, methylergonovine) —

cause sustained uterine tetanic contraction by acting on alpha-adrenergic and serotonin receptors, used IM/IV for postpartum hemorrhage, contraindicated in hypertension and preeclampsia. Prostaglandins: carboprost (PGF2-alpha) — IM for refractory postpartum hemorrhage; misoprostol (PGE1 analog) — oral, sublingual, rectal, or vaginal for cervical ripening, labor induction, and postpartum hemorrhage; dinoprostone (PGE2) — vaginal insert for cervical ripening.

5-Alpha Reductase Inhibitor

– A class of medications that inhibit the enzyme 5-alpha-reductase, which converts testosterone to dihydrotestosterone (DHT), the more potent androgen responsible for prostate growth and male pattern baldness. Two isoforms: Type I (predominant in skin and scalp) and Type II (predominant in the prostate). Finasteride inhibits primarily Type II (blocks 70% of DHT); dutasteride inhibits both Type I and Type II (blocks >90% of DHT). Indications: benign prostatic hyperplasia — reduces prostate volume, improves urinary flow, reduces risk of acute urinary retention and need for surgery (requires 6-12 months for maximal effect); male androgenetic alopecia — slows hair loss and promotes regrowth. Adverse effects: decreased libido, erectile dysfunction (2-5%), ejaculatory dysfunction, and gynecomastia. Serum PSA levels decrease by approximately 50% — adjusted PSA values are needed for prostate cancer screening.

Absorption

– The process by which a drug enters the bloodstream from its site of administration, such as the digestive tract, skin, or muscle.

ACE Inhibitors

– Angiotensin-converting enzyme inhibitors are a class of medications that block the conversion of angiotensin I to angiotensin II by inhibiting the angiotensin-converting enzyme (ACE, also known as kininase II). This results in decreased aldosterone secretion, reduced sodium and water retention, decreased vasoconstriction, and reduced sympathetic nervous system activity. ACE inhibitors also inhibit the breakdown of bradykinin, a vasodilator, which contributes to their antihypertensive effect but also contributes to the characteristic adverse effect of

dry cough, which occurs in approximately 10-20% of patients, and the less common but more serious angioedema.

Acetaminophen Mechanism

- Acetaminophen, also known as paracetamol, is an analgesic and antipyretic drug with weak anti-inflammatory activity, differing from NSAIDs in its mechanism and side effect profile. Its precise mechanism of action remains incompletely understood, but it is thought to inhibit a COX variant in the central nervous system, possibly COX-3, and may also activate descending serotonergic pain inhibition pathways and interact with the endocannabinoid system through its metabolite AM404. Acetaminophen inhibits prostaglandin synthesis in the central nervous system, reducing pain perception and fever, and also activates descending serotonergic pathways that modulate pain signalling at the spinal cord level.

Acetaminophen (Paracetamol)

- An analgesic and antipyretic drug that inhibits central COX enzymes and may have serotonergic and endocannabinoid mechanisms. It is first-line for mild pain and fever with fewer side effects than NSAIDs. Maximum daily dose is 4 grams (reduced to 2-3 grams in liver disease or alcohol use). Acetaminophen overdose causes hepatotoxicity due to the toxic metabolite NAPQI. Antidote is N-acetylcysteine, which replenishes glutathione stores.

Acetazolamide

- A carbonic anhydrase inhibitor diuretic. Blocks carbonic anhydrase in the proximal tubule, reducing bicarbonate reabsorption, producing a mild diuresis and metabolic acidosis. Uses: acute mountain sickness prophylaxis/treatment, glaucoma (reduces aqueous humor production), idiopathic intracranial hypertension, metabolic alkalosis, and as an adjunct in some seizure disorders and urinary alkalization. Given orally or IV. Side effects: paresthesias, hypokalemia, metabolic acidosis, renal stones, sulfonamide allergy cross-reactivity. Contraindicated in hepatic cirrhosis (hepatic encephalopathy risk) and severe renal impairment.

Acinetobacter baumannii resistance

- *Acinetobacter baumannii* is a gram-negative coc-

cobacillus that has emerged as a significant cause of healthcare-associated infections, particularly in intensive care units. The organism has intrinsic and acquired resistance mechanisms, including beta-lactamases, efflux pumps, and porin mutations. Multidrug-resistant and carbapenem-resistant strains are increasingly common. Treatment options are limited and may include polymyxins, tigecycline, and minocycline. Infection prevention strategies are critical for preventing nosocomial transmission, particularly as *Acinetobacter* can survive on environmental surfaces for extended periods.

Adverse Drug Reaction

- An adverse drug reaction is any noxious or unintended response to a drug that occurs at doses used for prophylaxis, diagnosis, or therapy. ADRs are classified as type A reactions, which are dose-dependent and predictable extensions of the drug's pharmacological effects, such as bleeding with warfarin or hypoglycemia with insulin; and type B reactions, which are idiosyncratic, unpredictable, and not dose-related, such as drug allergies and Stevens-Johnson syndrome. ADRs are further classified as type C, dose- and time-dependent reactions such as cumulative toxicity; type D, delayed effects such as carcinogenicity and teratogenicity; and type E, withdrawal reactions upon discontinuation.

Adverse Drug Reactions

- Any harmful or unintended response to a drug at normal doses. ADRs are classified as Type A (augmented, dose-dependent, predictable: side effects, toxicity) or Type B (bizarre, dose-independent, unpredictable: allergy, idiosyncrasy). ADRs are a major cause of morbidity and mortality, accounting for 5-7% of hospital admissions. Risk factors include polypharmacy, renal/hepatic impairment, age extremes, and genetic predisposition. Prevention involves careful prescribing and monitoring.

Agonist-Antagonist

- A drug that has mixed pharmacological activity, acting as an agonist at one receptor type and an antagonist at another, or as a partial agonist at a single receptor. Mixed opioid agonist-antagonists: pentazocine — kappa agonist and mu partial antagonist, producing analgesia with less respiratory depression and lower abuse potential than pure mu

agonists; nalbuphine — kappa agonist and mu antagonist; butorphanol — kappa agonist and mu antagonist. Partial agonists: buprenorphine — partial mu agonist and kappa antagonist, used for opioid use disorder due to ceiling effect on respiratory depression and lower abuse liability. The clinical advantage of agonist-antagonists is the reduced risk of respiratory depression and dependence compared to full mu agonists.

Aminoglycoside nephrotoxicity

- Kidney damage caused by aminoglycoside antibiotics, characterized by acute tubular necrosis. Nephrotoxicity is caused by accumulation of aminoglycosides in the proximal tubular cells. The risk is increased with prolonged therapy, high doses, concurrent nephrotoxic drugs, and renal impairment. Gentamicin is considered the most nephrotoxic aminoglycoside. The nephrotoxicity is usually reversible with early detection and discontinuation. Regular monitoring of serum creatinine and drug levels is essential for early detection of nephrotoxicity, and dose adjustment based on renal function is required to minimise the risk of acute kidney injury.

Aminoglycoside ototoxicity

- Damage to the inner ear caused by aminoglycoside antibiotics, resulting in hearing loss and vestibular dysfunction. Ototoxicity is caused by accumulation of aminoglycosides in the inner ear, damaging hair cells. The risk is increased with prolonged therapy, high doses, concurrent ototoxic drugs, and renal impairment. Amikacin is considered the most ototoxic aminoglycoside. Symptoms include tinnitus, hearing loss, and vertigo. Hearing loss may be irreversible. Baseline and periodic audiometry should be performed at baseline and repeated regularly during treatment, particularly in patients receiving high cumulative doses or those with pre-existing hearing impairment.

Aminoglycosides

- A class of bactericidal antibiotics that bind irreversibly to the 30S ribosomal subunit, causing misreading of messenger RNA and inhibiting protein synthesis. They include gentamicin, tobramycin, amikacin, and streptomycin. Aminoglycosides are particularly effective against aerobic gram-negative organisms including *Pseudomonas aeruginosa* and

have synergistic activity with beta-lactams against enterococci and staphylococci. They are poorly absorbed from the gastrointestinal tract and must be administered parenterally for systemic infections, with careful monitoring of serum concentrations to balance efficacy against nephrotoxicity and ototoxicity.

Analgesic

- A drug that relieves pain without producing loss of consciousness. Classes: non-opioids (acetaminophen, NSAIDs—act peripherally and on central prostaglandin synthesis), opioids (morphine, oxycodone, fentanyl—act on central and spinal opioid receptors), and adjuvants (anticonvulsants such as gabapentin/pregabalin, tricyclic antidepressants, and local anesthetics) used for neuropathic pain. Selection depends on pain type (nociceptive vs neuropathic), severity (WHO analgesic ladder), and comorbidities. Adverse effects: GI bleeding (NSAIDs), hepatotoxicity (acetaminophen), respiratory depression and dependence (opioids).

Angiotensin Receptor Blockers

- A class of cardiovascular drugs that selectively block the angiotensin II type 1 receptor, preventing the binding of angiotensin II and its effects including vasoconstriction, aldosterone secretion, and sympathetic activation. Unlike ACE inhibitors, ARBs do not affect bradykinin metabolism, resulting in lower rates of cough and angioedema. Common ARBs include losartan, valsartan, irbesartan, and olmesartan. ARBs have similar hemodynamic effects to ACE inhibitors but are generally better tolerated due to a lower incidence of cough and angioedema.

Antacids

- Medications that neutralise gastric acid, providing rapid symptomatic relief in dyspepsia, gastroesophageal reflux, and peptic ulcer disease. Commonly contain aluminium hydroxide, magnesium hydroxide, calcium carbonate, or sodium bicarbonate. Aluminium-based antacids can cause constipation; magnesium-based antacids can cause diarrhea; combination preparations balance these effects. Antacids also promote gastric mucosal defence by stimulating bicarbonate and prostaglandin secretion. Drug interactions: reduce absorption of tetracyclines, iron, digoxin, and bisphosphonates (separate

dosing by 2 hours). Not first-line for chronic GERD (PPIs preferred).

Antianginal

– A class of medications used to prevent or relieve angina pectoris (chest pain from myocardial ischemia). The three main classes of antianginal drugs target different mechanisms: nitrates (nitroglycerin, isosorbide mononitrate/dinitrate) — venodilators that reduce preload and myocardial oxygen demand; beta-blockers — reduce heart rate, contractility, and oxygen demand; and calcium channel blockers (verapamil, diltiazem, nifedipine) — vasodilators that reduce afterload and coronary spasm. Ranolazine is a newer antianginal agent that inhibits the late sodium current in cardiac myocytes, reducing intracellular calcium overload and improving diastolic function without affecting heart rate or blood pressure.

Antiarrhythmic

– A drug used to treat or prevent cardiac arrhythmias, classified by the Vaughan Williams system: Class I (sodium channel blockers: quinidine, lidocaine, flecainide), Class II (beta-blockers), Class III (potassium channel blockers prolonging repolarization: amiodarone, sotalol), Class IV (calcium channel blockers: verapamil, diltiazem), and Class V (other: digoxin, adenosine). Selection depends on the arrhythmia (AF, SVT, VT) and underlying heart disease. Antiarrhythmics can themselves be proarrhythmic; amiodarone requires monitoring for pulmonary, thyroid, hepatic, and ocular toxicity.

Antibiotic cycling

– The scheduled rotation of antimicrobial agents within a healthcare facility to reduce selective pressure for resistance. The strategy involves periodically changing the preferred antibiotics for specific infections. For example, cycling between carbapenems and fluoroquinolones for gram-negative infections. The evidence for antibiotic cycling is mixed, with some studies showing reductions in resistance and others showing no benefit. Cycling may be combined with other stewardship strategies including education, surveillance, and the development of evidence-based prescribing guidelines tailored to local resistance patterns.

Antibiotic de-escalation

– The process of narrowing antimicrobial spectrum based on microbiological results and clinical response. De-escalation aims to reduce selective pressure for resistance while maintaining therapeutic efficacy. The process involves identifying the causative organism and susceptibility pattern, then switching from broad-spectrum to narrow-spectrum agents. De-escalation should be performed as soon as possible, typically within 48-72 hours when culture results are available. This strategy reduces the risk of antibiotic resistance, selective pressure on the microbiome, superinfection risk, and adverse drug effects, while also lowering overall treatment costs.

Antibiotic mixing

– A stewardship strategy where different patients with the same indication receive different antibiotics concurrently, with the goal of reducing resistance emergence. For example, using different agents for ventilator-associated pneumonia in different patients within the same unit. The evidence for antibiotic mixing is limited, but theoretical models suggest it may reduce resistance emergence. This strategy may be combined with other stewardship strategies including prospective audit and feedback, formulary restriction, and computerised decision support to achieve optimal antimicrobial use.

Antibiotics

– Medications that kill or inhibit the growth of bacteria, used to treat bacterial infections such as pneumonia, strep throat, and urinary tract infections. They are ineffective against viral infections like colds or influenza. Overuse and misuse have driven antibiotic resistance, a growing public health crisis that makes infections harder to treat.

Anticonvulsants

– Medications used to prevent or control seizures in epilepsy and other seizure disorders. Mechanisms: enhance GABA activity (benzodiazepines, barbiturates, vigabatrin, tiagabine), block voltage-gated sodium channels (phenytoin, carbamazepine, lamotrigine), block calcium channels (gabapentin, pregabalin, ethosuximide), or inhibit glutamate release (levetiracetam). Choice depends on seizure type: sodium valproate for generalised, carbamazepine/lamotrigine for focal. Side effects: seda-

tion, dizziness, ataxia, rash, hepatotoxicity, teratogenicity (valproate). Therapeutic drug monitoring required for phenytoin and carbamazepine.

Antidiabetic

- A class of medications used to manage diabetes mellitus by lowering blood glucose levels through various mechanisms. Major classes include: biguanides (metformin) — reduce hepatic glucose production; sulfonylureas (glipizide, glyburide) — stimulate insulin secretion; meglitinides (repaglinide) — stimulate rapid, short-acting insulin secretion; thiazolidinediones (pioglitazone) — improve insulin sensitivity; DPP-4 inhibitors (sitagliptin) — increase incretin levels; GLP-1 receptor agonists (semaglutide, liraglutide) — stimulate insulin secretion, slow gastric emptying; SGLT2 inhibitors (empagliflozin, dapagliflozin) — increase urinary glucose excretion; insulin preparations — replace endogenous insulin; and alpha-glucosidase inhibitors (acarbose) — delay carbohydrate absorption.

Antidiarrheal

- A drug that reduces the frequency or volume of diarrhea. Loperamide, a peripheral mu-opioid receptor agonist, slows intestinal motility and reduces fluid loss without CNS effects; diphenoxylate/atropine combinations and bismuth subsalicylate are alternatives. Antidiarrheals are avoided in invasive/inflammatory diarrhea (dysentery, *C. difficile* infection) because they may prolong infection or precipitate toxic megacolon. Oral rehydration is first-line for dehydration. Octreotide is used for secretory diarrhea; cholestyramine for bile acid diarrhea.

Antiepileptic Drugs

- Medications used to prevent and control seizures by modulating neuronal excitability through various mechanisms. They can be classified by their primary mechanism of action. Sodium channel blockers including phenytoin, carbamazepine, and lamotrigine stabilize the inactivated state of voltage-gated sodium channels, reducing high-frequency repetitive firing. GABA-enhancing drugs including valproic acid, benzodiazepines, and vigabatrin increase inhibitory GABAergic transmission; glutamate receptor antagonists such as topiramate and felbamate reduce excitatory neurotransmission; and drugs with

multiple mechanisms including valproic acid and levetiracetam provide broad-spectrum seizure control through combined action on GABA, sodium channels, and calcium channels.

Antifungal

- A drug used to treat fungal infections. Classes: polyenes (amphotericin B—broad, fungicidal, for severe/systemic mycoses), azoles (fluconazole, itraconazole, voriconazole, posaconazole—inhibit ergosterol synthesis), echinocandins (caspofungin, micafungin, anidulafungin—inhibit cell wall glucan synthesis), and allylamines (terbinafine—for dermatophytes). Griseofulvin, flucytosine, and nystatin (topical/enteral) are additional agents. Selection depends on the organism, site, and host immunity. Antifungal resistance is emerging (*Candida auris*).

Antifungal prophylaxis

- The use of antifungal agents to prevent invasive fungal infections in high-risk patients. See microbiology.

Antigout

- A class of medications used to treat gout by reducing uric acid levels or controlling acute inflammation. Acute gout treatment: NSAIDs (indomethacin, naproxen) — first-line for pain and inflammation; colchicine — inhibits microtubule polymerization, reducing neutrophil chemotaxis and inflammation, most effective when started within 24 hours of attack; corticosteroids (oral, intra-articular, or IV) for refractory cases. Long-term urate-lowering therapy: xanthine oxidase inhibitors (allopurinol, febuxostat) — reduce uric acid production by inhibiting xanthine oxidase; uricosuric agents (probenecid, lesinurad) — increase renal uric acid excretion by inhibiting URAT1 transporter; and recombinant uricase (pegloticase) — enzymatically degrades uric acid, reserved for severe tophaceous gout.

Antihistamine

- A drug that blocks histamine receptors. H1 antihistamines treat allergic rhinitis, urticaria, pruritus, and (older sedating agents) insomnia and motion sickness. First-generation (diphenhydramine, chlorpheniramine): CNS-penetrant—sedating, anticholinergic (dry mouth, urinary retention, confusion in elderly). Second-generation (loratadine, cetirizine, fexofenadine): non-sedating, peripherally

selective. H₂ antihistamines (famotidine, ranitidine) reduce gastric acid (see H₂ Blockers). Used in anaphylaxis as adjuncts (after epinephrine).

Antihypertensive

- A drug that lowers blood pressure, used for hypertension management. Major classes: ACE inhibitors and ARBs (preferred first-line, renoprotective), calcium channel blockers, thiazide diuretics, beta-blockers (with CAD/heart failure), alpha-blockers, centrally acting agents (clonidine), and direct vasodilators (hydralazine, minoxidil). Combination therapy is often needed; lifestyle modification is foundational. Goals vary by risk (typically <130/80 mmHg). Adverse effects are class-specific; ACE inhibitor cough, hyperkalemia, and angioedema require vigilance. Hypertensive urgency/emergency requires urgent IV therapy.

Anti-inflammatory

- An agent that reduces inflammation. Nonsteroidal anti-inflammatory drugs (NSAIDs) inhibit cyclooxygenase, reducing prostaglandin synthesis; corticosteroids have broader anti-inflammatory actions via glucocorticoid receptor-mediated gene regulation; colchicine, methotrexate, sulfasalazine, and biologic agents (TNF inhibitors, IL-6 inhibitors) are used for inflammatory and autoimmune disease. Anti-inflammatories are used for pain, fever, arthritis, inflammatory bowel disease, asthma, and allergic conditions. Long-term use carries risks: GI ulceration, renal impairment, cardiovascular events (NSAIDs); immunosuppression, hyperglycemia, osteoporosis (corticosteroids).

Antimicrobial desensitization

- A procedure that involves administering gradually increasing doses of an antimicrobial to induce tolerance in patients with allergy. Desensitization is used when the causative agent is the only effective treatment and the patient has a history of hypersensitivity. The procedure is performed under close medical supervision with monitoring for anaphylaxis. It is most commonly performed for beta-lactam antibiotics in patients with severe allergy. Desensitization involves starting with very low doses, typically micrograms, and increasing gradually over several hours until the full therapeutic dose is tolerated, after which desensitisation must be maintained by

continuous drug exposure.

Antimicrobial drug interactions

- Interactions between antimicrobial agents and other medications. See microbiology.

Antimicrobial hypersensitivity reactions

- Hypersensitivity reactions to antimicrobial agents range from mild rash to life-threatening anaphylaxis. Beta-lactam antibiotics are the most common cause of drug allergy. Cross-reactivity between penicillins and cephalosporins is approximately 2%. Sulfonamide antibiotics can cause severe cutaneous reactions. Fluoroquinolones can cause photosensitivity and rare anaphylaxis. Vancomycin can cause red man syndrome, which is an infusion-related reaction rather than true allergy. Proper allergy assessment is essential, including skin testing when indicated, and documentation of the reaction type and severity to guide future prescribing decisions.

Antimicrobial resistance mechanisms

- Mechanisms by which bacteria develop resistance to antimicrobial agents. Major mechanisms include enzymatic inactivation (beta-lactamases, aminoglycoside-modifying enzymes), target modification (PBP alterations, ribosomal methylation), efflux pumps, and decreased permeability (porin mutations). Resistance can be intrinsic, acquired through mutation, or transferred horizontally via plasmids, transposons, and integrons. Understanding resistance mechanisms is essential for developing new antibiotics and for guiding empirical therapy based on local resistance surveillance data.

Antimicrobial Stewardship

- See infectious_disease.

Antineoplastic

- A drug used to treat cancer (chemotherapy). Categories: alkylating agents (cyclophosphamide, cisplatin), antimetabolites (methotrexate, 5-FU), antitumor antibiotics (doxorubicin), plant alkaloids (vincristine, paclitaxel), topoisomerase inhibitors (irinotecan, etoposide), hormonal agents, targeted therapies (TKIs, monoclonal antibodies), and immunotherapies (checkpoint inhibitors). Most act on rapidly dividing cells, causing myelosuppression, mucositis, alopecia, nausea, and gonadal toxicity.

Regimens combine drugs with different mechanisms and toxicities to maximize efficacy and minimize resistance.

Antioxidants

- Substances that prevent or slow oxidative damage to cells caused by free radicals (reactive oxygen and nitrogen species). Endogenous antioxidants: glutathione, superoxide dismutase, catalase. Dietary antioxidants: vitamin C (ascorbic acid — water-soluble, scavenges aqueous-phase radicals), vitamin E (tocopherol — lipid-soluble, protects cell membranes), beta-carotene (provitamin A), selenium (cofactor for glutathione peroxidase), and flavonoids. Despite theoretical benefits, large clinical trials have not consistently demonstrated reduced cardiovascular events or cancer with antioxidant supplementation. A balanced diet rich in fruits and vegetables provides adequate antioxidants.

Antiparasitic

- A drug used to treat infections caused by parasites (protozoa and helminths). Antiprotozoals: metronidazole (Giardia, amebiasis, trichomoniasis), tinidazole, chloroquine and artemisinin combinations (malaria), pyrimethamine (toxoplasmosis), pentamidine, and nifurtimox (Chagas). Anthelmintics: albendazole and mebendazole (roundworm, hookworm, pinworm, tapeworm), ivermectin (strongyloidiasis, onchocerciasis, scabies), praziquantel (schistosomiasis, flukes), and diethylcarbamazine (filariasis). Many require weight-based dosing and repeated courses; adverse effects depend on the class.

Antiparkinsonian

- A drug used to treat Parkinson disease and drug-induced parkinsonism. Classes: levodopa/carbidopa (most effective), dopamine agonists (pramipexole, ropinirole, rotigotine), MAO-B inhibitors (selegiline, rasagiline), COMT inhibitors (entacapone), anticholinergics (benztropine, trihexyphenidyl—for drug-induced parkinsonism and tremor), and amantadine (early/adjunct, dyskinesia). Selection depends on age, severity, and predominant symptoms; levodopa remains the gold standard.

Antipruritic

- A medication that relieves itching (pruritus). First-line for most causes: topical emollients and

moisturizers — restore skin barrier function; topical corticosteroids — reduce inflammation in atopic dermatitis, contact dermatitis, and psoriasis; topical antihistamines (diphenhydramine, doxepin) — block histamine H1 receptors in the skin; topical calcineurin inhibitors (tacrolimus, pimecrolimus) — for atopic dermatitis without steroid side effects. Systemic antipruritics: oral antihistamines (cetirizine, loratadine, hydroxyzine) — especially for urticaria; antidepressants (doxepin, mirtazapine) — for chronic pruritus; opioid antagonists (naltrexone) — for cholestatic pruritus; and aprepitant — an NK1 receptor antagonist for refractory pruritus.

Antipsychotic

- A drug used to treat psychotic disorders (schizophrenia, schizoaffective disorder, psychosis in bipolar/manic states and delirium). Typical (first-generation): haloperidol, chlorpromazine—D2 blockade, high EPS/tardive dyskinesia risk, hyperprolactinemia. Atypical (second-generation): clozapine, risperidone, olanzapine, quetiapine—D2/5-HT2A antagonism, fewer EPS but more metabolic side effects (weight gain, diabetes). Long-acting injectable formulations improve adherence. Adverse effects include neuroleptic malignant syndrome and QT prolongation.

Antipyretic

- A drug that reduces fever by lowering the hypothalamic set point, typically by inhibiting prostaglandin synthesis in the preoptic hypothalamus. Acetaminophen and NSAIDs (ibuprofen, aspirin) are the principal antipyretics. Fever is itself a beneficial host response, so antipyretics are reserved for patient comfort, particularly in children at risk of dehydration. Aspirin is contraindicated in children (Reye syndrome). Antipyretics are used in combination or rotation for control. Overdose of acetaminophen causes hepatotoxicity.

Antipyretics

- Medications that reduce fever by inhibiting cyclooxygenase (COX) enzymes, reducing hypothalamic prostaglandin E₂ synthesis and resetting the thermoregulatory set point. Common antipyretics: paracetamol (acetaminophen — preferred first-line, particularly in children and patients with contraindi-

cations to NSAIDs, but hepatotoxic in overdose), ibuprofen (NSAID, also anti-inflammatory, avoid in dehydration, renal impairment, and peptic ulcer disease), and aspirin (avoid in children due to Reye syndrome risk). Antipyretics should be used for symptomatic relief, not routinely for all fevers, as fever is a physiological defence mechanism.

Antiseptic

- See infectious disease.

Antitubercular Agents

- Antimicrobial drugs used to treat *Mycobacterium tuberculosis* infections. The first-line agents include isoniazid, which inhibits mycolic acid synthesis; rifampicin, which inhibits RNA polymerase; pyrazinamide, which disrupts membrane energetics; ethambutol, which inhibits arabinosyl transferase; and streptomycin, which inhibits protein synthesis. The standard regimen for drug-susceptible tuberculosis is a four-drug combination of isoniazid, rifampicin, pyrazinamide, and ethambutol for two months followed by a continuation phase of isoniazid and rifampicin for four months; treatment adherence is critical and directly observed therapy is recommended to prevent treatment failure and acquired drug resistance.

Antitussive

- A medication that suppresses the cough reflex, used for dry, non-productive cough. Centrally acting antitussives: dextromethorphan — acts on the cough center in the medulla oblongata, likely through sigma-1 receptor agonism, NMDA antagonism, and serotonin reuptake inhibition; codeine — a prodrug converted to morphine, acts on mu-opioid receptors in the cough center, controlled substance due to abuse potential, not recommended in children. Peripherally acting antitussives: benzonatate — a local anesthetic that reduces cough reflex by numbing stretch receptors in the respiratory tract; inhaled sodium cromoglycate and nedocromil — stabilize mast cells and reduce cough in asthma. Demulcents (honey, glycerin, lozenges) soothe irritated pharyngeal mucosa. Expectorants (guaifenesin) are not antitussives but increase mucus production to facilitate coughing up phlegm.

Antivirals

- Drugs that inhibit the replication of viruses, re-

ducing the severity and duration of viral infections. They are used for conditions such as influenza, herpes, HIV, hepatitis B and C, and COVID-19. Unlike antibiotics, antivirals target specific viral enzymes or life cycle stages and often work best when started early in the infection.

Aromatase Inhibitor

- A class of medications that inhibit aromatase, the enzyme that converts androgens (androstenedione, testosterone) to estrogens (estrone, estradiol) in peripheral tissues (adipose, breast, muscle, bone). Used primarily in hormone receptor-positive breast cancer in postmenopausal women. Third-generation aromatase inhibitors: anastrozole (nonsteroidal, reversible), letrozole (nonsteroidal, reversible), and exemestane (steroidal, irreversible). In postmenopausal women, AIs are first-line adjuvant therapy and first-line therapy for metastatic breast cancer (superior to tamoxifen). In premenopausal women, AIs are used in combination with ovarian suppression. Adverse effects: arthralgia and myalgia (20-50%, most common cause of discontinuation), accelerated bone loss (osteoporosis, fracture risk), hot flashes, and dyslipidemia. AIs do not cause endometrial cancer or thromboembolism (unlike tamoxifen).

Azole Antifungals

- A class of antifungal agents that inhibit the enzyme lanosterol 14- α -demethylase, a cytochrome P450 enzyme essential for ergosterol synthesis in fungal cell membranes. The depletion of ergosterol and accumulation of toxic methylated sterols disrupt membrane integrity and function. Azoles are divided into imidazoles including ketoconazole and clotrimazole, used primarily for topical infections, and triazoles including fluconazole, itraconazole, voriconazole, and posaconazole, which provide broader antifungal coverage; posaconazole and voriconazole have activity against *Aspergillus* species, while fluconazole has limited activity against this genus.

Bacteriophage therapy

- The use of bacterial viruses (bacteriophages) to treat bacterial infections. Bacteriophages are viruses that specifically infect and lyse bacteria. They have narrow specificity for target bacteria and do not affect normal flora. Phage therapy is being

studied for multidrug-resistant bacterial infections, particularly those failing conventional antibiotics. Clinical trials have shown promise for chronic pseudomonas infections and prosthetic joint infections. The main challenges include regulatory hurdles including standardised production, stability testing, pharmacokinetic characterisation, and regulatory approval pathways that vary across jurisdictions.

Barbiturate

– A class of CNS depressants derived from barbituric acid that enhance GABA-A receptor activity by increasing the duration of chloride channel opening (as opposed to benzodiazepines, which increase the frequency). At low doses: anxiolysis and sedation. At moderate doses: hypnosis and anesthesia. At high doses: respiratory depression, coma, and death. Classification by duration of action: ultra-short (thiopental, methohexital — IV induction agents), short/intermediate (pentobarbital, secobarbital — sedation, now rarely used), and long-acting (phenobarbital — anticonvulsant). Indications now limited: phenobarbital for neonatal seizures and status epilepticus when other agents fail; thiopental for rapid sequence induction historically. Adverse effects: narrow therapeutic index, respiratory depression, tolerance, physical dependence, severe withdrawal (anxiety, tremors, seizures, delirium), and enzyme induction (CYP3A4, CYP2C9). Drug interactions: reduces efficacy of oral contraceptives, warfarin, and many other drugs. Barbiturates are Schedule II-IV controlled substances.

Benzodiazepines

– A class of drugs that enhance the effect of the inhibitory neurotransmitter gamma-aminobutyric acid at the GABA-A receptor, increasing the frequency of chloride channel opening and producing anxiolytic, sedative, anticonvulsant, and muscle relaxant effects. They bind to an allosteric site on the GABA-A receptor, distinct from the GABA binding site, and potentiate the effect of GABA when it binds. Common benzodiazepines include diazepam, lorazepam, alprazolam, clonazepam, midazolam. They differ in potency, half-life, lipid solubility, and metabolic pathways, influencing their clinical applications for anxiety, insomnia, seizure disorders, and procedural sedation.

Beta Blockers

– A class of medications that block the effects of adrenaline on the body's beta receptors. They slow down the heart rate and reduce blood pressure, making them widely used for treating heart conditions, high blood pressure, and anxiety.

Beta-Lactam Antibiotics

– A large class of antimicrobial agents characterized by a beta-lactam ring in their molecular structure, which is essential for their bactericidal activity. They include penicillins, cephalosporins, carbapenems, and monobactams, all of which share the mechanism of inhibiting bacterial cell wall synthesis by binding to penicillin-binding proteins and preventing cross-linking of peptidoglycan chains. Beta-lactams are bactericidal, killing bacteria by weakening the cell wall, leading to osmotic lysis and cell death; they are the most widely used class of antibiotics globally, with spectrum determined by their affinity for specific PBPs and their ability to penetrate the outer membrane of gram-negative organisms.

Beta-lactamase inhibitor combinations

– Combinations of beta-lactam antibiotics with beta-lactamase inhibitors that extend activity against beta-lactamase producing organisms. The major combinations include amoxicillin-clavulanate, ampicillin-sulbactam, piperacillin-tazobactam, cefoperazone-sulbactam, and ceftolozane-tazobactam. Clavulanate, sulbactam, and tazobactam are beta-lactamase inhibitors that bind irreversibly to beta-lactamase enzymes, preventing degradation of the partner beta-lactam. Clavulanate has the strongest beta-lactamase inhibition; tazobactam is the most potent beta-lactamase inhibitor in clinical use, while avibactam is a newer non-beta-lactam inhibitor that effectively restores activity against class A and class C beta-lactamases.

Biguanide

– A class of oral antidiabetic drugs derived from guanidine, with metformin being the only biguanide in current clinical use (phenformin and buformin were withdrawn due to lactic acidosis risk). Metformin is the first-line pharmacotherapy for type

2 diabetes mellitus. Mechanism: activates AMP-activated protein kinase, reducing hepatic gluconeogenesis and glycogenolysis; improves peripheral insulin sensitivity (increases glucose uptake in skeletal muscle); and reduces intestinal glucose absorption. Metformin does not stimulate insulin secretion and therefore does not cause hypoglycemia as monotherapy. Effects: lowers HbA1c by 1-1.5%, weight neutral or modest weight loss, and improves lipid profile. Adverse effects: GI intolerance (diarrhea, nausea, metallic taste, 20-30%), vitamin B12 deficiency with chronic use, and lactic acidosis (rare, 3-10 per 100,000 patient-years, primarily in patients with contraindications). Contraindications: eGFR <30 mL/min, acute kidney injury, decompensated liver disease, and acute medical illness with hypoxia (sepsis, MI, shock). Extended-release formulations improve GI tolerability.

Bioavailability

- The fraction of an administered drug that reaches the systemic circulation in its unchanged active form. It is expressed as a percentage and is determined by the route of administration and the extent of first-pass metabolism. For intravenous administration, bioavailability is 100 percent by definition. For oral administration, bioavailability is typically less than 100 percent due to incomplete absorption and pre-systemic metabolism by gut wall enzymes and the liver. The fraction of an oral dose reaching systemic circulation can be increased by altering the formulation, using prodrugs, or co-administering with food or other drugs that affect absorption or first-pass metabolism.

Bioequivalence

- The property of two drug products (brand-name and generic) that have the same rate and extent of absorption when administered at the same molar dose under similar conditions, resulting in comparable bioavailability and therapeutic effect. The FDA requires generic drugs to demonstrate bioequivalence to the reference listed drug through pharmacokinetic studies showing that the 90% confidence interval of the ratio of generic-to-brand for AUC and C_{max} falls within 80-125%. Bioequivalence ensures that generic drugs can be substituted for brand-name drugs without dose adjustment, providing the same clinical efficacy and safety profile at a

lower cost.

Biotransformation

- The process by which drugs and other xenobiotics are chemically modified by metabolic enzymes, primarily in the liver, to facilitate elimination from the body. Biotransformation occurs in two phases. Phase I reactions (functionalization): oxidation, reduction, and hydrolysis catalyzed primarily by cytochrome P450 enzymes (CYP1A2, CYP2C9, CYP2C19, CYP2D6, CYP3A4), introducing or exposing functional groups (e.g., -OH, -NH₂, -COOH). Phase II reactions (conjugation): glucuronidation (UGT), sulfation (SULT), acetylation (NAT), methylation, and conjugation with glutathione (GST), attaching endogenous hydrophilic molecules to the drug or Phase I metabolite, increasing water solubility and promoting renal or biliary excretion. Biotransformation generally produces inactive, water-soluble metabolites, but some drugs undergo bioactivation (prodrugs) or produce toxic metabolites that contribute to drug toxicity.

Bisacodyl

- A stimulant laxative (diphenylmethane derivative) that stimulates colonic motility and enhances water/electrolyte secretion, producing a bowel movement within 6-12 hours (oral) or 15-60 minutes (suppository). Used for constipation, bowel preparation, and evacuation before procedures. Adverse effects: abdominal cramps, diarrhea, and electrolyte disturbances with overuse; chronic stimulant use may cause melanosis coli and dependence. Generally safe short-term; avoid in intestinal obstruction, acute abdomen, and with caution in inflammatory bowel disease.

Bismuth Subsalicylate

- An antidiarrheal and anti-ulcer agent (e.g., Pepto-Bismol) with antimicrobial, anti-inflammatory, and coating actions. Used for traveler's diarrhea (prophylaxis and treatment), dyspepsia, Helicobacter pylori eradication (quadruple therapy), and symptoms of indigestion. Adverse effects: black stools and black tongue (harmless, from bismuth sulfide), constipation, and tinnitus (salicylate); avoid in children/adolescents with viral illness (Reye syndrome risk) and with anticoagulants/aspirin.

Blood-Brain Barrier

- The blood-brain barrier is a highly selective semipermeable membrane that separates the circulating blood from the brain extracellular fluid, consisting of endothelial cells connected by tight junctions, astrocyte foot processes, and a basement membrane. The BBB restricts the passage of most molecules from the blood into the brain, protecting the central nervous system from toxins and pathogens while maintaining a stable environment for neural function. Only small, lipophilic molecules and gases can cross the BBB via passive diffusion or active transport; the BBB is disrupted in pathological conditions such as meningitis, ischemia, and multiple sclerosis, affecting drug distribution to the brain.

Bromocriptine

- An ergot dopamine agonist (D2) used for hyperprolactinemia (prolactinomas, galactorrhea), acromegaly (adjunct), Parkinson disease (less common now), and postpartum breast engorgement (historical). Also used for neuroleptic malignant syndrome. Adverse effects: nausea, orthostatic hypotension, dizziness, headache, cardiac valvulopathy (ergot, high doses), retroperitoneal fibrosis, and hallucinations. Cabergoline (longer-acting, better tolerated) is preferred for hyperprolactinemia.

Bumetanide

- A potent loop diuretic inhibiting the Na-K-2Cl cotransporter in the thick ascending limb of the loop of Henle. Used for edema in heart failure, cirrhosis, and renal disease, and for hypertension in renal impairment. Approximately 40 times more potent than furosemide; more bioavailable orally, so equivalent IV-to-oral dosing is possible. Adverse effects: hypokalemia, hyponatremia, hypomagnesemia, hypocalcemia, metabolic alkalosis, ototoxicity (with aminoglycosides), and dehydration/azotemia.

Bupropion

- An atypical antidepressant that inhibits dopamine and norepinephrine reuptake. Used for major depressive disorder, seasonal affective disorder, and smoking cessation (Zyban). Low sexual side effects and weight neutrality; energizing. Also used off-label for ADHD. Adverse effects: insomnia, dry

mouth, agitation, lowered seizure threshold (avoid in epilepsy, eating disorders, alcohol/benzodiazepine withdrawal), and hypertension. Contraindicated with MAOIs and bupropion-containing products. Sustained-release forms allow daily dosing.

Caffeine

- A naturally occurring xanthine alkaloid and central nervous system stimulant found in coffee, tea, chocolate, and many soft drinks and energy beverages. Mechanism: adenosine receptor antagonist (primarily A1 and A2A subtypes), increasing neuronal activity and promoting catecholamine release. Effects: increased alertness, reduced fatigue, improved cognitive performance, diuresis, and bronchodilation. Half-life: 3–7 hours in adults, prolonged in pregnancy, liver disease, and with oral contraceptives. Chronic use produces tolerance; abrupt cessation causes withdrawal syndrome (headache, fatigue, irritability, dysphoria) lasting 2–9 days. Acute toxicity (>500 mg): anxiety, insomnia, tremor, tachycardia; severe toxicity (>5 g): seizures, arrhythmias, death.

Carbapenem-resistant organisms

- Bacteria that are resistant to carbapenem antibiotics, typically through production of carbapenemases. The most important carbapenemases include KPC (*Klebsiella pneumoniae* carbapenemase), NDM (New Delhi metallo-beta-lactamase), and OXA-48-like enzymes. CRO are a major public health threat due to limited treatment options. Infections are associated with high mortality rates. Treatment options include ceftazidime-avibactam, meropenem-vaborbactam, and colistin-based combinations. Infection prevention and antimicrobial stewardship are critical for controlling the spread of carbapenem-resistant organisms in healthcare settings.

Carbidopa

- A peripheral dopa decarboxylase inhibitor that does not cross the blood-brain barrier; combined with levodopa to prevent its peripheral conversion to dopamine, reducing side effects (nausea, hypotension) and increasing CNS levodopa delivery. Standard combinations: carbidopa/levodopa (Sinemet), including controlled-release and orally disintegrating forms. Higher carbidopa ratios (25/100) reduce 'wearing off'. Carbidopa itself has no antiparkinsono-

nian effect but reduces peripheral dopamine-related adverse effects.

Carbolic Acid (Phenol)

– An aromatic organic compound (C_6H_5OH) with antiseptic, disinfectant, and caustic properties. Historically significant as the first surgical antiseptic introduced by Joseph Lister in 1867, dramatically reducing post-operative infection and mortality. Mechanism: denatures bacterial proteins and disrupts cell membranes. Phenol is bactericidal, fungicidal, and virucidal but is toxic to human tissues at high concentrations causing chemical burns and systemic toxicity (neurologic depression, cardiovascular collapse). Modern medical uses: phenol-based chemical peels (dermatology), nerve ablation for chronic pain (neurolysis), and as a preservative in some injectable medications. Safer, less toxic antiseptics (chlorhexidine, povidone-iodine) have largely replaced it for routine disinfection.

Carvedilol

– A nonselective beta-blocker with additional α_1 adrenergic blockade and antioxidant properties, producing vasodilation with balanced reduction of heart rate, contractility, and afterload. Used for heart failure with reduced ejection fraction (improves survival, NYHA II-IV), hypertension, and post-myocardial infarction ventricular dysfunction. Also treats angina. Metabolized by CYP2D6; must be titrated slowly (e.g., 3.125 mg BID upward). Adverse effects: dizziness, hypotension, bradycardia, fatigue, bronchospasm, and masking of hypoglycemia.

Caspofungin

– An echinocandin antifungal agent used in the treatment of invasive candidiasis, esophageal candidiasis, and invasive aspergillosis (as salvage therapy). Caspofungin inhibits beta-(1,3)-D-glucan synthase, disrupting fungal cell wall synthesis. The drug is available only intravenously and has a half-life of approximately 9-11 hours, allowing for once-daily dosing. Common adverse effects include headache, nausea, and phlebitis at the infusion site. Fever and rash have been reported. Hepatotoxicity has been reported, and the drug has fewer drug interactions than azole antifungals as it is not a significant CYP inhibitor.

Ceftazidime-avibactam

– A combination of the third-generation cephalosporin ceftazidime with the non-beta-lactam beta-lactamase inhibitor avibactam. Avibactam inhibits class A, class C, and some class D beta-lactamases, including KPC carbapenemases. This combination has activity against many carbapenem-resistant Enterobacteriaceae and *Pseudomonas aeruginosa*. It is indicated for complicated intra-abdominal infections, complicated urinary tract infections, and hospital-acquired pneumonia. The combination is administered intravenously and requires dose adjustment based on renal function; the most common adverse effects include nausea, diarrhea, and headache.

Cephalosporin

– A class of beta-lactam antibiotics derived from the fungus *Cephalosporium acremonium*, with a mechanism identical to penicillins — inhibition of bacterial cell wall synthesis by binding to penicillin-binding proteins and inhibiting transpeptidase. Cephalosporins are classified into five generations based on their antimicrobial spectrum. First generation (cefazolin, cephalexin): good gram-positive coverage (*Staph aureus*, *Strep pyogenes*), limited gram-negative coverage. Second generation (cefuroxime, cefoxitin, cefotetan): expanded gram-negative coverage including *H. influenzae* and anaerobes (cefoxitin). Third generation (ceftriaxone, cefotaxime, ceftazidime): broad gram-negative coverage including Enterobacteriaceae; ceftazidime also covers *Pseudomonas*. Fourth generation (cefepime): broad coverage including *Pseudomonas* and gram-positive with stability against AmpC beta-lactamases. Fifth generation (ceftaroline): anti-MRSA activity plus standard cephalosporin coverage. Adverse effects: hypersensitivity reactions (cross-reactivity with penicillins 10% based on similar beta-lactam ring structure), GI disturbances, and bleeding (cefotetan, due to N-methylthiotetrazole side chain causing hypoprothrombinemia).

Cetirizine

– A second-generation H1 antihistamine (metabolite of hydroxyzine) used for allergic rhinitis and urticaria. Slightly more sedating than loratadine/fexofenadine (some CNS penetration). Once daily; renally cleared (dose-reduce in renal impair-

ment). Adverse effects: somnolence (dose-related), dry mouth, and fatigue. Available OTC. Levocetirizine is the active enantiomer.

Chloramphenicol

- A broad-spectrum antibiotic with activity against gram-positive and gram-negative organisms, as well as *Rickettsia*. Chloramphenicol inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. It is indicated for serious infections when other agents are not appropriate, including bacterial meningitis and typhoid fever. Common adverse effects include bone marrow suppression, gray baby syndrome in neonates, and aplastic anemia. The drug is rarely used due to its toxicity profile. Although effective, its use is limited to life-threatening infections due to the availability of safer alternatives.

Citalopram

- A selective serotonin reuptake inhibitor (SSRI) used for major depressive disorder and (off-label) anxiety disorders. Well tolerated; lowest cost among SSRIs. Adverse effects: nausea, insomnia, sexual dysfunction, and dose-dependent QT prolongation (maximum 40 mg/day; 20 mg in elderly/CYP2C19 poor metabolizers—torsades risk). Serotonin syndrome and discontinuation syndrome; black-box warning for suicidality in young adults. Escitalopram (S-enantiomer) has fewer QT effects.

Clearance

- The volume of plasma from which a drug is completely removed per unit time, typically expressed in milliliters per minute or liters per hour. Total clearance is the sum of all clearance mechanisms, primarily hepatic and renal clearance. Hepatic clearance depends on hepatic blood flow, enzyme activity, and protein binding, with the hepatic extraction ratio determining the contribution of blood flow versus enzyme activity to clearance. High-extraction drugs like lidocaine have clearance that is highly dependent on hepatic blood flow, while low-extraction drugs like warfarin have clearance that is primarily determined by intrinsic enzyme activity and protein binding.

Clinical Trial Phases

- The stages of drug development: Phase I (safety, dosing, pharmacokinetics in 20-100 healthy volun-

teers); Phase II (efficacy and side effects in 100-300 patients with the target condition); Phase III (large-scale efficacy and safety comparison with standard treatment in 1,000-3,000 patients); Phase IV (post-marketing surveillance for long-term effects and rare adverse events). Each phase has specific endpoints and success criteria before advancing to the next phase.

Clostridioides difficile

- An anaerobic, spore-forming, toxin-producing gram-positive bacillus causing antibiotic-associated diarrhea and pseudomembranous colitis. Risk factors: antibiotics (especially clindamycin, fluoroquinolones, cephalosporins), hospitalization, age >65, PPIs, and immunosuppression. Toxins A and B damage colonic epithelium. Diagnosis: NAAT/PCR for toxin genes or toxin EIA. Treatment: vancomycin or fidaxomicin PO (first-line); metronidazole for mild disease when agents unavailable; fecal microbiota transplantation for recurrent disease. Infection control: contact precautions, handwashing with soap (alcohol gel is less effective).

Clostridioides difficile infection

- An infectious diarrhea caused by the bacterium *Clostridioides difficile*, typically occurring after disruption of normal gastrointestinal flora by antibiotics. *C. difficile* produces toxins A and B that cause colonic inflammation and diarrhea. Risk factors include antibiotic exposure, proton pump inhibitor use, and advanced age. Treatment options include vancomycin, fidaxomicin, and metronidazole. Recurrence occurs in approximately 25% of cases. Fecal microbiota transplantation is highly effective for recurrent *C. difficile* infection, with cure rates exceeding 90%.

Clostridium difficile Infection (CDI)

- An anaerobic, spore-forming, toxin-producing gram-positive bacillus causing antibiotic-associated diarrhea and pseudomembranous colitis. See [Clostridioides difficile](#).

Competitive Antagonist

- A competitive antagonist is a drug that binds to the same receptor site as an agonist and competes for binding, reducing the effect of the agonist without producing an effect of its own. The antagonism

is surmountable by increasing the agonist concentration, which shifts the dose-response curve of the agonist to the right without reducing the maximal response. This means that with enough agonist, the full effect can still be achieved. The degree of rightward shift depends on the concentration and the concentration of the antagonist; the relationship is quantitated using the Schild regression, which yields a pA_2 value representing the concentration of antagonist required to produce a twofold rightward shift of the agonist dose-response curve.

Controlled Substance

– A drug or chemical whose manufacture, possession, and use are regulated by government authorities due to its potential for abuse, dependence, or harm. In the United States, the Controlled Substances Act (CSA) classifies controlled substances into five schedules (I-V) based on their accepted medical use, abuse potential, and dependence liability. Schedule I: high abuse potential, no accepted medical use (heroin, LSD, marijuana federally). Schedule II: high abuse potential, severe dependence liability, accepted medical use with restrictions (morphine, oxycodone, fentanyl, cocaine, amphetamine). Schedule III: moderate to low abuse potential, moderate dependence liability (codeine-containing products, ketamine, anabolic steroids). Schedule IV: low abuse potential, limited dependence liability (benzodiazepines, zolpidem, tramadol). Schedule V: lowest abuse potential, limited dependence liability (codeine-containing antitussives, pregabalin). Healthcare providers must register with the DEA to prescribe controlled substances and comply with state and federal regulations.

Corticosteroids Mechanism

– Corticosteroids exert their anti-inflammatory and immunosuppressive effects primarily by binding to intracellular glucocorticoid receptors, which then translocate to the nucleus and modulate gene transcription. They transactivate anti-inflammatory genes including those encoding lipocortin-1, which inhibits phospholipase A2 and reduces arachidonic acid release, and they transrepress pro-inflammatory genes by inhibiting transcription factors including NF- κ B and AP-1. This reduces the production of prostaglandins, leukotrienes, and other inflammatory mediators, which underlies their

therapeutic efficacy in inflammatory conditions, autoimmune diseases, and allergic reactions.

COX Inhibitor

– A class of drugs that inhibit cyclooxygenase enzymes (COX-1 and COX-2), which catalyze the conversion of arachidonic acid to prostaglandins and thromboxanes. COX-1 is constitutively expressed in most tissues, producing prostaglandins that protect the gastric mucosa, maintain renal blood flow, and support platelet aggregation. COX-2 is induced during inflammation, producing prostaglandins that mediate pain, fever, and inflammation. Non-selective COX inhibitors (aspirin, ibuprofen, naproxen, indomethacin, diclofenac) inhibit both isoforms, providing analgesic, anti-inflammatory, and antipyretic effects but causing GI toxicity (gastritis, ulcers, bleeding) and platelet inhibition. Selective COX-2 inhibitors (celecoxib) provide anti-inflammatory effects with reduced GI toxicity but do not inhibit platelet aggregation and are associated with increased cardiovascular risk (MI, stroke). The COX hypothesis explains the therapeutic and adverse effects of NSAIDs.

Cream

– A semisolid emulsion (oil in water or water in oil) for topical application, containing a drug in an emulsion base. Creams are lighter, less greasy, and easier to spread than ointments, and are preferred for moist or oozing skin lesions. They penetrate less deeply than ointments and are cosmetically acceptable. Used for dermatologic conditions (corticosteroid creams, antifungals), analgesics, and moisturizers. Formulation (cream, ointment, gel, lotion, solution) affects drug delivery, occlusion, and patient acceptability.

CYP2C19 Polymorphism

– CYP2C19 is a cytochrome P450 enzyme involved in the metabolism of approximately 10 percent of drugs, including the antiplatelet agent clopidogrel, proton pump inhibitors, some antidepressants, and the antiepileptic drug phenytoin. Genetic polymorphisms result in poor metabolizer phenotypes in 2 to 5 percent of Caucasians and 15 to 20 percent of Asian populations. Poor metabolizers have reduced conversion of clopidogrel, a prodrug requiring CYP2C19-mediated activation, to its active metabo-

lite, leading to reduced antiplatelet efficacy and increased risk of stent thrombosis in poor metabolizers; alternative antiplatelet agents such as ticagrelor or prasugrel, which are not dependent on CYP2C19 activation, are preferred in such patients.

CYP2D6 Polymorphism

– CYP2D6 is a cytochrome P450 enzyme responsible for the metabolism of approximately 25 percent of commonly prescribed drugs, including codeine, tamoxifen, many antidepressants, and antipsychotics. Genetic polymorphisms in the CYP2D6 gene result in highly variable enzyme activity among individuals, classified into four phenotype groups: poor metabolizers with two non-functional alleles and absent enzyme activity; intermediate metabolizers with reduced activity; extensive metabolizers with normal activity, and ultrarapid metabolizers with increased enzyme activity due to gene duplication. This phenotypic variability has significant clinical implications for drugs metabolized by CYP2D6: codeine prodrug activation to morphine is reduced in poor metabolizers and enhanced in ultrarapid metabolizers, who may experience opioid toxicity at standard doses; tamoxifen efficacy is reduced in poor metabolizers; and antidepressant dosing may require individualisation based on CYP2D6 phenotype.

Cytochrome P450

– The cytochrome P450 system is a superfamily of heme-containing monooxygenase enzymes primarily located in the endoplasmic reticulum of hepatocytes, responsible for Phase I drug metabolism through oxidation, reduction, and hydrolysis reactions. The most important CYP isoforms in drug metabolism include CYP3A4, which metabolizes approximately 50 percent of all drugs; CYP2D6, responsible for approximately 25 percent of drug metabolism; CYP2C9, CYP2C19, CYP1A2, and CYP2E1. CYP enzymes can be induced or inhibited by various drugs and xenobiotics, leading to clinically significant drug interactions; enzyme induction occurs over days to weeks through increased gene transcription, while enzyme inhibition occurs rapidly through direct competition for the active site.

Dabigatran

– A direct oral anticoagulant that reversibly in-

hibits thrombin (factor IIa). Used for stroke prevention in nonvalvular atrial fibrillation and treatment/prophylaxis of venous thromboembolism. Fixed dosing, rapid onset, predictable pharmacokinetics, no routine monitoring. Prodrug requiring acid environment; capsules must not be opened. Adverse effects: bleeding, dyspepsia. Reversal agent: idarucizumab (specific antibody). Avoid in mechanical heart valves (valve thrombosis risk) and severe renal impairment.

Daptomycin resistance

– Resistance to daptomycin can develop through mutations in genes encoding cell membrane phospholipid synthesis. The mechanism involves changes in the bacterial cell membrane that reduce daptomycin binding. Resistance is more common in VRE than MRSA. Resistance can emerge during therapy, particularly in endocarditis and bacteremia. Daptomycin resistance is typically accompanied by vancomycin resistance, a phenomenon known as daptomycin-vancomycin cross-resistance. Combination therapy may be required in selected cases and careful monitoring of creatine kinase levels is recommended during daptomycin therapy.

Delamanid

– A nitroimidazole derivative used in the treatment of multidrug-resistant tuberculosis. Delamanid inhibits mycolic acid synthesis in *Mycobacterium tuberculosis*, disrupting the cell wall. It is indicated for pulmonary multidrug-resistant tuberculosis in combination with other agents. The drug is administered orally twice daily. Common adverse effects include headache, nausea, and QT prolongation. Delamanid is metabolized by plasma esterases and has minimal CYP450 interactions. The drug has demonstrated efficacy in MDR-TB treatment cohorts, with improved outcomes compared to background regimens alone.

Delavirdine

– A non-nucleoside reverse transcriptase inhibitor (NNRTI) that was previously used in combination antiretroviral therapy for HIV-1 infection but is now rarely used due to the availability of more effective and better-tolerated agents. Delavirdine binds to the HIV reverse transcriptase enzyme at a site distinct from the active site, causing a con-

formational change that inhibits enzymatic activity. The drug has relatively low potency compared to newer NNRTIs and requires dosing three times daily. Common adverse effects include rash, elevated transaminases, and nausea, and the drug has significant CYP3A4 inhibitory activity leading to numerous drug interactions, limiting its use in contemporary practice.

Dextroamphetamine

– A central nervous system stimulant (d-amphetamine isomer) increasing dopamine and norepinephrine. Used for ADHD and narcolepsy. Available as immediate and extended-release, and in mixed amphetamine salts (Adderall) and lisdexamfetamine (prodrug). Adverse effects: appetite suppression, insomnia, growth delay, tachycardia, hypertension, anxiety, and abuse potential (Schedule II). Cardiovascular screening (ECG for risk factors) before initiation; monitor growth in children.

Didanosine

– A nucleoside reverse transcriptase inhibitor (NRTI) used in the treatment of HIV-1 infection, typically as part of combination antiretroviral therapy. Didanosine is an adenosine analogue that inhibits viral reverse transcriptase, leading to chain termination of viral DNA synthesis. The drug requires acidic pH for stability and must be administered with buffer tablets or antacids to prevent gastric acid degradation. Didanosine has a bioavailability of approximately 30-40% when taken with buffer, buffer, and is dosed twice daily; common adverse effects include peripheral neuropathy, pancreatitis, and lactic acidosis, with pancreatitis being a potentially fatal complication that requires immediate discontinuation.

Diphenhydramine

– A first-generation H1 antihistamine with potent anticholinergic and sedative effects. Used for allergic reactions, urticaria/pruritus, motion sickness, insomnia (OTC sleep aid), and as an antitussive; IV form for anaphylaxis (adjunct) and acute dystonic reactions. Adverse effects: sedation, dry mouth, blurred vision, urinary retention, constipation, confusion (elderly—avoid), and anticholinergic toxicity in overdose (treated with physostigmine). Metabo-

lized by CYP2D6.

Disulfiram

– An aversive agent used to treat alcohol use disorder. Inhibits acetaldehyde dehydrogenase, causing accumulation of acetaldehyde when alcohol is consumed—producing flushing, tachycardia, nausea, vomiting, and hypotension ('acetaldehyde syndrome'). Provides a strong deterrent to drinking but requires motivation and abstinence. Adverse effects: hepatotoxicity, neuropathy, and psychosis. Contraindicated with alcohol-containing products, metronidazole, and severe cardiac/hepatic disease. Must warn patients to avoid all alcohol, including in foods and medications.

Diuretic

– A drug that increases urine production, used for edema (heart failure, cirrhosis, renal disease), hypertension, and electrolyte disorders. Classes: loop diuretics (furosemide, bumetanide, torsemide—most potent, act on the loop of Henle), thiazides (hydrochlorothiazide, chlorthalidone—distal tubule), potassium-sparing (spironolactone, eplerenone, amiloride—collecting duct), and osmotic (mannitol) and carbonic anhydrase inhibitors (acetazolamide). Adverse effects: electrolyte disturbances (hypokalemia, hyponatremia), dehydration, hypotension, and ototoxicity (loop diuretics). Spironolactone/eplerenone improve outcomes in heart failure.

DOACs

– Direct oral anticoagulants are a class of anticoagulant drugs that directly inhibit specific coagulation factors, providing an alternative to warfarin with more predictable pharmacokinetics and no routine monitoring. The factor Xa inhibitors include rivaroxaban, apixaban, and edoxaban, which directly and reversibly bind to the active site of factor Xa. The direct thrombin inhibitor dabigatran directly binds to and inhibits thrombin. DOACs have rapid onset of action, predictable pharmacokinetics, fixed dosing, fewer drug and food interactions than warfarin, and no requirement for routine coagulation monitoring, though they are more expensive and specific reversal agents are limited.

Docusate

- A stool softener (surfactant laxative) that increases water and fat incorporation into stool by lowering surface tension, facilitating defecation in patients who should avoid straining (post-MI, post-surgery, hemorrhoids) and for opioid-related constipation. Onset 12-72 hours. Limited efficacy as a true laxative; better for softening than for stimulating evacuation. Generally well tolerated; may cause mild cramping. Often combined with stimulant laxatives.

Doravirine

- A non-nucleoside reverse transcriptase inhibitor (NNRTI) used in combination antiretroviral therapy for HIV-1 infection. Doravirine binds to the HIV reverse transcriptase enzyme and inhibits its activity through a unique mechanism that maintains activity against strains resistant to first-generation NNRTIs. The drug has a favorable tolerability profile with minimal impact on lipid levels and body weight compared to other antiretrovirals. Common adverse effects include headache, nausea, and diarrhea. The drug has fewer drug interactions than other NNRTIs as it is not a significant inducer or inhibitor of CYP enzymes.

Dosage

- The amount and frequency of a drug administered to achieve a therapeutic effect while minimizing toxicity. Components: dose (amount, e.g., mg), dosing interval (frequency), route, and duration. Dosing is individualized using weight (mg/kg, especially children), body surface area (chemotherapy), renal and hepatic function (clearance), age, and therapeutic drug monitoring for narrow-therapeutic-index drugs. Loading doses achieve steady state rapidly; maintenance doses sustain it. Overdosing causes toxicity, underdosing causes therapeutic failure and antimicrobial resistance.

Dose-Response Curve

- A graphical representation of the relationship between the dose of a drug and the magnitude of its biological effect. The x-axis represents dose (typically on a logarithmic scale), and the y-axis represents the response (as percentage of maximum effect). The curve is sigmoidal in shape, characterized by: threshold (minimum dose producing a measurable effect), slope (steepness of the curve, in-

dicating how rapidly the effect changes with dose), maximal efficacy (the plateau, E_{max}), and potency (the dose producing 50% of maximal effect, ED_{50}). The therapeutic window is the range between the ED_{50} for the desired effect and the TD_{50} (toxic dose in 50% of patients). The therapeutic index ($TI = TD_{50} / ED_{50}$) measures relative safety. Dose-response curves are essential for determining appropriate dosing regimens and comparing drug potency and efficacy.

Dose-Response Relationship

- The dose-response relationship describes the quantitative relationship between the dose of a drug and the magnitude of the pharmacological response it produces. This relationship is typically represented as a sigmoidal curve when response is plotted against the log of the dose. The curve is characterized by several key parameters: the maximal effect or efficacy represents the maximum response achievable; the EC_{50} or ED_{50} represents the dose producing 50 percent of the maximal response and indicates the potency of the drug. The slope of the curve reflects the mechanism of drug action, with steeper slopes indicating a more direct relationship between dose and response, as seen with drugs that act on a single receptor type.

Doxazosin

- A selective α_1 adrenergic blocker causing vascular smooth muscle relaxation and reduced peripheral resistance. Used for hypertension and benign prostatic hyperplasia (relaxes prostatic smooth muscle). Extended-release formulation reduces first-dose hypotension. Adverse effects: orthostatic hypotension, dizziness, syncope (especially first dose), nasal congestion, and fatigue. α -blockers are not first-line for hypertension but useful in men with BPH and as add-on therapy. Potential association with heart failure in some trials—use with caution in patients with heart failure.

DPP-4 Inhibitors

- Dipeptidyl peptidase-4 inhibitors that prevent degradation of endogenous GLP-1 and GIP, enhancing incretin effects on insulin secretion. Examples include sitagliptin, saxagliptin, linagliptin, and alogliptin. They are well-tolerated with low hypoglycemia risk and weight neutrality. They have

modest glucose-lowering effects. Saxagliptin was associated with increased heart failure hospitalizations in the SAVOR-TIMI 53 trial. Linagliptin does not require dose adjustment for renal impairment.

Drug Allergy

- An adverse immune-mediated reaction to a medication, representing a hypersensitivity response that is distinct from side effects, toxicities, and idiosyncratic reactions. Drug allergies can be IgE-mediated causing immediate reactions including urticaria, angioedema, and anaphylaxis within minutes to hours; T-cell mediated causing delayed reactions including contact dermatitis, drug rash with eosinophils and systemic symptoms, and Stevens-Johnson syndrome occurring days to weeks after exposure; diagnosis involves skin testing, in vitro assays for specific IgE, and oral challenge in selected cases, with management based on avoidance of the offending drug and use of alternative agents.

Drug Classification Systems

- Drugs are classified using multiple complementary systems. The Anatomical Therapeutic Chemical (ATC) Classification System, maintained by the WHO, groups drugs into five levels: anatomical main group (e.g., cardiovascular system), therapeutic subgroup (e.g., antihypertensives), pharmacological subgroup (e.g., beta-blockers), chemical subgroup (e.g., selective beta-blockers), and chemical substance (e.g., metoprolol). The Therapeutic Classification groups drugs by their clinical use (e.g., antihypertensives, antidepressants, antibiotics). The Mechanism of Action Classification groups drugs by their molecular target (e.g., ACE inhibitors, calcium channel blockers, SSRIs). The Chemical Structure Classification groups drugs by their molecular composition (e.g., benzodiazepines, statins, penicillins). The Regulatory Classification includes prescription vs. over-the-counter status and controlled substance schedules. The Combination of these systems provides a comprehensive framework for understanding drug actions, interactions, and therapeutic applications.

Drug Dependence

- A state of physiological or psychological adaptation to a drug, characterized by a withdrawal syndrome upon discontinuation or dose reduction. Physical

dependence: the body has adapted to the presence of the drug, and abrupt cessation produces a predictable withdrawal syndrome specific to the drug class. Opioid withdrawal: anxiety, mydriasis, lacrimation, rhinorrhea, piloerection, yawning, diarrhea, and muscle cramps. Alcohol withdrawal: anxiety, tremor, autonomic hyperactivity, seizures, and delirium tremens. Benzodiazepine withdrawal: anxiety, insomnia, tremor, and seizures. Psychological (behavioral) dependence: a compulsive pattern of drug use, often associated with craving and difficulty controlling use. Dependence is distinct from addiction (substance use disorder), which involves loss of control over use despite negative consequences.

Drug-Drug Interactions

- When one drug alters the pharmacokinetics or pharmacodynamics of another. Pharmacokinetic interactions affect absorption, distribution, metabolism, or excretion (e.g., CYP inhibitors increasing warfarin levels). Pharmacodynamic interactions involve additive, synergistic, or antagonistic effects at the site of action (e.g., two drugs prolonging QT interval). Clinically significant interactions can be identified through databases, clinical experience, and therapeutic drug monitoring.

Drug-Induced Liver Injury

- Liver damage caused by medications, herbal products, or dietary supplements, representing the most common cause of acute liver failure in the United States. DILI can be dose-dependent and predictable, as with acetaminophen hepatotoxicity from overdose, or idiosyncratic and unpredictable, as with isoniazid, nitrofurantoin, and amoxicillin-clavulanate. The pathogenesis involves formation of reactive metabolites that bind to cellular proteins, triggering immune-mediated hepatocyte injury. DILI ranges from asymptomatic transaminase elevation to fulminant hepatic failure and death; early recognition and discontinuation of the offending agent are critical, as no specific therapy exists for most forms of DILI.

Drug Interactions

- Drug interactions occur when one drug affects the activity of another drug when both are administered together, potentially leading to therapeutic failure or toxicity. Pharmacokinetic interactions alter the

absorption, distribution, metabolism, or excretion of a drug. Absorption interactions include chelation of tetracyclines with calcium and antacids reducing absorption, and altered GI motility affecting drug absorption. Distribution interactions include displacement from protein binding sites, and drug interactions affecting protein binding. Pharmacodynamic interactions, where drugs have additive, synergistic, or antagonistic effects at the same receptor or physiological system, are equally important and can lead to enhanced therapeutic effects or unexpected toxicity.

Drug Metabolism Pharmacogenomics

– Pharmacogenomics of drug metabolism examines how genetic variations affect individual responses to drugs, enabling personalized medicine approaches to prescribing. The most clinically relevant pharmacogenes include CYP2D6, affecting metabolism of approximately 25 percent of drugs including codeine, tamoxifen, and many antidepressants; CYP2C19, affecting clopidogrel activation and proton pump inhibitor metabolism; CYP2C9, affecting warfarin metabolism; TPMT, affecting thiopurine metabolism; and Dand DPYD, affecting fluorouracil metabolism and risk of severe toxicity. Pre-emptive pharmacogenomic testing is increasingly being integrated into routine clinical practice to guide drug selection and dosing, with significant benefits in terms of efficacy and safety.

Drug Resistance

– The ability of microorganisms, cancer cells, or parasites to survive and proliferate despite exposure to drugs that were previously effective. In antimicrobial resistance, mechanisms include enzymatic inactivation of the drug such as beta-lactamase hydrolyzing penicillins, target modification such as PBP2a in MRSA conferring resistance to beta-lactams, efflux pumps actively pumping drugs out of the cell, decreased permeability through porin mutations, and metabolic bypassing of the inhibited pathway, allowing the pathogen to survive drug exposure; understanding these diverse mechanisms is essential for the rational design of new therapeutic strategies and for guiding appropriate antimicrobial stewardship interventions.

Drug Tolerance

– A decreased pharmacological response to a drug after repeated administration, requiring dose escalation to achieve the same effect. Tolerance develops through multiple mechanisms: pharmacokinetic tolerance — increased drug metabolism through enzyme induction (e.g., alcohol, barbiturates); pharmacodynamic tolerance — receptor downregulation (decreased number of receptors, e.g., opioids, beta-agonists) or receptor desensitization (uncoupling of receptors from signal transduction, e.g., beta-agonists); functional tolerance — compensatory physiological adaptations; and behavioral tolerance — learned adaptations to drug effects. Tolerance is distinct from dependence and addiction. Cross-tolerance occurs when tolerance to one drug confers tolerance to another drug in the same class (e.g., morphine and heroin).

Duloxetine

– A serotonin-norepinephrine reuptake inhibitor (SNRI) used for major depressive disorder, generalized anxiety disorder, diabetic peripheral neuropathy, fibromyalgia, chronic musculoskeletal pain (including osteoarthritis), and stress urinary incontinence. Adverse effects: nausea (common), dry mouth, insomnia, fatigue, hypertension, and sexual dysfunction; withdrawal syndrome with abrupt cessation (taper). Contraindicated with MAOIs and in uncontrolled narrow-angle glaucoma; caution in hepatic impairment.

Echinocandins

– A class of antifungal agents that inhibit beta-1,3-glucan synthase, an enzyme essential for synthesis of beta-1,3-glucan, a major component of the fungal cell wall. This unique mechanism targets a structure absent in mammalian cells, resulting in favorable toxicity profiles. The available agents include caspofungin, micafungin, and anidulafungin, all administered intravenously. Echinocandins are fungicidal against *Candida* species and fungistatic against *Aspergillus* species. The three available echinocandins have similar spectra of activity, though minor differences in pharmacokinetics and dosing schedules exist, and they are generally well tolerated with few drug interactions.

Efficacy

- The maximum therapeutic effect a drug or intervention can produce under ideal conditions (e.g., in a clinical trial). Efficacy is determined by the drug's mechanism of action and the receptor-effector system; it is measured by the E_{max} (maximal effect) on the dose-response curve. A drug with high efficacy produces a greater maximal response than one with low efficacy, regardless of dose. Efficacy is distinct from potency (the dose required to produce a given effect). Clinically, efficacy determines whether a drug can achieve the desired therapeutic outcome; a drug with insufficient efficacy will not be effective even at high doses. Not the same as effectiveness, which reflects real-world performance.

Enfuvirtide

- A fusion inhibitor used in combination antiretroviral therapy for HIV-1 infection in treatment-experienced patients with multidrug-resistant virus. Enfuvirtide is a synthetic peptide that mimics a region of the HIV-1 gp41 transmembrane protein, preventing the conformational change required for fusion of the viral envelope with the host cell membrane. The drug must be administered twice daily by subcutaneous injection, which is the primary limitation to its use. Common adverse effects include injection site reactions, and the drug is associated with an increased rate of lymph node enlargement and potential immune reconstitution syndromes when used as part of combination antiretroviral therapy.

Enoxaparin

- A low-molecular-weight heparin inhibiting factor Xa (and to a lesser extent thrombin) via antithrombin. Used for prophylaxis and treatment of deep vein thrombosis and pulmonary embolism, acute coronary syndromes, and as a bridge during anticoagulation interruption. Subcutaneous dosing (weight-based, BID or daily), predictable pharmacokinetics, no routine monitoring generally (anti-Xa monitoring in renal impairment/pregnancy). Adverse effects: bleeding, thrombocytopenia (less HIT than UFH), and injection-site hematoma. Reversed by protamine (partial). Caution in renal impairment (reduce dose); contraindicated with epidural/spinal anesthesia unless timing respected (neuraxial hematoma risk).

Entacapone

- A peripheral COMT (catechol-O-methyltransferase) inhibitor used as an adjunct to levodopa/carbidopa in Parkinson disease, extending levodopa's duration of action and reducing 'wearing-off'. Does not cross the blood-brain barrier. Adverse effects: dyskinesias (due to increased levodopa), nausea, diarrhea, urine discoloration (orange-brown), and hepatotoxicity (rare). Must be given with levodopa. Tolcapone (central COMT inhibitor) is rarely used due to hepatotoxicity.

Enterobacteriaceae carbapenem resistance

- Resistance to carbapenem antibiotics in Enterobacteriaceae, primarily through production of carbapenemases. The most important carbapenemases include KPC, NDM, and OXA-48-like enzymes. Carbapenem-resistant Enterobacteriaceae (CRE) are a major public health threat due to limited treatment options. Infections are associated with high mortality rates. Treatment options include ceftazidime-avibactam, meropenem-vaborbactam, and aminoglycosides. Infection prevention and antimicrobial stewardship are essential for controlling the spread of carbapenem-resistant Enterobacteriaceae in healthcare settings.

Enzyme Induction

- A process by which a drug or xenobiotic increases the synthesis or activity of drug-metabolizing enzymes, primarily cytochrome P450 enzymes in the liver, accelerating the metabolism of itself (autoinduction) or other drugs. Enzyme induction typically occurs over days to weeks as it requires new protein synthesis. Important enzyme inducers: rifampin (potent CYP3A4, CYP2C9, CYP2C19 inducer), carbamazepine, phenytoin, phenobarbital, St. John's wort, and chronic alcohol consumption. Clinical consequences: reduced efficacy of co-administered drugs (e.g., rifampin reduces oral contraceptive efficacy, requiring alternative contraception), increased metabolism of warfarin (requiring higher doses), and reduced cyclosporine levels in transplant patients. discontinuing an inducer can lead to increased drug levels of co-administered drugs, requiring dose reduction.

Enzyme Inhibition

- A process by which a drug inhibits the activity of drug-metabolizing enzymes, leading to increased plasma concentrations of co-administered drugs that are metabolized by the same enzyme. Enzyme inhibition occurs rapidly (hours to days) as it does not require new protein synthesis. Important enzyme inhibitors and their substrates: ketoconazole and ritonavir (potent CYP3A4 inhibitors — increase levels of statins, benzodiazepines, calcium channel blockers); cimetidine (inhibits CYP1A2, CYP2D6, CYP3A4); fluoxetine and paroxetine (CYP2D6 inhibitors — increase levels of atomoxetine, TCAs, and tamoxifen); amiodarone (CYP2C9 inhibitor — increases warfarin levels); grapefruit juice (inhibits intestinal CYP3A4 — increases levels of felodipine, simvastatin, cyclosporine). Clinical consequences: increased drug toxicity (e.g., rhabdomyolysis with simvastatin when given with potent CYP3A4 inhibitors), requiring dose reduction or alternative therapy.

Eplerenone

- A selective aldosterone (mineralocorticoid) receptor antagonist, a potassium-sparing diuretic. Used to reduce mortality in heart failure with reduced ejection fraction (post-MI and chronic HFrEF, NYHA II-IV) and for resistant hypertension. More selective than spironolactone with less gynecomastia/breast tenderness. Adverse effects: hyperkalemia (major), gynecomastia (less than spironolactone), and hypotension. Contraindicated with significant renal impairment, hyperkalemia, and strong CYP3A4 inhibitors (azole antifungals). Monitor potassium and renal function.

Eravacycline

- A fluorocycline antibiotic with activity against gram-positive and gram-negative organisms, including multidrug-resistant strains. Eravacycline inhibits bacterial protein synthesis by binding to the 30S ribosomal subunit. It has activity against MRSA, VRE, ESBL-producing Enterobacteriaceae, and anaerobes. The drug is indicated for complicated intra-abdominal infections. Eravacycline is administered intravenously and achieves high concentrations in abdominal tissues. Common adverse effects including nausea, vomiting, and infusion site reactions; eravacycline has a favourable

safety profile with minimal phototoxicity compared to other tetracyclines.

ESBL-producing organisms

- Bacteria that produce extended-spectrum beta-lactamases (ESBLs), enzymes that hydrolyze penicillins, cephalosporins, and monobactams. ESBLs are common in Enterobacteriaceae, particularly *Klebsiella pneumoniae* and *E. coli*. ESBL production confers resistance to most beta-lactam antibiotics except carbapenems. The prevalence of ESBL-producing organisms is increasing globally. Infections are associated with increased morbidity, mortality, and healthcare costs. Treatment typically requires carbapenemcarbapenems for serious infections, and antimicrobial stewardship is essential to preserve the utility of remaining effective agents.

Escitalopram

- A selective serotonin reuptake inhibitor (SSRI), the S-enantiomer of citalopram, used for major depressive disorder and generalized anxiety disorder. Increases synaptic serotonin; well tolerated, low drug-interaction profile (less QT prolongation than citalopram). Adverse effects: nausea, insomnia or somnolence, sexual dysfunction, and weight change; serotonin syndrome and discontinuation syndrome (taper); black-box warning for suicidal ideation in young adults. Once-daily dosing; onset of effect 2-6 weeks.

Esomeprazole

- The S-enantiomer of omeprazole, a proton pump inhibitor irreversibly inhibiting gastric H⁺/K⁺ ATPase. Used for GERD, erosive esophagitis, peptic ulcer disease, *H. pylori* eradication, and hypersecretory states. Greater acid suppression than omeprazole at equivalent doses; once daily, with an IV formulation for acute GI bleeding. Adverse effects: headache, diarrhea, hypomagnesemia, B12 deficiency, fracture risk, and *C. difficile* infection with chronic use. Cytochrome P450 (CYP2C19) metabolism.

Essential Medicines

- Drugs that satisfy the priority healthcare needs of a population, as defined by the WHO Model List of Essential Medicines. Selection criteria include efficacy, safety, comparative cost-effectiveness, and suitability for use in resource-limited settings.

The list includes approximately 400 drugs covering major disease areas: analgesics, anesthetics, antibiotics, antiepileptics, antihypertensives, antiretrovirals, antimalarials, vaccines, and others. The concept guides national formulary development, procurement, and rational prescribing worldwide.

Etravirine

- A second-generation non-nucleoside reverse transcriptase inhibitor (NNRTI) used in combination antiretroviral therapy for HIV-1 infection, particularly in treatment-experienced patients with NNRTI resistance. Etravirine binds to the HIV reverse transcriptase enzyme and inhibits its activity through a unique mechanism that maintains activity against strains resistant to first-generation NNRTIs. The drug has a high genetic barrier to resistance due to its flexible structure that allows it to adapt to changes in the reverse transcriptase enzyme structure, maintaining antiviral activity against a broad range of NNRTI-resistant variants.

Expectorants

- Medications that promote the clearance of mucus from the respiratory tract by increasing sputum volume and reducing its viscosity, facilitating productive cough. The most common expectorant is guaifenesin (glyceryl guaiacolate), which increases respiratory tract fluid secretion and reduces sputum adhesiveness. Guaifenesin is used for symptom relief in acute respiratory infections, chronic bronchitis, and COPD. Evidence for efficacy is moderate. Other expectorants: potassium iodide (rarely used due to side effects), ammonium chloride, and sodium citrate. Expectorants are distinguished from mucolytics (acetylcysteine, dornase alfa—break down the chemical structure of mucus) and antitussives (dextromethorphan, codeine—suppress the cough reflex). Adequate hydration is essential for expectorant efficacy.

Ezetimibe

- A cholesterol absorption inhibitor that blocks intestinal absorption of dietary and biliary cholesterol at the Niemann-Pick C1-like 1 (NPC1L1) transporter in the small intestine. Used for hypercholesterolemia, usually as add-on to statins or in statin-intolerant patients; reduces LDL and cardiovascular events in combination with statins after ACS. Ad-

verse effects: diarrhea, myalgia, transaminase elevation (with statins). Rare reports of muscle toxicity. Available alone or in combination with simvastatin or atorvastatin.

Fecal microbiota transplantation

- The transfer of fecal material from a healthy donor to a patient with recurrent *Clostridioides difficile* infection. The procedure aims to restore normal gastrointestinal flora and eliminate *C. difficile* colonization. FMT is highly effective, with cure rates exceeding 90% for recurrent *C. difficile* infection. The procedure can be administered by colonoscopy, nasojejunal tube, or oral capsules. Donor screening includes testing for bloodborne pathogens and gastrointestinal pathogens. FMT has revolutionized the management of recurrent *C. difficile* infection and is being investigated for other conditions associated with intestinal dysbiosis, including inflammatory bowel disease and metabolic syndrome.

Fenofibrate

- A fibric acid derivative (fibrate) activating PPAR- α , increasing HDL and reducing triglycerides, with modest LDL effects. Used for severe hypertriglyceridemia (pancreatitis risk), mixed dyslipidemia, and as an adjunct in residual hypertriglyceridemia. Adverse effects: myopathy (especially with statins, more with gemfibrozil), transaminase and creatinine elevation, gallstones, and pancreatitis. Dose-adjust in renal impairment. Fibrates are avoided with severe hepatic disease and in patients on other fibrates.

Fexofenadine

- A second-generation (non-sedating) H1 antihistamine used for allergic rhinitis and chronic urticaria. Peripherally selective with minimal sedation and anticholinergic effects; no significant CNS penetration. Adverse effects: headache, dizziness, and dry mouth. Transported by P-glycoprotein—avoid concurrent aluminum/magnesium antacids and fruit juices (reduce absorption). Available OTC. Loratadine and cetirizine are alternatives.

First-Pass Effect

- The metabolism of a drug by the liver and intestinal wall before it reaches the systemic circulation after oral administration. When a drug is absorbed

from the gastrointestinal tract, it travels through the portal venous system to the liver, where it may be extensively metabolized by cytochrome P450 enzymes before reaching the general circulation. This process significantly reduces the bioavailability of many drugs. The hepatic extraction ratio quantifies this effect: drugs with high extraction ratios have clearance that depends primarily on hepatic blood flow, while low-extraction drugs have clearance that depends on intrinsic enzyme activity and protein binding; this distinction has important implications for drug dosing in patients with liver disease and for predicting drug interactions.

Flecainide

- A class IC sodium channel blocker that slows conduction velocity with little effect on refractoriness. Used for suppression of supraventricular arrhythmias (atrial fibrillation in patients without structural heart disease—'pill-in-the-pocket', paroxysmal SVT) and ventricular arrhythmias. Contraindicated in ischemic heart disease and structural heart disease (CAST trial showed increased mortality after MI) and in significant LV dysfunction. Adverse effects: proarrhythmia (new/worsened arrhythmia), dizziness, blurred vision, and heart block. Requires ECG/electrolyte monitoring.

Fluoroquinolones

- Broad-spectrum bactericidal antibiotics that inhibit bacterial DNA gyrase and topoisomerase IV, enzymes essential for DNA replication, transcription, and repair. They are synthetic derivatives of nalidixic acid and include ciprofloxacin, levofloxacin, moxifloxacin, and others. Fluoroquinolones have excellent bioavailability, with oral dosing achieving serum concentrations comparable to intravenous administration. They distribute widely to tissues including the lungs, prostate, and bone; fluoroquinolones are generally well tolerated but carry boxed warnings for tendonitis and tendon rupture, peripheral neuropathy, CNS effects, and exacerbation of myasthenia gravis, and their use is reserved for situations where alternative treatment options are limited.

Fluoxetine

- A selective serotonin reuptake inhibitor (SSRI) used for major depressive disorder, obsessive-compulsive

disorder, bulimia, panic disorder, and premenstrual dysphoric disorder. Long half-life (fluoxetine 1-3 days; active metabolite norfluoxetine 7-15 days) allows once-daily or weekly dosing and produces a washout period (advantageous in discontinuation, problematic in toxicity/interactions). Adverse effects: nausea, insomnia, sexual dysfunction, agitation, hyponatremia (elderly), and serotonin syndrome. Strong CYP2D6 inhibitor—many interactions. Black-box warning for suicidality in young adults.

Fondaparinux

- A synthetic pentasaccharide that selectively inhibits factor Xa via antithrombin, with no direct thrombin inhibition. Used for prophylaxis and treatment of venous thromboembolism and acute coronary syndromes (as an alternative to LMWH). Subcutaneous, once daily, predictable, no routine monitoring; does not cause HIT (no platelet factor 4 interaction). Adverse effects: bleeding; not reversed by protamine. Contraindicated in severe renal impairment (creatinine clearance <30) and low body weight. Neuraxial anesthesia requires timing precautions.

Full Agonist

- A full agonist is a drug that binds to a receptor and produces the maximum possible biological response that the receptor can generate, achieving 100 percent of the maximal effect. Full agonists have both high affinity for the receptor and high intrinsic activity, meaning they are very effective at activating the receptor once bound. The efficacy of a full agonist is inherent to the drug-receptor interaction and cannot be exceeded by increasing the dose. Examples include morphine at mu-opioid receptors, with full agonists producing maximal activation, and their effect is determined by both the drug concentration at the receptor site and the receptor density in the target tissue.

Fungal Infection

- See Antifungal. Infections caused by fungi ranging from superficial (dermatophytes: tinea, candidiasis) to invasive/systemic disease (aspergillosis, candidemia, cryptococcosis, histoplasmosis) in immunocompromised hosts. Risk factors: neutropenia, transplantation, HIV/AIDS, corticosteroids, and di-

abetes. Diagnosis: culture, histopathology, antigen tests (galactomannan, beta-glucan, cryptococcal antigen), and PCR. Treatment depends on severity and organism: azoles, echinocandins, amphotericin B, and terbinafine.

Fungal resistance mechanisms

- Mechanisms by which fungi develop resistance to antifungal agents. Azole resistance occurs through upregulation of efflux pumps (CDR1, CDR2, MDR1), mutations in the target enzyme ERG11, and overexpression of ERG11. Echinocandin resistance is primarily due to mutations in the FKS1 and FKS2 genes encoding beta-(1,3)-D-glucan synthase. Amphotericin B resistance is rare but can occur through alterations in ergosterol biosynthesis. Multidrug resistance is increasingly common in *Candida glabrata*, with azole resistance being the most clinically challenging, particularly in *Candida glabrata* and *Candida auris*, and susceptibility testing is increasingly important for guiding antifungal therapy.

Furosemide

- A potent high-ceiling loop diuretic that reversibly inhibits the $Na^+/K^+/2Cl^-$ cotransporter (NKCC2) in the thick ascending limb of the loop of Henle. Induces rapid diuresis and natriuresis by disrupting the hypertonic medullary osmotic gradient. Indications: acute pulmonary edema, acute decompensated heart failure, edematous states (cirrhosis, nephrotic syndrome), hypercalcemia (increases urinary Ca^{2+} excretion), and hypertension. Adverse effects (mnemonic OH DANG): Ototoxicity (sensorineural hearing loss/tinnitus), Hypokalemia/Hypomagnesemia/Hypocalcemia, Dehydration/Hypotension, Allergy (sulfa drug reaction), Nephrotoxicity (interstitial nephritis), Gout (hyperuricemia due to uric acid reabsorption).

Gamma-Globulin

- A fraction of plasma proteins containing antibodies (immunoglobulins). Historically the term referred to a group of serum proteins with the slowest electrophoretic mobility (gamma region on serum protein electrophoresis). Currently synonymous with immunoglobulin preparations used for passive immunisation and immunotherapy. Indications: (1) Replacement therapy for primary immunodeficiency

(X-linked agammaglobulinaemia, common variable immunodeficiency); (2) Immunomodulation for autoimmune and inflammatory diseases (Kawasaki disease, Guillain-Barré syndrome, chronic inflammatory demyelinating polyneuropathy, ITP, myasthenia gravis, Stevens-Johnson syndrome). Administration: intravenous (IVIG) or subcutaneous (SCIG). Side effects: headache, fever, chills, myalgia, aseptic meningitis, thrombosis, anaphylaxis (rare, in IgA deficiency). Prepared by cold ethanol fractionation (Cohn method) from pooled human plasma from thousands of donors.

Gel

- A semisolid pharmaceutical formulation in which a liquid (usually water) is immobilized within a three-dimensional network of a gelling agent (e.g., carbomer, cellulose, alginate). Gels provide controlled drug release, cool sensation, and good skin compatibility; they are used for topical dermatologic products (antibiotics, antifungals, NSAIDs), ocular preparations, and oral gels. They are generally clear, non-greasy, and easily washed off.

Gelfoam

- An absorbable hemostatic agent made from purified porcine gelatin. Used in surgical settings to control bleeding where conventional hemostasis is difficult (liver, bone, neurosurgery). Mechanism: provides a physical matrix that promotes platelet aggregation and clot formation. Absorbed within 4-6 weeks. Prepared as a sterile sponge that can be cut to size and applied dry or saturated with thrombin. Contraindicated: infected wounds, gross contamination, intravascular use (risk of embolism). Brand examples: Gelfoam (Pfizer), Surgifoam (Ethicon).

Gemfibrozil

- A fibrate (PPAR-alpha agonist) used primarily for severe hypertriglyceridemia (reducing pancreatitis risk) and mixed hyperlipidemia. Raises HDL and lowers triglycerides markedly; modest LDL lowering. Adverse effects: myopathy/rhabdomyolysis—significantly increased with statin coadministration (interaction via glucuronidation inhibition; contraindicated with many statins), GI upset, gallstones, and increased INR with warfarin. Contrast with fenofibrate, which has less drug interaction risk. Not first-line for isolated hyperc-

cholesterolemia.

General Anesthetic

- An agent producing reversible loss of consciousness, amnesia, analgesia, and muscle relaxation sufficient for surgery. Inhaled agents (sevoflurane, isoflurane, desflurane, nitrous oxide) and intravenous agents (propofol, thiopental, etomidate, ketamine) are used; balanced anesthesia combines them with opioids, neuromuscular blockers, and adjuvants. Monitored by depth-of-anesthesia, hemodynamics, and end-tidal agent concentration. Complications: respiratory depression, hypotension, nausea/vomiting, malignant hyperthermia (succinylcholine/volatile agents), and postoperative cognitive dysfunction.

GLP-1 Receptor Agonists

- Glucagon-like peptide-1 receptor agonists are a class of injectable antidiabetic agents that mimic the effects of the incretin hormone GLP-1, which is secreted by intestinal L-cells in response to food intake. GLP-1 stimulates glucose-dependent insulin secretion, suppresses glucagon secretion, delays gastric emptying, and promotes satiety through central nervous system effects. Available agents include exenatide, liraglutide, dulaglutide, semaglutide, and tirzepatide, which is a dual GIP/GLP-1 agonist. GLP-1 receptor agonists improve glycaemic control with a low risk of hypoglycaemia and promote weight loss, making them particularly valuable in overweight or obese patients with type 2 diabetes; gastrointestinal side effects including nausea, vomiting, and diarrhea are common but often diminish with gradual dose titration.

Glycerin

- A colorless, odorless, sweet-tasting trihydroxy alcohol (glycerol) with humectant, osmotic, and solvent properties. Used as: an osmotic laxative (glycerin suppositories or enemas promote water retention and reflex defecation), a humectant in skin preparations, a vehicle/solvent in pharmaceuticals and cosmetics, and in otolaryngology (glycerin ear drops soften cerumen). Intravenous glycerol is used to reduce intracranial pressure. Generally safe; rectal use may irritate mucosa.

Glycerol (Glycerine)

- A triol compound ($\text{CH}_2\text{OH}-\text{CHOH}-\text{CH}_2\text{OH}$), a colourless, odourless, viscous liquid with a sweet

taste. Used in medicine and pharmaceuticals as a: humectant (retains moisture in topical preparations), laxative (glycerol suppositories for constipation), sweetener (in syrups, sugar-free alternatives), solvent for drugs, and osmotherapy agent (intravenous glycerol reduces intracranial pressure). Glycerol is also a by-product of soap manufacturing and biodiesel production (transesterification).

GnRH Agonist

- Gonadotropin-releasing hormone agonists are a class of medications that initially stimulate (flare effect, 1-3 weeks) and then suppress pituitary gonadotropin (LH and FSH) secretion through receptor downregulation, leading to profound suppression of sex steroid production (testosterone in men, estradiol in women). Used in: prostate cancer — medical castration (leuprolide, goserelin, triptorelin); breast cancer — ovarian suppression in premenopausal women; endometriosis and uterine fibroids — suppression of ovarian estrogen; central precocious puberty — halting pubertal progression; and assisted reproduction — controlled ovarian hyperstimulation protocols. The initial testosterone flare in prostate cancer can cause disease exacerbation (bone pain, spinal cord compression, urinary obstruction), mitigated by adding an antiandrogen (bicalutamide) for 2-4 weeks at initiation.

GnRH Antagonist

- A class of medications that competitively block GnRH receptors on pituitary gonadotrophs, producing immediate, reversible suppression of LH and FSH secretion without the initial flare effect seen with GnRH agonists. Used in: prostate cancer — degarelix (monthly subcutaneous injection) and relugolix (oral daily) provide rapid testosterone suppression without flare; endometriosis and uterine fibroids — elagolix (oral); assisted reproduction — cetrorelix and ganirelix prevent premature LH surge during controlled ovarian stimulation. Advantage over GnRH agonists: no initial flare, faster onset of suppression, and reversibility. Adverse effects: hot flashes, injection site reactions (degarelix), and osteoporosis with long-term use.

Guaifenesin

- An expectorant that thins and loosens bronchial mucus by increasing respiratory tract fluid and

reducing mucus viscosity, facilitating productive cough. Used for symptomatic relief of chest congestion and productive cough in upper respiratory infections and COPD. Typical adult dose 200-400 mg every 4 hours. Generally well tolerated; common side effects include nausea, vomiting, and dizziness. Efficacy is debated; hydration is an important adjunct. Available in many combination cold medications.

H2 Blocker (Histamine-2 Receptor Antagonist)

– A drug that blocks histamine H2 receptors on gastric parietal cells, reducing gastric acid secretion. Agents: cimetidine, ranitidine, famotidine, nizatidine. Used for GERD, peptic ulcer disease, and dyspepsia—less potent than PPIs. Adverse effects: headache, diarrhea, confusion (elderly, cimetidine), and rare thrombocytopenia. Cimetidine inhibits CYP450 (warfarin, theophylline, phenytoin) and has antiandrogenic effects (gynecomastia). Famotidine has the fewest interactions. Available OTC.

Half-Life

– Elimination half-life is the time required for the plasma concentration of a drug to decrease by 50 percent after reaching equilibrium. It is calculated from the elimination rate constant using the equation $t_{1/2} \text{ equals } 0.693 \text{ divided by the elimination rate constant}$. Half-life depends on both the volume of distribution and the clearance of the drug, with the relationship $t_{1/2} \text{ equals } 0.693 \text{ times } V_d \text{ divided by clearance}$. Drugs with large volumes of distribution or low clearance have long half-lives; understanding half-life is essential for determining appropriate dosing intervals, time to reach steady state, and duration of drug action after discontinuation.

Histamine

– A biogenic amine (imidazolyethylamine) synthesized from L-histidine by histidine decarboxylase, stored in basophils, mast cells, and platelets, and released during allergic and inflammatory responses. Histamine acts via four G-protein-coupled receptors: (1) H1 receptor: bronchoconstriction (asthma), vasodilation (hypotension, flushing), increased vascular permeability (urticaria, angioedema), pruritus, pain, mucus secretion, and CNS effects

(wakefulness). H1-antihistamines (cetirizine, loratadine, fexofenadine, chlorphenamine, promethazine, diphenhydramine) are used for allergic rhinitis, urticaria, pruritus, insomnia, motion sickness. (2) H2 receptor: gastric acid secretion (parietal cells). H2-antagonists (cimetidine, ranitidine, famotidine) are used for peptic ulcer disease, GORD, Zollinger-Ellison syndrome. (3) H3 receptor: pre-synaptic auto- and heteroreceptor in the CNS, inhibits histamine release and synthesis; inverse agonists/antagonists (pitolisant) are used for narcolepsy (increases wakefulness). (4) H4 receptor: expressed on immune cells (eosinophils, neutrophils, mast cells, dendritic cells), involved in chemotaxis and inflammation; H4 antagonists are under investigation for pruritus and asthma. Degradation: histamine N-methyltransferase and diamine oxidase. Histamine is also involved in gastric acid secretion, neurotransmission (wakefulness, appetite, learning), and smooth muscle contraction. Histamine poisoning (scombroid poisoning): from spoiled fish (tuna, mackerel) containing high levels of histamine due to bacterial decarboxylation, causes flushing, headache, urticaria, diarrhea within minutes, treated with H1-antihistamines.

Hydralazine

– A direct arteriolar vasodilator used for hypertension, particularly in preeclampsia/eclampsia (IV), and in combination with isosorbide dinitrate for heart failure with reduced ejection fraction in African Americans (improves survival). Mechanism: smooth muscle relaxation (nitric oxide pathway), reducing afterload. Adverse effects: reflex tachycardia (coadminister beta-blocker), headache, flushing, fluid retention (with diuretic), and drug-induced lupus with long-term high doses. Rapid acetylators have reduced effect. Also available orally (hypertension add-on).

Hydrochlorothiazide

– A thiazide diuretic inhibiting the sodium-chloride cotransporter in the distal convoluted tubule, promoting natriuresis and reducing plasma volume, with long-term vasodilation. Used for hypertension and mild edema. Lowers blood pressure effectively; useful in calcium stones and osteoporosis (reduces calciuria). Adverse effects: hypokalemia, hyponatremia, hyperglycemia, hyperuricemia (gout), hy-

percalcemia, hyperlipidemia, and photosensitivity. Less potent than chlorthalidone. Contraindicated in sulfonamide allergy and anuria.

Hypnotic

- A medication that induces, maintains, or improves sleep, used for insomnia. Major classes: benzodiazepine receptor agonists (Z-drugs: zolpidem, zaleplon, eszopiclone) — selective for GABA-A receptors containing alpha-1 subunits, promoting sleep onset with fewer next-day effects than benzodiazepines; melatonin receptor agonists (ramelteon, prolonged-release melatonin) — activate MT1 and MT2 receptors in the suprachiasmatic nucleus, regulating the sleep-wake cycle, no abuse potential; orexin receptor antagonists (suvorexant, daridorexant) — block orexin signaling that promotes wakefulness, used for sleep maintenance insomnia; sedating antidepressants (trazodone, doxepin, mirtazapine) — used in low doses for insomnia, especially with comorbid depression; and antihistamines (diphenhydramine, doxylamine) — sedating H1 antagonists available OTC, limited efficacy with chronic use due to tolerance.

Idiosyncratic Reaction

- An uncommon, unexpected, and often genetically determined adverse drug reaction that is unrelated to the drug's known pharmacology and usually dose-independent (a Type B reaction). Examples: sulfonamide-induced Stevens-Johnson syndrome, abacavir hypersensitivity (HLA-B*5701), isoniazid-induced hepatitis (slow acetylators), and malignant hyperthermia (ryanodine receptor mutation). Idiosyncratic reactions are unpredictable, potentially severe, and necessitate drug discontinuation; some can be prevented by pharmacogenetic screening.

Immunosuppressant

- A drug that reduces immune system activity, used to prevent organ transplant rejection and to treat autoimmune and inflammatory diseases. Agents: calcineurin inhibitors (cyclosporine, tacrolimus), antiproliferatives (azathioprine, mycophenolate), corticosteroids, mTOR inhibitors (sirolimus), and biologic agents (anti-TNF, anti-IL-6, rituximab). Adverse effects include increased infection risk, malignancy (especially lymphoma and skin cancer),

nephrotoxicity (calcineurin inhibitors), and bone marrow suppression. Dose is balanced between efficacy and infection risk.

Inotrope

- A drug that increases myocardial contractility (positive inotropy), used for cardiogenic shock, decompensated heart failure, and perioperative low-output states. Agents: dobutamine (beta-1 agonist), milrinone (PDE3 inhibitor), dopamine, epinephrine, norepinephrine (also vasopressors), and digoxin (chronic). Inotropes increase cardiac output and oxygen delivery but may worsen ischemia and arrhythmias and increase mortality with prolonged use. Vasopressors (norepinephrine, vasopressin, phenylephrine) raise blood pressure via vasoconstriction. Choice depends on hemodynamic profile (wet vs dry, cold vs warm).

Insulin Aspart

- A rapid-acting insulin analog (modified amino acid sequence) with onset 10-20 minutes, peak 1-3 hours, duration 3-5 hours. Used to cover prandial glucose (injected at or just after meals) in type 1 and type 2 diabetes; also used in continuous subcutaneous insulin infusion (pump) and IV in acute settings. Adverse effects: hypoglycemia, weight gain, and injection-site lipodystrophy (rotate sites). Lispro and glulisine are similar rapid-acting analogs.

Insulin Glargine

- A long-acting basal insulin analog with a flat, peakless profile providing near-24-hour coverage, administered once daily (or twice in some patients). Formed by modification of human insulin producing slow, steady absorption from the injection depot. Used for type 1 and type 2 diabetes (basal component). Adverse effects: hypoglycemia, weight gain, lipodystrophy. Contrast with intermediate (NPH) and short (regular) insulins. U-100 and U-300 (longer duration) strengths available.

Intramuscular (IM)

- A route of drug administration in which the drug is injected into skeletal muscle (deltoid, vastus lateralis, gluteus maximus). IM injection provides rapid absorption (muscle is highly vascular), avoids first-pass metabolism, and is used for vaccines, antibiotics (benzathine penicillin), depot preparations (medroxyprogesterone), and medications poorly ab-

sorbed orally. Absorption rate depends on blood flow and drug lipophilicity. Risks: pain, hematoma, nerve injury (sciatic), abscess, and injection into vessels.

Isavuconazole

- A triazole antifungal agent used in the treatment of invasive aspergillosis and mucormycosis. Isavuconazole inhibits fungal lanosterol 14- α demethylase, disrupting ergosterol synthesis and fungal cell membrane integrity. A key advantage is its broad-spectrum activity covering *Aspergillus*, *Candida*, *Cryptococcus*, *Mucorales*, and endemic fungi. The drug has excellent oral bioavailability of approximately 98% and is available as both intravenous and oral formulations. Unlike voriconazole, isavuconazole has minimal effect on CYP3A4 and does not prolong the QT interval to the same degree as voriconazole, giving it a more favourable drug interaction profile.

Isosorbide Dinitrate

- An organic nitrate (and prodrug) that releases nitric oxide, relaxing vascular smooth muscle—predominantly venous (preload reduction) with coronary dilation. Used for chronic stable angina prophylaxis, acute angina (sublingual/IV forms), and, with hydralazine, heart failure with reduced ejection fraction (improves survival in African Americans). Long-term continuous use produces nitrate tolerance (requires nitrate-free interval). Adverse effects: headache, flushing, hypotension, syncope, reflex tachycardia. Contraindicated with PDE5 inhibitors (sildenafil, tadalafil).

Laxative

- A drug that promotes bowel evacuation, used for constipation and bowel preparation. Classes: bulk-forming (psyllium, methylcellulose), osmotic (polyethylene glycol, lactulose, magnesium salts), stimulant (senna, bisacodyl), stool softener (docusate), and lubricant (mineral oil). Choice depends on constipation type and patient factors. Chronic stimulant laxative misuse can cause electrolyte disturbances and colonic dysmotility; bulk and osmotic agents are generally preferred for chronic use. Laxatives are contraindicated in intestinal obstruction.

Levodopa

- The precursor of dopamine that crosses the blood-

brain barrier; the most effective symptomatic treatment for Parkinson disease. Converted to dopamine in the brain by aromatic amino acid decarboxylase; always combined with carbidopa (peripheral decarboxylase inhibitor) to prevent peripheral conversion and side effects. Acute benefits: tremor, rigidity, bradykinesia. Long-term complications: motor fluctuations ('wearing off', 'on-off'), dyskinesias, and psychiatric effects. Withheld in psychosis; caution with MAOIs.

Liposomal amphotericin B

- A liposomal formulation of amphotericin B used in the treatment of severe systemic fungal infections, with reduced nephrotoxicity compared to conventional amphotericin B. The liposomal formulation encapsulates amphotericin B within lipid vesicles, which alters the drug's biodistribution and reduces renal tubular damage. It is the preferred formulation for neutropenic patients with fever and suspected fungal infections. The drug has broad-spectrum activity against *Candida*, *Aspergillus*, *Cryptococcus*. Additionally, liposomal amphotericin B is generally better tolerated with fewer infusion-related reactions and lower rates of nephrotoxicity, allowing for higher doses to be administered with improved therapeutic outcomes in critically ill patients with invasive fungal infections.

Loading Dose

- A higher initial dose of a drug administered to rapidly achieve therapeutic plasma concentrations, followed by lower maintenance doses to sustain the steady state. The loading dose is calculated as: Loading dose = $(V_d \times \text{desired concentration}) / \text{bioavailability}$. Indications: drugs with long half-lives where waiting 4-5 half-lives to reach steady state would delay clinical effect (amiodarone, half-life 40-55 days; digoxin, half-life 36-48 hours); drugs requiring immediate therapeutic effect (phenytoin for status epilepticus, antibiotics in sepsis, antiarrhythmics in unstable arrhythmias). The loading dose does not depend on clearance, only on the volume of distribution and the desired concentration. Caution is required for drugs with narrow therapeutic indices to avoid toxicity from the high initial dose.

Loop Diuretics

– A class of potent diuretics that act on the thick ascending limb of the loop of Henle by inhibiting the sodium-potassium-chloride cotransporter, blocking sodium and chloride reabsorption and producing a powerful natriuresis and diuresis. The prototypical loop diuretic is furosemide, with other agents including bumetanide and torsemide. Loop diuretics are the most potent diuretics available, producing greater sodium excretion than thiazides. They also increase calcium and magneLoop diuretics are used in the treatment of hypertension, heart failure, and oedematous states including cirrhosis and nephrotic syndrome, and their dosing must be individualised based on renal function and clinical response, with careful monitoring of electrolytes and volume status to avoid hypokalaemia, hypomagnesaemia, and volume depletion.

Loperamide

– A peripheral mu-opioid receptor agonist used as an antidiarrheal. It slows intestinal motility, reduces stool frequency and volume, and increases intestinal transit time without significant CNS effects (does not cross the blood-brain barrier at therapeutic doses) or analgesic activity. Adult dose: 4 mg initially, then 2 mg after each loose stool (max 16 mg/day). Side effects: constipation, abdominal cramps, nausea. Contraindicated in invasive bacterial diarrhea (dysentery, *C. difficile*) and intestinal obstruction; high doses are abused for opioid-like effects and can cause cardiac toxicity (QT prolongation).

Loratadine

– A second-generation (non-sedating) H1 antihistamine used for allergic rhinitis and chronic urticaria. Peripherally selective—minimal CNS penetration, minimal anticholinergic effects. Once daily; prodrug (desloratadine is active). Adverse effects: headache, dry mouth, and rare sedation. Available OTC. Few drug interactions; metabolized by CYP3A4/2D6. Cetirizine and fexofenadine are alternatives.

Macrolides

– A class of bacteriostatic antibiotics that bind to the 50S ribosomal subunit and inhibit translocation of peptidyl-tRNA during protein synthesis. The major macrolides include erythromycin, clar-

ithromycin, and azithromycin. Erythromycin has a narrow spectrum primarily against gram-positive organisms and is limited by gastrointestinal side effects from motilin receptor agonism. Clarithromycin has improved oral bioavailability and extended spectrum including *Haemophilus influenzae* and azithromycin has become a widely used agent for respiratory infections due to its extended half-life and once-daily dosing. Macrolides also have immunomodulatory and anti-inflammatory properties independent of their antimicrobial activity, which contribute to their efficacy in chronic respiratory diseases including cystic fibrosis, bronchiectasis, and diffuse panbronchiolitis.

Maintenance Dose

– The dose of a drug administered at regular intervals to maintain a desired steady-state concentration, balancing the rate of drug administration with the rate of elimination. The maintenance dose is calculated as: Maintenance dose rate = (Clearance x desired concentration) / Bioavailability. At steady state, the rate of drug administration equals the rate of elimination. Maintenance doses are determined by the drug's clearance and target therapeutic concentration. Factors affecting maintenance dose requirements: changes in clearance (renal impairment, hepatic impairment, drug interactions affecting metabolism), changes in volume of distribution (obesity, edema), and patient factors (age, weight, organ function). Maintenance dosing intervals are based on the drug's half-life, typically administered every half-life for drugs with short half-lives or at longer intervals for drugs with long half-lives.

Mannitol

– An osmotic diuretic that is freely filtered at the glomerulus but not reabsorbed, increasing tubular osmotic pressure and water excretion. Used to reduce intracranial pressure (cerebral edema) and intraocular pressure (acute glaucoma), and to promote diuresis in rhabdomyolysis/contrast nephropathy prophylaxis. IV infusion; side effects: fluid overload, hyponatremia or hypernatremia, pulmonary edema (with renal failure), and headache. Contraindicated in anuria and congestive heart failure. Filter for crystallization; avoid in significant renal impairment.

Maraviroc

– A CCR5 antagonist (entry inhibitor) used in combination antiretroviral therapy for HIV-1 infection in patients with CCR5-tropic virus. Maraviroc binds to the human CCR5 coreceptor on CD4+ T cells, preventing HIV-1 gp120 binding and viral entry. A critical requirement for maraviroc use is tropism testing to confirm the presence of CCR5-tropic virus, as the drug has no activity against CXCR4-tropic or dual/mixed-tropic virus. Common adverse effects include hepatotoxicity with elevated transaminases levels, which is typically reversible upon discontinuation; postural hypotension, diarrhea, nausea, and headache are also reported.

Maximum Tolerated Dose

– The highest dose of a drug that produces acceptable, manageable toxicity without causing unacceptable adverse effects, determined through dose-escalation studies, most commonly in Phase I clinical trials. The MTD identifies the dose range for subsequent efficacy studies. In oncology, the MTD is typically defined as the dose at which no more than 33% of patients experience dose-limiting toxicity (DLT) during the first treatment cycle. The 3+3 design is the classic approach: 3 patients are treated at each dose level; if 0/3 have DLT, the next cohort is escalated; if 1/3 have DLT, 3 more patients are treated at the same level; if 2/3 have DLT, the previous dose is declared the MTD. Modern adaptive designs (e.g., Bayesian continual reassessment method) are increasingly used.

Medical Cannabis and Cannabidiol (CBD)

– Cannabis (marijuana) and cannabidiol (CBD) are cannabinoid compounds derived from *Cannabis sativa* that interact with the endocannabinoid system (CB1 and CB2 receptors) to modulate pain, appetite, mood, and inflammation. THC (delta-9-tetrahydrocannabinol) is the primary psychoactive component responsible for euphoria, cognitive impairment, and dependence risk; CBD is non-intoxicating and has demonstrated anti-inflammatory, anxiolytic, and anticonvulsant properties. FDA-approved cannabinoid preparations: dronabinol and nabilone for chemotherapy-induced nausea and HIV/AIDS anorexia, and purified CBD (Epidiolex) for Dravet and Lennox-Gastaut syn-

dromes. Evidence supports medical cannabis for chronic neuropathic pain, multiple sclerosis spasticity, and chemotherapy-induced nausea, though data for most other conditions are limited by small trials and regulatory barriers. Risks: impaired driving, psychosis vulnerability (especially high-THC products), cannabinoid hyperemesis syndrome, pulmonary harm from smoking, and addiction (9% of users).

Medication Management

– The systematic process of optimizing pharmacotherapy to achieve therapeutic goals while minimizing adverse effects, encompassing prescribing, dispensing, administration, monitoring, and deprescribing. Key components: medication reconciliation at transitions of care (comparing patient's current regimen against new orders to prevent errors), adherence assessment (pill counts, pharmacy refill data, electronic monitoring), dose adjustment for renal/hepatic impairment, therapeutic drug monitoring (e.g., warfarin INR, vancomycin trough, lithium levels), and deprescribing (tapering or discontinuing unnecessary or harmful medications). Polypharmacy—use of ≥ 5 medications—increases risk of adverse drug events, falls, cognitive impairment, and hospitalization; an annual medication review using tools like the Beers Criteria and STOPP/START criteria is recommended for older adults. Patient education on indication, dose, timing, side effects, and drug–drug interactions is essential for safe and effective therapy.

Medications and Treatments

– all pharmacologic and therapeutic interventions used to prevent, manage, or cure disease, classified by mechanism of action, therapeutic class, and route of administration. Major drug classes: analgesics (NSAIDs, opioids, acetaminophen), cardiovascular agents (statins, ACE inhibitors, beta-blockers, diuretics, anticoagulants), antimicrobials (antibiotics, antivirals, antifungals), endocrine therapies (insulin, metformin, thyroid hormone, corticosteroids), psychotropics (SSRIs, antipsychotics, benzodiazepines, mood stabilizers), antineoplastics (chemotherapy, targeted therapy, immunotherapy), and disease-modifying biologic agents. Routes include oral, intravenous, intramuscular, subcutaneous, topical, inhaled, transdermal, intrathecal,

and intra-articular. The principles of pharmacotherapy: right drug, right dose, right route, right time, right patient—guided by evidence-based guidelines, contraindications, allergies, renal/hepatic function, and cost-effectiveness.

Medication Side Effects

- Unintended harmful responses to medications occurring at standard doses, ranging from mild (nausea, rash, dry mouth) to severe (anaphylaxis, Stevens-Johnson syndrome, QT prolongation, hepatotoxicity). ADRs are classified as Type A (augmented pharmacologic effect, predictable and dose-dependent, 80% of ADRs, e.g., bleeding with warfarin, hypoglycemia with insulin) and Type B (bizarre, unpredictable, immune-mediated or idiosyncratic, e.g., penicillin anaphylaxis, statin-induced myopathy). Risk factors: polypharmacy, advanced age, renal/hepatic impairment, genetic polymorphisms (CYP450 variants, HLA-B*5701 for abacavir hypersensitivity), and drug–drug interactions (e.g., simvastatin–clarithromycin). Management: prompt recognition, discontinuation or dose reduction, switching to alternative agent, and reporting to pharmacovigilance systems (FDA MedWatch). The Naranjo algorithm and causality assessment tools aid in determining likelihood of ADR.

Memantine

- An NMDA receptor antagonist (uncompetitive, low-to-moderate affinity) used for moderate to severe Alzheimer disease, often added to an acetylcholinesterase inhibitor. Blocks excessive glutamate-mediated excitotoxicity while preserving normal synaptic transmission. Once or twice daily oral. Adverse effects: dizziness, headache, constipation, confusion, and hypertension. Minimal cognitive side effects; renally cleared (reduce dose in renal impairment). Also used off-label for other dementias and neuropathic pain.

Meropenem-vaborbactam

- A combination of the carbapenem meropenem with the cyclic boronate beta-lactamase inhibitor vaborbactam. Vaborbactam inhibits class A and class C beta-lactamases, including KPC carbapenemases, but does not inhibit class D or metallo-beta-lactamases. This combination has activity against many carbapenem-resistant Enterobacteriaceae. It

is indicated for complicated urinary tract infections and is being studied for other indications. The combination is administered intravenously every 8 hours, with dose adjustment required for impaired renal function; the most common adverse effects include diarrhea, headache, nausea, and infusion-site reactions.

Methicillin-resistant Staphylococcus aureus

- Staphylococcus aureus resistant to beta-lactam antibiotics through acquisition of the *mecA* gene encoding penicillin-binding protein 2a (PBP2a). MRSA is a major cause of healthcare-associated and community-associated infections. Treatment options include vancomycin, daptomycin, linezolid, and trimethoprim-sulfamethoxazole. MRSA infections are associated with increased morbidity and mortality. Infection prevention strategies include hand hygiene, contact precautions, and decolonization protocols. MRSA colonisation and infection surveillance, decolonisation strategies using intranasal mupirocin and chlorhexidine bathing, and antimicrobial stewardship to preserve the effectiveness of remaining active agents.

Metoclopramide

- A dopamine (D2) receptor antagonist and 5-HT₃ antagonist used as a prokinetic antiemetic for gastroparesis, chemotherapy-induced and postoperative nausea, and GERD (facilitates gastric emptying). Adverse effects: acute dystonic reactions (young women), tardive dyskinesia (chronic use—black-box warning), parkinsonism, hyperprolactinemia, and QT prolongation. Contraindicated in GI obstruction, pheochromocytoma, and Parkinson disease. Domperidone is an alternative (peripheral).

Metronidazole

- A nitroimidazole antibiotic and antiprotozoal agent that is selectively toxic to anaerobic organisms and certain parasites. The drug is activated by reduction of its nitro group within anaerobic cells, generating toxic free radicals that damage DNA. Metronidazole is highly effective against anaerobic bacteria including *Bacteroides fragilis*, *Clostridium* species, and *Helicobacter pylori*, as well as protozoa including *Trichomonas vaginalis*, *Giardia lamblia*, and *Entamoeba histolytica*. It is the drug of choice for

C. difficile infection when used orally, for anaerobic infections above the diaphragm, and for bacterial vaginosis. Common adverse effects include metallic taste, nausea, and a disulfiram-like reaction with alcohol; prolonged use may cause peripheral neuropathy.

Micafungin

- An echinocandin antifungal agent used in the treatment and prophylaxis of invasive candidiasis and esophageal candidiasis. Micafungin inhibits beta-(1,3)-D-glucan synthase, disrupting fungal cell wall synthesis and leading to osmotic instability and cell death. A key advantage is its fungicidal activity against *Candida* species and fungistatic activity against *Aspergillus*. The drug is available only intravenously, as it is not absorbed orally. Common adverse effects include headache, nausea, and elevated transaminases; micafungin is also associated with an increased risk of hepatocellular tumors in animal studies, though the clinical significance in humans is uncertain.

Milrinone

- A phosphodiesterase-3 inhibitor with positive inotropic and vasodilatory (inodilator) actions, increasing cAMP in cardiac and vascular smooth muscle. Used short-term for acute decompensated heart failure and low cardiac output (bridging therapy, post-cardiac surgery), especially when beta-agonists are inadequate or patients are beta-blocked. IV infusion; half-life 2-3 hours (longer in renal impairment). Adverse effects: hypotension, arrhythmias (including VT), thrombocytopenia, and hypokalemia. May increase mortality with chronic use in class IV heart failure.

Minimum inhibitory concentration

- The lowest concentration of an antimicrobial agent that inhibits visible growth of a microorganism under standardized in vitro conditions. MIC is the gold standard for measuring antimicrobial susceptibility and is determined by broth microdilution or agar dilution methods. The MIC value is used to categorize isolates as susceptible, intermediate, or resistant based on established breakpoints. MIC values guide dosing decisions and can predict clinical outcomes. For some infections, including endocarditis and osteomyelitis, maintaining drug

concentrations above the MIC for the entire dosing interval is critical for achieving bacteriological cure, and time above the MIC is the key pharmacodynamic parameter for beta-lactam antibiotics.

Minoxidil

- A direct arteriolar vasodilator (potassium channel opener) used for severe refractory hypertension (usually with a beta-blocker and loop diuretic to counter reflex tachycardia and fluid retention), and topically for androgenetic alopecia (promotes hair regrowth). Adverse effects: hypertrichosis, pericardial effusion, reflex tachycardia, fluid retention, and headache. Dose is titrated; discontinue slowly. Topical use is generally well tolerated with minimal systemic effects.

Modafinil

- A wakefulness-promoting agent (mechanism not fully understood, likely dopaminergic) used for narcolepsy, obstructive sleep apnea residual sleepiness, and shift work sleep disorder; used off-label for fatigue and ADHD. Less abuse potential and fewer sympathomimetic effects than amphetamines. Adverse effects: headache, nausea, nervousness, and rare severe rash (SJS); decreases effectiveness of hormonal contraceptives (CYP3A4 induction). Once daily.

Montelukast

- A leukotriene receptor antagonist (LTRA) blocking cysteinyl leukotrienes (LTC₄, LTD₄, LTE₄) that cause bronchoconstriction, mucus secretion, and airway inflammation. Used as add-on maintenance therapy for asthma (particularly exercise-induced and aspirin-sensitive), allergic rhinitis, and bronchospasm prophylaxis. Oral, once daily. Generally well tolerated; adverse effects include headache and abdominal pain. A boxed warning addresses neuropsychiatric events (mood changes, agitation, depression, suicidal ideation). Not indicated for acute bronchospasm.

Mycobacterium avium complex

- A group of slowly growing mycobacteria that cause pulmonary disease and disseminated infection in immunocompromised patients. See microbiology.

Narrow Therapeutic Index

- A drug characteristic where there is a small difference between the therapeutic dose and the toxic

dose, requiring careful dosing and therapeutic drug monitoring to ensure efficacy while avoiding toxicity. Narrow therapeutic index drugs have a therapeutic index <2 - 3 (the ratio of toxic dose to effective dose). Examples: warfarin (TI 2), digoxin, aminoglycosides (gentamicin, tobramycin, amikacin), vancomycin, cyclosporine, tacrolimus, lithium, phenytoin, carbamazepine, valproic acid, theophylline, and thyroid hormones. Managing NTI drugs requires: regular monitoring of drug concentrations; individualized dosing based on pharmacokinetic parameters; awareness of drug interactions that can alter levels; and patient education about signs of toxicity.

Neuraminidase Inhibitors

- A class of antiviral drugs that inhibit the neuraminidase enzyme on the surface of influenza viruses, preventing the release of newly formed viral particles from infected cells and thereby limiting viral spread. The two available agents are oseltamivir, administered orally, and zanamivir, administered by inhalation. These drugs are effective against both influenza A and influenza B viruses. Neuraminidase cleaves sialic acid residues from glycoproteins on the cell surface, allowing release of newly formed viral particles; inhibition of neuraminidase prevents this release, limiting viral spread within the respiratory tract and reducing the duration and severity of influenza symptoms when started within 48 hours of symptom onset.

Nitrates

- Vasodilator drugs that release nitric oxide, causing relaxation of vascular smooth muscle through activation of guanylyl cyclase and increased cyclic GMP. They primarily cause venodilation at low doses, reducing preload and myocardial oxygen demand, and arterial dilation at higher doses, reducing afterload. Nitroglycerin is the prototype nitrate, available in sublingual tablets for acute angina, intravenous infusion for acute coronary syndromes, topical patches for prophylaxis, and oral sustained-release formulations for long-term prophylaxis. Nitrate tolerance develops rapidly with continuous exposure and requires a daily nitrate-free interval of 8-12 hours to maintain therapeutic efficacy; common adverse effects include headache, flushing, and postural hypotension.

Nitroglycerin

- An organic nitrate that releases nitric oxide, relaxing vascular smooth muscle—predominantly venous. Used for acute angina (sublingual spray/tablet, IV for ACS/heart failure), angina prophylaxis, and preload reduction in acute pulmonary edema. Rapid onset (1-3 min sublingual). Adverse effects: headache, flushing, hypotension, syncope, reflex tachycardia; tolerance with continuous use (nitrate-free interval required). Contraindicated with PDE5 inhibitors (sildenafil/tadalafil—severe hypotension) and in right ventricular infarction, severe aortic stenosis, and raised intracranial pressure.

Nitroprusside

- A direct-acting vasodilator (arterial and venous) releasing nitric oxide, used for hypertensive emergencies and controlled hypotension during surgery. IV infusion with rapid onset and offset; reduces both preload and afterload. Metabolized to cyanide and thiocyanate—toxicity (with prolonged/high-dose infusion, renal/hepatic impairment) causes lactic acidosis, confusion, and seizures. Protect from light. Adverse effects: hypotension, cyanide/thiocyanate toxicity, and methemoglobinemia. Monitor blood pressure continuously and cyanide levels with prolonged use.

Noncompetitive Antagonist

- A noncompetitive antagonist is a drug that reduces the effect of an agonist by a mechanism that cannot be overcome by increasing the agonist concentration. This occurs either through irreversible binding to the receptor, preventing agonist binding permanently, or through binding to an allosteric site that reduces receptor function regardless of agonist binding. The dose-response curve of the agonist is shifted to the right with a decrease in maximal response, meaning the full effect of the agonist is reduced or eliminated, distinguishing noncompetitive antagonism from competitive antagonism; this type of antagonism is often irreversible on the timescale of clinical drug therapy and requires synthesis of new receptors for recovery of full agonist responsiveness.

Non-tuberculous mycobacteria

- A group of mycobacterial species other than *M. tuberculosis* complex that cause disease in humans.

NTM include rapidly growing species (*M. abscessus*, *M. chelonae*, *M. fortuitum*) and slowly growing species (*M. avium* complex, *M. kansasii*). NTM infections are increasingly recognized, particularly in patients with chronic lung disease and immunocompromise. Treatment requires combination therapy based on species identification and susceptibility testing. Macrolides are backbone agents for many NTM infections; treatment is prolonged and requires multiple agents, with regimens tailored to species identification and susceptibility results, and outcomes vary widely depending on the species, extent of disease, and host immune status.

NSAIDs

- Nonsteroidal anti-inflammatory drugs are a class of drugs that inhibit cyclooxygenase enzymes, COX-1 and COX-2, reducing the synthesis of prostaglandins and thromboxanes from arachidonic acid. They produce analgesic, anti-inflammatory, antipyretic, and antiplatelet effects. COX-1 is constitutively expressed and maintains gastric mucosal protection, renal blood flow, and platelet aggregation. COX-2 is inducible and upregulated during inflammation. Traditional NSAIDs including ibuprofen, naproxen, and diclofenac have analgesic, antipyretic, and anti-inflammatory effects but carry risks including gastrointestinal bleeding and ulceration, renal impairment, and cardiovascular events; the risk-benefit profile must be evaluated for each patient based on their individual risk factors.

NSAIDs (Nonsteroidal Anti-Inflammatory Drugs)

- A class of analgesic, antipyretic, and anti-inflammatory drugs that inhibit cyclooxygenase (COX-1 and/or COX-2), reducing prostaglandin and thromboxane synthesis. Nonselective NSAIDs (ibuprofen, naproxen, indomethacin) block both COX-1 (gastric protection, platelets) and COX-2 (inflammation); COX-2 selective agents (celecoxib) reduce GI ulceration but retain cardiovascular risk. Uses: pain, inflammation, fever, arthritis, gout, dysmenorrhea. Adverse effects: GI bleeding/ulceration, renal impairment, fluid retention, hypertension, cardiovascular events, and aspirin-exacerbated respiratory disease.

Nucleoside Analogs

- A class of antiviral drugs that structurally resemble natural nucleosides and inhibit viral replication by interfering with DNA or RNA synthesis. They require intracellular phosphorylation by viral or cellular kinases to their active triphosphate form, which then competes with natural nucleotides for incorporation into the growing viral nucleic acid chain, causing chain termination or lethal mutagenesis. Examples include acyclovir for herpes simplex virus and varicella-zoster virus, tenofovir for HIV and hepatitis B, and ribavirin for hepatitis C, with resistance developing through mutations in the target viral enzymes that reduce drug binding affinity.

Off-Label Use

- The use of a licensed medication for an indication, dose, route, or patient population not included in its marketing authorisation (product licence). Off-label prescribing is legal, common in many areas of medicine (pediatrics—up to 50% of hospital prescriptions, oncology, psychiatry, obstetrics), and may represent best clinical practice when evidence supports the use (e.g., β -blockers in heart failure were off-label before regulatory approval). The prescriber bears responsibility for the patient's safety and should: (1) be satisfied that there is a sufficient evidence base (published studies, guidelines, expert consensus) to support the off-label use; (2) explain the off-label nature to the patient and obtain informed consent; (3) document the rationale in the medical record. Regulatory frameworks: in the UK, the MHRA allows off-label prescribing under the prescriber's professional responsibility; the FDA prohibits pharmaceutical companies from promoting off-label use but does not restrict physician prescribing. Notable examples: ketamine for treatment-resistant depression, metformin for gestational diabetes, and aspirin for primary prevention of cardiovascular disease (controversial).

Ointment

- A semi-solid, greasy topical preparation for application to the skin, mucous membranes, or eyes. Ointments are typically composed of a hydrophobic base (petrolatum, lanolin, paraffin, beeswax, vegetable oils) and may contain dissolved or suspended active pharmaceutical ingredients. Ointments have high occlusivity (form a water-repellent barrier, pre-

venting transepidermal water loss) and are preferred for dry, scaly, or lichenified skin conditions (psoriasis, chronic eczema, xerosis). They have higher drug penetration than creams (oil-in-water emulsions) or lotions due to their lipophilic nature. Disadvantages: greasy feel, staining of clothing, and less cosmetic acceptability than creams. Eye ointments (e.g., chloramphenicol, tetracycline) provide prolonged ocular contact time and are often used at bedtime. Ointment bases can be classified as hydrocarbon (petrolatum), absorption (lanolin—can absorb water), water-removable (emulsifying ointment), and water-soluble (polyethylene glycol).

Omadacycline

- A newer aminomethylcycline antibiotic with activity against gram-positive, gram-negative, and atypical organisms. Omadacycline inhibits bacterial protein synthesis by binding to the 30S ribosomal subunit. It has activity against MRSA, vancomycin-resistant enterococci, community-acquired pneumonia pathogens, and skin infections. The drug is available in both intravenous and oral formulations, allowing for IV-to-oral step-down therapy. Omadacycline is indicated for community-acquired bacterial pneumonia and acute bacterial skin infections, with common adverse effects including nausea, vomiting, and infusion-site reactions; photosensitivity is less common than with earlier tetracyclines.

Omeprazole

- A proton pump inhibitor (PPI) that irreversibly inhibits the gastric H⁺/K⁺ ATPase (proton pump) on parietal cells, profoundly reducing acid secretion. Used for GERD, peptic ulcer disease, *H. pylori* eradication (triple therapy), Zollinger-Ellison syndrome, and stress ulcer prophylaxis. Prodrug activated in acidic canaliculi; once daily before breakfast. Adverse effects: headache, diarrhea, hypomagnesemia, B12 deficiency with long-term use, osteoporosis/fracture risk, *C. difficile* infection, and drug interactions (CYP2C19). Pantoprazole, esomeprazole, lansoprazole are alternatives.

Opiate

- A natural alkaloid derived from the opium poppy (*Papaver somniferum*) or a semi-synthetic derivative that binds to opioid receptors. Natural opiates: morphine (prototypical opioid analgesic, gold stan-

dard for severe pain), codeine (prodrug metabolized to morphine by CYP2D6—poor metabolisers derive minimal analgesia), and thebaine (used in synthesis of semi-synthetic opioids—oxycodone, buprenorphine, naloxone). Semi-synthetic opiates: heroin (diamorphine—more lipid-soluble than morphine, rapid CNS penetration), oxycodone, and hydromorphone. See also Opioid for the broader class including synthetic opioids (fentanyl, methadone, tramadol). Historically, opium has been used for pain relief, diarrhea, and cough suppression for millennia. Opiates produce euphoria, miosis, respiratory depression, constipation, and physical dependence. Overuse leads to opioid use disorder (addiction).

Opioid Analgesics

- A class of drugs that bind to opioid receptors in the central and peripheral nervous systems, producing analgesia and other effects. There are three main opioid receptor types: mu receptors mediating analgesia, respiratory depression, euphoria, and physical dependence; delta receptors involved in analgesia and mood; and kappa receptors mediating analgesia and sedation. Morphine is the prototype opioid, derived from opium, with other natural opioids including codeine and semisynthetic opioids including fentanyl and methadone. Common adverse effects include respiratory depression, constipation, nausea and vomiting, sedation, tolerance, physical dependence, and the potential for addiction; careful dosing and monitoring are required to balance effective pain relief with the risk of adverse events.

Opioids

- A class of drugs that bind to opioid receptors in the central and peripheral nervous systems, producing analgesia and other effects. See [Opioid Analgesics](#).

Oral Hypoglycemic

- A class of drugs used to treat type 2 diabetes (with lifestyle). Classes: biguanides (metformin—first-line), sulfonylureas (glipizide, glyburide), meglitinides, thiazolidinediones (pioglitazone), DPP-4 inhibitors (sitagliptin), SGLT2 inhibitors (empagliflozin), GLP-1 receptor agonists (semaglutide, liraglutide—injectable), and alpha-glucosidase inhibitors. Choice based on glycemic control, weight, cardiovascular/renal risk, and hypoglycemia risk. SGLT2 inhibitors and GLP-1 agonists have cardio-

vascular and renal benefits; sulfonylureas and insulin carry hypoglycemia risk.

Orphan Drug

- A pharmaceutical agent developed specifically to treat a rare medical condition (affecting fewer than 200,000 people in the United States, as defined by the Orphan Drug Act of 1983). Orphan drug designation provides incentives including seven-year market exclusivity after FDA approval, tax credits for clinical trial costs, waived FDA application fees, and research grants. Examples include lumacaftor/ivacaftor for cystic fibrosis, nusinersen for spinal muscular atrophy, and eliglustat for Gaucher disease. The Orphan Drug Act has successfully stimulated development of treatments for previously neglected rare diseases.

Orphan Drugs

- Medicinal products developed for the diagnosis, prevention, or treatment of rare diseases (defined in the EU as affecting <5 per 10,000 people; in the US as affecting <200,000 people). Orphan drug designation provides incentives for pharmaceutical companies: 7 years of market exclusivity in the US (Orphan Drug Act 1983), 10 years in the EU (2000), reduced regulatory fees, tax credits for clinical research costs (25% in the US), and protocol assistance from regulatory agencies. More than 600 orphan drugs have been approved in the US since 1983. Examples: imiglucerase and miglustat (Gaucher disease), ivacaftor (cystic fibrosis—G551D mutation), eculizumab (paroxysmal nocturnal haemoglobinuria, atypical hemolytic uraemic syndrome), nusinersen (spinal muscular atrophy), and eliglustat (Gaucher disease type 1). Challenges: high drug costs (often >\$200,000 per patient per year), limited natural history data, small trial populations, and ethical concerns about equitable access. The UK Rare Diseases Framework (2021) prioritises timely diagnosis and access to treatment for rare diseases.

Over-the-Counter Drug

- A medication that can be purchased without a prescription, deemed safe and effective for self-medication when used according to label instructions. OTC drugs have established safety profiles, low toxicity, and clear dosing guidelines suitable for consumer use. Examples include acetaminophen,

ibuprofen, antihistamines (loratadine, diphenhydramine), antacids, and topical antifungals. The FDA determines OTC status based on safety, labeling adequacy, and the condition being treatable without professional supervision. Some drugs are switched from prescription to OTC status after post-marketing safety data accumulate.

Over-the-Counter (OTC)

- Medications available without a prescription, considered safe and effective for self-care with appropriate labeling and low abuse potential. Examples: acetaminophen, ibuprofen, antacids, antihistamines, decongestants, laxatives. Regulated in the US by the FDA (OTC monograph system) and Rx-to-OTC switches (e.g., omeprazole, loratadine). Despite availability, OTC drugs carry risks (hepatotoxicity from acetaminophen overdose, NSAID GI/renal effects, interactions with warfarin and antihypertensives). Pharmacists counsel on appropriate use.

Palliative Care

- Specialized medical care for serious illness focusing on symptom relief and quality of life. See oncology.

Pantoprazole

- A proton pump inhibitor reducing gastric acid secretion by irreversibly inhibiting the H⁺/K⁺ ATPase of parietal cells. Used for GERD, peptic ulcer disease, dyspepsia, *H. pylori* eradication, and acid hypersecretory states. Available oral and IV (used for stress ulcer prophylaxis in the ICU). Generally well tolerated; long-term use is associated with hypomagnesemia, vitamin B12 deficiency, increased fracture risk, and *C. difficile* infection. Fewer CYP interactions than omeprazole; esomeprazole is the S-enantiomer of omeprazole.

Partial Agonist

- A partial agonist is a drug that binds to a receptor and produces a biological response that is less than the maximum possible response, even when all receptors are occupied. Partial agonists have affinity for the receptor but lower intrinsic activity compared to full agonists, producing a submaximal response regardless of dose. The maximal effect of a partial agonist is always less than that of a full agonist acting at the same receptor. An important property of partial agonists is that they can act as functional antagonists in the presence of a full ag-

onist: by occupying receptors that would otherwise be activated by the full agonist, the partial agonist reduces the net response, which is the basis for their use in maintenance therapy for opioid dependence and smoking cessation.

Pharmacodynamics

- The study of the biochemical and physiological effects of drugs on the body and their mechanisms of action, describing what the drug does to the body. It encompasses drug-receptor interactions (binding affinity, intrinsic activity, efficacy), signal transduction pathways (second messengers, gene expression), dose-response relationships, and therapeutic vs. adverse effects. Key concepts: receptors — proteins or macromolecules that drugs bind to exert their effects; agonists — drugs that activate receptors to produce a response; antagonists — drugs that block receptor activation; partial agonists — drugs that produce a submaximal response even at full receptor occupancy; and allosteric modulators — drugs that bind to sites distinct from the orthosteric binding site to modulate receptor activity.

Pharmacogenomics

- The study of how genetic variations influence individual responses to drugs, including drug efficacy, toxicity, and metabolism. Genetic polymorphisms in drug-metabolizing enzymes, transporters, and receptors can lead to significant inter-individual variability in drug response. Examples: CYP2D6 poor metabolizers have reduced codeine activation to morphine, leading to ineffective analgesia; CYP2C19 poor metabolizers require reduced clopidogrel dosing; TPMT deficiency increases risk of severe myelosuppression with azathioprine; HLA-B*5701 testing is required before abacavir to prevent hypersensitivity reaction; UGT1A1*28 homozygotes have increased risk of irinotecan toxicity. Pharmacogenomic testing is increasingly integrated into clinical practice, guiding drug selection and dosing to optimize efficacy and minimize adverse effects.

Pharmacokinetics

- The study of drug movement through the body, describing what the body does to the drug, defined by four processes: Absorption — the process by which a drug enters the systemic circulation from its site of administration (oral, IV, IM, subcutaneous, top-

ical, inhalation); Distribution — the movement of drug from the circulation to body tissues, determined by blood flow, protein binding, tissue affinity, and barriers (blood-brain barrier, placental barrier); Metabolism — the chemical modification of drugs by enzymes (primarily hepatic CYP450) through Phase I (oxidation, reduction, hydrolysis) and Phase II (conjugation) reactions; and Excretion — the elimination of drugs and their metabolites from the body, primarily through the kidneys (glomerular filtration, tubular secretion, reabsorption) and also through bile, feces, lungs, and sweat. Pharmacokinetic parameters: half-life, clearance, volume of distribution, bioavailability, and steady state concentration.

Pharmacovigilance

- The science and activities relating to the detection, assessment, understanding, and prevention of adverse drug reactions and other drug-related problems. It encompasses post-marketing surveillance of drugs after they have been approved for clinical use, as pre-marketing clinical trials may not detect rare adverse effects, long-term effects, or effects in special populations. Pharmacovigilance systems collect adverse event reports from healthcare professionals, patients, and pharmaceutical companies, and uses data from multiple sources including clinical trials, spontaneous reporting, electronic health records, and published literature to generate safety signals that may lead to regulatory actions including label changes, warnings, and market withdrawals.

Phase II Metabolism

- Phase II metabolism, also known as conjugation reactions, involves the attachment of endogenous hydrophilic molecules to drugs or their Phase I metabolites, dramatically increasing water solubility and facilitating renal excretion. The major Phase II reactions include glucuronidation catalyzed by UDP-glucuronosyltransferases, which is the most common conjugation reaction and accounts for approximately 35 percent of Phase II metabolism; sulfation catalyzed by sulfotransferases; acetylation catalyzed by N-acetyltransferases; methylation; and conjugation with glutathione. Phase II metabolites are generally pharmacologically inactive and are rapidly excreted in urine or bile; the efficiency of these conjugation pathways depends on the availability of the endogenous substrate and the

activity of the conjugating enzymes, which can be influenced by genetic polymorphisms, drug interactions, and disease states.

Phase I Metabolism

- Phase I metabolism involves chemical modification of drug molecules through oxidation, reduction, and hydrolysis reactions, primarily catalyzed by the cytochrome P450 enzyme system in the liver. These reactions introduce or expose functional groups such as hydroxyl, amino, sulfhydryl, and carboxyl groups, typically increasing the polarity and water solubility of the parent compound. The most common Phase I reaction is oxidation, catalyzed by CYP enzymes requiring molecular oxygen and NADPH. Oxidation reactions introduce hydroxyl, carboxyl, or epoxide groups, while reduction reactions add hydrogen or remove oxygen, and hydrolysis reactions cleave ester or amide bonds; the resulting metabolites may be pharmacologically inactive, less active, equally active, or occasionally more active than the parent compound, and some undergo further Phase II conjugation for elimination.

Phenylephrine

- A selective α -1 adrenergic agonist causing vasoconstriction and increased blood pressure (systemic vascular resistance) with reflex bradycardia. Used for hypotension/shock (IV bolus/infusion, common in anesthesia and sepsis), nasal congestion (topical decongestant), and mydriasis (ophthalmic). Adverse effects: hypertension, reflex bradycardia, headache, and tissue ischemia with extravasation. Caution in hypertensive and cardiac patients; contraindicated in severe hypertension, hyperthyroidism, and narrow-angle glaucoma (ophthalmic use).

Phosphodiesterase Inhibitor

- A class of drugs that inhibit phosphodiesterase enzymes, which break down cyclic nucleotides (cAMP and cGMP), thereby increasing intracellular levels of these second messengers and potentiating their downstream effects. Nonselective PDE inhibitors: theophylline (PDE3 and PDE4 inhibition) — bronchodilator for asthma and COPD, also has anti-inflammatory effects. PDE3 inhibitors: milrinone — positive inotrope and vasodilator for acute decompensated heart failure. PDE4 inhibitors: roflumilast — used for severe COPD with chronic

bronchitis and frequent exacerbations; apremilast — used for psoriasis and psoriatic arthritis. PDE5 inhibitors: sildenafil, tadalafil, vardenafil — inhibit cGMP-specific PDE5 in corpus cavernosum, used for erectile dysfunction; also treat pulmonary arterial hypertension (sildenafil, tadalafil). Each PDE isozyme has distinct tissue distribution, allowing targeted therapeutic effects.

Polyethylene Glycol (PEG)

- An osmotic laxative used for constipation and bowel preparation for colonoscopy. PEG (e.g., Miralax, GoLYTELY) is a non-absorbable polymer that draws water into the colonic lumen, softening stool and stimulating defecation without significant electrolyte shifts. For chronic constipation: 17 g daily in water. For bowel prep: large-volume balanced electrolyte solutions (PEG-ELS) or low-volume with ascorbate. Generally well tolerated; bloating and cramping may occur; contraindicated in bowel obstruction.

Potassium-Sparing Diuretics

- Potassium-sparing diuretics act on the distal nephron to promote sodium excretion while minimizing potassium loss. They include epithelial sodium channel blockers such as amiloride and triamterene, and mineralocorticoid receptor antagonists such as spironolactone and eplerenone. Amiloride and triamterene directly block the epithelial sodium channel in the collecting duct, reducing sodium reabsorption and potassium secretion. Spironolactone and eplerenone competitively inhibit aldosterone binding to the mineralocorticoid receptor, blocking aldosterone-mediated sodium reabsorption and potassium excretion. Spironolactone is used as a diuretic in conditions associated with secondary hyperaldosteronism, including heart failure and hepatic cirrhosis, and as an antiandrogen in the treatment of acne, hirsutism, and female pattern hair loss. Hyperkalemia is the most important adverse effect and requires regular monitoring of serum potassium levels, particularly in patients with renal impairment or those receiving concurrent ACE inhibitors or ARBs.

Potency vs Efficacy

- Potency is the amount of drug required to produce a given effect, measured by the EC₅₀ (the concentra-

tion producing 50% of maximal effect). Drugs with higher potency achieve effects at lower doses (e.g., fentanyl is more potent than morphine). Potency is clinically relevant for dosing but does not indicate which drug is therapeutically superior. Efficacy is the maximum effect a drug can produce at saturating concentrations, measured by the Emax (plateau of the dose-response curve). Efficacy determines the clinical utility of a drug — a drug with high efficacy can produce an effect that a low-efficacy drug cannot. For example, morphine (high efficacy mu-opioid agonist) can relieve severe pain that codeine (low efficacy partial agonist) cannot. A drug can have high potency but low efficacy and vice versa.

Pramipexole

- A non-ergot dopamine agonist (D2/D3) used for Parkinson disease (as monotherapy in early disease or adjunct to levodopa) and restless legs syndrome. Activates striatal dopamine receptors. Adverse effects: nausea, orthostatic hypotension, somnolence (sudden sleep attacks—caution driving), impulse control disorders (pathological gambling, hypersexuality—important to warn), hallucinations, and leg edema. Renally cleared—reduce dose in renal impairment. Ropinirole and rotigotine (patch) are alternatives.

Prazosin

- A selective alpha-1 adrenergic antagonist causing vasodilation and reduced peripheral resistance. Used for hypertension, benign prostatic hyperplasia, and post-traumatic stress disorder-related nightmares (off-label). Marked first-dose orthostatic hypotension/syncope—start low and take at bedtime. Adverse effects: dizziness, orthostatic hypotension, headache, palpitations, and priapism (rare). Not first-line for hypertension but useful in combination. Shorter-acting than doxazosin/terazosin.

Prescription

- A written or electronic order by a licensed prescriber (physician, NP, PA, dentist) authorizing a pharmacy to dispense a specific drug to a specific patient. Components: patient identifiers, drug name, dose, route, frequency, quantity, refills, and prescriber signature. Controlled substances require DEA numbers and are scheduled by abuse potential (Schedule II-V). Prescription medications are regu-

lated to ensure safety, require professional supervision, and are dispensed with labeling and counseling. Errors in prescribing are a leading cause of adverse drug events.

Prescription Drug

- A medication that can only be dispensed with a valid prescription from a licensed healthcare provider, requiring professional oversight due to the drug's complexity, toxicity, or potential for harm. Prescription drugs undergo rigorous FDA approval through clinical trials (Phase I-IV) to establish safety and efficacy before marketing. Examples include antibiotics, antihypertensives, antidepressants, and most psychotropic medications. Prescribing requires consideration of indication, dosing, drug interactions, and monitoring parameters.

Prescription Medications

- Pharmaceutical drugs that require authorization from a licensed healthcare provider before they can be dispensed to a patient. These medications are regulated because they carry risks that necessitate professional oversight, including potential side effects, drug interactions, and the need for precise dosing. Physicians prescribe them based on a specific diagnosis, and patients must follow the prescribed regimen closely to achieve therapeutic benefits while minimizing adverse outcomes.

Procalcitonin-guided antibiotic therapy

- The use of procalcitonin levels to guide initiation and discontinuation of antibiotics. Procalcitonin is a biomarker that rises in bacterial infections and falls with effective treatment. Elevated levels support the need for antibiotic therapy, while declining levels support discontinuation. Procalcitonin-guided protocols have been shown to reduce antibiotic duration and exposure in respiratory infections and sepsis. The approach is most validated for lower respiratory tract infections and sepsis; however, false-positive results can occur in non-infectious inflammatory conditions and false-negative results in localized infections, so procalcitonin should be used as an adjunct to, rather than a replacement for, clinical judgement.

Prodrug

- A prodrug is a pharmacologically inactive com-

pound that is converted to an active drug through metabolic processes within the body. Prodrugs are designed to overcome limitations of the parent drug including poor bioavailability, rapid metabolism, lack of tissue selectivity, or unacceptable side effects. Examples include enalapril, which is hydrolyzed by hepatic esterases to the active form enalaprilat, an ACE inhibitor that is poorly absorbed orally; clopidogrel, which requires CYP2C19-mediated activation to its active metabolite; and valacyclovir, which undergoes hepatic hydrolysis to acyclovir, significantly improving oral bioavailability from 20% to 55%.

Propafenone

- A class IC antiarrhythmic with sodium channel blockade and weak beta-blocking activity. Used for paroxysmal atrial fibrillation (in patients without structural heart disease, including ‘pill-in-the-pocket’), supraventricular tachycardias, and ventricular arrhythmias. Contraindicated in ischemic heart disease, structural heart disease, and significant LV dysfunction (proarrhythmia). Metabolized by CYP2D6 (poor metabolizers need lower doses). Adverse effects: proarrhythmia, dizziness, metallic taste, bronchospasm (weak beta-blockade), and GI upset.

Propylthiouracil (PTU)

- A thioamide antithyroid drug that inhibits thyroid peroxidase (hormone synthesis) and blocks peripheral T4-to-T3 conversion. Used for hyperthyroidism/Graves disease—preferred in the first trimester of pregnancy (lower teratogenicity than methimazole) and in thyroid storm. Adverse effects: agranulocytosis, hepatotoxicity (fulminant hepatitis—black-box warning, more than methimazole), ANCA vasculitis, rash, and arthralgia. Requires monitoring of CBC and LFTs. Longer action allows less frequent dosing.

Protease Inhibitors

- A class of antiviral drugs that block viral proteases, enzymes essential for processing viral polyproteins into functional components needed for viral assembly and maturation. In HIV treatment, protease inhibitors including ritonavir, lopinavir, atazanavir, and darunavir inhibit HIV-1 protease, preventing the cleavage of Gag and Gag-Pol polyproteins into

structural proteins and enzymes. This results in the production of immature, non-infectious viral particles. Protease inhibitors are also used in the treatment of hepatitis C, where NS3/4A protease inhibitors including simeprevir, grazoprevir, and glecaprevir block viral polyprotein processing and are used in combination with other direct-acting antiviral agents to achieve high rates of sustained virological response.

Protein Binding

- The reversible association of drug molecules with plasma proteins, primarily albumin for acidic drugs and alpha-1 acid glycoprotein for basic drugs. Only unbound or free drug is pharmacologically active and available for distribution to tissues, metabolism by the liver, and excretion by the kidneys. The fraction of drug bound to protein is described by the binding ratio, which depends on the total drug concentration, total protein concentration, and the association constant; changes in protein binding can significantly affect drug disposition, particularly for highly bound drugs (greater than 90% bound), where small changes in binding can lead to large changes in free drug concentration, potentially affecting both efficacy and toxicity.

Proton Pump Inhibitor

- A class of medications that irreversibly inhibit the gastric H⁺/K⁺ ATPase (proton pump) in parietal cells, the final common pathway of gastric acid secretion, producing profound and sustained suppression of both basal and stimulated acid production. PPIs are prodrugs that require activation in the acidic environment of the parietal cell canaliculus, where they form a sulfenamide that binds covalently to cysteine residues of the proton pump. Available agents: omeprazole, lansoprazole, pantoprazole, rabeprazole, esomeprazole, and dexlansoprazole. Indications: gastroesophageal reflux disease (GERD), erosive esophagitis, peptic ulcer disease, *Helicobacter pylori* eradication (with antibiotics), Zollinger-Ellison syndrome, and prevention of NSAID-induced ulcers. Adverse effects: increased risk of *Clostridioides difficile* infection, pneumonia, hypomagnesemia, vitamin B12 deficiency, and osteoporosis-related fractures with long-term use. Rebound acid hypersecretion occurs upon discontinuation after >8 weeks of use.

Proton Pump Inhibitors (PPIs)

- A class of antisecretory drugs (e.g., omeprazole, lansoprazole, pantoprazole, esomeprazole) that irreversibly inhibit the H^+/K^+ ATPase enzyme (proton pump) in gastric parietal cells. Prodrugs activated in the acidic canaliculi of parietal cells. Indications: GERD, peptic ulcer disease, *H. pylori* eradication (triple therapy), Zollinger-Ellison syndrome, NSAID-induced ulcer prophylaxis. Long-term adverse effects: hypomagnesemia, Vitamin B12 deficiency, increased risk of *Clostridioides difficile* infection, hip fractures (decreased calcium absorption), and interstitial nephritis.

Pseudoephedrine

- A sympathomimetic (alpha-1 agonist, some beta effects) oral decongestant used for nasal congestion in colds and sinusitis. Increases nasal mucosal vasoconstriction. Adverse effects: insomnia, nervousness, tachycardia, hypertension, and urinary retention (BPH); avoid in uncontrolled hypertension, severe CAD, hyperthyroidism, and with MAOIs. Schedule/POS (behind-the-counter) in the US due to methamphetamine precursor use. Phenylephrine (oral) is an alternative with less efficacy.

Pseudomonas aeruginosa resistance

- *Pseudomonas aeruginosa* has intrinsic and acquired resistance mechanisms making it inherently resistant to many antibiotics. Intrinsic resistance includes low outer membrane permeability, efflux pumps, and chromosomal beta-lactamase. Acquired resistance can develop through mutations in target genes, acquisition of resistance plasmids, and overexpression of efflux pumps. Treatment typically requires antipseudomonal beta-lactams (piperacillin-tazobactam, cefepime, ceftazidime, carbapenems) or fluororoquinolones (ciprofloxacin, levofloxacin), often in combination therapy due to the high rate of resistance emergence during monotherapy; susceptibility testing is essential to guide treatment decisions.

Psittacosis

- See infectious disease.

QT Prolongation

- An electrocardiographic finding characterized by prolongation of the QT interval, representing the

time from ventricular depolarization to repolarization, which predisposes to the potentially fatal arrhythmia torsades de pointes. The corrected QT interval should be less than 440 milliseconds in men and 460 milliseconds in women. Numerous medications can prolong the QT interval by blocking the cardiac potassium channel encoded by the *KCNH2* gene, prolonging phase 3 of the cardiac action potential, prolonging repolarisation and increasing the risk of triggered activity, torsades de pointes, and sudden cardiac death; risk factors include female sex, advanced age, electrolyte disturbances (hypokalaemia, hypomagnesaemia), bradycardia, structural heart disease, and the use of multiple QT-prolonging medications.

Quinine

- An alkaloid derived from cinchona bark, with antimalarial, antipyretic, and skeletal muscle relaxant properties. Quinine is a blood schizonticide with activity against all *Plasmodium* species, but resistance has emerged in *P. falciparum*. Current indications: (1) Treatment of severe/complicated *falciparum* malaria (WHO—quinine IV infusion plus doxycycline or clindamycin; artesunate IV is now preferred due to lower mortality). (2) Babesiosis (combined with clindamycin). (3) Nocturnal leg cramps (used off-label—risk of serious adverse effects outweighs benefit; only if cramps are disabling and no alternative exists). Mechanism: accumulates in the parasite's food vacuole, inhibits haem polymerase, and prevents detoxification of haem (toxic to the parasite). Side effects: cinchonism (tinnitus, dizziness, headache, nausea, visual disturbances—dose-related, reversible), QT prolongation, hypoglycaemia (stimulates insulin secretion—dangerous in severe malaria), hypersensitivity (urticaria, flushing, hemolytic anemia), blackwater fever (massive intravascular haemolysis—rare, idiosyncratic). Contraindications: G6PD deficiency (hemolytic anemia), QT prolongation, myasthenia gravis, optic neuritis. Therapeutic range: 8–15 $\mu\text{g}/\text{mL}$. Quinine is also used in tonic water (bitter flavouring, subtherapeutic concentrations).

Quinupristin-dalfopristin

- A combination streptogramin antibiotic that inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. The combination is bacteri-

cidal against most gram-positive organisms including MRSA. It is indicated for vancomycin-resistant *Enterococcus faecium* infections. The drug is administered intravenously every 8-12 hours. Common adverse effects include arthralgia, myalgia, and infusion-related reactions including phlebitis. The drug is a potent inhibitor of CYP3A4 and can interact with numerous medications, particularly those that inhibit CYP3A4 and prolong the QT interval.

Receptor Desensitization

- A rapid decrease in the response of a receptor to continuous or repeated agonist stimulation, occurring within minutes to hours. Desensitization mechanisms: receptor phosphorylation by G protein-coupled receptor kinases which uncouples the receptor from G proteins, leading to rapid functional desensitization; beta-arrestin binding which sterically prevents G protein coupling and targets the receptor for internalization; receptor internalization (endocytosis) into intracellular compartments, reducing cell-surface receptor number; and receptor degradation (downregulation) after prolonged stimulation, reducing total receptor protein. Desensitization contributes to drug tolerance (e.g., beta-agonist desensitization in asthma, opioid receptor desensitization in chronic pain) and can be reversed by removing the agonist, allowing receptor recycling to the cell surface.

Renin Inhibitor

- A class of antihypertensive drugs that directly inhibit renin, the first and rate-limiting enzyme in the renin-angiotensin-aldosterone system. Renin catalyzes the conversion of angiotensinogen to angiotensin I, which is then converted to angiotensin II by ACE. Aliskiren is the only direct renin inhibitor available. It binds to the active site of renin, preventing angiotensinogen cleavage and reducing angiotensin I, angiotensin II, and aldosterone levels. Indication: hypertension. Aliskiren is used alone or in combination with other antihypertensives. Adverse effects: diarrhea (especially at higher doses), cough, hyperkalemia, and angioedema. Contraindicated in pregnancy (fetal renin-angiotensin system toxicity). Combination with ACE inhibitors or ARBs in diabetic patients with renal impairment is contraindicated due to increased risk of hyperkalemia, hypotension, and renal impairment.

Rezafungin

- A long-acting echinocandin antifungal agent used in the treatment of invasive candidiasis and candidemia. Rezafungin inhibits beta-(1,3)-D-glucan synthase with a unique pharmacokinetic profile characterized by an extremely long half-life of approximately 130 hours, allowing for once-weekly dosing after an initial loading regimen. This extended dosing interval is a significant advantage over other echinocandins and may improve adherence. The drug has excellent stability in solution and can be stored at room temperature, maintaining potency during extended infusion periods; common adverse effects include headache, nausea, diarrhea, and hypokalaemia; hepatotoxicity has been observed in clinical trials.

Ritalin

- A central nervous system stimulant, a piperidine derivative that blocks the reuptake of dopamine and noradrenaline (norepinephrine) by inhibiting the dopamine transporter (DAT) and noradrenaline transporter (NAT) in the prefrontal cortex, increasing their synaptic concentrations. See Methylphenidate.

Rivaroxaban

- A direct oral anticoagulant and selective factor Xa inhibitor. Used for stroke prevention in nonvalvular atrial fibrillation, treatment/prophylaxis of venous thromboembolism, and thromboprophylaxis after hip/knee replacement. Fixed once-daily dosing, rapid onset, no routine monitoring. Reduces dose in renal impairment (avoid if CrCl <15-30 depending on indication) and with strong CYP3A4/P-gp inhibitors. Adverse effects: bleeding; reversal agent: andexanet alfa. Avoid in mechanical valves and moderate/severe mitral stenosis.

Ropinirole

- A non-ergot dopamine agonist (D2/D3) used for Parkinson disease and restless legs syndrome. Adverse effects: nausea, dizziness, somnolence (sudden sleep attacks), orthostatic hypotension, impulse control disorders (gambling, hypersexuality), hallucinations, and leg edema. Extended-release for once-daily Parkinson dosing. Renally cleared (caution in renal impairment). Dose slowly; risk of augmentation in restless legs syndrome with long-term

use.

Route of Administration

- The path by which a drug enters the body, influencing absorption, onset, bioavailability, and first-pass metabolism. Enteral routes: oral, sublingual, buccal, rectal. Parenteral: intravenous (100 percent bioavailability, immediate onset), intramuscular, subcutaneous, intradermal. Other routes: inhalation, topical/transdermal, ophthalmic, otic, intranasal, vaginal, intrathecal, and intra-articular. Choice depends on drug properties (stability, absorption), therapeutic goal, and patient factors. Oral is most convenient; IV is used for emergencies and drugs with poor oral absorption.

Sedative

- A medication that reduces central nervous system activity, producing calming effects, drowsiness, and sleep at higher doses. Sedatives are used for anxiety, procedural sedation, insomnia, and as adjuncts in anesthesia. Classes include: benzodiazepines (midazolam, lorazepam, diazepam) — enhance GABA-A receptor activity, used for sedation, anxiolysis, and amnesia; barbiturates (phenobarbital, thiopental) — enhance GABA-A activity with broader CNS depression, largely replaced by benzodiazepines due to narrow therapeutic index and high dependence potential; propofol — an IV anesthetic that potentiates GABA-A receptors, rapid onset and offset, used for procedural sedation and general anesthesia; dexmedetomidine — an alpha-2 agonist producing sedation with minimal respiratory depression; and chloral hydrate — older sedative/hypnotic used for short-term sedation in children.

Selective Estrogen Receptor Modulator

- A class of medications that bind to estrogen receptors (ER-alpha and ER-beta) with tissue-specific agonist or antagonist activity, depending on the target tissue and differential co-regulator recruitment. Tamoxifen: antagonist in breast tissue (first-line adjuvant therapy for hormone receptor-positive breast cancer in premenopausal women), partial agonist in bone (preserves bone density) and endometrium (increases risk of endometrial cancer and hyperplasia), and improves lipid profile. Raloxifene: antagonist in breast and agonist in bone without endometrial

stimulation (used for osteoporosis prevention and treatment in postmenopausal women, reduces breast cancer risk). Toremifene: similar to tamoxifen for metastatic breast cancer. Bazedoxifene: used for postmenopausal osteoporosis, often combined with conjugated estrogens (duavee). Adverse effects: tamoxifen — hot flashes, vaginal dryness, and thromboembolism (2-3% risk). SERMs do not cause the systemic side effects of estrogen therapy.

Selegiline

- A selective, irreversible MAO-B inhibitor used for Parkinson disease (mild early disease or adjunct to levodopa) and (as oral disintegrating/selegiline transdermal) for depression. Sparing MAO-A in the gut at low oral doses, reducing tyramine risk (still require dietary precautions with higher doses or patch). Adverse effects: nausea, insomnia, dyskinesias, hypotension, and interactions with opioids (meperidine—serotonin syndrome) and SSRIs/SNRIs (avoid overlap).

Senna

- A stimulant laxative containing anthraquinone glycosides (sennosides) that are activated by colonic bacteria to stimulate colonic motility and fluid secretion. Onset: 6-12 hours; used for constipation and bowel preparation. Common side effects: abdominal cramps, nausea; chronic use may cause melanosis coli and electrolyte disturbances. Safe in pregnancy (short-term) and generally first-line among stimulants. Available as tablets, syrup, and suppositories.

Sertraline

- A selective serotonin reuptake inhibitor (SSRI) used for major depressive disorder, panic disorder, PTSD, OCD, social anxiety disorder, and premenstrual dysphoric disorder. Effective and well tolerated; mild CYP2D6 inhibition. Adverse effects: nausea, diarrhea, insomnia, sexual dysfunction, and hyponatremia (elderly); serotonin syndrome and discontinuation syndrome (taper); black-box warning for suicidality in young adults. Once-daily dosing; available in pregnancy-adjacent indications (postpartum depression) with monitoring.

SGLT2 Inhibitors

- Sodium-glucose co-transporter 2 inhibitors are a class of oral antidiabetic agents that block the re-

absorption of glucose in the proximal convoluted tubule of the kidney, promoting glycosuria and reducing blood glucose levels. The kidney normally filters approximately 180 grams of glucose daily, with SGLT2 responsible for approximately 90 percent of glucose reabsorption. By blocking this transporter, SGLT2 inhibitors increase urinary glucose excretion by 60 to 80 grams per day. Common agents include dapagliflozin, empagliflozin, and canagliflozin. In addition to glycaemic control, SGLT2 inhibitors have demonstrated significant cardiovascular and renal benefits in major outcome trials, reducing the risk of heart failure hospitalisation and progression of chronic kidney disease, making them an important treatment option in patients with type 2 diabetes and established cardiovascular or renal disease.

Side Effect

- An unintended pharmacological effect of a drug occurring at therapeutic doses, usually predictable from the drug's mechanism of action (a Type A reaction). Side effects are dose-dependent and may be bothersome but are often tolerable or transient (e.g., dry mouth with anticholinergics, sedation with antihistamines, cough with ACE inhibitors, GI upset with antibiotics). Side effects differ from toxicity (excessive dose), allergic reactions, and idiosyncratic reactions. Management includes dose reduction, alternate dosing, adjunctive treatment, or switching drugs.

Sleep Medications and Supplements

- Pharmacological agents used to treat insomnia and other sleep disorders when behavioral interventions alone are insufficient. Prescription sleep aids include benzodiazepine receptor agonists such as zolpidem, melatonin receptor agonists, and low-dose sedating antidepressants, while common over-the-counter options include antihistamines and melatonin supplements. These agents should be used with caution due to risks of dependence, tolerance, daytime drowsiness, and potential interactions with other medications, and are typically recommended for short-term use under medical supervision.

Solution

- A homogeneous mixture in which a drug (solute) is

dissolved in a liquid vehicle (solvent, usually water, saline, alcohol, or polyethylene glycol). Solutions provide rapid absorption (oral solutions, parenteral IV solutions), ease of swallowing, and flexible dosing; they require preservatives and have limited stability. Used for oral (syrups, drops), injectable (IV/IM), topical, ophthalmic, otic, and nasal administration. Contrast with suspensions (particles) and emulsions. Isotonicity, pH, and sterility are important for parenteral and ophthalmic solutions.

Somatostatin Analog

- A class of synthetic peptides that mimic the actions of native somatostatin, a hormone that inhibits the secretion of growth hormone, thyroid-stimulating hormone, insulin, glucagon, gastrin, and other GI hormones. Octreotide (short-acting, subcutaneous TID) and lanreotide (long-acting, IM every 4 weeks) are somatostatin analogs with longer half-lives (1-2 hours for octreotide vs. 2-3 minutes for native somatostatin). Indications: acromegaly — suppress GH and IGF-1 levels, reduce tumor size; neuroendocrine tumors (carcinoid syndrome, VIPoma, glucagonoma) — control hormone-related symptoms and may slow tumor growth; variceal bleeding — reduce splanchnic blood flow (octreotide infusion); and refractory diarrhea from chemotherapy or short bowel syndrome. Adverse effects: gallstones (25-50% due to inhibition of gallbladder contraction), bradycardia, hyperglycemia/hypoglycemia, and GI symptoms.

Spirolactone

- A nonselective aldosterone (mineralocorticoid) receptor antagonist and potassium-sparing diuretic. Used for heart failure with reduced ejection fraction (NYHA II-IV—reduces mortality, often with ACE/ARB + beta-blocker), resistant hypertension, primary hyperaldosteronism, ascites in cirrhosis, and acne/hirsutism in women (off-label). Adverse effects: hyperkalemia, gynecomastia (common, limiting), breast tenderness, menstrual irregularities, and hypotension. Monitor potassium and renal function; avoid with potassium supplements and strong potassium-raising drugs.

SSRIs

- Selective serotonin reuptake inhibitors are a class of antidepressant drugs that selectively inhibit the

reuptake of serotonin from the synaptic cleft into the presynaptic neuron by blocking the serotonin transporter, increasing serotonergic neurotransmission. Common SSRIs include fluoxetine, sertraline, paroxetine, citalopram, escitalopram, and fluvoxamine. They are first-line agents for major depressive disorder, generalized anxiety disorder, panic disorder, obsessive-compulsive disorder, posttraumatic stress disorder, premenstrual dysphoric disorder, and bulimia nervosa. Common adverse effects include nausea, insomnia, sexual dysfunction, and weight changes; SSRIs have a favourable safety profile in overdose compared to TCAs and MAOIs, making them the preferred first-line pharmacotherapy for most depressive and anxiety disorders.

Steady State

- The condition where the rate of drug administration equals the rate of elimination, resulting in constant average plasma concentrations with repeated dosing. During regular dosing at fixed intervals, steady state is achieved after approximately 4 to 5 half-lives, regardless of the dosing frequency or dose size. At steady state, the peak and trough concentrations fluctuate within a therapeutic range, with the degree of fluctuation determined by the dosing interval relative to the drug's half-life; the concept of steady state is fundamental to therapeutic drug monitoring and ensures that drug concentrations remain within therapeutic window for optimal efficacy and safety.

Stenotrophomonas maltophilia resistance

- *Stenotrophomonas maltophilia* is a gram-negative bacterium with intrinsic resistance to many antibiotics including carbapenems. The organism produces a chromosomal beta-lactamase (L1) that confers resistance to beta-lactams. Treatment options include trimethoprim-sulfamethoxazole, fluoroquinolones, and minocycline. *S. maltophilia* is an emerging opportunistic pathogen, particularly in immunocompromised patients and those with cystic fibrosis. The organism forms biofilms and is resistant to many disinfectants, contributing to its persistence in healthcare environments; treatment requires combination therapy based on susceptibility testing, and antimicrobial stewardship is critical for preserving the limited treatment options available

for this organism.

Stevens-Johnson Syndrome

- A severe, life-threatening mucocutaneous reaction characterized by widespread skin erythema, necrosis, and bullae formation with mucosal involvement (oral, ocular, genital). See [cardiology](#).

Streptokinase

- A thrombolytic agent that forms a plasminogen activator complex, converting plasminogen to plasmin and lysing fibrin clots. Used for STEMI, massive pulmonary embolism, and deep vein thrombosis (largely replaced by tissue plasminogen activator, which is more fibrin-specific and less antigenic). Given IV; associated with allergic reactions and antibodies after prior exposure (reduced efficacy with repeat use). Bleeding is the major adverse effect; contraindicated in active hemorrhage, recent surgery, and intracranial pathology.

Sulfonamide

- A class of antibiotics (sulfamethoxazole, sulfadiazine, sulfasalazine) that inhibit bacterial dihydropteroate synthase, blocking folate synthesis—bacteriostatic. Often combined with trimethoprim (co-trimoxazole: TMP-SMX). Used for UTIs, PCP (pneumocystis pneumonia), toxoplasmosis, Nocardia, and MRSA. Adverse effects: hypersensitivity reactions (rash, Stevens-Johnson syndrome), crystaluria (hydrate, alkalinize), photosensitivity, hemolysis in G6PD deficiency, and hyperkalemia (TMP). Avoid in sulfa allergy and in pregnancy near term.

Sulfonamides

- A class of bacteriostatic antibiotics that competitively inhibit dihydropteroate synthase, an enzyme essential for folic acid synthesis in bacteria. They are structural analogs of para-aminobenzoic acid and compete with PABA for the active site of the enzyme. Trimethoprim is combined with sulfamethoxazole to produce synergistic bactericidal activity by blocking sequential steps in folate synthesis. Co-trimoxazole, the combination of trimethoprim and sulfamethoxazole, is used for urinary tract infections, *Pneumocystis jirovecii* pneumonia, and other infections; hypersensitivity reactions to sulfonamides are common, particularly in patients with HIV infection, and range from mild rash to severe cutaneous adverse drug reactions including Stevens-Johnson

syndrome.

Sulfonylureas

- Oral antidiabetic agents that stimulate insulin secretion from pancreatic beta cells by blocking ATP-sensitive potassium channels on the beta cell membrane. This causes membrane depolarization, opening of voltage-gated calcium channels, calcium influx, and exocytosis of insulin-containing granules. They are effective at lowering blood glucose but carry a risk of hypoglycemia because they stimulate insulin secretion regardless of glucose levels. First-generation sulfonylureas include tolbutamide and chlorpropamide; second-generation sulfonylureas including glipizide, glyburide, and glimepiride are more potent, have a more favourable side effect profile, and are dosed once or twice daily. Sulfonylureas remain an important treatment option for type 2 diabetes, particularly in resource-limited settings where cost is a significant consideration.

Sulphonamides

- A class of antimicrobial agents containing the sulfonamide group (SO_2NH_2). Sulphonamides were the first effective systemic antibacterial agents (Prontosil, 1935—Gerhard Domagk). Mechanism: competitive inhibition of dihydropteroate synthase, blocking folate synthesis (para-aminobenzoic acid analogue)—bacteriostatic. Spectrum: broad—Gram-positive (*Streptococcus*, *Staphylococcus*), Gram-negative (*E. coli*, *Klebsiella*, *Haemophilus*, *Nocardia*), and some protozoa (*Toxoplasma*, *Plasmodium*). Clinical uses: (1) Sulfamethoxazole combined with trimethoprim (co-trimoxazole)—first-line for *Pneumocystis jirovecii* pneumonia (PCP), *Nocardia*, *Toxoplasma* encephalitis, and UTIs. (2) Sulfadiazine—with pyrimethamine for toxoplasmosis. (3) Sulfasalazine—used in inflammatory bowel disease and rheumatoid arthritis (5-ASA prodrug). (4) Mafenide and silver sulfadiazine—topical for burn wounds. (5) Sulfacetamide—ophthalmic drops for conjunctivitis. Adverse effects: hypersensitivity reactions (rash, Stevens–Johnson syndrome/toxic epidermal necrolysis—rare but life-threatening, fever, serum sickness), crystalluria (prevented by adequate hydration and urine alkalinisation—risk with older, less soluble sulphonamides), hemolytic anemia in G6PD deficiency, bone marrow suppres-

sion, photosensitivity, and kernicterus in neonates (displaces bilirubin from albumin—contraindicated in pregnancy, breastfeeding, and infants <2 months). Drug interactions: potentiates warfarin, methotrexate, and sulfonylureas.

Suppository

- A solid, single-dose dosage form designed to be inserted into a body orifice (rectum, vagina, or urethra) where it melts, softens, or dissolves, releasing the active pharmaceutical ingredient for local or systemic effects. Rectal suppositories (the most common): base materials (cocoa butter/theobroma oil, hard fat/Witepsol, glycerogelatin, polyethylene glycol). Indications: local—hemorrhoids (anusoal, hydrocortisone), constipation (glycerol, bisacodyl); systemic—antiemetics (prochlorperazine, promethazine), antipyretics/analgesics (paracetamol, diclofenac), bronchodilators (theophylline), and antiemetics when oral route is unavailable (nausea/vomiting, post-operative). Advantages: bypasses first-pass hepatic metabolism (some drugs achieve higher bioavailability), useful when oral route is unavailable (NPO, vomiting, unconscious patients), and avoids GI irritation. Insertion: supine or lateral position, push past the internal anal sphincter, retain for 15–30 minutes. Vaginal suppositories (pessaries): for local treatment of vaginal infections (clotrimazole, metronidazole, oestrogen) and contraception.

Suspension

- A pharmaceutical formulation in which fine solid drug particles are dispersed (not dissolved) in a liquid vehicle, often with suspending agents and stabilizers. Suspensions are used when a drug is poorly soluble, for oral (antibiotic suspensions, antacids), topical, ophthalmic, and parenteral (depot) administration. They require shaking before use to ensure uniform dosing and may settle over time. Bioavailability depends on particle size. Contrast with solutions (dissolved) and emulsions (liquid-liquid).

Sympatholytic

- An agent that blocks the sympathetic nervous system, used to treat hypertension, sympathetic overactivity, and catecholamine excess. Classes: beta-blockers (propranolol, metoprolol), alpha-blockers (prazosin, doxazosin, phenoxybenzamine), centrally

acting agents (clonidine, methyldopa), and neuron blockers (reserpine, guanethidine). Effects: reduced heart rate and contractility, vasodilation, lowered blood pressure, and reduced sympathetic reflexes. Adverse effects: bradycardia, hypotension, fatigue, bronchospasm (beta-blockers in asthma), and rebound hypertension on abrupt withdrawal.

Tablet

- A solid dosage form of compressed drug plus excipients (binders, fillers, disintegrants, lubricants, coatings). Types: immediate-release, enteric-coated (resistant to gastric acid), sustained/controlled-release, sublingual, buccal, effervescent, chewable, and orally disintegrating. Tablets provide dose accuracy, stability, ease of administration, and mass production. They should generally not be crushed (sustained-release/enteric forms) unless directed. Some tablets are scored for splitting.

Tedizolid pharmacokinetics

- Tedizolid has a longer half-life than linezolid, allowing for once-daily dosing. The drug has approximately 90% oral bioavailability. Tedizolid is metabolized to an active metabolite (tzd-M1) that contributes to efficacy. The drug achieves high concentrations in skin and soft tissues. Tedizolid does not inhibit monoamine oxidase to the same degree as linezolid, reducing drug interaction potential. The drug is excreted primarily in feces.

Teicoplanin

- A glycopeptide antibiotic related to vancomycin with a longer half-life allowing for less frequent dosing. Teicoplanin inhibits cell wall synthesis by binding to D-Ala-D-Ala precursors. It has activity against gram-positive organisms including MRSA. The drug is administered intravenously or intramuscularly, with once-daily or less frequent dosing after loading. Common adverse effects include injection site reactions, rash, and nephrotoxicity. Teicoplanin achieves higher tissue concentrations than vancomycin, making it useful for deep-seated infections including bone and joint infections, endocarditis, and prosthetic device infections; teicoplanin is not available in the United States but is widely used in Europe and other regions.

Tenecteplase

- A modified tissue plasminogen activator (TNK-

tPA) thrombolytic with longer half-life, higher fibrin specificity, and resistance to PAI-1. Used for acute ischemic stroke and STEMI. Given as a single IV bolus (weight-based), simplifying administration. Adverse effects: hemorrhage (intracranial—major concern), allergic reactions. Contraindications: active bleeding, recent surgery/trauma, uncontrolled hypertension, and intracranial pathology. Time to treatment is critical.

Teratogenicity

- The ability of a drug, chemical, or infectious agent to cause birth defects or developmental abnormalities when exposure occurs during pregnancy. The risk of teratogenic effects depends on the timing of exposure, with the embryonic period from 3 to 8 weeks after fertilization being the most critical for organogenesis. Certain drugs have well-established teratogenic effects: thalidomide causes limb defects, isotretinoin causes craniofacial, cardiac, and CNS abnormalities, and sodium valproate is associated with neural tube defects; the management of drug therapy during pregnancy requires careful risk-benefit assessment, minimising exposure during organogenesis whenever possible, and using alternative agents with established safety profiles for the treatment of chronic conditions in women of childbearing potential.

Terazosin

- A selective alpha-1 adrenergic blocker causing vascular and prostatic smooth muscle relaxation. Used for benign prostatic hyperplasia (improves urinary flow) and hypertension. Adverse effects: first-dose orthostatic hypotension/syncope (start low, at bedtime), dizziness, nasal congestion, and fatigue. Not first-line for hypertension but useful in men with BPH. Doxazosin and prazosin are related alpha-blockers.

Terbinafine

- An allylamine antifungal agent that inhibits squalene epoxidase, an early enzyme in the ergosterol biosynthesis pathway, causing accumulation of squalene and depletion of ergosterol in the fungal cell membrane. The accumulation of squalene is fungicidal, while ergosterol depletion disrupts membrane function. Terbinafine has excellent activity against dermatophytes including *Trichophyton*, *Microspo-*

rum, and Epidermophyton species, making it the treatment of choice for dermatophyte infections of the skin and nails. Unlike azole antifungals, terbinafine does not significantly inhibit CYP450 enzymes and has a lower potential for drug interactions; adverse effects include mild gastrointestinal disturbances, headache, and taste disturbance, with rare cases of hepatotoxicity requiring periodic liver function monitoring during prolonged therapy.

Tetracyclines

- A class of bacteriostatic antibiotics that bind reversibly to the 30S ribosomal subunit and block the attachment of aminoacyl-tRNA to the acceptor site, inhibiting protein synthesis. They include tetracycline, doxycycline, and minocycline. Tetracyclines have a broad spectrum of activity against gram-positive and gram-negative bacteria, atypical organisms including Chlamydia, Mycoplasma, and Rickettsia, and the malaria parasite. Doxycycline is the most commonly used tetracycline for clinical use, with excellent oral bioavailability, favourable pharmacokinetics allowing once- or twice-daily dosing, and a well-established safety profile; tetracyclines also have anti-inflammatory and immunomodulatory properties that are independent of their antimicrobial activity and contribute to their efficacy in acne vulgaris and rosacea.

Therapeutic Drug Monitoring

- The clinical practice of measuring specific drug concentrations in blood or plasma to individualize drug dosing and ensure therapeutic effectiveness while minimizing toxicity. TDM is particularly important for drugs with narrow therapeutic indices, where small changes in concentration can lead to therapeutic failure or toxicity. Examples include aminoglycoside antibiotics where both subtherapeutic and supratherapeutic concentrations can occur, vancomycin with target trough concentrations for vancomycin requiring trough monitoring in the range of 10-20 mcg/mL depending on the infection type and severity; other drugs requiring TDM include digoxin, lithium, theophylline, cyclosporine, tacrolimus, and certain anticonvulsants including phenytoin and valproic acid.

Therapeutic Index

- The therapeutic index is a quantitative measure of

the relative safety of a drug, defined as the ratio of the dose that produces toxicity in 50 percent of the population to the dose that produces the desired therapeutic effect in 50 percent of the population. A wider therapeutic index indicates a larger margin of safety, meaning there is a greater difference between effective and toxic doses. Drugs with narrow therapeutic indices require careful dosing and monitoring because small changes in doses in drug concentration produce significant clinical consequences; drugs with narrow therapeutic indices require individualised dosing based on patient factors, therapeutic drug monitoring, and careful management of drug interactions to maintain concentrations within the therapeutic window and avoid toxicity.

Therapeutics

- The branch of medicine concerned with the treatment of disease, encompassing all interventions used to prevent, manage, or cure illness. Therapeutics includes: pharmacotherapy (drug treatment—most common), surgery (therapeutic procedures), radiotherapy (ionizing radiation for cancer), physical therapy (physiotherapy, rehabilitation), psychological therapy (CBT, psychotherapy), gene and cell therapy, immunotherapy, and complementary/alternative medicine. Principles: (1) Evidence-based medicine: treatment decisions based on the best available evidence (randomised controlled trials, systematic reviews, meta-analyses, clinical guidelines). (2) Individualised therapy: patient-specific factors (age, genetics, comorbidities, concurrent medications, preferences) guide treatment choice. (3) Risk–benefit assessment: consider efficacy, safety, tolerability, cost, and quality of life. (4) Therapeutic index: the ratio of toxic to therapeutic dose; drugs with a narrow therapeutic index (warfarin, lithium, digoxin, phenytoin) require therapeutic drug monitoring. (5) Adherence/compliance: the extent to which a patient follows prescribed treatment; poor adherence (50% of chronic disease patients) is a major cause of treatment failure. (6) Polypharmacy: use of multiple medications (≥ 5) increases risk of adverse drug reactions, drug interactions, and non-adherence. (7) Deprescribing: systematic withdrawal of inappropriate or unnecessary medications.

Therapeutic Window

- The range of plasma drug concentrations between the minimum effective concentration (producing a therapeutic effect) and the minimum toxic concentration (producing toxicity), in which efficacy is achieved with acceptable toxicity. Drugs with a narrow therapeutic window (digoxin, warfarin, lithium, aminoglycosides, cyclosporine) require therapeutic drug monitoring and careful dosing because small changes in concentration cause therapeutic failure or toxicity. The width of the window relates to the therapeutic index (TD50/ED50).

Thiazide Diuretics

- Thiazide diuretics act on the distal convoluted tubule by inhibiting the sodium-chloride cotransporter, reducing sodium and chloride reabsorption and producing natriuresis and diuresis. They are less potent than loop diuretics but have a longer duration of action, typically 6 to 12 hours. Common thiazides include hydrochlorothiazide, chlorthalidone, and metolazone. Thiazides are first-line antihypertensive agents, particularly effective in elderly patients with isolated systolic hypertension and in patients of African descent; adverse effects include hypokalaemia, hyperuricaemia, hyperglycaemia, hypercalcaemia, and metabolic alkalosis, and they should be used with caution in patients with diabetes mellitus, gout, and electrolyte imbalances.

Thiopental Sodium

- An ultra-short-acting barbiturate, used for induction of general anesthesia (IV, onset 30–60 seconds, duration 5–10 minutes) and as a third-line agent for raised intracranial pressure (cerebroprotective effect: reduces cerebral metabolism, cerebral blood flow, and intracranial pressure). Mechanism: enhances GABA_A receptor activity (prolongs chloride channel opening). Side effects: dose-dependent respiratory depression, hypotension (decreased cardiac output, peripheral vasodilation), laryngospasm, and tissue necrosis/extravasation injury (highly alkaline, pH 10.5—administer through a secure IV line). Contraindications: porphyria (acute intermittent porphyria—induces haem oxygenase, precipitates attack), severe shock, status asthmaticus, and hypersensitivity to barbiturates. Thiopental was also used in lethal injection protocols (US) and for barbiturate coma (refractory intracranial hypertension).

Now largely replaced by propofol (faster recovery, fewer side effects) for routine anesthetic induction. Historical: 'truth serum' myth—thiopental reduces inhibition but does not produce truthful statements reliably.

Thrombolytic

- A drug that dissolves blood clots by activating plasminogen to plasmin, which degrades fibrin. Agents: alteplase (tPA), tenecteplase (TNK-tPA), reteplase, streptokinase, urokinase. Indications: acute ischemic stroke (within 4.5 hours), STEMI, massive pulmonary embolism, and acute limb ischemia. Administration is IV; the major risk is hemorrhage (especially intracranial). Contraindications include active bleeding, recent surgery/trauma, and uncontrolled hypertension. Time to treatment is critical for benefit.

Tigecycline

- A glycylicycline antibiotic derived from minocycline with expanded spectrum of activity. Tigecycline inhibits bacterial protein synthesis by binding to the 30S ribosomal subunit. It has activity against gram-positive organisms including MRSA and VRE, gram-negative organisms including ESBL-producing Enterobacteriaceae, and anaerobes. Tigecycline is indicated for complicated intra-abdominal infections, complicated skin infections, and community-acquired pneumonia. The drug is administered intravenously twice daily, with common adverse effects including nausea, vomiting, abdominal pain, and hepatotoxicity; tigecycline carries a FDA black box warning for increased all-cause mortality compared to comparator agents, particularly in patients treated for hospital-acquired pneumonia, and should be reserved for situations where alternative treatment options are limited or inadequate.

Tolbutamide

- A first-generation sulfonylurea oral hypoglycaemic agent used in the management of type 2 diabetes. Mechanism: stimulates insulin secretion from pancreatic β -cells by binding to the sulfonylurea receptor (SUR1) on ATP-sensitive potassium (K_{ATP}) channels, causing membrane depolarisation, calcium influx, and exocytosis of insulin granules. Tolbutamide has a short half-life (4–7 hours) and is metabolized by the liver to inactive metabolites (CYP2C9).

It is less potent and shorter-acting than second-generation sulfonylureas (glibenclamide/glyburide, gliclazide, glipizide, glimepiride). Clinical use: now rarely used (largely replaced by newer sulfonylureas and other oral agents). Indication: adjunct to diet and exercise in type 2 diabetes when metformin is contraindicated or not tolerated. Side effects: hypoglycaemia (less frequent than with longer-acting sulfonylureas), weight gain, and hypersensitivity reactions (rash, photosensitivity). The University Group Diabetes Program (UGDP) trial (1970s) suggested an increased cardiovascular mortality with tolbutamide, though this finding has been disputed. Drug interactions: potentiates effect of alcohol (disulfiram-like reaction), warfarin, and NSAIDs; diminished effect with thiazide diuretics, corticosteroids, and rifampicin.

Tolerance

- A decreased response to a drug after repeated administration, requiring dose escalation to achieve the same effect. Unlike tachyphylaxis, tolerance develops over weeks to months of chronic use. The mechanisms include pharmacokinetic tolerance from increased drug metabolism through enzyme induction, pharmacodynamic tolerance from receptor down-regulation and desensitization, and learned or behavioral tolerance from compensatory physiological responses. Opioid tolerance is a major clinical challenge in chronic pain management, leading to the need for gradual dose escalation, careful assessment of risk versus benefit, and the use of multidisciplinary approaches including non-opioid analgesics, interventional procedures, and behavioural therapies.

Torsemide

- A potent loop diuretic inhibiting the Na-K-2Cl cotransporter in the loop of Henle. Used for edema in heart failure, cirrhosis, and renal disease, and hypertension. More consistently absorbed than furosemide; long duration; oral-to-IV conversion is nearly 1:1. May have less mortality effect than furosemide in heart failure trials. Adverse effects: hypokalemia, hyponatremia, hypomagnesemia, hypocalcemia, dehydration, ototoxicity, and hyperuricemia. Half-life 3-4 hours (longer in renal/hepatic failure).

TPMT Polymorphism

- Thiopurine S-methyltransferase is an enzyme that metabolizes thiopurine drugs including azathioprine, 6-mercaptopurine, and thioguanine, which are used in the treatment of leukemia, inflammatory bowel disease, and autoimmune conditions. TPMT catalyzes the S-methylation of thiopurines, diverting them away from the formation of active thioguanine nucleotides that cause cytotoxicity. Genetic polymorphisms in the TPMT gene result in variable enzyme activity, with approximately 10 percent of the population having intermediate activity and approximately 0.3% having low or absent activity; patients with intermediate or low TPMT activity are at increased risk of severe myelosuppression when treated with standard doses of thiopurines, and pre-treatment TPMT genotyping or phenotyping is recommended to guide initial dosing and minimise the risk of haematological toxicity.

Tramadol

- An atypical opioid analgesic (weak mu-agonist plus serotonin and norepinephrine reuptake inhibition) used for moderate pain. Prodrug (M1, via CYP2D6) contributes analgesia; efficacy varies with CYP2D6 genotype. Adverse effects: nausea, dizziness, sedation, constipation, seizures (at high doses, in epilepsy, with SSRIs/SNRIs/TCAs), serotonin syndrome, and dependence (Schedule IV). Caution in renal/hepatic impairment; avoid in opioid-naïve children post-tonsillectomy.

Tranquillisers

- A class of drugs that have a calming or sedative effect, reducing anxiety, tension, and agitation. Historically classified as major tranquilisers (antipsychotics/neuroleptics—for psychosis) and minor tranquilisers (anxiolytics—for anxiety). The term is now less common in clinical practice. Major tranquilisers (antipsychotics): first-generation/typical (chlorpromazine, haloperidol, fluphenazine—block D₂ receptors), second-generation/atypical (risperidone, olanzapine, quetiapine, aripiprazole, clozapine—block D₂ and 5-HT_{2A} receptors). Used for schizophrenia, bipolar mania, agitation, and treatment-resistant depression. Minor tranquilisers (anxiolytics): benzodiazepines (diazepam, lorazepam, alprazolam—enhance GABA_A activity), buspirone (5-HT_{1A} partial agonist—non-sedating,

no dependence), and β -blockers (propranolol—for performance anxiety, somatic symptoms). Adverse effects: (1) Benzodiazepines—dependence, tolerance, withdrawal (rebound anxiety, insomnia, seizures), sedation, cognitive impairment, falls. (2) Antipsychotics—extrapyramidal side effects (dystonia, parkinsonism, akathisia, tardive dyskinesia), weight gain, metabolic syndrome, hyperprolactinaemia, QT prolongation. Non-pharmacological alternatives: cognitive behavioural therapy, relaxation techniques, and mindfulness.

Transdermal

- A route of drug administration delivering drug through intact skin into the systemic circulation via a patch or gel, bypassing first-pass metabolism and providing steady plasma concentrations over hours to days. Examples: nitroglycerin, fentanyl, nicotine, estrogen, clonidine, rotigotine. Absorption depends on drug lipophilicity, molecular size, skin site, and occlusion. Advantages: sustained release, improved adherence, avoidance of GI irritation. Risks: skin irritation, dosing limitations (potent, lipophilic drugs only), and accidental exposure (fentanyl patch).

Trimethoprim-sulfamethoxazole

- A fixed-dose combination of trimethoprim and sulfamethoxazole that synergistically inhibits folate synthesis. TMP-SMX is indicated for urinary tract infections, *Pneumocystis jirovecii* pneumonia, and community-acquired pneumonia. The combination is bactericidal against many gram-positive and gram-negative organisms. Common adverse effects include hypersensitivity reactions, bone marrow suppression, and hyperkalemia. The drug is contraindicated in patients with folate deficiency and in late pregnancy; resistance is increasingly common among many bacterial species, particularly *E. coli*, and susceptibility testing is essential before prescribing TMP-SMX for urinary tract infections.

Triptan

- A class of medications used for acute migraine treatment, acting as 5-HT_{1B}/1D receptor agonists. 5-HT_{1B} receptors are located on cranial blood vessels; activation causes vasoconstriction of dilated meningeal arteries. 5-HT_{1D} receptors are located on presynaptic trigeminal nerve terminals; activation inhibits the release of vasoactive neuropeptides (cal-

citonin gene-related peptide, substance P), reducing neurogenic inflammation and pain transmission. Available triptans: sumatriptan (first, available as oral, subcutaneous, intranasal, and rectal), rizatriptan, zolmitriptan, naratriptan, eletriptan, almotriptan, and frovatriptan. Contraindications: ischemic heart disease, Prinzmetal angina, uncontrolled hypertension, hemiplegic migraine, and basilar migraine. Adverse effects: chest tightness/pressure (may mimic cardiac ischemia but typically benign), paresthesias, dizziness, and injection site reactions. Triptans should be taken early in the migraine attack for optimal efficacy.

Tyrosine Kinase Inhibitor

- A class of targeted cancer therapy drugs that inhibit tyrosine kinases, enzymes that phosphorylate tyrosine residues on proteins and activate signaling pathways involved in cell growth, proliferation, differentiation, and survival. Tyrosine kinase mutations or overexpression drive many cancers. TKIs are small molecules (oral) or monoclonal antibodies (IV). Examples: imatinib — BCR-ABL inhibitor for chronic myeloid leukemia (first TKI approved, revolutionized CML treatment); erlotinib and gefitinib — EGFR inhibitors for non-small cell lung cancer with EGFR mutations; sorafenib and sunitinib — multi-kinase inhibitors (VEGFR, PDGFR, RAF) for renal cell carcinoma and hepatocellular carcinoma; osimertinib — third-generation EGFR TKI for T790M mutant NSCLC. Adverse effects vary by target: hypertension (VEGF inhibitors), rash and diarrhea (EGFR inhibitors), fatigue, and hand-foot skin reaction.

Unguentum

- A semi-solid, greasy topical preparation for application to the skin, mucous membranes, or eyes. See [Ointment](#).

Valproate (Sodium Valproate)

- Valproate (valproic acid, sodium valproate, divalproex sodium) is a broad-spectrum antiepileptic drug effective against all seizure types (generalised tonic-clonic, absence, myoclonic, and partial seizures). It is also used as a mood stabiliser in bipolar disorder (particularly for acute mania and maintenance) and for prophylaxis of migraine headaches. Mechanism: multiple actions including enhancement

of GABAergic transmission (by increasing GABA synthesis via glutamic acid decarboxylase activation and inhibiting GABA transaminase), blockade of voltage-gated sodium channels, and inhibition of T-type calcium channels. Pharmacokinetics: well absorbed orally, highly protein-bound (90%), extensively metabolized in the liver (glucuronidation, beta-oxidation, and CYP-mediated oxidation), half-life 9-16 hours. Adverse effects: dose-related (tremor, weight gain, alopecia, sedation, thrombocytopenia, elevated liver enzymes), idiosyncratic (hepatotoxicity — highest risk in children under 2 years on polytherapy, pancreatitis), teratogenic (neural tube defects, spina bifida — absolute contraindication in pregnancy unless no alternative, requiring high-dose folic acid supplementation), and polycystic ovary syndrome with long-term use. Monitoring: serum levels (therapeutic range 50-100 mcg/mL), LFTs, CBC, and pregnancy testing. Drug interactions: inhibits CYP2C9, displaces protein-bound drugs (phenytoin).

Vancomycin-resistant Enterococcus

- Enterococci resistant to vancomycin through acquisition of *vanA* or *vanB* gene clusters encoding altered cell wall precursors. VRE is a significant cause of healthcare-associated infections, particularly in immunocompromised patients. Treatment options include linezolid, daptomycin, and quinupristin-dalfopristin (for *E. faecium* only). VRE infections are associated with increased mortality and healthcare costs. Infection prevention strategies include hand hygiene, contact precautions, and environmental decontamination, and antimicrobial stewardship to preserve the effectiveness of remaining active agents.

Vaughan Williams Classification

- The Vaughan Williams classification categorizes antiarrhythmic drugs into four classes based on their primary mechanism of action. Class I agents block sodium channels and slow conduction velocity, further subdivided into IA with moderate sodium channel blockade and action potential prolongation including quinidine and procainamide, IB with fast sodium channel binding and action potential shortening including lidocaine and mexiletine, and IC with slow sodium channel binding and minimal effect

on action potential duration; class II agents are beta-blockers that reduce sympathetic activity and slow AV conduction; class III agents block potassium channels, prolonging repolarisation; and class IV agents are calcium channel blockers that slow AV conduction; while clinically useful, the classification has limitations as many drugs have multiple mechanisms of action and it does not account for all clinically important antiarrhythmic drugs.

Viagra (Sildenafil)

- Sildenafil is a phosphodiesterase type 5 (PDE5) inhibitor used primarily for erectile dysfunction (ED) and pulmonary arterial hypertension (PAH, as Revatio). Mechanism: PDE5 degrades cGMP in penile corpus cavernosum smooth muscle; sildenafil inhibits PDE5, increasing cGMP levels and enhancing nitric oxide (NO)-mediated vasodilation and smooth muscle relaxation, improving penile blood flow during sexual stimulation. For PAH: sildenafil dilates pulmonary vasculature, reducing pulmonary vascular resistance. Pharmacokinetics: oral, onset within 30-60 minutes, duration 4-6 hours, metabolized by CYP3A4. Adverse effects: headache, flushing, dyspepsia, nasal congestion, visual disturbances (blue tinged vision/cyanopsia due to PDE6 inhibition in retinal photoreceptors), and myalgia. Serious: priapism (erection >4 hours — medical emergency), hypotension (especially when combined with nitrates — absolute contraindication due to risk of severe hypotension and syncope), and non-arteritic anterior ischemic optic neuropathy (NAION, rare). Contraindications: concurrent nitrate therapy, severe hepatic impairment, severe hypotension, and recent stroke or MI.

Vibrio vulnificus infections

- Infections caused by *Vibrio vulnificus*, a gram-negative bacterium found in warm seawater and raw seafood. *V. vulnificus* can cause wound infections, septicemia, and gastroenteritis. The most severe form is necrotizing fasciitis and primary septicemia, which can be fatal. Risk factors include liver disease, immunocompromise, and iron overload states. Treatment requires doxycycline combined with a third-generation cephalosporin. Early wound care and antibiotic therapy are essential. The organism has a high case-fatality rate, and prevention involves avoiding consumption of raw or undercooked

seafood, particularly in patients with liver disease or immunocompromising conditions.

Volume of Distribution

- A theoretical pharmacokinetic parameter that relates the total amount of drug in the body to the plasma concentration, calculated as V_d equals amount of drug in the body divided by plasma concentration. It represents the apparent volume into which a drug distributes and is not a true anatomical volume. A small volume of distribution, such as 3 to 5 liters, indicates that the drug remains primarily in the plasma and does not extensively distribute into tissues, as seen with drugs that are highly protein-bound and extensively distributed to tissues; understanding volume of distribution is critical for calculating loading doses, interpreting drug concentrations, and predicting the extent of drug distribution to the site of action.

Voriconazole

- A triazole antifungal agent used in the treatment of invasive aspergillosis, candidemia, and other serious fungal infections. Voriconazole inhibits the fungal cytochrome P450 enzyme lanosterol 14- α demethylase, preventing ergosterol synthesis and disrupting fungal cell membrane integrity. The drug has broad-spectrum activity against *Aspergillus*, *Candida*, *Cryptococcus*, and other fungi. A key advantage of voriconazole over itraconazole is its excellent oral bioavailability of approximately 96% and has a long half-life allowing for twice-daily oral dosing after an initial intravenous loading regimen; voriconazole is associated with visual disturbances (photopsia, altered color perception), hepatotoxicity, and QT prolongation, and requires therapeutic drug monitoring due to non-linear pharmacokinetics and significant inter-individual variability in plasma concentrations; drug interactions are numerous due to CYP2C19 and CYP3A4 inhibition.

Weight Loss Medications

- Pharmacologic agents approved for the treatment of obesity when used in conjunction with lifestyle modifications. These medications work through various mechanisms, including appetite suppression through GLP-1 receptor agonists such as semaglutide, inhibition of fat absorption with orlistat, or combination therapies targeting multiple neuropep-

tide pathways. They are indicated for individuals with a body mass index of 30 or higher, or 27 or higher with obesity-related comorbidities, and require ongoing medical supervision due to potential side effects and the need for monitoring.

Withdrawal Symptoms

- See Withdrawal Syndrome. used primarily for erectile dysfunction (ED) and pulmonary arterial hypertension (PAH, as Revatio). Mechanism: PDE5 degrades cGMP in penile corpus cavernosum smooth muscle; sildenafil inhibits PDE5, increasing cGMP levels and enhancing nitric oxide (NO)-mediated vasodilation and smooth muscle relaxation, improving penile blood flow during sexual stimulation. For PAH: sildenafil dilates pulmonary vasculature, reducing pulmonary vascular resistance. Pharmacokinetics: oral, onset within 30-60 minutes, duration 4-6 hours, metabolized by CYP3A4. Adverse effects: headache, flushing, dyspepsia, nasal congestion, visual disturbances (blue tinged vision/cyanopsia due to PDE6 inhibition in retinal photoreceptors), and myalgia. Serious: priapism (erection >4 hours — medical emergency), hypotension (especially when combined with nitrates — absolute contraindication due to risk of severe hypotension and syncope), and non-arteritic anterior ischemic optic neuropathy (NAION, rare). Contraindications: concurrent nitrate therapy, severe hepatic impairment, severe hypotension, and recent stroke or MI.

Withdrawal Syndrome

- A predictable set of signs and symptoms that occur when a drug is discontinued or the dose is reduced after chronic use, reflecting the physiological rebound from drug adaptation. Specific withdrawal syndromes: Opioid withdrawal (not life-threatening but intensely uncomfortable): yawning, lacrimation, rhinorrhea, piloerection (cold turkey), mydriasis, abdominal cramps, diarrhea, nausea, vomiting, muscle aches, and drug craving. Alcohol withdrawal (potentially life-threatening): tremor, anxiety, autonomic hyperactivity (tachycardia, hypertension, diaphoresis), insomnia, seizures (6-48 hours after last drink), and delirium tremens (48-96 hours later: agitation, hallucinations, autonomic instability, and altered mental status). Benzodiazepine withdrawal: anxiety, insomnia, tremor, palpitations, and seizures (may be delayed with long-

acting agents). SSRI discontinuation syndrome: dizziness, paresthesias, nausea, headache, and irritability (not life-threatening). Management involves gradual tapering (detoxification), supportive care, and pharmacotherapy (benzodiazepines for alcohol withdrawal, methadone/buprenorphine for opioid withdrawal).

Xanthine Oxidase Inhibitor

- A class of medications that inhibit xanthine oxidase, the enzyme that catalyzes the final steps of purine metabolism: hypoxanthine to xanthine and xanthine to uric acid. By inhibiting this enzyme, XOIs reduce uric acid production and lower serum uric acid levels, used for management of chronic gout and tumor lysis syndrome. Allopurinol (first-line, 40+ years of clinical use): a purine analog that acts as a competitive substrate and is metabolized to oxypurinol (active metabolite with a long half-life of 18-30 hours). Dosing starts at 100 mg daily, titrated to target serum urate <6 mg/dL. Febuxostat: a non-purine selective XOI, metabolized in the liver, dose 40-80 mg daily, preferred in patients with allopurinol hypersensitivity or renal impairment. Cardiotoxicity warning: febuxostat has a higher risk of cardiovascular death compared to allopurinol in patients with preexisting CVD. Adverse effects: allopurinol hypersensitivity syndrome (DRESS, Stevens-Johnson syndrome, most severe, risk increased in HLA-B*5801 carriers, especially Han Chinese and African Americans), rash, and GI upset.

Zalcitabine

- A nucleoside reverse transcriptase inhibitor (NRTI) that was previously used in combination antiretroviral therapy for HIV-1 infection but is now rarely used because more effective and better-tolerated agents are available. Zalcitabine is a cytidine analogue that inhibits viral reverse transcriptase by competing with deoxycytidine triphosphate and causing DNA-chain termination. Its principal dose-limiting adverse effect was peripheral neuropathy; pancreatitis and lactic acidosis were also reported. Zalcitabine was withdrawn from the market in 2006.

Zidovudine (AZT)

- A thymidine-analogue nucleoside reverse-transcriptase inhibitor that is phosphorylated

intracellularly and incorporated into HIV DNA, causing chain termination. It is now used selectively because combination antiretroviral regimens have better tolerability and resistance profiles. Important adverse effects include macrocytic anemia, neutropenia, myopathy, lactic acidosis, and hepatic steatosis.

Medication Adherence

- The extent to which a patient's medication-taking behavior corresponds with the agreed treatment plan. Adherence is influenced by understanding, adverse effects, cost, access, regimen complexity, beliefs, and cognitive or social factors.

Medication Reconciliation

- A structured process of obtaining and comparing the most accurate medication list with current prescriptions at transitions of care. It identifies omissions, duplications, incorrect doses, interactions, and unintended changes.

Deprescribing

- A planned, supervised process of reducing the dose or stopping a medication for which harms, burden, or lack of benefit outweigh expected benefit. It requires review of indication, withdrawal risk, disease recurrence, and patient goals.

Polypharmacy

- Use of multiple medications by one patient, often defined numerically as five or more concurrent medicines. It increases the risk of interactions, adverse effects, prescribing cascades, nonadherence, and medication errors, although some multidrug regimens are clinically appropriate.

Contraindication

- A clinical circumstance in which a medication or intervention should not be used because the potential harm outweighs expected benefit. Contraindications may be absolute or relative and can depend on dose, route, indication, or patient-specific factors.

Boxed Warning

- The most prominent safety warning required in prescribing information for a medicine when there is a serious or life-threatening risk. It communicates major hazards and does not necessarily mean that the medication is never appropriate.

Medication Error

- A preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of a healthcare professional, patient, or consumer. Errors can occur during prescribing, transcribing, dispensing, administration, or monitoring.

Renal Dose Adjustment

- Modification of a medication dose, dosing interval, or both to account for reduced kidney clearance. The adjustment should use an appropriate estimate of renal function, drug-specific pharmacokinetics, treatment indication, and therapeutic monitoring when available.

Hepatic Dose Adjustment

- Modification of medication selection or dosing because impaired liver function may reduce metabolism, transport, protein synthesis, or biliary excretion. Standardized liver tests do not always predict drug clearance, so drug-specific guidance is required.

Area Under the Concentration-Time Curve (AUC)

- The integral of a drug's plasma concentration over time. AUC estimates total systemic exposure and is used to compare bioavailability, guide dosing for selected medicines, and characterize pharmacokinetic interactions.

Maximum Plasma Concentration (C_{max})

- The highest measured plasma concentration after a dose. C_{max} and the time to reach it are used to describe absorption rate, peak-related toxicity, and comparative pharmacokinetics.

Pharmacokinetic Interaction

- A drug interaction that changes absorption, distribution, metabolism, or excretion of another drug, thereby altering its concentration over time. Enzyme inhibition, enzyme induction, transporter effects, and altered gastric pH are common mechanisms.

Pharmacodynamic Interaction

- A drug interaction in which one drug changes the effect of another at its site of action without necessarily changing its concentration. Effects may

be additive, synergistic, or antagonistic, such as combined respiratory depression or bleeding risk.

Generic Medicine

- A medicine containing the same active ingredient, strength, dosage form, route, and intended clinical effect as an approved reference product. Regulatory requirements generally include demonstration of pharmaceutical equivalence and bioequivalence.

Biosimilar

- A biologic medicine highly similar to an approved reference biologic, with no clinically meaningful differences in safety, purity, or potency for its approved uses. Because biologics are complex, biosimilarity is established through a comparative evidence program rather than simple chemical identity.

Medication Adverse-Effect Profile

- The clinically relevant pattern of predictable pharmacologic effects and harmful reactions associated with a medication. It includes common dose-related effects, serious rare events, organ-specific toxicity, interactions, and monitoring requirements.

Drug Withdrawal

- A clinically significant syndrome or return of symptoms caused by abrupt reduction or cessation of a drug after physiologic adaptation or dependence has developed. Tapering is required for some medications to reduce withdrawal and rebound effects. **Atovaquone–proguanil**
- An antimalarial combination used for prevention and treatment of *Plasmodium falciparum* malaria and selected travel-related malaria regimens.

Chapter 32

Physiology

Acetylcholine

- A major neurotransmitter in both the central and peripheral nervous systems. In the peripheral nervous system, it is released at the neuromuscular junction (nicotinic receptors) to excite skeletal muscle, at all autonomic ganglia (nicotinic receptors), and at parasympathetic postganglionic terminals (muscarinic receptors). In the CNS, acetylcholine modulates arousal, attention, learning, and memory, and its degeneration in the basal forebrain contributes to Alzheimer disease. Synthesized from choline and acetyl-CoA by choline acetyltransferase; degraded rapidly by acetylcholinesterase. Anticholinesterases (neostigmine, physostigmine) prolong its action; botulinum toxin blocks its release.

Acid Base Balance

- The physiological regulation of hydrogen ion concentration in body fluids, maintaining arterial pH between 7.35 and 7.45. Three lines of defense: chemical buffers (bicarbonate, proteins, phosphate) act instantaneously; the respiratory system adjusts PaCO_2 within minutes via CO_2 exhalation; and the kidneys adjust bicarbonate reabsorption and H^+ excretion over hours to days. Disturbances are classified as acidosis or alkalosis and by etiology as metabolic (primary bicarbonate abnormality) or respiratory (primary PaCO_2 abnormality). Compensatory responses attempt to restore pH toward normal. Arterial blood gas analysis is essential for evaluation.

Acidosis

- An acid-base disturbance in which the concentration of hydrogen ions increases, tending to lower arterial blood pH below 7.35. Metabolic acidosis results from reduced bicarbonate, increased acid production or ingestion, or impaired renal acid ex-

cretion; causes include lactic acidosis, ketoacidosis, severe diarrhoea, renal failure, and toxic alcohols. Respiratory acidosis results from alveolar hypoventilation and carbon dioxide retention, as in chronic lung disease, respiratory depression, or neuromuscular weakness. Compensation occurs through increased ventilation in metabolic acidosis and renal bicarbonate retention with enhanced acid excretion in respiratory acidosis. Assessment includes arterial or venous blood gas analysis, serum electrolytes, anion gap, and evaluation of the underlying cause.

Action Potential

- A rapid, all-or-nothing depolarization of the cell membrane that propagates along excitable membranes (neurons, muscle, some endocrine cells). Phases: resting potential (-70 mV in neurons, maintained by the Na^+/K^+ ATPase and potassium leak channels), threshold (typically -55 mV) opens voltage-gated sodium channels causing rapid depolarization, followed by sodium channel inactivation and opening of voltage-gated potassium channels producing repolarization and a brief hyperpolarization (afterhyperpolarization). Refractory periods (absolute then relative) ensure one-way propagation and limit firing frequency. Conduction velocity is increased by myelination (saltatory conduction) and larger axon diameter.

Active Transport

- Movement of substances across cell membranes against their concentration gradient, requiring energy input, typically from ATP hydrolysis. Primary active transport directly uses ATP: the Na^+/K^+ ATPase pumps 3 Na^+ out and 2 K^+ in per ATP, maintaining the electrochemical gradient essential for neuronal signaling, cell volume regulation, and secondary active transport. Other examples include

the Ca^{2+} ATPase, $\text{H}^{+}/\text{K}^{+}$ ATPase (gastric acid secretion), and ABC transporters. Secondary active transport uses the Na^{+} gradient established by the $\text{Na}^{+}/\text{K}^{+}$ ATPase to cotransport or countertransport other solutes (e.g., SGLT1 for glucose and amino acid cotransport in the intestine, $\text{Na}^{+}/\text{Ca}^{2+}$ exchanger in cardiac muscle).

Aldosterone

- A mineralocorticoid hormone produced by the zona glomerulosa of the adrenal cortex, the final effector of the renin-angiotensin-aldosterone system (RAAS). Aldosterone acts on principal cells of the collecting duct, increasing ENaC (epithelial sodium channel) expression on the apical membrane and $\text{Na}^{+}/\text{K}^{+}$ ATPase on the basolateral membrane, promoting sodium reabsorption and potassium secretion. Water follows sodium osmotically, expanding extracellular fluid volume and increasing blood pressure. Aldosterone secretion is stimulated by angiotensin II, hyperkalaemia, and ACTH, and inhibited by ANP and hypokalaemia. Excessive aldosterone (Conn syndrome) causes hypertension with hypokalaemia, metabolic alkalosis, and suppressed renin.

Allele

- Alternative form of a gene at a particular locus. See genetics.

Allosteric Regulation

- The regulation of enzyme activity by the binding of an effector molecule at a site other than the active site (allosteric site), causing a conformational change that alters the enzyme's activity. Allosteric enzymes typically have multiple subunits with cooperative binding kinetics (sigmoidal rather than hyperbolic velocity curves). Positive allosteric effectors (activators) shift the curve leftward (increase affinity for substrate, decrease K_m), while negative allosteric effectors (inhibitors) shift the curve rightward (decrease affinity, increase K_m). Classic examples include oxygen binding to hemoglobin (cooperative, with 2,3-BPG as a negative allosteric effector), aspartate transcarbamoylase (ATCase) in pyrimidine synthesis, and feedback inhibition in metabolic pathways.

Alveolar Ventilation

- The volume of fresh air reaching the alveoli per minute, representing the portion of minute ventila-

tion that participates in gas exchange. Calculated as (tidal volume - dead space volume) x respiratory rate. Normal alveolar ventilation is approximately 4-5 L/min. It is the physiologically relevant determinant of arterial CO_2 and O_2 : decreased alveolar ventilation causes hypercapnia and hypoxemia, while increased alveolar ventilation produces hypocapnia. Anatomic dead space (150 mL) plus alveolar dead space (ventilated but unperfused alveoli) constitutes physiologic dead space. In health, physiologic and anatomic dead space are nearly equal.

Amino Acid Catabolism

- The breakdown of amino acids after protein digestion, with the amino group removed and the carbon skeleton metabolized for energy or gluconeogenesis/ketogenesis. Transamination: amino groups are transferred to α -ketoglutarate, forming glutamate, by aminotransferases requiring pyridoxal phosphate (PLP, vitamin B6) as a cofactor. ALT (alanine aminotransferase) and AST (aspartate aminotransferase) are clinically important: elevated levels indicate liver damage (ALT is more liver-specific) or myocardial injury (AST). Following transamination, the α -keto acids enter gluconeogenesis or the TCA cycle, and ammonium is converted to urea in the urea cycle.

Apoptosis

- Programmed cell death. See oncology.

Atrial Natriuretic Peptide

- A peptide hormone secreted by atrial myocytes in response to atrial stretch from volume expansion. ANP promotes natriuresis and diuresis by increasing glomerular filtration rate, inhibiting sodium reabsorption in the collecting ducts, and reducing renin and aldosterone secretion. It also relaxes vascular smooth muscle, reducing blood pressure and afterload. Actions oppose the renin-angiotensin-aldosterone system. B-type natriuretic peptide (BNP) from ventricular myocytes is released with ventricular wall stress and is a widely used biomarker for heart failure diagnosis and prognosis.

Autophagy

- Cellular self-degradation process delivering cytoplasmic components to lysosomes for recycling. Macroautophagy: phagophore forms, expands to autophagosome (LC3-II on membrane), fuses with

lysosome (autolysosome) for degradation. Selective autophagy: mitophagy (damaged mitochondria), xenophagy (pathogens), aggrephagy (protein aggregates). Regulated by mTOR (inhibits) and AMPK (activates). Functions: nutrient recycling during starvation, quality control, development, immunity. Dysregulation: cancer, neurodegeneration, infection, aging.

Baroreceptor Reflex

– The rapid neural mechanism for short-term blood pressure regulation, involving baroreceptors (mechanoreceptors) in the carotid sinus (innervated by CN IX) and aortic arch (innervated by CN X). When blood pressure rises, baroreceptors increase their firing rate, signaling the cardiovascular center in the medulla. The response: increased parasympathetic (vagal) output to the heart (decreasing HR) and decreased sympathetic output (decreasing HR, contractility, and peripheral resistance), lowering blood pressure towards normal. The reflex is essential for maintaining blood pressure stability during postural changes and blood volume fluctuations.

Basal Metabolic Rate (BMR)

– See clinical_nutrition.

Bile Salt Emulsification

– Bile salts (derived from cholesterol in the liver) are amphipathic molecules with hydrophobic and hydrophilic regions that act as biological detergents, emulsifying dietary lipids into smaller droplets (micelles). This increases the surface area of lipid substrate available for pancreatic lipase action. Bile salts form mixed micelles with phospholipids, cholesterol, and fat-soluble vitamins (A, D, E, K), facilitating their transport across the unstirred water layer to the enterocyte brush border for absorption. Bile salts are reabsorbed in the terminal ileum via the apical sodium-dependent bile acid transporter (ASBT) and returned to the liver through the enterohepatic circulation, recycling 6-10 times daily.

Blood Coagulation

– The cascade of enzymatic reactions converting circulating fibrinogen into an insoluble fibrin clot. The extrinsic pathway is initiated by tissue factor (factor III) released from damaged vessels; the intrinsic pathway is initiated by contact activation (factor XII); both converge on a common pathway: fac-

tor X activation, prothrombin (factor II) to thrombin, and thrombin converting fibrinogen to fibrin, which is cross-linked by factor XIII. Coagulation requires vitamin K-dependent factors (II, VII, IX, X) and calcium. Regulated by antithrombin, protein C/protein S, and tissue factor pathway inhibitor. Tested clinically by PT (extrinsic/common) and aPTT (intrinsic/common).

Blood Flow

– The volume of blood passing through a vessel, organ, or the systemic circulation per unit time, typically expressed in mL/min. Governed by the hemodynamic equivalent of Ohm's law: flow = pressure gradient / resistance. Total cardiac output (5 L/min at rest) equals systemic blood flow. Local blood flow is regulated by autoregulation (myogenic, metabolic), endothelial factors (nitric oxide, endothelin), and sympathetic innervation. Flow may be laminar or turbulent (Reynolds number >2000). Organs with high flow per gram (kidneys, heart, brain) are most vulnerable to reduced perfusion.

Blood Pressure

– The force exerted by blood against arterial walls, measured in millimeters of mercury (mmHg). Systolic pressure (peak during ventricular ejection, normally approximately 120 mmHg) and diastolic pressure (minimum during ventricular relaxation, normally approximately 80 mmHg). Mean arterial pressure (MAP) is approximately diastolic + one-third pulse pressure (approximately 93 mmHg). MAP is the average pressure driving blood through the systemic circulation. Blood pressure depends on cardiac output and systemic vascular resistance ($MAP = CO \times SVR$). It is regulated by short-term mechanisms (baroreceptor reflex, chemoreceptor reflex, and hormonal responses: ADH, adrenaline) and long-term mechanisms (renin-angiotensin-aldosterone system and renal body fluid regulation by the kidneys).

Blood Viscosity

– The internal friction of blood that resists flow, determined primarily by hematocrit (red cell concentration), with smaller contributions from plasma proteins and temperature. Normal whole-blood viscosity is approximately 3-4 times that of water. In-

creased viscosity (polycythemia, hyperproteinemia, dehydration) raises vascular resistance and cardiac workload, while reduced viscosity (anemia, low protein) lowers resistance. Viscosity has greatest effect in small vessels and at low flow rates; at the capillary level, viscosity falls due to the Fahraeus-Lindqvist effect.

Body Temperature

- The balance between heat production (metabolism, muscle activity) and heat loss (radiation, conduction, convection, evaporation). See [Temperature \(Body Temperature\)](#).

Bohr Effect

- The decrease in hemoglobin's oxygen affinity (right shift of the dissociation curve) caused by decreased pH (increased H^+) and increased PCO_2 . In metabolically active tissues, CO_2 production and lactic acid accumulation lower the local pH, causing hemoglobin to release more oxygen precisely where it is needed most. The mechanism involves protonation of hemoglobin histidine residues, which stabilize the T (tense, low-affinity) state. The Bohr effect is quantified as approximately 0.48 pH units per $\log_{10} PCO_2$ change and is clinically significant in conditions that alter acid-base status, enhancing oxygen delivery in exercising muscle and hypoxic tissues.

Calciferol

- Vitamin D is a fat-soluble vitamin (actually a prohormone) essential for calcium and phosphorus homeostasis and bone health. See [Vitamin D: Calcitriol](#).

Calorie

- A unit of energy measurement used in nutrition to quantify the energy content of foods and energy expenditure of the body. One kilocalorie (kcal, commonly called a Calorie with capital C) equals the energy required to raise 1 kilogram of water by 1 degree Celsius. The body derives energy from macronutrients: carbohydrates and proteins provide 4 kcal/g, fats provide 9 kcal/g, and alcohol provides 7 kcal/g. Total daily energy expenditure comprises basal metabolic rate (60–75%), thermic effect of food (10%), and physical activity (15–30%). Caloric balance determines body weight: excess calories are stored as fat; caloric deficit leads to

weight loss.

Capillary

- The smallest blood vessel in the body, forming a microscopic network (capillary bed) that connects arterioles to venules. Capillary walls consist of a single layer of endothelial cells (frequently fenestrated) and a basement membrane, allowing exchange of oxygen, carbon dioxide, nutrients, wastes, and other substances between blood and interstitial fluid. Types: continuous (most common, in muscle, skin, lung, CNS–blood-brain barrier), fenestrated (kidney, intestine, endocrine glands, with pores for rapid filtration), and sinusoidal/discontinuous (liver, bone marrow, spleen with large gaps allowing passage of cells and large molecules). Starling forces—hydrostatic and oncotic pressures—govern fluid movement across capillary walls.

Carbon Dioxide Transport

- The movement of CO_2 from tissues to lungs. CO_2 is carried in blood in three forms: dissolved (approximately 10 percent), bound to hemoglobin as carbamino compounds (approximately 20 percent), and as bicarbonate (approximately 70 percent). In red cells, carbonic anhydrase converts CO_2 and water to carbonic acid, which dissociates to H^+ (buffered by hemoglobin) and bicarbonate, which exits via the chloride shift (Hamburger phenomenon). In the lungs the reactions reverse, and CO_2 diffuses into the alveoli. The Haldane effect: deoxygenated hemoglobin binds CO_2 and H^+ more readily, enhancing CO_2 uptake in tissues.

Cardiac Cycle

- The sequence of events occurring during one complete heartbeat, consisting of systole (contraction) and diastole (relaxation). See [cardiology](#).

Cardiac Output

- The volume of blood pumped by the heart per minute, calculated as the heart rate multiplied by the stroke volume.

Cell

- The fundamental structural and functional unit of all living organisms. See [anatomy](#).

Chemoreceptor

- A sensory receptor that responds to changes in blood or CSF chemistry, involved in respiratory and

cardiovascular regulation. Peripheral chemoreceptors (carotid bodies at the carotid bifurcation, innervated by CN IX; aortic bodies by CN X) detect arterial hypoxemia ($\text{PaO}_2 < 60 \text{ mmHg}$), hypercapnia, and acidemia, and stimulate increased ventilation and sympathetic activity. Central chemoreceptors in the ventrolateral medulla respond primarily to CO_2/H^+ in the CSF. Peripheral chemoreceptors are essential for the hypoxic ventilatory response and become dominant ventilatory drivers in chronic CO_2 retainers (e.g., COPD).

Cholecystokinin

- CCK is a peptide hormone produced by I-cells in the duodenal and jejunal mucosa in response to fatty acids (long-chain fatty acids are the most potent stimuli) and amino acids in the chyme. CCK's primary actions: stimulates gallbladder contraction (promoting bile release for fat emulsification and absorption), stimulates pancreatic enzyme secretion (acinar cells), relaxes the sphincter of Oddi, slows gastric emptying (reducing the rate of acid delivery to the duodenum), and promotes satiety (acting on the hypothalamus via CCK-B receptors). CCK is also found in the brain as a neurotransmitter. Its secretion is inhibited by trypsin and chymotrypsin (negative feedback via trypsin-sensitive CCK-releasing factor). CCK analogues are used as diagnostic agents in gallbladder imaging.

Cholesterol Synthesis

- Occurs in all nucleated cells (primarily liver and intestine, approximately 1 g/day production), using acetyl-CoA as the precursor through approximately 30 enzymatic steps. See biochemistry.

Chromosome

- Thread-like structure of nucleic acids and protein found in nucleus, carrying genetic information. See genetics.

Circadian Rhythm

- The approximately 24-hour endogenous biological cycle regulating sleep-wake behavior, hormone secretion, body temperature, metabolism, and other physiological processes. Generated by the suprachiasmatic nucleus of the hypothalamus, which is entrained to the environment primarily by light via the retinohypothalamic tract. Key hormones: melatonin (secreted by the pineal gland at night, pro-

moting sleep) and cortisol (peak in early morning). Disruption from shift work, jet lag, or light exposure at night is associated with sleep disorders, metabolic dysfunction, and cardiovascular risk.

Clotting

- The cascade of enzymatic reactions converting circulating fibrinogen into an insoluble fibrin clot. See [Blood Coagulation](#).

Competitive Inhibition

- A type of enzyme inhibition where the inhibitor (I) competes with the substrate (S) for binding to the enzyme's active site. The inhibitor structurally resembles the substrate and binds reversibly to the free enzyme (E), forming an EI complex that cannot proceed to product. The apparent K_m increases (lower apparent affinity for substrate) while V_{max} remains unchanged (since the inhibition can be overcome by sufficiently high substrate concentrations). On a Lineweaver-Burk plot: lines intersect on the y-axis (same $1/V_{max}$) but have different slopes and x-intercepts (increasing apparent K_m). Competitive inhibition is reversible and clinically exploited by enzyme inhibitors such as statins (HMG-CoA reductase), ACE inhibitors, and many chemotherapeutic agents that resemble natural substrates.

Cytokine

- Small signaling proteins (5-25 kDa) mediating cell-to-cell communication in immunity, inflammation, and hematopoiesis. Families: interleukins (IL-1 to IL-38), interferons (IFN-alpha/beta/gamma), tumor necrosis factors (TNF-alpha/beta), colony-stimulating factors (G-CSF, GM-CSF), chemokines (IL-8, MCP-1, RANTES), growth factors (TGF-beta, PDGF). Actions: autocrine, paracrine, endocrine. Receptors: cytokine receptor superfamilies (type I/II, hematopoietin, interferon, TNF receptor). Cytokine storm: hyperinflammatory syndrome (severe infection, CAR-T therapy, COVID-19). Therapeutic: monoclonal antibodies (anti-TNF, anti-IL6, anti-IL1), recombinant cytokines (filgrastim, erythropoietin).

Cytoskeleton

- Dynamic protein filament network providing structural support, cell shape, intracellular transport, and cell division. Three main components: (1) Microfilaments (actin, 7 nm): cell cortex, stress fibers,

contractile ring (cytokinesis), lamellipodia/filopodia (motility), myosin interaction (muscle contraction). (2) Intermediate filaments (10 nm): mechanical strength, nuclear lamina (lamins), keratin (epithelia), vimentin (mesenchymal), neurofilaments (neurons). (3) Microtubules (25 nm, alpha/beta tubulin): mitotic spindle, cilia/flagella (axoneme: 9+2), intracellular transport (kinesin/dynein), centriole/centrosome organization. Motor proteins: dynein (minus-end directed), kinesin (plus-end directed, except kinesin-14).

Dead Space

– The volume of ventilated air that does not participate in gas exchange. Anatomic dead space: the conducting airways (nose, pharynx, trachea, bronchi, terminal bronchioles) that warm, humidify, and filter inspired air but contain no alveoli for gas exchange. Approximately 150 mL in a 70 kg adult. Physiologic dead space includes anatomic dead space plus alveolar dead space (ventilated alveoli that are not perfused, as in pulmonary embolism). Normally, physiologic dead space equals anatomic dead space (approximately 150 mL), but in pulmonary embolism, hypotension, or lung disease, alveolar dead space increases, reducing effective alveolar ventilation. The dead space fraction (VD/VT) is measured by the Bohr equation and is clinically important in assessing ventilatory efficiency.

Defecation

– The process of eliminating feces from the body. Filling of the rectum triggers stretch receptors that initiate the defecation reflex via the sacral spinal cord (S2-S4), causing contraction of the rectal wall and relaxation of the internal anal sphincter. Voluntary control of the external anal sphincter (innervated by the pudendal nerve) permits deferral of defecation until socially appropriate. The gastrocolic reflex (mass movements stimulated by eating) and colonic peristalsis move feces into the rectum. Constipation and diarrhea reflect disturbances in motility, water absorption, or sphincter function.

Depolarization

– The change in membrane potential toward a less negative (more positive) value, typically caused by inward sodium or calcium current. In neurons, depolarization to threshold triggers an action potential.

In cardiac muscle, depolarization (phase 0) is mediated by fast sodium channels in ventricular/atrial myocytes and by L-type calcium channels in the SA and AV nodes. Depolarization spreads via gap junctions. On the ECG, atrial depolarization produces the P wave and ventricular depolarization the QRS complex. Sustained depolarization inactivates voltage-gated sodium channels, contributing to the refractory period.

Diffusion

– The net movement of molecules from an area of higher concentration to lower concentration due to random thermal motion (Brownian motion). Fick's first law states that the rate of diffusion is proportional to the concentration gradient, surface area, and diffusion coefficient, and inversely proportional to membrane thickness: $J = -P \times A \times (C_1 - C_2)/d$, where J is flux, P is the permeability coefficient, A is surface area, and d is thickness. Simple diffusion occurs for small, nonpolar molecules (O₂, CO₂, N₂, steroid hormones) that can dissolve in and pass through the lipid bilayer without a transporter. Factors affecting diffusion rate include: concentration gradient, temperature, molecular size, lipid solubility, membrane surface area, and membrane thickness. In biological systems, diffusion is effective over short distances (less than 100 micrometres), which is why capillaries are narrow and alveoli are thin-walled.

DNA

– Deoxyribonucleic acid, the hereditary material in humans and most organisms. Double helix of two antiparallel strands (sugar-phosphate backbone, nitrogenous bases: A-T, G-C). Human genome: 3 billion base pairs, 20,000 protein-coding genes. Organized into 23 chromosome pairs (22 autosomes + XY/XX) in nucleus; mitochondrial DNA (mtDNA) separate. DNA replication: semi-conservative, bidirectional from origins. Mutations: point mutations, insertions, deletions, copy number variations, translocations.

DNA Double Helix

– The molecular structure of DNA described by Watson and Crick in 1953, consisting of two antiparallel polynucleotide chains wound around each other in a right-handed helix. The sugar-phosphate back-

bone is on the exterior; nitrogenous bases project inward. Complementary base pairing: adenine (A) pairs with thymine (T) via two hydrogen bonds; guanine (G) pairs with cytosine (C) via three hydrogen bonds. The helix has a major groove (22 Angstrom) and minor groove (12 Angstrom) where proteins interact with specific base sequences without unwinding the DNA. This structure enables information storage, replication, transcription, and repair, and is the foundation of molecular genetics.

DNA Repair Mechanisms

– Cellular processes that correct DNA damage caused by replication errors, chemicals, radiation, and reactive oxygen species. Mismatch repair (MMR): corrects base-base mismatches and insertion-deletion loops that escape proofreading during replication. MutS (MSH2/MSH6 in eukaryotes) recognizes the mismatch; MutL (MLH1/PMS2) nicks the newly synthesized strand; exonuclease removes the error; DNA polymerase and ligase fill the gap. Deficiency causes Lynch syndrome (hereditary nonpolyposis colorectal cancer, HNPCC), the most common cause of hereditary colorectal cancer. Base excision repair (BER): repairs small, non-helix-distorting lesions such as oxidised or alkylated bases. Nucleotide excision repair (NER): repairs bulky, helix-distorting lesions such as UV-induced pyrimidine dimers. Double-strand break repair: homologous recombination (HR, error-free, uses sister chromatid as template) and non-homologous end joining (NHEJ, error-prone, active in G1 phase).

DNA Replication

– The semi-conservative process by which DNA duplicates before cell division, producing two identical daughter molecules each containing one original and one new strand. Key steps: (1) initiation at origins of replication (*oriC* in bacteria, multiple origins in eukaryotes), where helicase (DnaB in bacteria, MCM complex in eukaryotes) unwinds the double helix; (2) single-strand binding proteins (SSB) stabilize unwound DNA; (3) primase (DnaG) synthesizes short RNA primers; (4) DNA polymerase III (prokaryotes) or DNA polymerase delta/epsilon (eukaryotes) extends the primer, adding nucleotides to the 3' end; (5) on the leading strand, synthesis is continuous; on the lagging strand, synthesis is discontinuous, producing Okazaki fragments; (6)

RNA primers are removed by DNA polymerase I (prokaryotes) or RNase H and FEN1 (eukaryotes); (7) DNA ligase seals the nicks between fragments. Telomerase extends telomeres to prevent chromosome shortening in germ cells and stem cells.

Electrolytes

– Ions in body fluids that carry an electrical charge and are essential for normal physiologic function. Major electrolytes: sodium (Na^+ , 135–145 mEq/L, primary extracellular cation, regulates fluid balance and membrane potential), potassium (K^+ , 3.5–5.0 mEq/L, primary intracellular cation, critical for cardiac and neuromuscular function), chloride (Cl^- , 98–106 mEq/L, major extracellular anion, follows sodium), bicarbonate (HCO_3^- , 22–28 mEq/L, buffer in acid-base balance), calcium (Ca^{2+} , 8.5–10.5 mg/dL, bone structure, muscle contraction, coagulation), magnesium (Mg^{2+} , 1.7–2.2 mg/dL, enzyme cofactor, neuromuscular stability), and phosphate (PO_4^{3-} , 2.5–4.5 mg/dL, energy metabolism, bone structure). Electrolyte imbalances cause a wide range of symptoms and are routinely measured by basic metabolic panel or comprehensive metabolic panel.

Electron Transport Chain

– Series of protein complexes (I–IV) and mobile carriers (ubiquinone, cytochrome c) in the inner mitochondrial membrane that transfer electrons from NADH and FADH₂ to oxygen, pumping protons to create electrochemical gradient used by ATP synthase. See biochemistry.

Endocytosis

– Process by which cells internalize extracellular material by engulfing it with the cell membrane, forming intracellular vesicles. Phagocytosis ("cell eating") involves engulfing large particles (>0.5 micrometers) such as bacteria or debris, forming a phagosome that fuses with lysosomes for digestion. This is performed by macrophages, neutrophils, and dendritic cells as part of innate immunity. Pinocytosis ("cell drinking") non-specifically engulfs extracellular fluid and dissolved solutes in small vesicles (approximately 0.1 micrometres). Receptor-mediated endocytosis (clathrin-dependent) is highly specific: ligands bind to surface receptors, which cluster in clathrin-coated pits, forming coated vesicles that are

uncoated and delivered to early endosomes. Examples include LDL uptake (deficiency causes familial hypercholesterolaemia), transferrin-bound iron uptake, and growth factor internalisation.

Endoplasmic Reticulum

- Interconnected network of membranous tubules and sacs continuous with the nuclear envelope. Rough ER: studded with ribosomes, site of synthesis of secretory, membrane, and lysosomal proteins; co-translational insertion into ER lumen. Smooth ER: lacks ribosomes, site of lipid synthesis (steroids, phospholipids), detoxification (cytochrome P450), calcium storage, and glycogen metabolism (in liver). ER quality control: chaperones (BiP, calnexin, calreticulin) fold proteins; misfolded proteins undergo ER-associated degradation (ERAD). Unfolded protein response (UPR) activated by ER stress (IRE1, PERK, ATF6 pathways).

Endorphin

- Endogenous opioid peptides (beta-endorphin, enkephalins, dynorphins) produced by the pituitary, hypothalamus, and immune cells that bind opioid receptors (μ , δ , κ) to produce analgesia, euphoria, and modulation of pain perception and stress responses. Beta-endorphin is derived from proopiomelanocortin and released with ACTH during stress and exercise ('runner's high'). Endorphins act in the periaqueductal gray and spinal dorsal horn to inhibit pain transmission. They are degraded by enkephalinases; naloxone is an opioid receptor antagonist.

Enzyme

- Biological catalyst (protein or RNA) that accelerates chemical reactions by lowering activation energy. See biochemistry.

Excitation-Contraction Coupling

- The sequence of events linking an action potential to muscle contraction. In skeletal muscle: the action potential travels down the T-tubule, triggering calcium release from the sarcoplasmic reticulum via ryanodine receptors (calcium-induced calcium release mediated by voltage-gated dihydropyridine receptors). Calcium binds troponin C, moving tropomyosin to expose actin binding sites for cross-bridge formation; contraction continues while cytosolic calcium is elevated, and relaxation follows

calcium reuptake by SERCA. In cardiac muscle, calcium also enters through L-type channels and triggers greater SR release. The mechanism couples electrical excitation to mechanical contraction.

Exocytosis

- Process by which intracellular vesicles fuse with the plasma membrane, releasing their contents into the extracellular space and incorporating membrane proteins/lipids into the cell membrane. The SNARE complex (v-SNARE on vesicles and t-SNARE on target membrane) mediates vesicle docking and fusion. Calcium-triggered exocytosis occurs in neurons (neurotransmitter release at synapses), endocrine cells (hormone secretion), and exocrine cells (enzyme secretion). Constitutive exocytosis continuously delivers membrane components and secreted proteins (collagen, matrix proteins) in all cells. Regulated exocytosis stores secretory vesicles until a signal (typically increased cytosolic Ca^{2+}) triggers fusion. Defects in exocytosis underlie diseases such as botulism (toxin cleaves SNARE proteins) and familial haemophagocytic lymphohistiocytosis.

Facilitated Diffusion

- Passive transport of molecules across cell membranes via specific transmembrane protein carriers or channels, moving substances down their concentration gradient without energy expenditure. Channel-mediated facilitated diffusion uses ion channels (voltage-gated, ligand-gated, or mechanically-gated) for rapid ion movement. Carrier-mediated facilitated diffusion uses specific carrier proteins that undergo conformational changes to transport molecules like glucose (via GLUT transporters) and amino acids. GLUT1 (erythrocytes, brain), GLUT2 (liver, pancreas), GLUT3 (neurons), GLUT4 (muscle, adipose, insulin-responsive). The rate of facilitated diffusion is limited by transporter number (saturable, following Michaelis-Menten kinetics) and is specific, saturable, and inhibitable.

Filtration Fraction

- The fraction of renal plasma flow that is filtered at the glomerulus, calculated as GFR divided by renal plasma flow (RPF). Normal GFR is approximately 125 mL/min and RPF is approximately 625 mL/min, yielding a filtration fraction of approximately 0.20 (20 percent). This means that

approximately 20 percent of the plasma entering the glomerulus is filtered; the remaining 80 percent continues through the efferent arteriole to the peritubular capillaries. Changes in filtration fraction reflect changes in glomerular capillary hydrostatic pressure, plasma oncotic pressure, or renal blood flow. Increased filtration fraction (as in diabetic nephropathy) raises peritubular capillary oncotic pressure, enhancing reabsorption. Decreased filtration fraction suggests reduced GFR relative to RPF, as seen in prerenal azotaemia.

Forced Expiratory Volume

- The volume of air forcibly exhaled in a specified time during a maximal expiratory effort. FEV1 is the volume exhaled in the first second; normally at least 70-80 percent of the forced vital capacity (FEV1/FVC ratio). An obstructive ventilatory defect (asthma, COPD) reduces FEV1 and the FEV1/FVC ratio (below 0.70), while a restrictive defect (pulmonary fibrosis, chest wall disease) reduces both FEV1 and FVC with a normal or elevated ratio. FEV1 is used to grade COPD severity (GOLD staging) and to assess bronchodilator responsiveness.

Frank-Starling Mechanism

- The physiological principle stating that stroke volume increases as end-diastolic volume (preload) increases, up to an optimal point. See [cardiology](#).

Functional Residual Capacity

- The volume of air remaining in the lungs at the end of a normal expiration, equal to the sum of expiratory reserve volume plus residual volume (approximately 2.2-3 L in adults). FRC represents the lung volume at which the outward recoil of the chest wall balances the inward recoil of the lungs, the resting equilibrium position. FRC maintains alveolar stability and continuous gas exchange during breathing. It is increased in COPD/emphysema and obstructive disease (air trapping, hyperinflation), decreased in restrictive lung disease, obesity, and supine posture. Measured by body plethysmography or gas dilution methods.

G-Protein Coupled Receptors

- The largest family of cell surface receptors with seven transmembrane alpha-helical domains. Upon ligand binding, the receptor undergoes a confor-

mational change that activates an associated heterotrimeric G-protein (G α , G β , G γ). The G α subunit exchanges GDP for GTP and dissociates from the G β - γ complex. Gs-proteins activate adenylyl cyclase (increasing cAMP), Gi-proteins inhibit adenylyl cyclase (decreasing cAMP), and Gq-proteins activate phospholipase C (producing IP3 and DAG, increasing intracellular Ca²⁺). The system provides signal amplification and is the target of many drugs (beta-blockers, antihistamines, opioids) and bacterial toxins (cholera toxin permanently activates Gs, pertussis toxin inactivates Gi).

Galactosemia

- See biochemistry.

Galvanism

- The application of a direct electric current for therapeutic or diagnostic purposes. Named after Luigi Galvani (1737-1798). Historical uses: galvanic stimulation of muscles, iontophoresis (introduction of ionised drugs through skin), electroconvulsive therapy (modified). Modern context: galvanic vestibular stimulation (research tool), dental galvanism (electrochemical reaction between dissimilar dental metals causing oral discomfort or metallic taste).

Gastric Acid

- Hydrochloric acid secreted by gastric parietal cells, producing an intragastric pH of 1-3. Secretion is stimulated by histamine (H2 receptors), gastrin (CCK-B/gastrin receptors), and acetylcholine (M3 muscarinic receptors), and inhibited by somatostatin, prostaglandins, and luminal acid (negative feedback). Acid activates pepsinogen to pepsin, aids protein digestion, sterilizes ingested bacteria, and promotes iron and calcium absorption. Excessive acid causes peptic ulcer disease and GERD; deficient acid (achlorhydria) predisposes to infections and vitamin B12 malabsorption. Inhibited therapeutically by PPIs, H2 blockers, and anticholinergics.

Gastrin Secretion

- Gastrin is a peptide hormone produced by G-cells in the gastric antrum and duodenum, stimulating hydrochloric acid secretion by parietal cells, pepsinogen secretion by chief cells, and growth of the gastric mucosa. Stimuli for release include: gastric distension, amino acids (especially phenylalanine

and tryptophan) and peptides in the stomach, and vagal stimulation (via GRP, gastrin-releasing peptide). Gastrin acts on cholecystokinin-B (CCK-B) receptors on parietal cells and histamine-releasing enterochromaffin-like (ECL) cells (which in turn stimulate parietal cells via histamine H₂ receptors). Gastrin release is inhibited by low antral pH (negative feedback via somatostatin from D-cells). Zollinger-Ellison syndrome (gastrinoma) causes severe peptic ulcer disease from unregulated gastrin secretion.

Gaucher Disease

- See genetics.

Gene

- Basic unit of heredity, segment of DNA encoding a functional product (protein or RNA). See genetics.

Gene Therapy

- Treatment by introducing, removing, or changing genetic material. See genetics.

Glomerular Filtration Rate

- Volume of plasma filtered by the glomeruli per unit time normally ninety to one hundred twenty milliliters per minute per one point seven three square meters body surface area. See nephrology.

Gluconeogenesis

- Metabolic pathway generating glucose from non-carbohydrate precursors (lactate, glycerol, glucogenic amino acids). See biochemistry.

Glutamate

- The principal excitatory neurotransmitter in the central nervous system. Synthesized from glutamine or alpha-ketoglutarate and acting on ionotropic receptors (AMPA, kainate, NMDA) for fast synaptic transmission and metabotropic receptors (mGluR1-8) for modulation. Glutamate is essential for normal synaptic transmission, learning, and memory (long-term potentiation). However, excessive glutamate release causes excitotoxicity—neuronal injury mediated by excessive calcium influx—implicated in stroke, traumatic brain injury, status epilepticus, and neurodegenerative diseases. Uptake by excitatory amino acid transporters terminates its action.

Glycogen Storage Diseases

- A group of inherited disorders caused by deficiencies in enzymes involved in glycogen metabolism,

affecting the liver, muscle, or both. Type I (von Gierke disease): glucose-6-phosphatase deficiency, causing severe fasting hypoglycemia, hepatomegaly (massive glycogen and fat accumulation), lactic acidosis, hyperuricemia, and hyperlipidemia. Type II (Pompe disease): acid alpha-glucosidase (lysosomal acid maltase) deficiency, causing accumulation of glycogen in lysosomes, leading to cardiomegaly, hypertrophic cardiomyopathy, and muscle weakness; infantile form is fatal without enzyme replacement therapy. Type III (Cori disease): debranching enzyme deficiency, milder hypoglycaemia and hepatomegaly. Type V (McArdle disease): muscle glycogen phosphorylase deficiency, causing exercise intolerance, myoglobinuria, and second wind phenomenon.

Glycogenesis

- See biochemistry.

Glycogenolysis

- Breakdown of glycogen to glucose-1-phosphate (converted to glucose-6-phosphate). See biochemistry.

Glycolysis

- Metabolic pathway breaking down glucose (6C) to pyruvate (3C), generating 2 ATP (net) and 2 NADH. See biochemistry.

Golgi Apparatus

- Membrane-bound organelle (Golgi complex) consisting of flattened cisternae (cis, medial, trans) that modifies, sorts, and packages proteins and lipids from the ER for secretion or delivery to other organelles. Key functions: N- and O-linked glycosylation (addition/modification of carbohydrate chains), proteolytic processing, sulfation, phosphorylation, and sorting via signal sequences (M6P for lysosomes, KDEL for ER retrieval). Vesicles bud from trans-Golgi network (TGN) to plasma membrane (constitutive/regulated secretion), lysosomes, or endosomes. Brefeldin A disrupts Golgi by inhibiting ARF1.

Golgi Tendon Organ

- A mechanoreceptor located at the junction between a skeletal muscle and its tendon, innervated by Ib afferent fibers. The Golgi tendon organ detects tension generated by muscle contraction or passive stretch. Unlike the muscle spindle, it is arranged in series with the muscle fibers and is therefore

more sensitive to active contraction than to stretch. Activation inhibits the homonymous muscle via the Ib inhibitory interneuron (autogenic inhibition) and excites antagonists, providing a protective reflex against excessive tension that could damage the muscle or tendon.

Graded Potentials

– Local changes in membrane potential that vary in magnitude proportional to stimulus strength, unlike all-or-none action potentials. They include receptor potentials (in sensory receptors), postsynaptic potentials (EPSPs and IPSPs at synapses), and pacemaker potentials (in cardiac/specialized cells). Graded potentials decay with distance from their source (decremental conduction) because they spread passively through the cytoplasm. They can summate temporally (rapid successive stimuli) and spatially (simultaneous stimuli from multiple sources), integrating signals at the axon hillock. If the summed depolarisation reaches threshold (approximately -55 mV), an action potential is triggered. Graded potentials are essential for sensory transduction and synaptic communication and are the basis for the all-or-none law of neural signalling.

Growth Factor

– Proteins that stimulate cell growth, proliferation, differentiation, and survival. Major families: EGF (epidermal growth factor), FGF (fibroblast growth factor), PDGF (platelet-derived), VEGF (vascular endothelial), TGF-beta (transforming), NGF (nerve), IGF (insulin-like), HGF (hepatocyte). Receptors: receptor tyrosine kinases (RTKs), dimerization $\rightarrow$ autophosphorylation $\rightarrow$ downstream signaling (RAS/MAPK, PI3K/Akt). Roles: wound healing, angiogenesis, development, tissue regeneration. Clinical: growth factor therapy (EPO, G-CSF, VEGF inhibitors in cancer, anti-VEGF in AMD).

Haldane Effect

– The decrease in hemoglobin's CO₂ carrying capacity when oxygen binds to it, facilitating CO₂ release at the lungs. Deoxygenated hemoglobin (deoxyhemoglobin) is a better buffer for H⁺ ions and forms more carbaminohemoglobin than oxyhemoglobin. In the tissues: oxygen unloading increases hemoglobin's ability to bind CO₂ (as carbaminohemoglobin) and buffer H⁺ (from CO₂ hy-

dration to carbonic acid), enhancing CO₂ loading. In the lungs: oxygen binding displaces CO₂ from hemoglobin and reduces H⁺ buffer capacity, promoting CO₂ release into the alveoli. The Haldane effect explains that approximately 20 percent of CO₂ transport is via carbaminohemoglobin. Together with the Bohr effect, it optimizes O₂ delivery and CO₂ removal, a concept known as the "Haldane-Bohr coupling" that is essential for efficient gas exchange.

Homeostasis

– The maintenance of stable internal conditions despite external changes. See general.

Hormone

– Chemical messenger secreted by endocrine glands into blood, acting on distant target organs with specific receptors. See biochemistry.

Humoral Immunity

– The component of adaptive immunity mediated by antibodies produced by B lymphocytes (plasma cells) that neutralize extracellular pathogens and toxins. Humoral responses defend against bacteria, viruses outside cells, and parasites. Primary response: naïve B cells recognize antigen, undergo activation, class switching, and affinity maturation in germinal centers, producing IgM then IgG; the secondary response to re-exposure is faster, larger, and of higher affinity due to memory B cells. Antibodies act by neutralization, opsonization, complement activation, and antibody-dependent cellular cytotoxicity. Defective humoral immunity causes recurrent sinopulmonary bacterial infections.

Hyperpolarization

– A change in membrane potential to a more negative value, moving it further from threshold and making the cell less excitable. Occurs when potassium leaves the cell (opening of voltage-gated potassium channels, as in the afterhyperpolarization after an action potential) or when chloride enters (GABA-A receptor activation). In neurons, GABAergic hyperpolarization inhibits firing; in cardiac cells, hyperpolarization of the resting potential by acetylcholine slows SA node rate (bradycardia). Hyperkalemia also hyperpolarizes, paradoxically reducing excitability.

Hypoxic Pulmonary

Vasoconstriction

– The unique response of pulmonary arterioles to low alveolar oxygen tension (PO₂ less than approximately 60 mmHg), causing vasoconstriction. Unlike systemic vessels that dilate in response to hypoxia, pulmonary vessels constrict, redirecting blood flow away from poorly ventilated alveoli toward better-ventilated regions, optimizing ventilation-perfusion (V/Q) matching. The mechanism involves inhibition of voltage-gated K⁺ channels in pulmonary artery smooth muscle cells, causing membrane depolarization, Ca²⁺ influx via L-type Ca²⁺ channels, and vasoconstriction. Chronic global hypoxia (as in COPD, high altitude) causes sustained vasoconstriction leading to pulmonary hypertension, right ventricular hypertrophy (cor pulmonale), and vascular remodelling. This response is unique to the pulmonary circulation; systemic vessels dilate in hypoxia.

Immune Response

– The coordinated reaction of the immune system to foreign substances (antigens), pathogens, or abnormal cells. The innate immune response acts rapidly and non-specifically (physical barriers, phagocytes, complement, NK cells, inflammation). The adaptive immune response is slower, antigen-specific, and provides immunological memory: humoral immunity via antibodies (B cells) and cell-mediated immunity via T cells (CD4⁺ helpers, CD8⁺ cytotoxic). The primary response occurs on first exposure; secondary responses are faster and stronger. Dysregulation causes autoimmunity, allergy/hypersensitivity, or immunodeficiency. Vaccination exploits the adaptive memory response.

JAK-STAT Pathway

– A rapid signaling pathway for cytokines and growth factors (interferons, interleukins, erythropoietin, growth hormone) that lack intrinsic enzymatic activity. Ligand binding to the cytokine receptor causes receptor dimerization and activation of associated Janus kinases (JAK1, JAK2, JAK3, TYK2) by trans-phosphorylation. Activated JAKs phosphorylate tyrosine residues on the receptor cytoplasmic domain, creating docking sites for STAT (signal transducers and activators of transcription) proteins, which are phosphorylated by JAKs, form homo- or heterodimers, and translocate to the nucleus where

they bind gamma-interferon activation site (GAS) or interferon-stimulated response element (ISRE) sequences to regulate gene transcription. The pathway is negatively regulated by SOCS (suppressor of cytokine signalling) proteins, PTPs (protein tyrosine phosphatases), and PIAS (protein inhibitor of activated STAT).

Ketogenesis

– See biochemistry.

Leukopoiesis

– The production and development of white blood cells (leukocytes) from hematopoietic stem cells in the bone marrow, regulated by colony-stimulating factors and interleukins. Neutrophils, eosinophils, and basophils derive from the myeloid lineage; lymphocytes (B, T, NK cells) from the lymphoid lineage; monocytes develop into macrophages and dendritic cells in tissues. Each lineage is stimulated by specific growth factors (e.g., G-CSF for neutrophils, IL-5 for eosinophils, IL-7 for lymphocytes). Leukopoiesis increases during infection and inflammation. Growth factors (filgrastim) are used clinically to treat neutropenia.

Ligand

– Any molecule that binds specifically to a biological receptor, macromolecule, or active site. In pharmacology and physiology, ligands include hormones, neurotransmitters, drugs, and toxins that bind receptors to initiate (agonist), block (antagonist), or modulate signaling. Binding is governed by affinity (tightness) and is typically reversible. The ligand-receptor interaction produces a conformational change that initiates intracellular signal transduction. Examples: insulin binding to the insulin receptor, acetylcholine to muscarinic receptors, oxygen to hemoglobin.

Lipoprotein Metabolism

– See biochemistry.

Lysosome

– Membrane-bound organelles containing hydrolytic enzymes (acid hydrolases: proteases, lipases, nucleases, glycosidases) functioning at low pH (4.5–5.0) maintained by V-ATPase proton pump. Degrade macromolecules from endocytosis, phagocytosis, and autophagy. Lysosomal enzymes synthesized in rough ER, tagged with mannose-6-phosphate

(M6P) in Golgi, targeted to lysosomes. Lysosomal storage diseases (Tay-Sachs, Gaucher, Niemann-Pick, Pompe, Fabry) result from enzyme deficiencies causing substrate accumulation. Lysosomes also involved in plasma membrane repair, cholesterol homeostasis (NPC1), and exocytosis.

Meiosis

– See genetics.

Membrane Potential

– The electrical potential difference across a cell membrane, approximately -70 mV in most neurons (resting membrane potential). Established by the unequal distribution of ions (primarily K⁺, Na⁺, Cl⁻) across the membrane and selective permeability. The Nernst equation calculates the equilibrium potential for a single ion: $E = (RT/zF) \ln([ion\ outside]/[ion\ inside])$. At body temperature for a monovalent cation, this simplifies to $E = 61.5 \log([out]/[in])$ mV. The Goldman equation accounts for multiple ion permeabilities to calculate the resting membrane potential: $V_m = 61.5 \log((PK[K^+]_o + PNa[Na^+]_o + PCl[Cl^-]_i) / (PK[K^+]_i + PNa[Na^+]_i + PCl[Cl^-]_o))$. The resting membrane is most permeable to K⁺ (via leak channels), so V_m is close to E_K (approximately -94 mV for K⁺). Changes in ion permeability (e.g., Na⁺ channels opening during depolarisation) drive electrical signalling.

Michaelis-Menten Kinetics

– The mathematical model describing the rate of enzyme-catalyzed reactions as a function of substrate concentration. The Michaelis-Menten equation: $v = (V_{max} \times [S]) / (K_m + [S])$, where v is the reaction velocity, V_{max} is the maximum velocity (when all enzyme is saturated with substrate), $[S]$ is the substrate concentration, and K_m is the Michaelis constant (the substrate concentration at which $v = V_{max}/2$). K_m reflects the enzyme's affinity for its substrate: a low K_m indicates high affinity (the enzyme reaches half-maximal velocity at a low substrate concentration). The turnover number ($k_{cat} = V_{max}/[Et]$) describes the catalytic efficiency; the ratio k_{cat}/K_m is the best measure of enzyme specificity, approaching the diffusion limit for perfect enzymes. Lineweaver-Burk (double reciprocal) plots linearise the equation: $1/v = K_m/V_{max} \times 1/[S] + 1/V_{max}$.

Micturition

– The process of urination, coordinated by the pontine micturition center, parasympathetic (pelvic nerve, S2-S4) contraction of the detrusor muscle, and relaxation of the internal (involuntary) and external (voluntary, pudendal nerve) urethral sphincters. The bladder fills at low pressure (compliance) until stretch receptors trigger the micturition reflex. In infants and animals, micturition is a spinal reflex; in adults, cortical control permits voluntary initiation and deferral. Disorders include urinary retention, incontinence, overactive bladder, and neurogenic bladder. Urodynamic studies evaluate the process.

Migrating Motor Complex

– Cyclical patterns of intense gastrointestinal motility occurring during fasting (interdigestive period), sweeping residual food, bacteria, and debris from the stomach through the small intestine to the colon. Each cycle lasts approximately 90-120 minutes and has four phases: Phase I (quiescence, approximately 45-60 minutes), Phase II (irregular contractions, approximately 30 minutes), Phase III (regular high-amplitude contractions at maximum frequency, approximately 5-15 minutes, the "housekeeper" phase that propels luminal contents distally), and Phase IV (declining activity returning to Phase I). The MMC is regulated by the migrating motor complex, motilin (released during fasting), and the enteric nervous system. Disruption of the MMC is associated with small intestinal bacterial overgrowth (SIBO).

Mitochondria

– Double-membrane organelles known as the "powerhouse of the cell," generating ATP through oxidative phosphorylation. Outer membrane is permeable; inner membrane is highly folded (cristae) and contains the electron transport chain and ATP synthase. Mitochondrial matrix contains TCA cycle enzymes, fatty acid beta-oxidation, and mitochondrial DNA (mtDNA, 16.5 kb, maternal inheritance). Mitochondria also regulate apoptosis (cytochrome c release), calcium homeostasis, ROS production, and heme/iron-sulfur cluster synthesis. Dysfunction causes mitochondrial diseases (MELAS, MERRF, LHON), contributes to neurodegeneration, aging, and metabolic disorders.

Mitosis

- See genetics.

Motor Unit

- A single alpha motor neuron and all the skeletal muscle fibers it innervates. The number of muscle fibers per motor unit determines precision of control: small motor units (few fibers, e.g., extraocular and hand muscles) provide fine movement; large motor units (hundreds to thousands of fibers, e.g., gastrocnemius) provide gross power. All fibers of a motor unit contract synchronously (all-or-none). Recruitment follows the size principle: small (slow, fatigue-resistant) motor units are recruited first, followed by larger (fast, fatigable) units as force demand increases.

Muscle Contraction

- The shortening or tension generation of muscle produced by the interaction of actin and myosin myofilaments. In skeletal and cardiac muscle, contraction follows excitation-contraction coupling: calcium binds troponin, tropomyosin moves aside, and myosin cross-bridges cycle against actin (sliding filament mechanism) using ATP. Types: isometric (tension without length change) and isotonic (shortening against constant load). Skeletal muscle contracts only when stimulated by a motor neuron; cardiac muscle contracts rhythmically by pacemaker activity; smooth muscle contraction is sustained, calcium-dependent, and regulated by autonomic nerves, hormones, and local factors.

Mutation

- Permanent change in DNA sequence. See genetics.

Na⁺/K⁺ ATPase

- The sodium-potassium pump is a P-type ATPase found in the plasma membrane of all animal cells, directly consuming approximately 20-30 percent of cellular ATP. It pumps 3 Na⁺ ions out of the cell and 2 K⁺ ions in per ATP hydrolyzed, establishing steep electrochemical gradients: high Na⁺ outside, high K⁺ inside. This gradient is essential for maintaining the resting membrane potential (approximately -70 mV), driving secondary active transport (e.g., glucose and amino acid absorption in the intestine and kidney, Na⁺/Ca²⁺ exchange), and regulating cell volume. The pump is inhibited by cardiac glycosides such as ouabain and digoxin (used in heart failure

to increase intracellular Ca²⁺ and contractility).

Natural Killer Cell

- A type of innate lymphoid cell (lymphocyte) that provides early defense against virus-infected cells and tumor cells without prior sensitization. NK cells recognize stressed or missing-self cells (absent or altered MHC class I) and kill them by releasing perforin and granzymes, or through antibody-dependent cellular cytotoxicity. They also secrete cytokines (interferon-gamma, TNF) that activate macrophages and shape the adaptive response. Regulated by activating and inhibitory receptors. Deficiencies cause severe herpesvirus infections. Large granular lymphocyte morphology on blood smear.

Necrosis

- Death of tissue. See [pathology](#).

Negative Feedback

- A regulatory mechanism in which the output of a system feeds back to decrease or reverse the initiating stimulus, maintaining homeostasis around a set point. Examples: insulin secretion in response to hyperglycemia lowers blood glucose, which then reduces insulin secretion; the hypothalamic-pituitary-thyroid axis (TRH, TSH, thyroid hormone) is self-limiting; baroreceptors counteract changes in blood pressure; body temperature regulation opposes deviations from the set point. Negative feedback is the dominant homeostatic mechanism and underlies normal endocrine, cardiovascular, and metabolic regulation. Disruption causes disease (e.g., autonomous hormone secretion).

Nephron Function

- The nephron is the functional unit of the kidney, with approximately 1 million per kidney. Each nephron consists of a renal corpuscle (glomerulus and Bowman's capsule) and a renal tubule (proximal convoluted tubule, loop of Henle, distal convoluted tubule, and collecting duct). The nephron performs three primary functions: filtration (at the glomerulus, producing approximately 180 L/day of ultrafiltrate), reabsorption (reclaiming approximately 99 percent of filtered water and solutes), and secretion (transporting substances from the blood into the tubular lumen for elimination). The loop of Henle establishes the medullary osmotic gradient for urine concentration; the collecting duct performs final

regulation of water and electrolyte balance under the control of ADH and aldosterone.

Noncompetitive Inhibition

- A type of enzyme inhibition where the inhibitor binds at a site distinct from the active site (allosteric site), and can bind to both the free enzyme (E) and the enzyme-substrate complex (ES) with equal affinity. The inhibitor does not compete with the substrate and cannot be overcome by increasing substrate concentration. The apparent V_{max} decreases (fewer functional enzyme molecules) while K_m remains unchanged (substrate affinity is unaffected since the inhibitor does not compete for the active site). On a Lineweaver-Burk plot: lines intersect on the x-axis (same $-1/K_m$) with different slopes and y-intercepts. Noncompetitive inhibition is less common than competitive inhibition in pharmacology but is important in metal ion toxicity and certain pesticide actions.

Nucleus

- The membrane-bound organelle containing the genetic material (DNA) in eukaryotic cells. Surrounded by the nuclear envelope (double membrane with nuclear pores for transport). Contains chromatin (DNA + histone proteins), nucleolus (ribosome biogenesis), and nuclear matrix. The nuclear pores regulate nucleocytoplasmic transport of proteins, RNA, and ribosomal subunits. During mitosis, the nuclear envelope breaks down (open mitosis) and reforms in daughter cells. The nucleus is the site of DNA replication, transcription, and RNA processing.

Oncotic Pressure

- The osmotic pressure exerted by plasma proteins (predominantly albumin) that do not freely cross the capillary wall. Normal plasma oncotic pressure is approximately 25-28 mmHg. It opposes the hydrostatic pressure that drives fluid out of capillaries, favoring fluid reabsorption at the venular end. According to Starling forces, net filtration = $K_f [(P_c - P_i) - (\pi_c - \pi_i)]$. Reduced plasma proteins (hypoalbuminemia in cirrhosis, nephrotic syndrome, malnutrition) lower oncotic pressure, decreasing fluid reabsorption and causing edema and ascites.

Osmosis

- The net movement of water molecules across a

semipermeable membrane from a region of lower solute concentration (higher water concentration) to a region of higher solute concentration (lower water concentration). Driven by the osmotic pressure difference, which is proportional to the number of solute particles. Osmolarity is measured in osmoles per liter (mOsm/L); normal plasma osmolarity is approximately 285-295 mOsm/L. Tonicity describes the effect of a solution on cell volume: hypotonic solutions cause cell swelling (osmotic lysis), hypertonic solutions cause cell shrinkage (crenation). The concept is clinically critical for intravenous fluid therapy: normal saline (0.9 percent NaCl, approximately 308 mOsm/L) is isotonic and does not cause red blood cell lysis; hypotonic fluids (0.45 percent NaCl) may cause haemolysis if infused rapidly.

Osmotic Pressure

- The pressure required to prevent the movement of water across a semipermeable membrane when a solute concentration gradient exists, proportional to the number of dissolved particles (van't Hoff law: $\pi = iCRT$). It is a colligative property depending on particle number, not particle identity. In physiology, tonicity describes the effective osmotic pressure for impermeant solutes: isotonic solutions (0.9 percent saline, 5 percent dextrose) cause no red cell volume change; hypotonic solutions cause cell swelling/lysis; hypertonic solutions cause cell shrinkage. Plasma osmolality (275-295 mOsm/kg) is regulated by ADH and thirst.

Oxidative Phosphorylation

- Process generating ATP using energy released by electron transfer through the electron transport chain. See biochemistry.

Oxygen Consumption

- The volume of oxygen consumed by the body per unit time, reflecting overall metabolic rate. Resting oxygen consumption ($\dot{V}O_2$) in a normal adult is approximately 250 mL/min (about 3.5 mL/kg/min, 1 MET). It is calculated as cardiac output $\times$ (arterial O_2 content - venous O_2 content) by the Fick principle. Oxygen consumption increases with exercise, fever, and hyperthyroidism, and decreases with hypothermia, hypothyroidism, and anesthesia. Maximum oxygen consumption ($\dot{V}O_{2\max}$) measures aerobic capacity and is used in cardiopulmonary

exercise testing and heart failure prognosis.

Oxygen Delivery

- The rate at which oxygen is transported from the lungs to the tissues, equal to cardiac output multiplied by arterial oxygen content: $DO_2 = CO \times CaO_2$. Arterial oxygen content = $(1.34 \times \text{hemoglobin} \times SaO_2) + (0.003 \times PaO_2)$. Normal oxygen delivery is approximately 1000 mL/min. Determinants include cardiac output, hemoglobin concentration, and oxygen saturation. Oxygen delivery declines with anemia, hypoxemia, reduced cardiac output, or carbon monoxide poisoning. The balance between delivery and consumption determines tissue oxygenation; a critical DO_2 threshold leads to anaerobic metabolism and lactate production.

Oxygen-Hemoglobin Dissociation Curve

- The sigmoidal relationship between partial pressure of oxygen (PO_2) and hemoglobin oxygen saturation (SO_2). The curve reflects hemoglobin's cooperative binding: oxygen binding to one subunit increases affinity for subsequent oxygen molecules. At PO_2 of 100 mmHg (alveolar), hemoglobin is approximately 98 percent saturated. At PO_2 of 40 mmHg (mixed venous), saturation is approximately 75 percent. The steep portion of the curve (PO_2 20-60 mmHg) allows large oxygen unloading with small PO_2 decreases in tissue capillaries. The curve is shifted rightward (decreased affinity) by increased temperature, decreased pH (Bohr effect), increased PCO_2 , and increased 2,3-BPG, enhancing oxygen unloading. Leftward shifts (increased affinity) occur with decreased temperature, increased pH, and decreased 2,3-BPG (e.g., stored blood), reducing oxygen unloading. fetal hemoglobin (HbF) has a left-shifted curve for placental oxygen transfer.

Pancreatic Enzyme

- Digestive enzymes secreted by pancreatic acinar cells into the duodenum, including proteases (trypsinogen, chymotrypsinogen, proelastase, procarboxypeptidases), amylase (starch digestion), and lipase (triglyceride digestion), along with bicarbonate from ductal cells to neutralize gastric acid. Enzymes are secreted in inactive zymogen form and activated in the duodenum (trypsinogen to trypsin by enterokinase; trypsin then activates the others)

to prevent autodigestion. Lipase requires bile salts and colipase for efficient fat digestion. Deficiency (chronic pancreatitis, cystic fibrosis) causes malabsorption, steatorrhea, and protein-energy malnutrition.

Pentose Phosphate Pathway

- A cytoplasmic glucose oxidation pathway running parallel to glycolysis, primarily in the liver, adipose tissue, adrenal cortex, and red blood cells. It has two phases: the oxidative phase (producing NADPH and ribose-5-phosphate) and the non-oxidative phase (interconverting sugar phosphates). Key enzyme: glucose-6-phosphate dehydrogenase (G6PD), the rate-limiting enzyme, producing NADPH. NADPH is essential for: fatty acid and steroid biosynthesis, maintaining reduced glutathione (protecting red blood cells from oxidative damage and preventing haemolysis), and cytochrome P450 detoxification. The non-oxidative phase recycles ribose-5-phosphate to glycolytic intermediates. G6PD deficiency (X-linked, common in Mediterranean, African, and Asian populations) causes hemolytic anemia triggered by oxidative stress from drugs (primaquine, sulphonamides) or fava beans.

Peristalsis

- Rhythmic sequential contractions of longitudinal and circular smooth muscle that propel gastrointestinal contents in an aboral (oral to anal) direction. The peristaltic reflex involves stretch activation of the intestinal wall: proximal to the stretch, longitudinal muscle contracts and circular muscle relaxes (ascending contraction); distally, circular muscle contracts and longitudinal muscle relaxes (descending relaxation). This is mediated by the myenteric (Auerbach's) plexus: excitatory neurotransmitters (acetylcholine, substance P) cause proximal contraction, and inhibitory neurotransmitters (VIP, nitric oxide) cause distal relaxation. Peristalsis propels chyme at a rate of approximately 1 cm/min in the small intestine, 5-10 cm/min in the esophagus, and is slower in the colon. Disorders include achalasia (failure of LES relaxation), intestinal pseudo-obstruction, and Hirschsprung disease.

Peroxisome

- Single-membrane organelles containing oxidative enzymes (catalase, urate oxidase, D-amino acid ox-

idase) that produce and degrade hydrogen peroxide (H₂O₂). Functions: very-long-chain fatty acid beta-oxidation, plasmalogen synthesis (ether phospholipids for myelin), bile acid synthesis, cholesterol synthesis (initial steps), amino acid catabolism, ROS detoxification. Peroxisomes import proteins post-translationally via PTS1/PTS2 signals. Disorders: Zellweger syndrome (peroxisome biogenesis), X-linked adrenoleukodystrophy (VLCFA accumulation), Refsum disease (phytanic acid).

Phenylketonuria

- See genetics.

Phospholipase C Pathway

- A GPCR signaling pathway activated primarily by Gq-protein coupled receptors (e.g., alpha-1 adrenergic, muscarinic M1/M3, vasopressin V1, angiotensin II AT1 receptors). When the Gq-alpha subunit is activated, it stimulates phospholipase C-beta (PLC-beta), which cleaves the membrane phospholipid phosphatidylinositol 4,5-bisphosphate (PIP₂) into two second messengers: inositol 1,4,5-trisphosphate (IP₃) and diacylglycerol (DAG). IP₃ is a water-soluble molecule that diffuses through the cytoplasm and binds to IP₃ receptors on the endoplasmic reticulum, triggering Ca²⁺ release into the cytoplasm. DAG remains in the membrane and activates protein kinase C (PKC), which phosphorylates downstream target proteins. The Ca²⁺ signal activates calmodulin-dependent kinases (CaMK), and the pathway mediates smooth muscle contraction, neurotransmitter release, hormone secretion, and cell proliferation.

Phytomenadione

- Vitamin K is a fat-soluble vitamin essential for the post-translational gamma-carboxylation of glutamate residues to gamma-carboxyglutamate (Gla) in specific clotting factors (II, VII, IX, X, protein C, protein S) and anticoagulant proteins (protein C, protein S, protein Z). See [Vitamin K: Phylloquinone](#).

Platelet Aggregation

- The adhesion and clumping of platelets to form a hemostatic plug at sites of vascular injury. Following exposure of subendothelial collagen, platelets adhere via von Willebrand factor and GPIb receptors, become activated (shape change, granule release of

ADP, thromboxane A₂, serotonin), and aggregate by linking activated GPIIb/IIIa receptors with fibrinogen. Aggregation amplifies primary hemostasis and is essential for clot formation. Inhibited therapeutically by aspirin (irreversible COX-1 inhibition), clopidogrel and ticagrelor (P2Y₁₂ ADP receptor blockade), and GPIIb/IIIa antagonists. Platelet aggregation testing (e.g., aggregometry) evaluates platelet function.

Positive Feedback

- A regulatory mechanism in which an output amplifies the initiating stimulus, producing an accelerating or self-reinforcing response that drives the system away from equilibrium and toward completion of an event. Examples: the oxytocin-induced uterine contractions of labor strengthen until delivery; sodium channel opening during an action potential causes further depolarization; platelet activation promotes further activation during hemostasis; the LH surge of ovulation. Positive feedback loops are inherently unstable and are typically terminated by an external event.

Proprioception

- The sense of body position, movement, and joint position arising from mechanoreceptors in muscles (muscle spindles), tendons (Golgi tendon organs), and joints, as well as skin receptors. Signals ascend via the dorsal column-medial lemniscal pathway (conscious proprioception) and the spinocerebellar tract (unconscious). Proprioception is essential for coordinated movement, posture, balance, and motor learning. Loss (peripheral neuropathy, dorsal column disease such as tabes dorsalis) produces ataxia, unsteadiness with eyes closed (positive Romberg sign), and impaired fine motor control. Tested by joint position sense and vibration sense.

Protein

- Polymer of amino acids linked by peptide bonds. See biochemistry.

Protein Folding

- The process by which newly synthesized polypeptide chains acquire their functional three-dimensional structures. The amino acid sequence (primary structure) determines the folding pathway. Key structural levels: primary (amino acid sequence), secondary (alpha-helices and beta-sheets

formed by hydrogen bonding), tertiary (overall 3D fold of a single polypeptide), and quaternary (arrangement of multiple subunits). Chaperone proteins assist proper folding: Hsp70 (heat shock protein 70) binds exposed hydrophobic regions of nascent polypeptides; Hsp60 (chaperonin, GroEL/GroES in bacteria) provides an isolated compartment for folding. Misfolded proteins are targeted for degradation by the ubiquitin-proteasome system. Protein misfolding causes conformational diseases including Alzheimer's (amyloid-beta), Parkinson's (alpha-synuclein), prion diseases (Creutzfeldt-Jakob), and cystic fibrosis (CFTR misfolding).

Proximal Tubule Reabsorption

– The proximal convoluted tubule (PCT) reabsorbs approximately 65 percent of filtered sodium, water, glucose, amino acids, bicarbonate, and phosphate. Sodium reabsorption is the driving force for most solute and water transport: the basolateral Na^+/K^+ ATPase creates a low intracellular Na^+ concentration, allowing Na^+ entry from the tubular lumen via secondary active transporters ($\text{Na}^+/\text{glucose}$, $\text{Na}^+/\text{amino acid}$ cotransporters on the apical membrane; Na^+/H^+ exchanger). Water follows sodium osmotically via aquaporins (AQP1) in the proximal tubule. Glucose and amino acids are completely reabsorbed in the early PCT via sodium-coupled transporters (SGLT2 for glucose, SGLT1 for glucose and amino acids) until their transport maximum (T_m) is exceeded. Bicarbonate is reabsorbed via H^+ secretion (Na^+/H^+ exchanger) and carbonic anhydrase in the brush border. Phosphate reabsorption is regulated by PTH (decreases reabsorption, increases phosphate excretion).

Pulmonary Surfactant

– A phospholipid-protein mixture produced by type II alveolar pneumocytes that reduces surface tension at the air-liquid interface within alveoli. The primary component is dipalmitoylphosphatidylcholine (DPPC, lecithin), which forms a monolayer that reduces surface tension to near zero during expiration. Surfactant prevents alveolar collapse (atelectasis) at end-expiration by reducing the collapsing force, increases lung compliance, and stabilizes alveoli of different sizes (preventing small alveoli from collapsing into larger ones via the LaPlace relationship).

Surfactant is produced from approximately week 24 of gestation, and its deficiency in premature infants causes respiratory distress syndrome (RDS) with atelectasis, hypoxaemia, and the need for surfactant replacement therapy and mechanical ventilation.

Pyruvate

– The three-carbon alpha-keto acid produced at the end of glycolysis from phosphoenolpyruvate by pyruvate kinase. Under aerobic conditions, pyruvate enters the mitochondrial matrix via the mitochondrial pyruvate carrier (MPC) and is converted to acetyl-CoA by the pyruvate dehydrogenase complex (PDC), an irreversible reaction that also produces CO_2 and NADH. The PDC requires five co-factors derived from vitamins: thiamine pyrophosphate (B1), FAD (B2), NAD^+ (B3), CoA (from pantothenic acid, B5), and lipoic acid. Under anaerobic conditions, pyruvate is reduced to lactate by lactate dehydrogenase, regenerating NAD^+ for continued glycolysis. Pyruvate is the branch point between aerobic (TCA cycle) and anaerobic (lactate) metabolism, and its fate is determined by oxygen availability and tissue metabolic demands.

Receptor

– A protein that binds a specific signaling molecule (ligand) and initiates a cellular response. Types: (1) Cell surface: ion channel (nicotinic AChR), G-protein coupled (GPCR: adrenergic, muscarinic, opioid), enzyme-linked (RTK: insulin receptor, cytokine receptors). (2) Intracellular: nuclear (steroid, thyroid, vitamin D), cytoplasmic (some steroid). Signal transduction: ligand binding $\rightarrow$ conformational change $\rightarrow$ second messengers (cAMP, IP_3/DAG , Ca^{2+}) or kinase cascades (MAPK, PI3K/Akt, JAK/STAT). Desensitization: phosphorylation, internalization, downregulation. Clinical: drug targets (agonists, antagonists, inverse agonists).

Receptor Tyrosine Kinases

– Single-pass transmembrane receptors with intrinsic tyrosine kinase activity in their intracellular domain. Ligand binding (e.g., insulin, EGF, PDGF, FGF) induces receptor dimerization and autophosphorylation of tyrosine residues. Phosphorylated tyrosines serve as docking sites for intracellular signaling proteins containing SH2 domains, activating

downstream cascades: the Ras-MAP kinase pathway (cell proliferation and differentiation), the PI3-kinase/Akt pathway (cell survival and metabolism), and the PLC-gamma pathway (Ca^{2+} signalling). RTKs are frequently mutated or overexpressed in cancer (e.g., HER2 in breast cancer, EGFR in lung cancer), making them important therapeutic targets for tyrosine kinase inhibitors (imatinib, gefitinib, trastuzumab).

Refractory Period

- The period after an action potential during which a cell cannot (absolute refractory period) or can only partially (relative refractory period) generate a new action potential. The absolute refractory period results from sodium channel inactivation and ensures one-way action potential propagation and prevents summation; the relative refractory period reflects recovery of some sodium channels with continued potassium conductance, allowing a second action potential only if stimulated more strongly. In cardiac muscle, the long refractory period prevents tetany and allows rhythmic pumping; shortened cardiac refractoriness (QT prolongation, early afterdepolarizations) predisposes to arrhythmias.

Renal Clearance

- The volume of plasma completely cleared of a substance by the kidneys per unit time, measured in mL/min. Clearance of any substance X is calculated as: $\text{CX} = (\text{Ux} \times \text{V})/\text{Px}$, where Ux is urine concentration, V is urine flow rate, and Px is plasma concentration. Inulin clearance equals GFR (approximately 125 mL/min) because inulin is freely filtered but neither reabsorbed nor secreted. Para-aminohippuric acid (PAH) clearance approximates renal plasma flow (approximately 625 mL/min) because it is both filtered and completely secreted by the proximal tubule. Creatinine clearance is the most common clinical GFR estimate; cystatin C is a more accurate alternative unaffected by muscle mass. The concept is essential for determining drug dosing in renal impairment.

Renin-Angiotensin-Aldosterone System

- The RAAS is a hormonal cascade regulating blood pressure, fluid volume, and electrolyte balance. Stimulus: decreased renal perfusion pressure (de-

tected by baroreceptors in the afferent arteriole), decreased sodium delivery to the macula densa, or increased sympathetic activity. Renin (from juxtaglomerular cells) cleaves angiotensinogen (from the liver) to angiotensin I. Angiotensin-converting enzyme (ACE, primarily in pulmonary endothelium) converts angiotensin I to angiotensin II. Angiotensin II is a potent vasoconstrictor, stimulates aldosterone secretion (Na^+ and water retention), increases ADH release, enhances thirst, increases sympathetic activity, and promotes cardiac and vascular remodelling. The RAAS is a target of ACE inhibitors, angiotensin receptor blockers (ARBs), direct renin inhibitors, and mineralocorticoid receptor antagonists for treating hypertension and heart failure.

Repolarization

- The return of the membrane potential toward the resting value after depolarization. In neurons and skeletal/cardiac muscle, repolarization is primarily caused by the efflux of potassium through voltage-gated potassium channels and inactivation of sodium channels. In cardiac tissue, phase 3 repolarization is mediated by delayed rectifier potassium currents (IKr, IKs); drugs that block these currents prolong repolarization and the QT interval, predisposing to torsades de pointes. On the ECG, ventricular repolarization produces the T wave. Disturbed repolarization (ST changes, T wave abnormalities) is a key marker of ischemia and electrolyte imbalance.

Residual Volume

- The volume of air remaining in the lungs after a maximal forced expiration, approximately 1.2 L in adults. Residual volume cannot be measured by simple spirometry because it cannot be exhaled; it is measured by body plethysmography, helium dilution, or nitrogen washout. It keeps alveoli patent and prevents alveolar collapse at end expiration, maintaining continuous gas exchange. Residual volume is increased in obstructive lung disease (air trapping, COPD, emphysema) and decreased in restrictive lung disease.

Respiratory Physiology

- The study of pulmonary function encompassing ventilation (movement of air), gas exchange (diffusion of O_2 and CO_2 across the alveolar-

capillary membrane), transport of gases in blood, and regulation of breathing. Key concepts include lung volumes and capacities, alveolar ventilation, dead space, ventilation-perfusion matching, the oxygen-hemoglobin dissociation curve, and the chemoreceptor-mediated control of ventilation. Understanding respiratory physiology underpins the interpretation of spirometry, blood gases, and the management of respiratory failure, hypoxemia, and hypercapnia.

Respiratory Rate

- The number of breaths per minute. Normal adult respiratory rate is 12-20 breaths/min at rest; normal newborn rate is 30-60. Tachypnea (>20 in adults) occurs with fever, hypoxia, acidosis, pain, anxiety, and lung disease; bradypnea (<12) with sedative/opioid overdose, hypothyroidism, and raised intracranial pressure; Kussmaul respirations (deep, rapid) with metabolic acidosis (DKA); Cheyne-Stokes with heart failure and brainstem lesions. Respiratory rate is the first vital sign to change in acute illness and a key component of early warning scores.

Resting Membrane Potential

- The steady electrical potential difference across the cell membrane of an unstimulated cell, typically -70 mV in neurons, -80 to -90 mV in skeletal and cardiac muscle, and -50 to -60 mV in smooth muscle. It is generated by the differential distribution of ions established by the Na^+/K^+ ATPase (3 Na^+ out, 2 K^+ in) and maintained by selective membrane permeability—highest to potassium—so the potential approaches the potassium equilibrium potential (Nernst, -90 mV), with small contributions from sodium and chloride leak. The resting potential is the baseline from which depolarization (toward threshold) or hyperpolarization (away) occurs.

Retinol

- Vitamin A (retinol) is a fat-soluble vitamin essential for vision, immune function, cell differentiation, and reproduction. See [Vitamin A: Retinal](#).

Ribosome

- Ribonucleoprotein complexes (rRNA + proteins) that synthesize proteins by translating mRNA. Two subunits: 60S (large, 28S/5.8S/5S rRNA) and 40S (small, 18S rRNA) in eukaryotes (80S complete). Prokaryotes have 50S/30S (70S complete). Free

ribosomes in cytosol make cytosolic/nuclear proteins; bound ribosomes on rough ER make secretory/membrane/organellar proteins. Each ribosome has A, P, and E sites for tRNA binding. Translation: initiation (start codon recognition), elongation (codon-anticodon pairing, peptide bond formation), termination (stop codon recognition).

RNA

- Ribonucleic acid, single-stranded nucleic acid (ribose sugar, uracil instead of thymine). Types: mRNA (messenger, carries genetic code from DNA to ribosome), tRNA (transfer, brings amino acids to ribosome, anticodon-codon pairing), rRNA (ribosomal, structural/catalytic component of ribosome), snRNA (spliceosomal, intron removal), miRNA/siRNA (regulatory, post-transcriptional silencing), lncRNA (long non-coding, chromatin regulation), piRNA (transposon silencing in germline). Transcription: RNA polymerase II synthesizes pre-mRNA from DNA template.

Salivation

- The secretion of saliva by the salivary glands. Salivation is controlled by the autonomic nervous system: parasympathetic stimulation (CN VII—submandibular and sublingual glands; CN IX—parotid gland) produces profuse, watery saliva via acetylcholine acting on muscarinic M_3 receptors; sympathetic stimulation produces scanty, viscous saliva via noradrenaline acting on β -adrenergic receptors. Salivation is triggered by: sight, smell, or thought of food (cephalic phase), mechanical stimulation of the mouth (food in the oral cavity), and the presence of acid or chemical irritants. The salivary center is located in the medulla oblongata (superior and inferior salivatory nuclei). Daily volume: 1–1.5 L. Hypersalivation (sialorrhoea) can be caused by oral inflammation, teething, pregnancy, neurological disorders (Parkinson disease, motor neuron disease, cerebral palsy, rabies), gastro-esophageal reflux, and medications (clozapine, anticholinesterases). Hyposalivation (xerostomia/dry mouth): Sjögren syndrome, radiation therapy to the head and neck, medications (anticholinergics, antidepressants, antihistamines, diuretics), diabetes, and dehydration.

Saltatory Conduction

- The rapid propagation of action potentials along

myelinated nerve fibers, where the action potential appears to "jump" from one Node of Ranvier to the next. Myelin (produced by Schwann cells in the PNS and oligodendrocytes in the CNS) insulates the axon, preventing ion flow across the internodal membrane. Action potentials are generated only at the nodes (approximately 1 mm apart), where voltage-gated Na^+ channels are concentrated. The local current from one node depolarises the next node to threshold, causing saltatory conduction at speeds up to 50 m/s in myelinated fibers (compared to approximately 0.5 m/s in unmyelinated fibers). Saltatory conduction is energy-efficient, as Na^+/K^+ ATPase activity is required only at the nodes. Demyelinating diseases such as multiple sclerosis (CNS) and Guillain-Barré syndrome (PNS) slow or block conduction, causing neurological deficits.

Second Messenger Systems

– Intracellular signaling molecules that relay extracellular signals (first messengers: hormones, neurotransmitters, growth factors) to cellular responses. Major second messengers: cAMP (produced by adenylyl cyclase from ATP, activated by Gs-GPCRs; activates PKA; degraded by phosphodiesterase; example: epinephrine binding beta-1 receptors in the heart increasing heart rate and contractility). cGMP (produced by guanylyl cyclase; activated by nitric oxide in smooth muscle causing vasodilation; also activated by natriuretic peptides ANP/BNP). IP₃ (produced by phospholipase C from PIP₂, releases Ca^{2+} from ER). DAG (produced with IP₃, activates PKC). Ca^{2+} itself acts as a second messenger, activating calmodulin and CaMK. Second messenger systems provide signal amplification: a single activated receptor can activate many G-proteins, each activating an enzyme that produces many second messenger molecules.

Second Messengers

– Intracellular signaling molecules generated in response to extracellular signals (first messengers like hormones or neurotransmitters). cAMP (cyclic adenosine monophosphate): produced from ATP by adenylyl cyclase, activated by Gs-protein coupled receptors, activates protein kinase A (PKA); degraded by phosphodiesterase. IP₃ (inositol 1,4,5-trisphosphate): produced from PIP₂ by phospholipase C, triggers Ca^{2+} release from the endoplasmic

reticulum. DAG (diacylglycerol): remains in the membrane along with IP₃, and together they activate protein kinase C (PKC). Ca^{2+} is a versatile second messenger that binds calmodulin, activating CaMKII (in neurons, critical for long-term potentiation and memory formation). The second messenger concept is central to understanding hormone action, drug effects, and intracellular communication.

Secretin

– A peptide hormone produced by S-cells in the duodenal and jejunal mucosa in response to acidic chyme (pH less than 4.5) entering the duodenum from the stomach. Secretin's primary action is to stimulate the pancreatic ductal cells to secrete a bicarbonate-rich fluid, neutralizing duodenal acid and raising the pH to approximately 7-8, which optimizes pancreatic enzyme activity. Secretin also inhibits gastric acid secretion and gastric motility (slowing gastric emptying), stimulates bile secretion and gallbladder contraction, and enhances the effects of cholecystokinin (CCK). Secretin release is inhibited by H^+ buffering in the duodenum (negative feedback). Secretin was the first hormone discovered (Bayliss and Starling, 1902), establishing the concept of hormonal regulation.

Segmentation

– A pattern of intestinal motility involving localized, rhythmic contractions of circular muscle that segment the intestinal contents, mixing them with digestive secretions and increasing contact with the absorptive mucosal surface. Unlike peristalsis, segmentation does not propel contents distally. It occurs predominantly in the fed state in the small intestine, at a frequency determined by the slow wave rhythm of the intestine (approximately 12 per minute in the duodenum, 8 per minute in the ileum). The contractions are mediated by the enteric nervous system and the interstitial cells of Cajal (pacemaker cells). Segmentation is essential for efficient digestion and absorption; loss of segmentation occurs in intestinal obstruction and ileus.

Sensory Nerves

– Nerves that transmit sensory information from peripheral receptors to the central nervous system. Sensory (afferent) neurons have their cell bodies in the dorsal root ganglia (spinal nerves) or cra-

nial nerve ganglia (cranial nerves). Sensory receptors: mechanoreceptors (touch, pressure, vibration, stretch—Pacinian corpuscles, Meissner corpuscles, Merkel discs, Ruffini endings), thermoreceptors (cold—A δ fibers; warm—unmyelinated C fibers), nociceptors (pain—A δ fibers: fast, sharp, localised; C fibers: slow, dull, diffuse), chemoreceptors (taste, smell, O₂, CO₂, pH), and photoreceptors (rods and cones in the retina). Sensory pathways: spinothalamic tract (pain, temperature, crude touch—crosses in spinal cord), dorsal columns/medial lemniscus (fine touch, vibration, proprioception—crosses in medulla), and trigeminothalamic tract (facial sensation). Dermatomes: areas of skin supplied by a single spinal nerve (C4—shoulder, C6—thumb, C8—little finger, T4—nipple, T10—umbilicus, L4—medial foot, S1—lateral foot). Sensory deficits help localise neurological lesions at the level of the peripheral nerve, plexus, nerve root, spinal cord, brainstem, thalamus, or cortex.

Shivering

– Involuntary, rhythmic skeletal muscle contraction generating heat in response to cold exposure or fever, a key thermoregulatory response under hypothalamic (preoptic area) control. Shivering can increase heat production 3-5 fold. It is triggered when core temperature falls below the set point and sympathetic activation increases muscle tone, followed by rhythmic oscillation. Shivering also occurs during fever when the set point is raised. Postoperative shivering after anesthesia is common and treated with warming. It increases metabolic rate and oxygen consumption, relevant in hypothermic or post-arrest patients.

Signal Transduction

– The process by which an extracellular signal (hormone, neurotransmitter, growth factor, drug) binding to a cell-surface or intracellular receptor is converted into a specific intracellular response. Major pathways: G protein-coupled receptors (adenyl cyclase/cAMP, phospholipase C/IP₃/DAG), receptor tyrosine kinases (Ras-MAPK, PI3K-Akt), ligand-gated ion channels, and nuclear receptors (steroid/thyroid hormones modulating gene transcription). Pathways involve second messengers (cAMP, calcium, DAG, IP₃), phosphorylation cas-

cades, and transcription factors. Dysregulated signal transduction underlies cancer, diabetes, and many endocrinopathies; many drugs target these pathways.

Sliding Filament

– The mechanism of muscle contraction in which actin filaments slide past myosin filaments, shortening the sarcomere without changing filament lengths. Myosin cross-bridges bind actin, undergo a power stroke using ATP hydrolysis, detach, and reattach to new actin sites in a cyclic manner. The extent of sliding is limited by the overlap between thin (actin) and thick (myosin) filaments. Active tension depends on sarcomere length (Frank-Starling-like length-tension relationship in muscle). Contraction stops when calcium is pumped back into the sarcoplasmic reticulum, allowing tropomyosin to block cross-bridge binding.

Stretch Reflex

– A monosynaptic spinal reflex in which stretching a muscle (e.g., a tap on the patellar tendon) excites muscle spindles, generating an afferent signal (Ia fibers) that directly excites the alpha motor neurons of the same muscle, causing contraction and resistance to stretch. Reciprocal inhibition via Ia inhibitory interneurons relaxes antagonists. The stretch reflex maintains posture, resists gravity, and is tested by deep tendon reflexes (e.g., patellar, biceps, ankle). Reduced reflexes indicate lower motor neuron lesions; hyperactive reflexes with clonus indicate upper motor neuron lesions.

Sweating

– The secretion of sweat by eccrine glands, the primary heat-loss mechanism in humans, controlled by sympathetic cholinergic innervation (in contrast to the catecholaminergic sympathetic response elsewhere). Evaporation of sweat cools the skin; sweating is triggered by elevated core temperature (hypothalamic preoptic area), exercise, emotional stress, and fever. Sweat contains water, sodium chloride, urea, and lactate. Loss of sodium through sweat is clinically relevant in cystic fibrosis (elevated sweat chloride—the diagnostic test). Disorders include hyperhidrosis (excessive sweating) and anhidrosis (impaired sweating, predisposing to hyperthermia).

Sympathetic Nervous System

– The division of the autonomic nervous system responsible for the 'fight or flight' response, preparing the body for intense physical activity or stress. Sympathetic preganglionic neurons originate in the intermediolateral column of the spinal cord gray matter (T1–L2), making it the thoracolumbar system. Preganglionic fibers are short and synapse in the paravertebral sympathetic chain ganglia (bilaterally, 22 ganglia) or prevertebral ganglia (celiac, superior mesenteric, inferior mesenteric, aorticorenal). The neurotransmitter of preganglionic fibers is acetylcholine (nicotinic receptors); postganglionic fibers release noradrenaline (norepinephrine) at target organs (adrenergic α and β receptors), except sweat glands and some blood vessels (cholinergic). Sympathetic effects: pupil dilation (mydriasis), increased heart rate and contractility (chronotropic and inotropic— β_1), bronchodilation (β_2), vasoconstriction of skin and splanchnic vessels (α_1), vasodilation of skeletal muscle vessels (β_2), increased sweating (cholinergic), increased renin secretion (β_1), decreased GI motility and secretion (α_2 , β_2), contraction of sphincters (urinary, anal— α_1), ejaculation, and release of glucose (glycogenolysis— β_2 , gluconeogenesis). The adrenal medulla (modified sympathetic ganglion) secretes adrenaline (epinephrine, 80%) and noradrenaline (20%) into the bloodstream. The sympathetic nervous system also controls blood pressure via the baroreceptor reflex.

Synapse

– The specialized junction between a neuron and another neuron (or effector cell—muscle, gland) where information is transmitted from one cell to another. Types: (1) Chemical synapses (most common in the nervous system)—the presynaptic terminal releases neurotransmitter molecules into the synaptic cleft (20–40 nm wide) in response to an action potential. Neurotransmitters diffuse across the cleft and bind to postsynaptic receptors (ionotropic—ligand-gated ion channels, fast response; metabotropic—G-protein coupled receptors, slow, modulatory). This generates either an excitatory postsynaptic potential (EPSP—depolarisation) or inhibitory postsynaptic potential (IPSP—hyperpolarisation). Summation of many EPSPs reaching threshold generates a new

action potential. (2) Electrical synapses—gap junctions (connexin proteins) allow direct flow of ions between cells, enabling very fast, bidirectional transmission (found in smooth and cardiac muscle, some CNS regions). Key neurotransmitters: glutamate (main excitatory CNS transmitter), GABA (main inhibitory CNS transmitter), acetylcholine (neuromuscular junction, autonomic ganglia), dopamine, noradrenaline, serotonin, and neuropeptides (substance P, endorphins). Synaptic plasticity: long-term potentiation (LTP) and long-term depression (LTD)—mechanisms of learning and memory. The synapse is the site of action of many drugs (anaesthetics, antidepressants, antipsychotics, anxiolytics, muscle relaxants) and toxins (botulinum toxin—blocks ACh release, tetanus toxin—blocks inhibitory interneurons).

Taste

– The sensation produced by the interaction of chemical substances with taste receptor cells (TRCs) on the tongue, palate, pharynx, epiglottis, and upper esophagus. Taste is one of the five primary senses (gustation). Five basic taste qualities: sweet (sugars, artificial sweeteners—T1R2/T1R3 receptors), sour (acids—protons, PKD2L1 receptor), salty (sodium ions—ENaC channel), bitter (alkaloids, toxins—T2R receptor family, 25 subtypes), and umami (savory—glutamate, T1R1/T1R3 receptor). Taste buds (5,000) are housed in papillae on the tongue: fungiform (anterior), foliate (lateral), circumvallate (posterior), and filiform (no taste buds—mechanical). Each taste bud contains 50–100 TRCs with microvilli exposed to the oral cavity via a taste pore. Taste information is transmitted via cranial nerves: facial (CN VII—chorda tympani, anterior two-thirds of tongue), glossopharyngeal (CN IX—posterior one-third), and vagus (CN X—epiglottis and pharynx) to the nucleus of the solitary tract in the medulla, then to the thalamus (VPM) and primary gustatory cortex (insula and operculum). Taste disorders: ageusia (loss of taste), hypogeusia (reduced), dysgeusia (distorted), and phantom taste perception. Causes: viral infections (COVID-19—anosmia and ageusia are hallmark symptoms), medications (ACE inhibitors—metallic taste), chemotherapy, head trauma, radiation, Bell palsy, and ageing. Taste is closely linked to smell

(olfaction); much of what is perceived as 'taste' is actually retronasal olfaction.

Tay-Sachs Disease

- Autosomal recessive lysosomal storage disorder (HEXA gene, hexosaminidase A). See biochemistry.

TCA Cycle

- The tricarboxylic acid (Krebs) cycle occurs in the mitochondrial matrix, completing the oxidation of acetyl-CoA (from carbohydrates, fats, and proteins) to CO₂ while generating reducing equivalents (NADH, FADH₂) for the electron transport chain. Eight steps: (1) citrate synthase (acetyl-CoA + oxaloacetate to citrate), (2) aconitase (citrate to isocitrate), (3) isocitrate dehydrogenase (rate-limiting, isocitrate to alpha-ketoglutarate, producing NADH and CO₂), (4) alpha-ketoglutarate dehydrogenase complex (alpha-ketoglutarate to succinyl-CoA, producing NADH and CO₂, requiring TPP, lipoic acid, CoA, FAD, NAD⁺), (5) succinyl-CoA synthetase (succinyl-CoA to succinate, producing GTP), (6) succinate dehydrogenase (succinate to fumarate, producing FADH₂, also Complex II of ETC), (7) fumarase (fumarate to malate), (8) malate dehydrogenase (malate to oxaloacetate, producing NADH). The cycle produces 3 NADH, 1 FADH₂, and 1 GTP per acetyl-CoA, yielding approximately 10 ATP equivalents.

Temperature (Body Temperature)

- The balance between heat production (metabolism, muscle activity) and heat loss (radiation, conduction, convection, evaporation). Normal core body temperature: 36.5–37.5°C (97.7–99.5°F), regulated by the hypothalamus (preoptic anterior hypothalamus—thermoregulatory center). Temperature is measured orally (sublingual—0.3–0.5°C below core), axillary (0.5–1.0°C below core), tympanic (close to core, infrared), rectal (closest to core), or via esophageal/pulmonary artery catheter (gold standard—core). Circadian variation: lowest at 4–6 AM, highest at 4–6 PM. Effects of exercise, digestion, menstrual cycle (0.5°C rise post-ovulation). Hyperthermia: elevated temperature due to failed thermoregulation (heat stroke, malignant hyperthermia, neuroleptic malignant syndrome)—does not respond to antipyretics. Fever (pyrexia): regulated temperature elevation driven by cytokines (IL-1, IL-6, TNF,

prostaglandin E₂) in response to infection, inflammation, or tissue damage—responds to antipyretics. Hypothermia: core temperature <35°C. Fever of unknown origin (FUO): temperature >38.3°C (101°F) for ≥3 weeks with no diagnosis after 1 week of inpatient investigation.

Thermoneutral Zone

- The range of ambient temperatures over which body temperature is maintained by basal metabolic heat production alone, without additional thermoregulatory responses such as shivering or sweating. In humans the zone is approximately 27–32 degrees C for a resting nude adult. Within the zone, vasomotor tone adjusts heat loss. Below it, heat-conserving (vasoconstriction, shivering, nonshivering thermogenesis) responses begin; above it, heat-dissipating (vasodilation, sweating) responses occur. The zone narrows with age, anesthesia, and prematurity—preterm infants have a high surface-to-volume ratio and limited thermoregulation.

Thermoregulation

- The physiological maintenance of core body temperature near the set point (37 degrees C) via a balance of heat production and heat loss, controlled by the preoptic area of the hypothalamus. Heat production includes basal metabolism, muscular activity, shivering, and nonshivering thermogenesis (brown fat); heat loss occurs via radiation, conduction, convection, and evaporation (sweating). Sensors in skin and core detect temperature, and effectors adjust vasomotor tone, sweating, shivering, and behavior. Fever reflects a raised set point (pyrogens, prostaglandins). Failure causes hypo- or hyperthermia.

Tidal Volume

- The volume of air inspired or expired during each normal breath, approximately 500 mL (6–8 mL/kg) in a resting adult. Tidal volume is measured by spirometry. Minute ventilation = tidal volume x respiratory rate (6 L/min). Only a portion reaches the alveoli (alveolar ventilation) after subtracting dead space (150 mL). Low tidal volumes cause hypoventilation, atelectasis, and hypercapnia; excessive tidal volumes (lung-protective ventilation typically 6 mL/kg) cause ventilator-induced lung injury—barotrauma, volutrauma, biotrauma.

Ventilation-perfusion matching depends on appropriate tidal volume distribution.

Transcription

- Synthesis of RNA from DNA template by RNA polymerase. See biochemistry.

Translation

- Decoding of mRNA sequence into polypeptide chain by ribosomes. See biochemistry.

Tubular Reabsorption

- The process by which the renal tubules return filtered water and solutes from the tubular lumen to the blood, reclaiming 99 percent of the glomerular filtrate. Proximal tubule: reabsorbs 65 percent of sodium, most glucose, amino acids, water, bicarbonate, phosphate, and urate. Loop of Henle: countercurrent multiplier concentrating the medullary interstitium; ascending limb reabsorbs NaCl but is water-impermeable. Distal convoluted tubule: sodium/chloride cotransport. Collecting duct: aldosterone-regulated sodium reabsorption, ADH-regulated water reabsorption. Impaired reabsorption causes glucosuria, aminoaciduria, phosphaturia, and renal salt/water wasting.

Tubular Secretion

- The transport of substances from the peritubular capillary blood into the tubular lumen, a second mechanism (besides filtration) by which the kidney eliminates waste and regulates ions. Organic anions (PAH, penicillins, urate) and organic cations (creatinine, histamine, many drugs) are actively secreted in the proximal tubule via OAT and OCT transporters. Potassium and hydrogen ions are secreted in the distal tubule and collecting duct (potassium-sparing diuretics block this). Secretion is important for rapid clearance of drugs and endogenous waste and explains why some substances (PAH) are cleared in one pass.

Tubuloglomerular Feedback

- A feedback mechanism at the juxtaglomerular apparatus (JGA) that adjusts GFR based on tubular fluid NaCl concentration. The macula densa cells (specialized tubular epithelial cells in the thick ascending limb) sense NaCl concentration via the NKCC2 cotransporter. When GFR is high, increased NaCl delivery to the macula densa triggers release of ATP and adenosine, causing affer-

ent arteriole constriction and reducing GFR. When GFR is low, decreased NaCl delivery causes afferent arteriole dilation (via increased nitric oxide and prostaglandins), increasing GFR. This feedback loop maintains a relatively constant NaCl delivery to the distal tubule and stabilises GFR despite changes in blood pressure. The JGA also releases renin in response to low NaCl, activating the RAAS. Tubuloglomerular feedback is impaired in diabetic nephropathy and during ACE inhibitor therapy.

Uncompetitive Inhibition

- A type of enzyme inhibition where the inhibitor binds only to the enzyme-substrate (ES) complex at a site distinct from the active site, forming an inactive ESI complex. The inhibitor cannot bind to the free enzyme. Both V_{max} and K_m decrease: V_{max} decreases because the ESI complex is non-productive (fewer active ES complexes), and K_m decreases because the inhibitor effectively traps substrate in the ES complex (increasing apparent substrate affinity). On a Lineweaver-Burk plot: lines are parallel, with different slopes and both x- and y-intercepts changing (same slope, different y-intercept and x-intercept). Uncompetitive inhibition is rare in single-substrate reactions but occurs in multisubstrate reactions (e.g., inhibition of lactate dehydrogenase by pyruvate at high concentrations) and is the mechanism of some drugs such as methotrexate (inhibition of dihydrofolate reductase when bound to NADPH).

Urea Cycle

- See biochemistry.

Urine Formation

- The process by which the kidney produces urine through three steps: glomerular filtration (formation of 180 L/day ultrafiltrate), tubular reabsorption (return of 99 percent of water and most solutes), and tubular secretion (active addition of waste and ions). Net result: 1-2 L/day of urine containing urea, creatinine, and excess electrolytes. Regulated by hormones: ADH (water reabsorption), aldosterone (sodium reabsorption, potassium secretion), atrial natriuretic peptide (natriuresis), and parathyroid hormone (calcium/phosphate). Urinalysis and the composition of urine reflect filtration, reabsorption, and secretion functions.

Vitamin A: Retinal

– Vitamin A (retinol) is a fat-soluble vitamin essential for vision, immune function, cell differentiation, and reproduction. In the eye, retinol is oxidized to retinal (retinaldehyde), which binds to opsin in the photoreceptor outer segments forming rhodopsin (in rods) and photopsins (in cones). Light absorption by 11-cis-retinal causes isomerization to all-trans-retinal, triggering the phototransduction cascade (G-protein transducin activation, phosphodiesterase activation, cGMP hydrolysis, Na⁺ channel closure, and hyperpolarisation of the photoreceptor cell). Vitamin A deficiency causes night blindness (nyctalopia), xerophthalmia (dry cornea), Bitot spots, keratomalacia, and increased infection risk. Excess vitamin A (hypervitaminosis A) causes hepatotoxicity, teratogenicity, and raised intracranial pressure.

Vitamin B Complex

– The vitamin B complex comprises eight water-soluble B vitamins that function primarily as coenzymes or cofactors in cellular metabolism: Vitamin B1 (thiamine, a cofactor in carbohydrate metabolism and nerve function), Vitamin B2 (riboflavin, precursor of FAD/FMN in oxidation-reduction reactions), Vitamin B3 (niacin, precursor of NAD⁺/NADP⁺), Vitamin B5 (pantothenic acid, component of coenzyme A), Vitamin B6 (pyridoxine, cofactor in amino acid metabolism and neurotransmitter synthesis), Vitamin B7 (biotin, cofactor in carboxylation reactions), Vitamin B9 (folate/folic acid, essential for one-carbon transfer in nucleotide synthesis), and Vitamin B12 (cobalamin, cofactor for methionine synthase and methylmalonyl-CoA mutase). B vitamins are obtained from a wide variety of foods (meat, eggs, dairy, legumes, leafy greens, whole grains) and are generally not stored in large quantities, requiring regular dietary intake. Deficiencies cause specific syndromes (beriberi for B1, pellagra for B3, megaloblastic anemia for B9/B12, see individual entries).

Vitamin B12: Cobalamin

– Vitamin B12 (cobalamin) is a water-soluble vitamin containing cobalt, essential for two enzymatic reactions: (1) methionine synthase (cytoplasmic, requiring methylcobalamin), converting homocysteine to methionine (linking to folate metabolism), and (2) methylmalonyl-CoA mutase (mitochondrial, requir-

ing adenosylcobalamin), converting methylmalonyl-CoA to succinyl-CoA (in odd-chain fatty acid and branched-chain amino acid metabolism). Intrinsic factor (IF, from gastric parietal cells) is essential for B12 absorption in the terminal ileum. B12 deficiency causes megaloblastic anemia (with hypersegmented neutrophils), peripheral neuropathy, subacute combined degeneration of the spinal cord (dorsal columns and corticospinal tracts), and glossitis. Pernicious anemia is an autoimmune condition causing IF deficiency.

Vitamin B1: Thiamine

– Thiamine (thiamine pyrophosphate, TPP) is a water-soluble B vitamin essential as a cofactor for several key metabolic enzymes: pyruvate dehydrogenase (linking glycolysis to the TCA cycle), alpha-ketoglutarate dehydrogenase (TCA cycle), transketolase (pentose phosphate pathway), and branched-chain alpha-ketoacid dehydrogenase (branched-chain amino acid catabolism). Thiamine deficiency causes: beriberi (dry: peripheral neuropathy and muscle wasting; wet: high-output heart failure with edema and vasodilation), and Wernicke-Korsakoff syndrome (confusion, ataxia, ophthalmoplegia, and amnesia, commonly seen in chronic alcoholism). Wernicke encephalopathy is a medical emergency treated with intravenous thiamine before glucose administration to prevent Korsakoff psychosis.

Vitamin B3: Niacin

– Niacin (nicotinic acid and nicotinamide) is a water-soluble vitamin that serves as the precursor for the coenzymes NAD⁺ (nicotinamide adenine dinucleotide) and NADP⁺ (nicotinamide adenine dinucleotide phosphate), which are essential for over 400 enzymatic reactions including glycolysis, the TCA cycle, oxidative phosphorylation, and fatty acid synthesis. NAD⁺ is a key electron carrier in catabolic reactions; NADP⁺ is important in anabolic reactions and antioxidant defense (via glutathione). Niacin deficiency causes pellagra, characterized by the 4 Ds: dermatitis (photosensitive), diarrhea, dementia, and death. Pellagra is endemic in populations consuming maize-based diets low in tryptophan (niacin precursor). Therapeutic niacin (in high doses) lowers triglycerides and LDL while raising HDL.

Vitamin B6: Pyridoxine

– Pyridoxine (pyridoxal phosphate, PLP, the active form) is a water-soluble B vitamin essential as a cofactor for over 100 enzymatic reactions, particularly in amino acid metabolism. Key reactions include transamination (ALT, AST), decarboxylation (producing neurotransmitters: serotonin from 5-HTP, dopamine/norepinephrine from L-DOPA, GABA from glutamate, histamine from histidine), and glycogen phosphorylase (glycogenolysis). PLP is also required for heme synthesis (ALA synthase step), sphingolipid synthesis, and serine racemization. PLP is also required for amino acid transport across cell membranes. Pyridoxine deficiency is rare but causes dermatitis, glossitis, microcytic anemia, peripheral neuropathy, and seizures in infants. Isoniazid (tuberculosis treatment) can cause B6 deficiency as a side effect, requiring supplementation.

Vitamin B9: Folate

– Folate (folic acid, tetrahydrofolate/THF) is a water-soluble B vitamin essential for one-carbon transfer reactions in nucleotide synthesis (thymidylate synthesis for DNA, purine synthesis), amino acid metabolism (methionine synthesis from homocysteine), and methylation reactions. THF carries one-carbon units at various oxidation states (methyl, methylene, methenyl, formyl, formimino). Key reactions: thymidylate synthase converts dUMP to dTMP (DNA synthesis, the target of 5-fluorouracil), and methionine synthase converts homocysteine to methionine (requiring methylcobalamin/B12). Folate deficiency causes megaloblastic anemia (identical to B12 deficiency), neural tube defects in pregnancy (spina bifida, anencephaly), and elevated homocysteine (cardiovascular risk factor). Folic acid supplementation before and during early pregnancy prevents neural tube defects.

Vitamin C (Ascorbic Acid)

– A water-soluble vitamin and a powerful antioxidant, essential for collagen synthesis (required for proline and lysine hydroxylation in collagen triple helix formation), carnitine synthesis, neurotransmitter synthesis (dopamine to norepinephrine), and iron absorption (reduces ferric to ferrous iron in the gut). Humans lack L-gulonolactone oxidase and cannot synthesise vitamin C, requiring dietary intake (citrus fruits, berries, kiwi, tomatoes, pep-

pers, broccoli). Vitamin C deficiency causes scurvy: impaired wound healing, gingival hyperplasia and bleeding (swollen, bleeding gums), perifollicular haemorrhages, ecchymoses, coiled hairs, joint pain, fatigue, and anemia. In severe cases, scurvy causes haemarthrosis, intraosseous bleeding, and death. Vitamin C is also a cofactor for dopamine beta-hydroxylase (norepinephrine synthesis). High-dose vitamin C has been used as an unproven treatment for the common cold and has been investigated in sepsis and cancer (intravenous high-dose as adjunctive therapy, limited evidence).

Vitamin D: Calcitriol

– Vitamin D is a fat-soluble vitamin (actually a prohormone) essential for calcium and phosphorus homeostasis and bone health. Cholecalciferol (D3) is synthesized in the skin from 7-dehydrocholesterol by UVB radiation, or obtained from diet (ergocalciferol/D2 from plants, D3 from animal sources). It is hydroxylated in the liver to 25-hydroxyvitamin D (calcidiol), then in the kidney to the active form 1,25-dihydroxyvitamin D (calcitriol) by 1-alpha-hydroxylase (regulated by PTH, low calcium, and low phosphate; inhibited by FGF23 and high phosphate). Calcitriol increases intestinal calcium and phosphate absorption, promotes renal calcium reabsorption, and mobilises calcium from bone. Vitamin D deficiency causes rickets in children (soft, deformed bones) and osteomalacia in adults (bone pain, weakness, fractures).

Vitamin E: Tocopherol

– Vitamin E (alpha-tocopherol) is a fat-soluble vitamin and the body's primary lipid-soluble antioxidant, protecting polyunsaturated fatty acids in cell membranes from lipid peroxidation by free radicals (reactive oxygen species). It donates a hydrogen atom to lipid peroxyl radicals, breaking the chain reaction of lipid peroxidation. Vitamin E works synergistically with vitamin C (which regenerates reduced vitamin E at the membrane-cytosol interface) and selenium (as a cofactor for glutathione peroxidase) in protecting against oxidative damage. Vitamin E deficiency is rare but occurs in fat malabsorption syndromes (cystic fibrosis, abetalipoproteinaemia) and causes peripheral neuropathy, spinocerebellar ataxia, retinopathy, and haemolysis (due to red blood cell membrane lipid peroxidation).

Vitamin K: Phylloquinone

– Vitamin K is a fat-soluble vitamin essential for the post-translational gamma-carboxylation of glutamate residues to gamma-carboxyglutamate (Gla) in specific clotting factors (II, VII, IX, X, protein C, protein S) and anticoagulant proteins (protein C, protein S, protein Z). The gamma-carboxylation reaction, catalyzed by gamma-glutamyl carboxylase, requires reduced vitamin K (vitamin K hydroquinone) as a cofactor and is essential for the calcium-binding function of these proteins, allowing them to bind calcium and phospholipid membranes. Vitamin K deficiency causes bleeding (elevated PT/INR), most commonly in newborns (given prophylactic vitamin K at birth), patients with fat malabsorption, or those on warfarin therapy (which inhibits vitamin K epoxide reductase, preventing recycling of vitamin K). The antidote is vitamin K administration.

Withdrawal Reflex

– A protective polysynaptic spinal reflex in which a painful stimulus causes flexion (withdrawal) of the stimulated limb, removing it from the source of injury, with reciprocal extension of the contralateral limb (crossed extensor reflex) to maintain posture. The reflex arc: nociceptors $\rightarrow$ afferent fibers $\rightarrow$ spinal interneurons $\rightarrow$ flexor motor neurons. It is involuntary, rapid, and mediated at the spinal level, though modulated by descending pathways. Absent with lower motor neuron lesions and spinal shock; exaggerated with upper motor neuron lesions. Evaluated as part of the neurologic examination.

Zymogen (Proenzyme)

– An inactive precursor of an enzyme that requires proteolytic cleavage to become catalytically active. Zymogens are synthesised and stored in cells (typically in secretory vesicles or zymogen granules) and are activated at the appropriate site and time by specific proteases, preventing premature or inappropriate enzymatic activity that could damage the cell of origin or surrounding tissues. The conversion of a zymogen to an active enzyme involves the cleavage of one or more specific peptide bonds, which induces a conformational change that exposes the active site. Major zymogen systems in human physiology: digestive zymogens (secreted by the exocrine pancreas and gastric chief cells as inactive precursors

to prevent autodigestion — trypsinogen $\rightarrow$ trypsin, chymotrypsinogen $\rightarrow$ chymotrypsin, proelastase $\rightarrow$ elastase, procarboxypeptidase $\rightarrow$ carboxypeptidase, pepsinogen $\rightarrow$ pepsin in the stomach, activated by gastric acid), clotting cascade (coagulation factors circulate as inactive zymogens — prothrombin $\rightarrow$ thrombin, fibrinogen $\rightarrow$ fibrin, factor X $\rightarrow$ Xa, etc. — activated sequentially in the coagulation cascade), fibrinolytic system (plasminogen $\rightarrow$ plasmin), complement system (complement proteins C1-C9 circulate as inactive zymogens, activated by classical, lectin, or alternative pathways), and procollagen (procollagen $\rightarrow$ collagen by procollagen peptidases). The pancreas is particularly dependent on zymogen physiology: the pancreatic acinar cells synthesise and package digestive enzymes as zymogens in zymogen granules, which are secreted into the pancreatic duct and activated in the duodenum by enteropeptidase (enterokinase). Premature activation of trypsinogen to trypsin within the pancreas causes acute pancreatitis (autodigestion of pancreatic tissue).

Intracellular Fluid (ICF)

– The fluid contained within cells, comprising approximately two thirds of total body water in a typical adult. Its major solutes include potassium, magnesium, phosphate, and intracellular proteins, and its composition is maintained by selective membrane transport.

Extracellular Fluid (ECF)

– The fluid outside cells, including plasma and interstitial fluid. Sodium, chloride, and bicarbonate are its principal effective solutes; ECF volume and composition are regulated by the kidneys, cardiovascular system, and endocrine mechanisms.

Stroke Volume

– The volume of blood ejected by one ventricle during a single cardiac contraction, calculated as end-diastolic volume minus end-systolic volume. It is influenced by preload, afterload, and myocardial contractility.

Ejection Fraction

– The fraction of end-diastolic ventricular volume ejected during systole, calculated as stroke volume divided by end-diastolic volume. Left-ventricular ejection fraction is commonly used to character-

ize systolic function but does not fully represent diastolic or right-ventricular performance.

Preload

- The myocardial fiber stretch at the end of diastole, approximated clinically by ventricular end-diastolic volume or pressure. Within physiologic limits, increased preload increases contractile force through the Frank-Starling mechanism.

Afterload

- The load against which a ventricle contracts to eject blood. It is related to arterial pressure, vascular resistance, ventricular geometry, and outflow obstruction and influences stroke volume and myocardial oxygen demand.

Systemic Vascular Resistance (SVR)

- The resistance to blood flow offered by the systemic circulation, determined mainly by arteriolar tone. It is calculated from the pressure gradient across the systemic circulation and cardiac output and is a major determinant of arterial pressure.

Lung Compliance

- The change in lung volume produced by a given change in transpulmonary pressure. Reduced compliance increases the work of breathing, whereas excessive compliance may occur when elastic recoil is lost, as in emphysema.

Ventilation-Perfusion Ratio (V/Q)

- The relationship between alveolar ventilation and pulmonary capillary perfusion. Regional mismatch is a major cause of impaired oxygenation; low V/Q produces venous admixture, while high V/Q reflects wasted ventilation.

Diffusing Capacity of the Lung

- The capacity of the respiratory membrane to transfer gas from alveolar air into pulmonary capillary blood. It depends on surface area, membrane thickness, gas properties, hemoglobin, and pulmonary capillary blood volume and is commonly measured with carbon monoxide as DLCO.

Airway Resistance

- The opposition to airflow through the conducting airways, determined largely by airway radius and flow pattern. Bronchoconstriction, mucus, edema, and reduced elastic traction increase resistance; be-

cause resistance varies strongly with radius, small changes can markedly affect work of breathing.

Osmolality

- The concentration of osmotically active particles per kilogram of solvent. Plasma osmolality is determined mainly by sodium and its accompanying anions, glucose, and urea and governs water movement across cell membranes.

Free Water Clearance

- The rate at which the kidneys excrete water in excess of or less than the amount needed to produce urine isotonic to plasma. Positive clearance indicates excretion of dilute urine; negative clearance indicates retention of water through concentration of urine.

Countercurrent Multiplication

- The renal medullary process in which opposing tubular fluid flow and selective permeability along the loop of Henle generate a corticomedullary osmotic gradient. This gradient permits collecting-duct water reabsorption when antidiuretic hormone is present.

Antidiuretic Hormone (ADH)

- A hypothalamic hormone released from the posterior pituitary in response to increased plasma osmolality or reduced effective circulating volume. It increases collecting-duct water permeability through V2 receptors and promotes vasoconstriction through V1 receptors.

Hypothalamic-Pituitary-Adrenal Axis (HPA Axis)

- An endocrine regulatory pathway in which hypothalamic corticotropin-releasing hormone stimulates pituitary ACTH secretion, which stimulates adrenal cortisol production. Cortisol exerts negative feedback and coordinates metabolic, immune, and stress responses.

Insulin Secretion

- Release of insulin from pancreatic beta cells in response primarily to increased plasma glucose, with amplification by incretin hormones and nutrients. Insulin promotes glucose uptake, glycogen synthesis, lipogenesis, and protein synthesis while suppressing hepatic glucose production.

Synaptic Plasticity

- Activity-dependent change in the strength or structure of synaptic transmission. Long-term potentiation and long-term depression are important cellular mechanisms underlying learning, memory, adaptation, and some forms of chronic pain.

Nociception

- Neural processing of noxious thermal, mechanical, or chemical stimuli that may result in the perception of pain. It includes transduction, transmission, modulation, and projection; nociception and pain are related but not identical concepts.

Bicarbonate

- The principal extracellular buffer anion, formed from carbon dioxide and water and regulated chiefly by the lungs and kidneys. The bicarbonate-carbonic-acid system helps maintain arterial pH; serum bicarbonate is commonly used to assess metabolic components of acid-base disorders.

Erythropoiesis

- The process by which haematopoietic stem and progenitor cells develop into mature red blood cells. It occurs primarily in adult bone marrow and is regulated chiefly by erythropoietin in response to tissue oxygenation; maturation requires iron, vitamin B12, folate, and appropriate marrow function.

Chapter 33

Psychiatry

Addiction

- A chronic, relapsing brain disorder characterized by compulsive substance use or behavior despite harmful consequences. It involves changes in brain reward, motivation, and memory circuits, leading to impaired control over the behavior. Treatment often combines medication, behavioral therapy, and social support.

Aggression

- Verbal or physical behavior intended to threaten, harm, or dominate another person or object. It may occur with mania, psychosis, personality disorders, dementia, delirium, substance intoxication or withdrawal, traumatic brain injury, or severe frustration. Assessment prioritizes immediate safety, medical causes, and risk to self or others; management begins with calm de-escalation and treatment of the underlying cause, with medication or restraint used only when necessary to prevent harm.

Adjustment Disorder

- Emotional or behavioral symptoms in response to an identifiable stressor occurring within three months of the onset of the stressor. The symptoms are disproportionate to the severity of the stressor and cause significant distress or impairment. It resolves within six months of the termination of the stressor. Subtypes include with depressed mood, with anxiety, with mixed anxiety and depressed mood, with disturbance of conduct, with mixed disturbance of emotions, and unspecified.

Affective Flattening

- A significant reduction in the range and intensity of emotional expression. It is a negative symptom of schizophrenia characterized by reduced facial expression, monotonous voice, and decreased body

language. It is distinct from blunted affect (reduced range) and constricted affect (narrowed range). It is less responsive to antipsychotics.

Agitation

- A state of excessive motor activity, emotional excitement, and restlessness. In psychiatric settings, it may be a symptom of mania, psychosis, delirium, substance intoxication, or withdrawal. Acute agitation is managed with de-escalation techniques first, then pharmacological management with benzodiazepines (lorazepam), antipsychotics (haloperidol, olanzapine IM), or combination (B52: diphenhydramine + haloperidol + lorazepam). Physical restraints are used as a last resort.

Agoraphobia

- Anxiety disorder characterized by fear and avoidance of situations where escape might be difficult or help unavailable during a panic-like episode. See neurology.

Alcohol Use Disorder

- A problematic pattern of alcohol use leading to significant impairment or distress. Severity is classified as mild (2–3 criteria), moderate (4–5 criteria), or severe (6 or more criteria). Criteria include drinking more or longer than intended, persistent desire to cut down, spending excessive time with alcohol, craving, failure to fulfill obligations, continued use despite social or interpersonal problems, and tolerance and withdrawal. Withdrawal can include seizures, delirium tremens, and autonomic hyperactivity. Severe alcohol withdrawal can progress to delirium tremens, a life-threatening condition with a mortality rate of 5–15 percent if untreated. Management of alcohol withdrawal involves the CIWA-Ar (Clinical Institute Withdrawal Assessment for Alcohol, revised) scale to guide ben-

zodiazepine administration. First-line treatment is symptom-triggered benzodiazepine therapy (lorazepam, diazepam, or chlordiazepoxide). Supportive care includes intravenous fluids, thiamine supplementation to prevent Wernicke-Korsakoff syndrome (100 mg IV or IM daily), correction of electrolyte disturbances (hypokalaemia, hypomagnesaemia, hypophosphataemia), and multivitamins. Carbamazepine and gabapentin are alternative treatments for mild-to-moderate withdrawal. Severe withdrawal may require ICU admission and management of delirium tremens.

Alcohol Withdrawal

- Symptoms occurring after cessation or reduction of prolonged heavy drinking. Timeline includes: tremor and anxiety at 6–12 hours, perceptual disturbances at 12–24 hours, withdrawal seizures at 24–48 hours, and delirium tremens at 48–96 hours. Delirium tremens includes autonomic hyperactivity, tremor, hallucinations, and confusion with a mortality rate of 5–15% if untreated. CIWA-Ar scale guides management. Benzodiazepines are first-line treatment.

Alogia

- Poverty of speech or poverty of content of speech, a negative symptom of schizophrenia. It manifests as brief, empty replies to questions, reduced spontaneous speech, and lack of elaboration. It reflects dysfunction in the mesocortical dopamine pathway and is less responsive to antipsychotic medications than positive symptoms.

Anhedonia

- The inability to experience pleasure from activities that were previously enjoyable. It is a core symptom of major depressive disorder and a negative symptom of schizophrenia. It is mediated by dysfunction in the brain's reward circuitry, particularly the mesolimbic dopamine system.

Anorexia Nervosa

- Restriction of energy intake leading to low body weight, fear of weight gain, body image disturbance. See [pediatrics](#).

Anorgasmia

- Persistent or recurrent delay in, or absence of, orgasm following a normal sexual excitement phase. Causes: antidepressants (especially SSRIs, the most

common iatrogenic cause), psychosocial factors (anxiety, relationship issues, past trauma), neurological disorders (spinal cord injury, multiple sclerosis, diabetic neuropathy), hormonal abnormalities (low testosterone, hypothyroidism), and pelvic surgery. Management: for SSRI-induced anorgasmia, strategies include dose reduction, drug holiday, switching to bupropion or mirtazapine, or augmentation with buspirone, cyproheptadine, or sildenafil. Psychosexual therapy and behavioural techniques are effective for psychogenic causes. Prognosis depends on etiology; medication-induced anorgasmia is usually reversible.

Anticholinergic Burden

- The cumulative effect of taking multiple medications with anticholinergic properties. It can cause dry mouth, constipation, urinary retention, blurred vision, confusion, and delirium, especially in elderly patients. Many psychiatric medications (TCAs, first-generation antipsychotics, some antihistamines) have anticholinergic effects.

Anticonvulsant Mood Stabilizers

- Antiepileptic drugs used as mood stabilizers in bipolar disorder. Valproate (divalproex) is effective for acute mania and rapid cycling. Carbamazepine is effective for acute mania but has numerous drug interactions via CYP3A4 induction. Lamotrigine is effective for bipolar depression prevention but not acute mania. All require monitoring for side effects and drug levels (except lamotrigine, which is dose-titrated).

Antisocial Personality Disorder

- A pattern of disregard for and violation of the rights of others occurring since age 15 years. At least three of seven criteria: failure to conform to social norms, deceitfulness, impulsivity, irritability and aggressiveness, reckless disregard for safety, consistent irresponsibility, and lack of remorse. Diagnosis requires evidence of conduct disorder before age 15. Associated with psychopathy, which includes affective and interpersonal features beyond the DSM criteria.

Anxiety

- A normal emotional response to perceived danger, but anxiety disorders involve excessive, persistent worry that interferes with daily life. Symptoms can

include restlessness, rapid heart rate, muscle tension, and avoidance behaviors. Common types include generalized anxiety disorder, panic disorder, social anxiety, and phobias, all of which are treatable with therapy and medication.

Anxiety Disorder

- A group of psychiatric conditions characterized by excessive fear, anxiety, and related behavioral disturbances. Includes generalized anxiety disorder (GAD), panic disorder, social anxiety disorder, specific phobias, and agoraphobia. GAD: persistent, excessive worry about multiple domains for ≥ 6 months, with restlessness, fatigue, difficulty concentrating, irritability, muscle tension, and sleep disturbance. Treatment: SSRIs/SNRIs (sertraline, escitalopram, venlafaxine), buspirone, benzodiazepines for short-term use, and cognitive-behavioral therapy (CBT).

Applied Behavior Analysis

- A behavioral intervention based on learning theory principles that uses systematic reinforcement to shape desired behaviors and reduce problematic behaviors. It is the primary evidence-based intervention for autism spectrum disorder, particularly in young children. Core components include positive reinforcement, prompting, fading, chaining, and generalization. It requires intensive, structured sessions.

Attention-Deficit/Hyperactivity Disorder

- A neurodevelopmental disorder characterized by persistent patterns of inattention, hyperactivity, and impulsivity that interfere with functioning or development. Three presentations: predominantly inattentive, predominantly hyperactive-impulsive, and combined. Inattention symptoms include difficulty sustaining attention, poor organization, forgetfulness, and distractibility. Hyperactivity-impulsive symptoms include fidgeting, excessive talking, difficulty waiting turns, and interrupting. Must have symptoms present before age 12. Diagnosis is clinical, using DSM-5 criteria, supported by rating scales (Conners Rating Scales, SNAP-IV, Vanderbilt Assessment Scale), collateral history from parents and teachers, and neuropsychological testing to evaluate attention and executive function. Management includes pharmacological treatment with psychostimu-

lants (methylphenidate, dexamphetamine, lisdexamphetamine) as first-line, non-stimulant options (atomoxetine, guanfacine, clonidine), and behavioural interventions (parent training, behavioural classroom management, organisational skills training). Prognosis with treatment is good; untreated ADHD is associated with academic underachievement, social difficulties, substance misuse, and occupational impairment in adulthood.

Attention-Deficit/Hyperactivity Disorder (ADHD)

- A neurodevelopmental condition marked by persistent inattention, hyperactivity, and impulsivity that interferes with daily functioning. In children, symptoms often include difficulty staying seated, frequent interrupting, and trouble sustaining attention. Adults may experience restlessness, poor time management, and difficulty concentrating, though hyperactivity often diminishes with age.

Atypical Features

- A specifier for depressive episodes characterized by mood reactivity, significant weight gain or increased appetite, hypersomnia, leaden paralysis, and a long-standing pattern of interpersonal rejection sensitivity. Atypical depression often presents in younger patients and may respond preferentially to MAOIs or SSRIs rather than TCAs.

Autism Spectrum Disorder

- Neurodevelopmental disorder characterized by persistent deficits in social communication and social interaction across multiple contexts, restricted and repetitive patterns of behavior, interests, or activities. See neurology.

Avoidant Personality Disorder

- A pattern of social inhibition, feelings of inadequacy, and hypersensitivity to negative evaluation. At least four of seven criteria: avoids occupational activities involving interpersonal contact, unwilling to get involved unless certain of being liked, shows restraint within intimate relationships due to fear of shame, preoccupied with being criticized or rejected in social situations, inhibited in new interpersonal situations due to feelings of inadequacy, views self as socially inept, and is unwilling to get involved unless certain of being liked. Diagnosis is clinical using DSM-5 criteria. Treatment includes psycho-

dynamic therapy and CBT focusing on social skills training and graded exposure to feared social situations. Pharmacotherapy with SSRIs may help with comorbid social anxiety. Prognosis is guarded, as the disorder is typically lifelong, though symptoms may improve with treatment.

Avolition

- A severe lack of motivation to initiate and perform self-directed, purposeful activities. It is a negative symptom of schizophrenia and is seen in severe depression. It manifests as neglect of personal hygiene, inability to complete tasks, and social withdrawal. It is mediated by dysfunction in the prefrontal cortex and dopamine reward pathways.

Benzodiazepine Use Disorder

- A problematic pattern of benzodiazepine use leading to significant impairment. Benzodiazepines include alprazolam, clonazepam, diazepam, and lorazepam. Dependence can develop rapidly with regular use. Withdrawal can be life-threatening, presenting with anxiety, insomnia, tremor, seizures, and psychosis. Cross-tolerance with alcohol exists. Abrupt discontinuation should be avoided; gradual taper is essential.

Benzodiazepine Withdrawal

- Symptoms from cessation or reduction of prolonged benzodiazepine use. Early symptoms include anxiety, insomnia, tremor, and diaphoresis. Severe withdrawal can include seizures, psychosis, and delirium. Withdrawal severity depends on the half-life of the benzodiazepine, duration of use, and dose. Abrupt discontinuation after chronic use can be fatal. A slow taper, often switching to a long-acting benzodiazepine, is the standard approach.

Bereavement

- Natural grief response to the death of a loved one, marked by sadness, yearning, and preoccupation with the deceased, experienced in waves that diminish over weeks to months with preserved self-esteem. Distinct from major depression by its wave-like quality and preserved self-worth. Persistence beyond twelve months with marked impairment may indicate prolonged grief disorder. See Prolonged Grief Disorder.

Bipolar Disorder

- A mood disorder characterized by episodes of ma-

nia/hypomania and depression. Bipolar I: at least one manic episode (elevated mood, grandiosity, decreased need for sleep, pressured speech, increased goal-directed activity, risky behavior) lasting ≥ 1 week or requiring hospitalization. Bipolar II: hypomanic episodes and major depressive episodes without full mania. Treatment: mood stabilizers (lithium, valproate, lamotrigine), atypical antipsychotics, and psychotherapy. Antidepressants used cautiously due to risk of mood switching.

Bipolar I Disorder

- A mood disorder defined by at least one manic episode lasting at least seven days or requiring hospitalization. A manic episode is a distinct period of abnormally elevated, expansive, or irritable mood and increased goal-directed activity or energy. Associated symptoms include inflated self-esteem, decreased need for sleep, pressured speech, flight of ideas, distractibility, increased activity, and risky behavior. Major depressive episodes may occur but are not required for diagnosis.

Bipolar II Disorder

- A mood disorder characterized by at least one hypomanic episode and at least one major depressive episode, with no history of a full manic episode. The depressive episodes in bipolar II tend to be more frequent and longer-lasting than in bipolar I, leading to greater cumulative disability. Patients may be misdiagnosed with unipolar depression if the hypomanic episodes are not identified.

Body Dysmorphic Disorder

- Preoccupation with one or more perceived defects or flaws in physical appearance that are not observable or appear slight to others. The individual performs repetitive behaviors in response to appearance concerns such as mirror checking, excessive grooming, skin picking, reassurance seeking, and comparing. The preoccupation causes clinically significant distress or impairment. Insight is often poor, and patients may seek cosmetic procedures that do not resolve the concern.

Borderline Personality Disorder

- A pattern of instability in interpersonal relationships, self-image, and affects, with marked impulsivity. At least five of nine criteria: frantic efforts to avoid abandonment, unstable and intense relation-

ships, identity disturbance, impulsivity, recurrent suicidal behavior, affective instability, chronic feelings of emptiness, inappropriate intense anger, and transient paranoid ideation or dissociation. Strongly associated with childhood trauma, especially sexual abuse. DBT is the evidence-based treatment of choice. Other treatments include mentalisation-based therapy (MBT), transference-focused psychotherapy (TFP), and general psychiatric management (GPM). Pharmacotherapy targets specific symptoms: SSRIs for mood instability, low-dose antipsychotics for cognitive-perceptual symptoms, and mood stabilisers for affective dysregulation. Prognosis is guarded; symptoms typically improve with age and treatment, but functional impairment often persists.

Brief Psychotic Disorder

- A disturbance characterized by the sudden onset of at least one psychotic symptom: delusions, hallucinations, disorganized speech, or grossly disorganized or catatonic behavior. The disturbance lasts at least one day but less than one month, after which the individual fully returns to premorbid functioning. It may occur in response to a very stressful event and is diagnosed only when the disturbance is not better explained by another psychotic disorder, mood disorder, or substance use.

Bulimia Nervosa

- Binge eating followed by compensatory behaviors (vomiting, laxatives, exercise). See [pediatrics](#).

Caffeine Withdrawal

- A syndrome occurring after abrupt cessation or reduction of caffeine use. Symptoms include headache, fatigue, depressed mood, difficulty concentrating, and flu-like symptoms. Onset is typically 12–24 hours after last caffeine intake, peak at 20–51 hours, and duration of 2–9 days. It is one of the most commonly experienced withdrawal syndromes.

Cannabis Use Disorder

- A problematic pattern of cannabis use leading to significant impairment. Criteria include tolerance and withdrawal (irritability, anger, decreased appetite, restlessness, anxiety, sleep disturbance). Cannabis intoxication includes euphoria, impaired judgment, and time distortion. High-potency concentrates (dabbing) increase the risk of dependence.

Cannabinoid hyperemesis syndrome presents with cyclic vomiting in heavy users.

Catatonia

- A neuropsychiatric syndrome characterized by motor abnormalities including immobility, mutism, posturing, waxy flexibility, stereotypy, mannerisms, grimacing, echolalia, and echopraxia. It can occur in mood disorders, psychotic disorders, medical conditions, or as catatonia due to another medical condition. Lorazepam challenge and ECT are first-line treatments. Immobility and autonomic instability suggest malignant catatonia.

Claustrophobia

- An anxiety disorder characterized by an intense, irrational fear of enclosed or confined spaces (e.g., lifts, tunnels, MRI scanners, windowless rooms). Individuals experience marked anxiety, panic attacks, and avoidance behaviour. Prevalence: approximately 5–10% of the general population. Claustrophobia is classified as a specific phobia (situational type) in DSM-5. The fear is out of proportion to the actual danger and causes significant distress or functional impairment. Pathophysiology involves conditioned fear responses, catastrophic misinterpretation of bodily sensations, and possibly a heightened sensitivity to suffocation cues. Management: CBT with graded in vivo exposure is the most effective treatment; virtual reality exposure therapy is an emerging alternative. Pharmacotherapy (SSRIs, benzodiazepines) may be used adjunctively. Prognosis is excellent with treatment; most patients achieve significant symptom reduction.

Cognitive Behavioral Therapy

- A structured, time-limited psychotherapy that identifies and modifies maladaptive thought patterns (cognitive distortions) and behaviors. It is based on the cognitive model that thoughts, feelings, and behaviors are interconnected. CBT uses techniques including cognitive restructuring, behavioral activation, exposure, and skills training. It is the most evidence-based psychotherapy for depression, anxiety disorders, OCD, PTSD, and eating disorders.

Cognitive Behavioral Therapy for Insomnia (CBT-I)

- Cognitive behavioral therapy for insomnia is a structured, evidence-based program that targets

the thoughts and behaviors perpetuating poor sleep. Components include sleep restriction, stimulus control, cognitive restructuring, and sleep hygiene education. CBT-I is recommended as first-line treatment for chronic insomnia and yields durable improvements without the risks of sleep medications.

Cognitive Distortions

- Systematic errors in thinking that perpetuate negative emotional states and maladaptive behaviors. Common distortions include all-or-nothing thinking, catastrophizing, mind reading, overgeneralization, emotional reasoning, and should statements. CBT focuses on identifying and modifying these patterns.

Comorbidity

- Presence of one or more additional conditions co-occurring with a primary disease. See general.

Compulsions

- Repetitive behaviors or mental acts that the individual feels driven to perform in response to an obsession or according to rigid rules. They are aimed at preventing or reducing anxiety or preventing some dreaded event, but are not connected in a realistic way with what they are designed to neutralize. Common compulsions include washing, checking, counting, ordering, arranging, and mental rituals. Time-consuming compulsions (more than one hour daily) are associated with greater severity.

Conduct Disorder

- A childhood/adolescent disorder characterized by a persistent pattern of violating others' basic rights or major age-appropriate norms. Behaviors: aggression to people/animals, destruction of property, deceitfulness/theft, and serious rule violations. Diagnosis requires ≥ 3 criteria in the past 12 months with functional impairment. Risk factors: abuse, neglect, parental substance use, and genetic predisposition. Treatment: parent management training, multisystemic therapy, and CBT; limited pharmacotherapy for comorbid conditions.

Consultation-Liaison Psychiatry

- The subspecialty of psychiatry focused on the interface between psychiatry and general medical illness. Psychiatrists provide consultation on medical-surgical wards for patients with psychiatric symptoms arising from or coexisting with medical conditions. Common issues include delirium, depres-

sion in medically ill patients, factitious disorder, adjustment reactions, and capacity assessments. It requires expertise in both psychiatric and medical conditions.

Functional Neurological Symptom Disorder (Conversion Disorder)

- A condition in which patients present with neurological symptoms (weakness, paralysis, non-epileptic seizures, sensory loss, gait abnormalities, dystonia, speech difficulties) that cannot be explained by structural neurological disease. The symptoms are not intentionally produced (unlike malingering or factitious disorder). Diagnosis is based on positive neurological signs demonstrating incompatibility with recognized neurological disease, not merely on normal investigations. Treatment: psychoeducation, physical therapy, CBT, and treatment of comorbid psychiatric conditions. The older terms conversion disorder and hysteria are retained as aliases.

Countertransference

- The therapist's emotional reactions to the patient, which may be influenced by the therapist's own unresolved conflicts or may be a response to the patient's transference. Awareness of countertransference is essential for effective therapy and can provide valuable clinical information about the patient's interpersonal style.

Cross-Tolerance

- Tolerance to one substance that extends to another substance with a similar mechanism of action. For example, tolerance to one benzodiazepine extends to all benzodiazepines, and tolerance to alcohol extends partially to benzodiazepines due to shared GABA-A receptor mechanisms. Cross-tolerance is clinically relevant when switching between substances of the same class.

Cultural Psychiatry

- The study and clinical practice of how cultural factors influence mental health, illness expression, diagnosis, and treatment. Cultural concepts of distress, idioms of distress, and cultural syndromes must be considered. The DSM-5 includes a Cultural Formulation Interview. Culture influences symptom presentation, help-seeking behavior, treatment adherence, and the therapeutic relationship.

Cyclothymic Disorder

- A chronic mood disorder characterized by numerous periods of hypomanic symptoms and periods of depressive symptoms over at least two years (one year in children and adolescents). The hypomanic and depressive symptoms do not meet criteria for a hypomanic or major depressive episode. The patient is never symptom-free for more than two months at a time. It carries a 15–50% risk of developing bipolar I or II disorder.

Defense Mechanisms

- Unconscious psychological strategies used to manage anxiety and protect the ego from distressing thoughts or feelings. Mature defenses include sublimation, humor, and altruism. Immature defenses include projection, denial, splitting, and acting out. Understanding defense mechanisms helps clinicians conceptualize personality organization.

Delayed Ejaculation

- A sexual dysfunction characterized by a persistent or recurrent delay in, infrequency of, or absence of ejaculation during partnered sexual activity, lasting ≥ 6 months and causing marked distress. Prevalence: 1–5% of men. Lifelong vs. acquired. Causes: psychosocial (masturbatory style discrepancy, relationship issues, performance pressure, religious upbringing), medication-induced (SSRIs, antipsychotics, alpha-blockers, thiazide diuretics), neurological (spinal cord injury, multiple sclerosis, diabetic neuropathy), surgical (radical prostatectomy, retroperitoneal lymph node dissection), and hormonal (low testosterone, hyperprolactinemia). Diagnosis: clinical interview distinguishing anejaculation from retrograde ejaculation (post-orgasmic urine analysis). Treatment: address underlying cause, switch/reduce offending medications, vibratory stimulation (for neurogenic), electroejaculation (for fertility), psychotherapy, and off-label cabergoline or oxytocin (limited evidence).

Delirium

- Acute onset fluctuating disturbance in attention and awareness. See [geriatrics](#).

Delirium Tremens

- The most severe form of alcohol withdrawal syndrome, a medical emergency with mortality of 5–15% if untreated. Typically occurs 48–96 hours after

the last drink in individuals with chronic heavy alcohol use. Characterized by: altered mental status (confusion, disorientation), profound autonomic hyperactivity (tachycardia, hypertension, hyperthermia, diaphoresis), tremor, hallucinations (visual, tactile, auditory), agitation, and seizures. Risk factors: prior DTs, concurrent infection or illness, electrolyte abnormalities. Management: ICU admission, benzodiazepines (diazepam or lorazepam, high-dose titrated to symptom control), thiamine, correction of electrolyte disturbances, and supportive care (hydration, nutrition, monitoring).

Delusional Disorder

- A disorder characterized by the presence of one or more delusions lasting one month or more in the context of relatively preserved functioning. The delusions are non-bizarre (involving real-life situations that could conceivably occur, such as being followed, infected, loved from afar, or conspired against). If hallucinations are present, they are not prominent and are related to the delusional theme. The behavior is not clearly bizarre or odd beyond the impact of the delusion.

Denial

- A defense mechanism in which a person refuses to accept an unpleasant reality. It is a common initial response to traumatic events and terminal illness diagnoses. While adaptive in the short term, chronic denial can prevent appropriate medical treatment and psychological processing.

Dependent Personality Disorder

- A pattern of submissive and clinging behavior related to an excessive need to be taken care of. At least five of eight criteria: difficulty making everyday decisions without excessive advice, needing others to assume responsibility, difficulty expressing disagreement due to fear of loss of support, difficulty initiating projects, going to excessive lengths to obtain nurturance, feeling uncomfortable or helpless when alone, urgently seeking another relationship when one ends, and unrealistically preoccupied with fears of being left to care for self. Diagnosis is clinical using DSM-5 criteria. Treatment includes psychodynamic psychotherapy and CBT focusing on building autonomy and assertiveness. Pharmacotherapy is used for comorbid depression or anxiety. Prognosis

is variable, with some improvement possible with long-term therapy.

Depersonalization-Derealization Disorder

- Persistent or recurrent experiences of depersonalization, derealization, or both. Depersonalization includes experiences of unreality, detachment, or being an outside observer with respect to one's thoughts, feelings, sensations, body, or actions. Derealization includes experiences of unreality or detachment with respect to surroundings. The individual maintains intact reality testing, meaning they recognize the experiences as subjective and not objectively real.

Depression

- Major depressive disorder is a common, disabling mood disorder characterized by persistent sadness and loss of interest or pleasure in activities, affecting approximately 7 percent of adults worldwide annually. According to DSM-5 criteria, diagnosis requires five or more of the following symptoms present during the same 2-week period representing a change from previous functioning, with at least one being either depressed mood or anhedonia: depressed mood most of the day nearly every day, marked diminished interest or pleasure in all or almost all activities most of the day nearly every day, significant weight loss or gain, insomnia or hypersomnia, psychomotor agitation or retardation, fatigue or loss of energy, feelings of worthlessness or excessive or inappropriate guilt, diminished ability to think or concentrate, and recurrent thoughts of death or suicidal ideation. The episode causes clinically significant distress or impairment. Depression is the leading cause of disability worldwide and is a major risk factor for suicide. Treatment includes antidepressants (SSRIs, SNRIs, bupropion, mirtazapine as first-line), psychotherapy (CBT, interpersonal therapy, behavioural activation), and combination therapy for moderate-to-severe depression. Electroconvulsive therapy (ECT) is the most effective treatment for severe depression with psychotic features or treatment resistance. Prognosis is variable; many patients achieve remission, but recurrence rates are high, particularly without maintenance treatment. Management of suicide risk is a priority.

Dialectical Behavior Therapy

- A comprehensive cognitive-behavioral treatment originally developed for borderline personality disorder. It combines cognitive-behavioral techniques with mindfulness and acceptance strategies. Core modules include mindfulness, distress tolerance, emotion regulation, and interpersonal effectiveness. DBT is the treatment of choice for borderline personality disorder and has been adapted for substance use disorders, eating disorders, and PTSD.

Dissociation

- A disruption in the normal integration of consciousness, memory, identity, emotion, perception, behavior, and sense of self. It exists on a spectrum from normal (daydreaming) to pathological (DID, depersonalization-derealization). It is strongly associated with childhood trauma and can be triggered by stress, sleep deprivation, and certain substances.

Dissociative Amnesia

- Inability to recall important autobiographical information, usually of a traumatic or stressful nature, that is inconsistent with ordinary forgetting. The amnesia may be localized, selective, generalized, or continuous. In dissociative amnesia with dissociative fugue, there is purposeful travel or bewildered wandering associated with amnesia for identity or other important autobiographical information.

Dissociative Disorder

- DSM-5 category comprising disruption of the normally integrated functions of consciousness, memory, identity, perception, and behaviour, including dissociative amnesia, dissociative identity disorder, and depersonalization-derealization disorder. Strongly associated with severe early-life trauma. Diagnosis is clinical, after exclusion of organic causes. Treatment is trauma-informed phased psychotherapy with pharmacotherapy for comorbid conditions.

Dissociative Identity Disorder

- The presence of two or more distinct personality states or an experience of possession involving marked discontinuity in sense of self, agency, affect, behavior, memory, perception, cognition, and/or sensory-motor functioning. Identity disruption is accompanied by gaps in recall of everyday events, personal information, and/or traumatic events that are inconsistent with ordinary forgetting. The distur-

bance causes clinically significant distress or impairment and is not part of a broadly accepted cultural or religious practice. Caused by severe childhood trauma, particularly prolonged and severe abuse in early childhood. The presentation is often misunderstood and can be confused with malingering. Diagnosis requires careful clinical assessment using structured interviews (SCID-D). Treatment focuses on trauma-informed psychotherapy, with phases of stabilisation, trauma processing, and integration. Medications treat comorbid symptoms. Prognosis is guarded.

Dysthymia (Persistent Depressive Disorder)

– A chronic form of depression with depressed mood for most of the day, more days than not, for ≥ 2 years (≥ 1 year in children/adolescents). Symptoms: poor appetite or overeating, insomnia or hypersomnia, low energy, low self-esteem, poor concentration, and hopelessness. Does not meet full criteria for major depressive episode continuously. Double depression: MDE superimposed on dysthymia. Treatment: SS-RIs/SNRIs and psychotherapy (CBT, interpersonal therapy).

Eating Disorder

– A group of conditions characterized by abnormal eating habits and distorted body image, including anorexia nervosa, bulimia nervosa, binge eating disorder, and avoidant/restrictive food intake disorder (ARFID). Anorexia: severe calorie restriction, intense fear of weight gain, and body image disturbance with dangerously low weight. Bulimia: binge eating followed by purging behaviors. Binge eating: recurrent binge eating without purging. Treatment: nutritional rehabilitation, CBT, family-based therapy for adolescents, and fluoxetine for bulimia. Medical complications require monitoring.

Electroconvulsive Therapy

– A neuromodulation treatment involving the induction of a generalized seizure under general anesthesia using electrical current applied to the scalp. It is the most effective treatment for severe depression, especially with psychotic features, catatonia, or suicidal ideation. It is also effective for severe mania and treatment-resistant schizophrenia. Cognitive side effects include transient memory impairment. Bilat-

eral electrode placement is more effective but has more cognitive side effects than unilateral placement. ECT is highly effective, with response rates of 70-90 percent for severe depression. The mechanism of action is not fully understood but involves modulation of neurotransmitter systems, neuroplasticity, and increased hippocampal neurogenesis. Modern ECT is performed under general anesthesia with muscle relaxation, using brief electrical pulses to induce a generalised seizure lasting approximately 20-60 seconds. Contraindications include raised intracranial pressure, recent myocardial infarction, and unstable vascular aneurysms. Memory loss (both retrograde and anterograde) is the most significant side effect and is usually transient. Maintenance ECT is sometimes used to prevent relapse.

Erectile Disorder

– A sexual dysfunction characterized by persistent or recurrent difficulty achieving or maintaining an erection sufficient for sexual activity, or a marked decrease in erectile rigidity, lasting ≥ 6 months and causing marked distress. Prevalence: 10-20% of men under 60, rising to 40-70% over age 70. Etiology: organic (vascular disease, diabetes, hypertension, hyperlipidemia, obesity, smoking, hypogonadism, neurological conditions, postsurgical) and psychogenic (performance anxiety, depression, relationship conflict). Diagnosis: clinical history, IIEF-5 questionnaire, nocturnal penile tumescence testing, penile duplex Doppler ultrasound, and hormonal profile. First-line treatment: PDE5 inhibitors (sildenafil, tadalafil, vardenafil, avanafil). Second-line: intracavernosal injections (alprostadil, papaverine, phentolamine), vacuum erection devices, and low-intensity shockwave therapy. Third-line: penile prosthesis surgery. Treat underlying medical conditions and offer psychotherapy for psychogenic factors.

Euphoria

– An intense feeling of well-being, elation, or happiness, which can be a normal emotional response or a pathologic symptom. In medical contexts, euphoria is most commonly associated with: substance use (opioids, stimulants-cocaine, amphetamines, MDMA, cannabis, alcohol), psychiatric disorders (mania in bipolar I disorder-elevated, expansive, or irritable mood with increased energy), neuro-

logic conditions (multiple sclerosis–lesional euphoria, frontal lobe syndromes), and endocrine disorders (Cushing syndrome, hyperthyroidism). Euphoric mood is distinguished from euthymia (normal mood) and from the emotional lability of pseudobulbar affect. Pathologic euphoria may impair judgment and lead to risky behavior.

Excoriation Disorder

- Recurrent skin picking resulting in skin lesions. The individual has made repeated attempts to decrease or stop the skin picking. The skin picking causes clinically significant distress or impairment. It is not attributable to a medical condition or substance. Common sites include face, arms, and hands. The picking may be automatic or focused and is often preceded by tension and followed by relief.

Exhibitionistic Disorder

- A paraphilic disorder involving recurrent, intense sexual arousal from exposing one's genitals to an unsuspecting person. The individual has acted on these urges or they cause marked distress or interpersonal difficulty. Duration ≥ 6 months. Onset typically before age 18. Treatment: CBT and SSRIs.

Extrapyramidal Symptoms

- Drug-induced movement disorders caused by D2 receptor blockade in the nigrostriatal pathway. They include acute dystonia (muscle spasm, typically within hours of starting), akathisia (inner restlessness), drug-induced parkinsonism (tremor, rigidity, bradykinesia after weeks of use), and tardive dyskinesia (involuntary movements after months to years). EPS is more common with high-potency typical antipsychotics. Anticholinergic agents (benztropine, diphenhydramine) treat acute dystonia and parkinsonism, and beta-blockers (propranolol) treat akathisia. Tardive dyskinesia is managed by switching to a second-generation antipsychotic with lower D2 potency (clozapine, quetiapine) and adding VMAT2 inhibitors (valbenazine, deutetrabenazine). Prevention involves using the lowest effective dose of antipsychotic and regular monitoring using the Abnormal Involuntary Movement Scale (AIMS).

Factitious Disorder

- Presentation of physical or psychological symptoms or imposing injury or disease on another, with the

deceptive intention of assuming the sick role. In factitious disorder imposed on self, the individual falsifies signs or symptoms, induces injury or disease, and presents to medical providers. In factitious disorder imposed on another, the individual falsifies symptoms in another person. The deceptive behavior occurs even in the absence of obvious external rewards.

Female Orgasmic Disorder (Anorgasmia)

- A sexual dysfunction characterized by a persistent or recurrent delay in, infrequency of, or absence of orgasm, or markedly reduced intensity of orgasmic sensation, in $\geq 75\%$ of sexual encounters, lasting ≥ 6 months and causing marked distress. Lifelong (primary, never achieved orgasm by any means) vs. acquired (previously able) vs. situational (only with certain partners or activities). Prevalence: 10-15% of women. Causes: psychosocial (anxiety, distraction, lack of knowledge, relationship issues, negative attitudes toward sex), medication-induced (SSRIs — most common, antipsychotics), medical (spinal cord injury, multiple sclerosis, diabetes, pelvic surgery), and partner factors. Diagnosis: clinical DSM-5 criteria. Treatment: education, directed masturbation, CBT, mindfulness-based sex therapy, sensate focus, and vibratory stimulation. Switching to bupropion or adding buspirone may help with SSRI-induced anorgasmia. Flibanserin and bremelanotide are approved for HSDD not anorgasmia specifically.

Female Sexual Interest/Arousal Disorder

- A sexual dysfunction in women characterized by absent or reduced sexual interest, thoughts, or receptivity, and/or absent or reduced sexual arousal (genital or nongenital), persisting for ≥ 6 months and causing marked distress. Combines the former DSM-IV diagnoses of hypoactive sexual desire disorder and female sexual arousal disorder. Prevalence: 10-20% of women. Etiology: multifactorial (relationship factors, partner factors, individual vulnerability, medical/psychiatric comorbidities, medication effects). Diagnosis: clinical DSM-5 criteria. Treatment: psychotherapy (CBT, mindfulness-based sex therapy), sensate focus exercises, education, addressing relationship factors, and pharmacotherapy (flibanserin, bremelanotide, off-label testosterone

therapy). Lubricants and vaginal moisturizers for arousal complaints.

Fetishistic Disorder

– A paraphilic disorder characterized by recurrent, intense sexual arousal from either the use of nonliving objects (fetish) or a highly specific focus on nongenital body parts (partialism), lasting ≥ 6 months and causing distress or impairment or involving acting on these urges. Common fetishes: shoes, feet, footwear, leather, lingerie, and rubber. Fetishism is common in the general population (up to 30% report some fetish interest) and typically only becomes a disorder when it causes significant distress, impairment, or involves nonconsenting individuals or causes harm. Most common in males. Treatment: CBT, aversion therapy (historical, controversial), and SSRIs.

Frotteuristic Disorder

– A paraphilic disorder involving recurrent, intense sexual arousal from touching or rubbing against a nonconsenting person, lasting ≥ 6 months and causing distress or impairment or involving acting on these urges. Typically occurs in crowded public places (subways, buses, concerts). The individual rubs their genitals against the victim's buttocks or thighs. Onset: adolescence, almost exclusively male. Typically decreasing with age. Legal consequences: sexual offense charges. Treatment: CBT, relapse prevention, and SSRIs.

Gender Dysphoria

– Psychological distress resulting from incongruence between one's experienced gender and assigned gender at birth. Persists for ≥ 6 months and causes significant impairment. Onset in childhood (may resolve) or adolescence/adulthood (persistent). Diagnosis: DSM-5 requires marked incongruence between experienced/expressed gender and primary/secondary sex characteristics, with strong desire to be rid of them or to have opposite sex characteristics. Treatment: gender-affirming care including hormone therapy (testosterone/estrogen), puberty blockers for adolescents, and surgical interventions. Access to affirming care improves mental health outcomes.

Generalized Anxiety Disorder

– Characterized by excessive, difficult-to-control anxiety and worry about multiple events or activities

occurring more days than not for at least six months. Associated symptoms include restlessness, being easily fatigued, difficulty concentrating, irritability, muscle tension, and sleep disturbance. The anxiety causes significant distress or impairment. It is often comorbid with depression and other anxiety disorders.

Genito-Pelvic Pain/Penetration Disorder

– A sexual dysfunction characterized by persistent or recurrent difficulties with vaginal penetration, marked vulvovaginal or pelvic pain during intercourse, fear or anxiety about penetration, and/or tensing of the pelvic floor muscles, lasting ≥ 6 months and causing marked distress. Combines the former DSM-IV diagnoses of vaginismus and dyspareunia. Prevalence: 3-15% of women. Etiology: multifactorial (pelvic floor hypertonicity, history of sexual trauma, anxiety, endometriosis, vulvodynia, interstitial cystitis, postpartum/perimenopausal changes, inadequate lubrication). Diagnosis: clinical interview, pelvic exam, and exclusion of organic causes (infection, endometriosis, adhesions). Treatment: multimodal — pelvic floor physical therapy, dilator therapy, CBT/sex therapy, lubricants, topical lidocaine, vaginal estrogen (if atrophic), trigger point injections, and treatment of underlying medical conditions. Graded exposure to penetration is key.

Grief

– A natural emotional response to loss, particularly the death of a loved one, but also following other significant losses such as divorce, job loss, or declining health. It encompasses a range of feelings including sadness, anger, guilt, and numbness, often occurring in waves rather than linear stages. While grief is not a mental disorder, prolonged or disabling grief may be diagnosed as prolonged grief disorder and benefit from specialized therapy.

Hallucination

– A perception in the absence of an external stimulus, experienced as real and occurring in objective space. Hallucinations can involve any sensory modality: auditory (most common, voices commenting or conversing—characteristic of schizophrenia, also in bipolar mania, psychotic depression), visual (formed

or unformed–delirium, dementia, Charles Bonnet syndrome in visually impaired with preserved cognition, Lewy body dementia), olfactory (unusual odours–temporal lobe epilepsy, olfactory reference syndrome), gustatory (tastes–seizures, psychosis), tactile (formication–cocaine/amphetamine use, alcohol withdrawal, delusional infestation), and somatic (sensations within the body). Hallucinations are distinct from: illusions (distortions of real external stimuli), hallucinations in sleep (hypnagogic at sleep onset, hypnopompic on waking–normal if not distressing), and pseudohallucinations (experienced as lacking objective reality, located inside the head, often in PTSD). Hallucinations in the context of psychiatric illness must be differentiated from those due to: delirium (acute, fluctuating, medical cause), dementia (chronic, progressive), epilepsy (ictal/postictal, especially temporal lobe), drugs (stimulants, hallucinogens like LSD, psilocybin, ketamine, withdrawal from alcohol/benzodiazepines), sensory deprivation, and migraine (visual aura). Management: treat underlying cause; antipsychotics for psychiatric disorders (olanzapine, risperidone, clozapine for refractory auditory hallucinations); ECT for severe psychotic depression.

Histrionic Personality Disorder

– A pattern of excessive emotionality and attention-seeking. At least five of eight criteria: discomfort when not the center of attention, inappropriate sexually seductive behavior, displays rapidly shifting and shallow emotions, uses physical appearance for attention, speaks in an impressionistic and vague manner, shows self-dramatization and theatricality, is suggestible, and considers relationships more intimate than they actually are.

Hoarding Disorder

– Persistent difficulty discarding or parting with possessions, regardless of their actual value. The individual perceives a need to save items and experiences distress at the thought of discarding them. This results in accumulation of possessions that congest and clutter active living areas. The hoarding is not attributable to another medical condition and causes significant distress or impairment. It is distinct from collecting, which is organized and purposeful.

Hypnosis

– A state of focused attention, reduced peripheral awareness, and heightened suggestibility, resembling a trance-like state but distinct from sleep. Hypnosis is induced by a procedure (hypnotic induction) involving focused concentration, relaxation, and guided imagery. Characteristics: absorption (deep involvement in the experience, narrowed attention), dissociation (automaticity, detachment from immediate environment), suggestibility (heightened responsiveness to suggestions, both verbal and non-verbal). The subject remains aware, oriented, and able to resist suggestions. Clinical applications: (1) Pain management (acute and chronic pain, labour, dental procedures, cancer-related pain), (2) Anxiety and stress reduction (medical procedures, phobias, performance anxiety), (3) Irritable bowel syndrome (good evidence, NICE recommended), (4) Smoking cessation and habit modification (moderate evidence), (5) Post-traumatic stress disorder (as adjunctive therapy), (6) Nausea and vomiting (chemotherapy-related). Hypnotherapy is a regulated profession in many countries; clinical hypnosis should only be practiced by appropriately trained healthcare professionals. Contraindications: severe mental illness with psychotic features (delusions, hallucinations–hypnosis may worsen), dissociative identity disorder, epilepsy (rarely, may trigger seizure). Theories of mechanism: involvement of prefrontal cortex deactivation (reduced executive function and reality testing) and enhanced connectivity between the prefrontal cortex and insula (increased body awareness and interoception).

Hypoactive Sexual Desire Disorder (HSDD)

– A sexual dysfunction characterized by persistently or recurrently deficient or absent sexual thoughts, fantasies, and desire for sexual activity, causing marked distress or interpersonal difficulty. In DSM-5, HSDD in women is merged with female sexual arousal disorder into female sexual interest/arousal disorder. In men, it remains a separate diagnosis. Prevalence: 10-15% of men, 20-30% of women. Causes: psychosocial (relationship conflict, stress, depression, anxiety), hormonal (low testosterone, hyperprolactinemia, menopause), medication-induced (SSRIs, antipsy-

chotics, hormonal contraceptives), and medical (diabetes, thyroid disease, chronic illness). Diagnosis: clinical interview ruling out other psychiatric disorders, medication effects, and medical conditions. Lab work: testosterone (total and free), prolactin, TSH. Treatment: treat underlying cause, modify offending medications, psychotherapy (CBT, sensate focus), and for women: flibanserin (Addyi) or bremelanotide (Vyleesi); for men with low testosterone: testosterone replacement therapy.

Hypomania

– Distinct period of abnormally elevated, expansive, or irritable mood with increased energy lasting at least four consecutive days, observable by others but without marked functional impairment, hospitalisation, or psychotic features. The defining feature of bipolar II disorder, distinguished from mania by duration, severity, and absence of psychosis. Management uses mood stabilisers and atypical antipsychotics. See [Hypomanic Episode](#).

Hypomanic Episode

– A distinct period of abnormally elevated, expansive, or irritable mood with increased energy lasting at least four consecutive days. The episode is not severe enough to cause marked impairment in functioning or necessitate hospitalization, and there are no psychotic features. The change in functioning is observable by others. Hypomanic episodes are the defining feature of bipolar II disorder and may transition to full mania or major depression.

Ideas of Reference

– The false belief that unrelated events, objects, or people have a particular and unusual significance specifically for the patient. For example, believing that TV newscasters are sending personal messages or that strangers are conspiring against them. While common in schizotypal personality disorder, they can also occur in schizophrenia and bipolar disorder.

Illness Anxiety Disorder

– Preoccupation with having or acquiring a serious illness, with minimal or no somatic symptoms present. The individual has a high level of anxiety about health, performs excessive health-related behaviors, and experiences maladaptive avoidance. Symptoms persist for at least six months. The individual is not delusional and insight may vary. Previously known

as hypochondriasis.

Insomnia Disorder

– Difficulty initiating or maintaining sleep, or early-morning awakening with inability to return to sleep, at least three nights per week for at least three months. The individual experiences clinically significant distress or impairment in functioning. Despite adequate opportunity for sleep, the individual is unable to obtain sufficient sleep. It is not better explained by another sleep disorder, substance use, or medical condition. Cognitive behavioral therapy for insomnia (CBT-I) is first-line treatment. Pharmacological options include benzodiazepine receptor agonists (zolpidem, zaleplon, eszopiclone), melatonin receptor agonists (ramelteon), orexin receptor antagonists (suvorexant, lemborexant), and sedating antidepressants (trazodone, doxepin, mirtazapine). Benzodiazepines are generally avoided due to tolerance and dependence risks. Sleep hygiene measures and stimulus control are essential components of management.

Intellectual Disability

– Neurodevelopmental disorder with onset in the developmental period, characterised by deficits in intellectual and adaptive functioning across conceptual, social, and practical domains. DSM-5 grades severity by adaptive functioning: mild, moderate, severe, profound. Etiology is heterogeneous—genetic, prenatal, perinatal, postnatal, or idiopathic. Management is multidisciplinary, emphasising early intervention, education, behavioural supports, and treatment of comorbidities.

Intermittent Explosive Disorder

– A disorder characterized by recurrent, impulsive, problematic outbursts of verbal or physical aggression that are grossly disproportionate to the provocation. The outbursts are not premeditated and cause marked distress or functional impairment. Age >6 years. Not better explained by another disorder (ADHD, conduct disorder, PTSD, ASD) or substance intoxication. Diagnosis: DSM-5 criteria including aggressive outbursts occurring twice weekly for 3 months (verbal/non-destructive) or 3 outbursts involving damage/injury in the past year. Treatment: CBT (anger management, relaxation), SSRIs (fluoxetine), and mood stabilizers.

Interpersonal Psychotherapy

- A time-limited, evidence-based psychotherapy for depression that focuses on the interpersonal context of mood symptoms. It identifies four problem areas: grief, role disputes, role transitions, and interpersonal deficits. IPT helps patients improve interpersonal functioning and social support. It is an alternative to CBT for depression and has been adapted for eating disorders, postpartum depression, and adolescent depression.

Leukotomy

- A neurosurgical procedure involving the cutting of white matter fibers in the prefrontal cortex, also known as frontal lobotomy or prefrontal leukotomy. Developed by Egas Moniz (Nobel Prize 1949) and Walter Freeman. Leukotomy was used for severe psychiatric disorders (schizophrenia, severe depression, OCD) from the 1930s to 1950s, before the advent of effective psychopharmacology. The transorbital lobotomy (Freeman, using an ice pick-like instrument through the orbit) was a simplified outpatient procedure. Use declined dramatically in the 1950s with the introduction of antipsychotics (chlorpromazine) and antidepressants, and due to severe lasting side effects. Side effects of leukotomy: apathy, emotional blunting, inattention, executive dysfunction, cognitive impairment, seizures (5-10%), and death. Leukotomy is rarely performed today, but modern stereotactic procedures (anterior capsulotomy, cingulotomy, subcaudate tractotomy) are used in extremely severe, treatment-refractory cases of OCD and depression.

Lithium

- A mood-stabilising medication used primarily for bipolar disorder (mania, hypomania, and prophylaxis of recurrent episodes). See Lithium Toxicity and Bipolar Disorder.

Lithium Toxicity

- A potentially life-threatening condition caused by lithium levels exceeding the therapeutic range (0.6–1.2 mEq/L). Mild toxicity (1.5–2.0 mEq/L): nausea, vomiting, diarrhea, coarse tremor, muscle weakness. Moderate toxicity (2.0–2.5 mEq/L): confusion, ataxia, blurred vision, dysarthria. Severe toxicity (above 2.5 mEq/L): seizures, coma, cardiac arrhythmias, renal failure, and potentially death.

Treatment includes stopping lithium, IV fluids, and hemodialysis for severe cases. NSAIDs, ACE inhibitors, and thiazide diuretics increase lithium levels.

Lysergic Acid Diethylamide (LSD)

- A potent hallucinogenic drug (psychedelic) classified as a Schedule 1 controlled substance (high abuse potential, no accepted medical use). LSD acts as a partial agonist at serotonin 5-HT_{2A} receptors in the prefrontal cortex, leading to altered sensory perception, mood, and cognition. Effects: visual hallucinations (geometric patterns, intensified colours, trails), synaesthesia (cross-modal sensory experience, e.g., hearing colours), profound introspection, euphoria/dysphoria, altered sense of time, depersonalization, and mystical experiences. Onset: 30-60 minutes after oral ingestion. Peak: 2-4 hours. Duration: 8-12 hours. Dose: typical 50-200 microgram. Adverse effects: 'bad trip' (anxiety, panic, paranoia, fear of losing control), flashbacks (recurrence of drug effect weeks to months later, Hallucinogen Persisting Perception Disorder-HPPD), exacerbation of pre-existing psychiatric illness (psychosis, bipolar disorder), and acute toxicity (hyperthermia, hypertension, tachycardia, seizures, serotonin syndrome). LSD is not considered physically addictive (does not produce withdrawal or compulsive drug-seeking behaviour), but tolerance develops rapidly (cross-tolerance with other 5-HT_{2A} agonists like psilocybin and mescaline). Medical research: renewed interest in using LSD and other psychedelics (psilocybin, MDMA, ayahuasca) for treatment-resistant depression, anxiety in terminal illness, PTSD, and substance use disorders in controlled clinical settings.

Major Depressive Disorder

- A mood disorder characterized by at least one major depressive episode consisting of five or more symptoms during the same two-week period. At least one symptom must be either depressed mood or loss of interest or pleasure (anhedonia). Symptoms include significant weight change, insomnia or hypersomnia, psychomotor agitation or retardation, fatigue, feelings of worthlessness or excessive guilt, diminished concentration, and recurrent thoughts of death or suicidal ideation. The episode causes clinically significant distress or impairment. MDD is the

leading cause of disability worldwide, affecting approximately 7 percent of adults annually. Treatment involves antidepressants (SSRIs, SNRIs, bupropion, mirtazapine), psychotherapy (CBT, interpersonal therapy, behavioural activation), and combination therapy for moderate-to-severe episodes. ECT is reserved for severe, psychotic, or treatment-resistant depression. Prognosis is variable; recurrence is common, and maintenance treatment is recommended.

Male Hypoactive Sexual Desire Disorder

– A sexual dysfunction in men characterized by persistently deficient or absent sexual/erotic thoughts or desire for sexual activity, causing marked distress. Prevalence: 5-15% of men. Distinguish from erectile disorder (men may have ED but intact desire). Causes: low testosterone (primary or secondary hypogonadism), hyperprolactinemia, depression, relationship conflict, medication side effects (SSRIs, antipsychotics, beta-blockers, spironolactone), chronic illness (diabetes, CKD, COPD), and aging. Diagnosis: total and free testosterone, prolactin, TSH, and clinical interview. Treatment: testosterone replacement (if confirmed hypogonadal), treat hyperprolactinemia, switch offending medications, CBT, and sex therapy. Testosterone is not recommended for age-related low T without clear hypogonadism.

Malingering

– The intentional fabrication or exaggeration of physical or psychological symptoms for external incentives (avoiding work, obtaining financial compensation, evading criminal prosecution, obtaining drugs). Not a psychiatric illness (coded as a V-code/Z-code). Suspicion raised by: non-compliance with treatment, antisocial personality disorder, discrepancies between reported symptoms and objective findings, and symptoms that emerge in specific contexts (legal, military, disability evaluation). Diagnosis: collateral information, psychological testing (MMPI-2 validity scales). No psychiatric treatment; management involves confrontation and documentation.

Mania

– A distinct period of abnormally elevated, expansive, or irritable mood with increased goal-directed activity or energy, lasting ≥ 1 week (or any duration if hospitalization required). Requires ≥ 3 of:

inflated self-esteem, decreased need for sleep, pressured speech, flight of ideas, distractibility, increased goal-directed activity, and excessive involvement in risky activities. Causes significant functional impairment or psychosis. Core feature of bipolar I disorder. Treatment: mood stabilizers (lithium, valproate) and atypical antipsychotics.

Manic Episode

– A distinct period lasting at least seven days (or any duration if hospitalization is required) of abnormally elevated, expansive, or irritable mood with increased energy or activity. At least three symptoms must be present: inflated self-esteem or grandiosity, decreased need for sleep, pressured speech, flight of ideas or racing thoughts, distractibility, increased goal-directed activity or psychomotor agitation, and excessive involvement in pleasurable activities with high potential for painful consequences (e.g., buying sprees, sexual indiscretions, risky investments). The mood disturbance is severe enough to cause marked impairment in social or occupational functioning, requires hospitalisation to prevent harm to self or others, or includes psychotic features. First-line treatment is lithium or valproate, with atypical antipsychotics (olanzapine, quetiapine, risperidone, aripiprazole, and asenapine) as effective alternatives. Benzodiazepines are used as adjunctive therapy for acute agitation. ECT is highly effective for severe or refractory mania.

Melancholic Features

– A specifier for major depressive episodes characterized by a loss of interest or pleasure in all or almost all activities, a depressed mood that is qualitatively distinct from grief, prominent psychomotor retardation or agitation, significant anorexia or weight loss, excessive guilt, and worsening of mood in the morning. It suggests a more severe, biologically driven depression with better response to antidepressants or ECT.

Melatonin Receptor Agonists

– Medications that act on MT1 and MT2 receptors in the suprachiasmatic nucleus to regulate circadian rhythms. Ramelteon is approved for insomnia with sleep onset difficulty. It has no abuse potential and does not cause dependence. It is a useful alternative to benzodiazepines for sleep initiation problems.

Mental Health

– Mental health encompasses emotional, psychological, and social well-being, affecting how individuals think, feel, behave, and handle stress, relationships, and decision-making. Common mental disorders: anxiety disorders (generalized anxiety, panic, phobias, social anxiety—lifetime prevalence 29%), depressive disorders (major depressive disorder, persistent depressive disorder—lifetime prevalence 21%), bipolar disorder (manic-depressive illness), schizophrenia and other psychotic disorders, and trauma/stressor-related disorders (PTSD, adjustment disorder). The biopsychosocial model recognizes genetic vulnerability (heritability 30–50% for major depression), neurobiologic factors (neurotransmitter dysregulation, HPA-axis abnormalities), psychological factors (maladaptive cognitions, coping deficits), and social determinants (childhood adversity, poverty, discrimination, isolation). Treatment: psychotherapy (CBT, DBT, psychodynamic, interpersonal therapy), pharmacotherapy (antidepressants, mood stabilizers, antipsychotics, anxiolytics), neuromodulation (ECT, TMS, ketamine/esketamine for treatment-resistant depression), and social support interventions. Screening (PHQ-9, GAD-7, AUDIT-C) in primary care improves detection and outcomes.

Mental Status Examination

– A structured assessment of the patient’s current psychological functioning performed during the clinical interview. It evaluates appearance, behaviour, speech, mood, affect, thought process, thought content, perceptions, cognition, insight, and judgment. It provides a snapshot of the patient’s mental state at the time of evaluation and is documented in the psychiatric note.

Monoamine Oxidase Inhibitors

– Antidepressants that inhibit monoamine oxidase, the enzyme responsible for breaking down serotonin, norepinephrine, and dopamine. MAOIs include phenelzine, tranylcypromine, isocarboxazid, and selegiline (transdermal). They are effective for atypical depression and treatment-resistant depression. The major risk is hypertensive crisis from tyramine-rich foods (“cheese reaction”). They are contraindicated with sympathomimetics, meperidine, and other serotonergic agents due to risk of

serotonin syndrome. Dietary restrictions require avoidance of aged cheeses, cured meats, fermented foods, and certain alcoholic beverages (tyramine-rich foods). The transdermal selegiline patch bypasses gastrointestinal MAO and does not require dietary restrictions at the lowest dose. MAOIs are reserved for treatment-resistant cases due to their side effect profile and drug interactions.

Mood Stabilizers

– Medications used to treat mood episodes in bipolar disorder and prevent recurrence. The primary mood stabilizers are lithium, valproate, carbamazepine, and lamotrigine. Each has a different mechanism and side effect profile. Lithium is the only agent with demonstrated anti-suicide properties. Valproate is particularly effective for rapid-cycling bipolar disorder. Lamotrigine is more effective for bipolar depression than mania.

Motivational Interviewing

– A client-centered, directive counseling method for enhancing intrinsic motivation to change by exploring and resolving ambivalence. Developed by Miller and Rollnick, it uses the spirit of partnership, acceptance, compassion, and evocation. Core skills include open-ended questions, affirmations, reflections, and summaries. It is particularly effective for substance use disorders and health behavior change.

Narcissistic Personality Disorder

– A pattern of grandiosity, need for admiration, and lack of empathy. At least five of nine criteria: grandiose sense of self-importance, preoccupation with fantasies of unlimited success, belief of being “special,” requires excessive admiration, sense of entitlement, interpersonally exploitative, lacks empathy, envious of others or believes others are envious, and shows arrogant, haughty behaviors. May present as grandiose or vulnerable (covert) narcissism.

Narcolepsy

– A chronic sleep disorder characterized by excessive daytime sleepiness and irresistible sleep attacks, with or without cataplexy (sudden bilateral loss of muscle tone triggered by strong emotions). Narcolepsy type 1: with cataplexy, caused by loss of hypocretin/orexin neurons in the hypothalamus. Other features: sleep paralysis (inability to move upon falling asleep or waking),

hypnagogic/hypnopompic hallucinations, and disrupted nighttime sleep. Diagnosis: polysomnography followed by MSLT (mean sleep latency <8 minutes, ≥ 2 SOREM periods). Treatment: wake-promoting agents (modafinil, armodafinil, solriamfetol), sodium oxybate for cataplexy/EDS, and SSRIs/SNRIs for cataplexy.

Neuroleptic

– An older term for antipsychotic medications, derived from their ability to produce a state of mental indifference and motor slowing. The term is now largely replaced by “antipsychotic,” though it is still used in specific contexts such as neuroleptic malignant syndrome. Typical neuroleptics are first-generation antipsychotics.

Neuroplasticity

– The brain’s ability to reorganize its structure, function, and connections in response to experience, learning, and injury. It is relevant to psychiatric treatment because antidepressants, psychotherapy, and ECT are thought to promote neuroplastic changes including neurogenesis in the hippocampus and synaptic remodeling.

Obsessions

– Recurrent, persistent, intrusive, and unwanted thoughts, urges, or images that are experienced as intrusive and cause marked anxiety or distress. Common obsessions include contamination fears, fears of harming oneself or others, need for symmetry, taboo thoughts (sexual, religious, or aggressive), and doubt. The individual recognizes the obsessions as excessive or irrational in many cases (good insight).

Obsessive-Compulsive Disorder

– Characterized by the presence of obsessions, compulsions, or both. Obsessions are recurrent, persistent, intrusive, and unwanted thoughts, urges, or images that cause marked anxiety or distress. The individual attempts to ignore or suppress them or neutralize them with some other thought or action. Compulsions are repetitive behaviors or mental acts that the individual feels driven to perform in response to an obsession or according to rigid rules. They are aimed at preventing or reducing anxiety or preventing a dreaded event, but are not connected in a realistic way with what they are designed to neu-

tralise. Compulsions are time-consuming (taking more than one hour per day) and cause significant distress or impairment. Insight varies: good or fair insight (the individual recognizes the beliefs are probably not true), poor insight, or absent insight (delusional beliefs). First-line treatment is CBT with exposure and response prevention (ERP) and SSRIs (fluoxetine, fluvoxamine, sertraline, paroxetine, or escitalopram) at higher doses than used for depression. The combination of CBT and SSRI is superior to either alone. Prognosis is variable; symptoms may be chronic but are usually responsive to treatment.

Obsessive-Compulsive Personality Disorder

– A pattern of preoccupation with orderliness, perfectionism, and mental and interpersonal control, at the expense of flexibility and efficiency. At least four of eight criteria: preoccupied with details, rules, lists, organization, or schedules to the extent that the major point of the activity is lost; shows perfectionism that interferes with task completion; excessively devoted to work; overconscientious and inflexible about morality; unable to discard worn-out objects; reluctant to delegate tasks unless others submit to their way of doing things. Diagnosis is clinical using DSM-5 criteria. Treatment is challenging as patients rarely seek help voluntarily. Psychodynamic therapy and CBT may help address perfectionism and control. Pharmacotherapy targets comorbid depression or anxiety. Prognosis is guarded, as the personality traits are ego-syntonic and resistant to change.

OCD

– Characterized by the presence of obsessions, compulsions, or both. See [Obsessive-Compulsive Disorder](#).

Opioid Overdose

– A medical emergency characterized by the classic triad of respiratory depression, miosis (pinpoint pupils), and decreased level of consciousness. It can progress to respiratory arrest, cardiovascular collapse, and death. Treatment involves airway management, naloxone administration (0.4–2 mg IV/IM, may repeat), and monitoring for re-narcotization as naloxone wears off. Fentanyl and its analogs require

higher and repeated naloxone doses.

Opioid Use Disorder

- A problematic pattern of opioid use leading to significant impairment or distress. Opioids include heroin, fentanyl, morphine, oxycodone, and hydrocodone. Criteria are the same eleven as for substance use disorders generally. Overdose presents with respiratory depression, miosis, and decreased level of consciousness. Naloxone is the antidote. Treatment includes methadone, buprenorphine, and naltrexone.

Oppositional Defiant Disorder

- A childhood/adolescent disorder characterized by a persistent pattern (≥ 6 months) of angry/irritable mood, argumentative/defiant behavior, and vindictiveness. Symptoms: often loses temper, is touchy/easily annoyed, angry/resentful, argues with authority figures, actively defies rules, deliberately annoys others, blames others for mistakes, and has been spiteful/vindictive at least twice in the past 6 months. Milder than conduct disorder (no aggression toward people/animals, no destruction of property). Risk factor for development of conduct disorder. Treatment: parent management training, CBT, and school-based interventions.

Orexin Receptor Antagonists

- Medications that block orexin (hypocretin) receptors to promote sleep. Suvorexant and lemborexant are approved for insomnia. They reduce wakefulness by blocking the arousal system. They have lower abuse potential than benzodiazepines and do not cause respiratory depression.

OSFED

- Other Specified Feeding or Eating Disorder, used when the clinical presentation causes significant distress or impairment but does not meet full criteria for any of the specific eating disorders. Examples include atypical anorexia nervosa (all criteria met except weight is within or above normal range), sub-threshold bulimia nervosa or binge eating disorder, purging disorder, and night eating syndrome.

Other Specified Sexual Dysfunction

- A category for sexual dysfunction symptoms that cause distress but do not meet full criteria for any specific sexual dysfunction. Examples: sexual aver-

sion (extreme avoidance of or aversion to genital sexual contact), inadequate vaginal lubrication without pain, persistent genital arousal disorder (unwanted genital arousal without sexual desire, PGAD), and sexual dysfunction due to medical conditions not otherwise covered. Management is tailored to the specific presentation.

Panic Attack

- An abrupt surge of intense fear or discomfort reaching a peak within minutes. The individual experiences at least four of thirteen symptoms: palpitations, sweating, trembling, shortness of breath, feelings of choking, chest pain, nausea, dizziness, chills or heat, paresthesias, derealization or depersonalization, fear of losing control, and fear of dying. Panic attacks are not limited to panic disorder and occur in many psychiatric and medical conditions.

Panic Disorder

- Recurrent unexpected panic attacks, which are abrupt surges of intense fear or discomfort peaking within minutes. During attacks, individuals experience at least four of thirteen symptoms: palpitations, sweating, trembling, shortness of breath, feelings of choking, chest pain, nausea, dizziness, chills or heat sensations, paresthesias, derealization, fear of losing control, and fear of dying. At least one attack is followed by persistent worry about additional attacks or maladaptive behavioral changes aimed at avoiding future attacks. Panic disorder is a chronic condition with a relapsing-remitting course. The lifetime prevalence is approximately 3-5 percent, with onset typically in late adolescence or early adulthood. The fear of having another panic attack leads to a cycle of escalating anxiety and avoidance. Agoraphobia frequently co-occurs. Diagnosis is clinical using DSM-5 criteria. First-line treatment includes CBT with interoceptive exposure and SSRIs (sertraline, paroxetine, fluoxetine, escitalopram) or SNRIs (venlafaxine). Benzodiazepines (alprazolam, clonazepam) are effective acutely but avoided as first-line due to tolerance and dependence. Prognosis is good with treatment; most patients achieve significant symptom reduction.

Paraphilia

- A condition characterized by intense and persistent sexual interest in atypical objects, situations,

or individuals. Examples: exhibitionism, fetishism, frotteurism, pedophilic disorder, sexual masochism, sexual sadism, transvestic disorder, voyeurism, and paraphilia not otherwise specified. Diagnosis requires that the paraphilia causes distress or impairment or involves harm to others. Treatment: CBT, SSRI medications, and antiandrogens in selected cases.

Pedophilic Disorder

– A paraphilic disorder characterized by intense and recurrent sexual attraction to prepubescent children (generally age ≤ 13), lasting ≥ 6 months, and causing distress or impairment or involving acting on these urges. Diagnosis requires the individual is ≥ 16 years old and ≥ 5 years older than the child. Assessment: clinical interview, phallometric testing. Treatment: CBT focusing on relapse prevention and cognitive distortions; pharmacotherapy (SSRIs, antiandrogens — medroxyprogesterone acetate, cyproterone acetate, GnRH agonists like leuprolide) to reduce libido. Ethical and legal considerations are paramount.

Perinatal Psychiatry

– The subspecialty focused on psychiatric disorders during pregnancy and the postpartum period. Common conditions include perinatal depression, perinatal anxiety, perinatal OCD, and postpartum psychosis. Medication selection must balance maternal mental health with fetal or neonatal exposure risks. SSRIs are generally considered safe, while lithium and valproate carry teratogenic risks. Breastfeeding considerations influence medication choice.

Persistent Depressive Disorder

– formerly called dysthymia, a chronic depressive mood lasting at least two years in adults (one year in children and adolescents). Patients experience depressed mood for more days than not, along with at least two additional symptoms: poor appetite or overeating, insomnia or hypersomnia, low energy, low self-esteem, poor concentration, or feelings of hopelessness. During a two-year period, the patient has never been symptom-free for more than two months.

Personality Disorder

– A group of mental disorders characterized by enduring maladaptive patterns of thinking, feeling,

and behaving that deviate from cultural expectations and cause functional impairment. Cluster A (odd/eccentric): paranoid, schizoid, schizotypal. Cluster B (dramatic/erratic): antisocial, borderline, histrionic, narcissistic. Cluster C (anxious/fearful): avoidant, dependent, obsessive-compulsive. Diagnosis requires onset in adolescence or early adulthood and stability over time. Treatment: psychotherapy (DBT for borderline, CBT, psychodynamic); limited pharmacotherapy for specific symptoms.

Postpartum Depression

– Major depressive or manic episodes occurring during pregnancy or within four weeks of delivery (DSM-5). The term is often used more broadly to cover depressive episodes up to one year postpartum. Risk factors include prior depression, lack of social support, stressful life events, and hormonal fluctuations. Postpartum psychosis is a distinct, more severe entity requiring immediate psychiatric hospitalization.

Postpartum Psychosis

– See obstetrics_gynecology.

Posttraumatic Stress Disorder (PTSD)

– A psychiatric disorder that develops after exposure to a traumatic event (death, serious injury, sexual violence). Presents with 4 symptom clusters: re-experiencing (intrusive memories, flashbacks, nightmares), avoidance (of trauma reminders), negative alterations in cognition and mood, and hyperarousal (hypervigilance, exaggerated startle, irritability). Duration > 1 month with functional impairment. Risk factors: prior trauma, lack of social support, female sex, and peritraumatic dissociation. Diagnosis: DSM-5 criteria. Treatment: trauma-focused CBT (prolonged exposure, cognitive processing therapy), EMDR, and SSRIs (sertraline, paroxetine). Prognosis: chronic without treatment.

Premature (Early) Ejaculation

– A sexual dysfunction characterized by a persistent or recurrent pattern of ejaculation occurring within approximately 1 minute of vaginal penetration and before the individual wishes it, occurring in $\geq 75\%$ of sexual encounters, lasting ≥ 6 months, and causing marked distress. Prevalence: 20-30% of men, the most common male sexual dysfunction. Lifelong

(primary) vs. acquired (secondary to ED, prostatitis, hyperthyroidism, anxiety, or relationship issues). Diagnosis: clinical DSM-5 criteria (IELT, perceived control, distress). Treatment: first-line — behavioral techniques (stop-start, squeeze technique), topical anesthetics (lidocaine-prilocaine cream). Pharmacotherapy: dapoxetine (short-acting SSRI, on-demand, approved in many countries outside the US), off-label SSRIs (paroxetine 10-40 mg, sertraline 50-200 mg) daily or on-demand, and clomipramine. Treat underlying ED if present.

Premenstrual Dysphoric Disorder

– A severe, debilitating form of premenstrual syndrome characterized by marked mood symptoms (depression, anxiety, irritability, mood swings), physical symptoms (breast tenderness, bloating, fatigue), and functional impairment that occur during the luteal phase and remit within days of menses onset. Symptoms must occur in most menstrual cycles for the past year and cause significant distress. Distinguishing from PMS: greater severity and predominance of affective symptoms. Diagnosis: prospective daily symptom charting for ≥ 2 cycles. Treatment: SSRIs (intermittent luteal phase or continuous), combined oral contraceptives (drospirenone-containing), CBT, and GnRH agonists in refractory cases.

Projection

– A defense mechanism in which unacceptable thoughts, feelings, or impulses are attributed to others. For example, a patient who is angry at the therapist may accuse the therapist of being angry at them. It is common in paranoid thinking, delusional disorders, and personality disorders.

Psychodynamic Therapy

– A form of depth psychology that explores how unconscious processes, early life experiences, and internal conflicts influence current thoughts, feelings, and behaviors. It involves exploration of transference and countertransference, defense mechanisms, and the therapeutic relationship as a vehicle for change. Brief psychodynamic therapy is time-limited and focused on specific conflicts. It is effective for depression, anxiety, personality disorders, and somatic symptom disorders.

Psychogenic Non-Epileptic

Seizures

– Seizure-like episodes that are not caused by abnormal electrical activity in the brain. They are a form of conversion disorder with attacks or seizures. Events may include shaking, stiffening, unresponsiveness, and other movements. Diagnosis requires clinical evidence of incompatibility with epilepsy and can be confirmed by video-EEG monitoring showing normal EEG during an event. Treatment includes psychotherapy and education about the diagnosis.

Psychopharmacology

– The study and clinical application of medications used to treat psychiatric disorders. It involves understanding drug mechanisms, pharmacokinetics, drug interactions, and side effect profiles. It is the foundation of biological psychiatry and enables evidence-based medication management for mood, anxiety, psychotic, and cognitive disorders.

Psychotherapy

– A structured treatment in which a trained therapist helps a person understand and change distressing thoughts, emotions, behaviors, or relationship patterns. Major approaches include cognitive behavioral therapy, psychodynamic therapy, interpersonal therapy, supportive therapy, exposure-based therapy, and family or group therapy. Psychotherapy is used for depression, anxiety, trauma-related disorders, personality disorders, eating disorders, substance-use disorders, and many other conditions; it may be used alone or combined with medication and social support.

PTSD

– See [Post-Traumatic Stress Disorder](#).

Purging Disorder

– Recurrent purging behavior to influence weight or shape in the absence of binge eating. Self-induced vomiting, misuse of laxatives, diuretics, or other medications. It is classified under Other Specified Feeding or Eating Disorder (OSFED). It can lead to electrolyte imbalances, dental erosion, Russell's sign, and esophageal tears.

Reactive Attachment Disorder

– A pattern of inhibited, emotionally withdrawn behavior toward adult caregivers. The child rarely or

minimally seeks comfort when distressed and rarely or minimally responds to comfort when distressed. The child shows a pattern of persistently irritable and sad mood that is not limited to interactions with caregivers. It results from a pattern of insufficient care including social neglect, repeated changes of primary caregivers, or rearing in unusual settings.

Restless Legs Syndrome

- An urge to move the legs, usually accompanied by uncomfortable sensations, that begins or worsens during rest, is relieved by movement, and occurs predominantly in the evening or night. The condition causes significant distress or impairment. It is associated with iron deficiency, renal failure, pregnancy, and peripheral neuropathy. Ferritin levels below 50 ng/mL should be supplemented. Dopaminergic agents and alpha-2-delta ligands (gabapentin, enacarbil) are used for treatment.

Schizoaffective Disorder

- A disorder characterized by an uninterrupted period of illness during which there is a major mood episode concurrent with criterion A of schizophrenia (delusions, hallucinations, disorganized speech, grossly disorganized or catatonic behavior, or negative symptoms). The individual must also have delusions or hallucinations for at least two weeks in the absence of a major mood episode. The mood episodes are present for the majority of the total duration of the illness.

Schizoid Personality Disorder

- A pattern of detachment from social relationships with a restricted range of emotional expression. At least four of seven criteria: neither desires nor enjoys close relationships, almost always chooses solitary activities, has little interest in sexual experiences, takes pleasure in few activities, lacks close friends, appears indifferent to praise or criticism, and shows emotional coldness, detachment, or flattened affect.

Schizophrenia

- A severe chronic mental illness characterized by psychotic symptoms (hallucinations, delusions, disorganized thinking) and negative symptoms (avolition, alogia, anhedonia, blunted affect), with cognitive impairment and functional decline. Diagnosis: ≥ 2 core symptoms for ≥ 1 month with continuous signs for ≥ 6 months. Onset typically in late adoles-

cence/early adulthood. Treatment: antipsychotic medications (first-generation: haloperidol; second-generation: risperidone, olanzapine, clozapine for refractory), psychosocial interventions, and family education.

Schizotypal Personality Disorder

- A pattern of social and interpersonal deficits marked by acute discomfort with and reduced capacity for close relationships, cognitive or perceptual distortions, and eccentricities of behavior. Features include ideas of reference, odd beliefs or magical thinking, unusual perceptual experiences, odd thinking and speech, suspiciousness, inappropriate affect, and constricted affect. It shares genetic and phenomenological features with schizophrenia.

Seasonal Affective Disorder

- A specifier of recurrent major depressive episodes that occur at a specific time of year, most commonly winter (with remission in spring/summer). Symptoms: hypersomnia, hyperphagia with carbohydrate craving, weight gain, fatigue, and low energy. Associated with reduced sunlight exposure disrupting circadian rhythms and serotonin regulation. Treatment: light therapy (10,000 lux, 30 minutes upon waking), CBT-SAD, SSRIs/bupropion, and agomelatine. Dawn simulation and vitamin D supplementation may help.

Sedatives

- A class of drugs that produce a calming or drowsy effect by depressing the central nervous system. See [pharmacology](#).

Selective Mutism

- Consistent failure to speak in specific social situations where speaking is expected despite speaking in other situations. The disturbance interferes with educational or occupational achievement or social communication. Must last for at least one month and is not attributable to lack of knowledge of or comfort with the spoken language. Most commonly seen in children and often co-occurs with social anxiety disorder.

Self-Harm

- Intentional self-inflicted injury without suicidal intent, also termed non-suicidal self-injury; common methods include cutting, burning, and self-hitting. Prevalent in adolescents and in borderline person-

ality disorder, depression, eating disorders, and trauma, serving affect regulation or self-punishment. Associated with increased subsequent suicide risk. Management centres on dialectical behaviour therapy and treatment of underlying disorders.

Separation Anxiety Disorder

– Developmentally inappropriate and excessive fear or anxiety concerning separation from attachment figures. The individual may have recurrent excessive distress when anticipating or experiencing separation from home or major attachment figures. Symptoms may include worry about harm befalling attachment figures, worry about experiencing an event causing separation, reluctance to leave home or go out alone, and nightmares involving separation. Must persist for four weeks in children and six months in adults. Diagnosis is clinical using DSM-5 criteria. Treatment includes CBT with graded exposure to separation situations and SSRIs (fluoxetine, sertraline, fluvoxamine) for moderate-to-severe cases. Involving parents in treatment is essential. Prognosis is good with treatment; untreated separation anxiety may persist and predispose to other anxiety disorders in adulthood.

Serotonin-Norepinephrine Reuptake Inhibitors

– Antidepressants that block the reuptake of both serotonin and norepinephrine. They include venlafaxine, duloxetine, desvenlafaxine, and levomilnacipran. SNRIs are used for major depressive disorder, generalized anxiety disorder, diabetic neuropathy, fibromyalgia, and chronic pain. They are particularly useful in patients with fatigue and poor concentration. Side effects include those of SSRIs plus hypertension (especially at higher doses).

Serotonin-Norepinephrine-Dopamine Reuptake Inhibitors

– A class of antidepressants that inhibit reuptake of serotonin, norepinephrine, and dopamine. The primary agent is bupropion, which also acts as a norepinephrine-dopamine reuptake inhibitor. It is used for depression, smoking cessation, and as augmentation. It lacks sexual side effects and weight gain associated with SSRIs.

Sexual Masochism Disorder

– A paraphilic disorder characterized by recurrent, in-

tense sexual arousal from the act of being humiliated, beaten, bound, or otherwise made to suffer, lasting ≥ 6 months and causing distress or impairment or involving acting on these urges. Asphyxiophilia (sexual arousal from oxygen restriction): the most dangerous form, associated with accidental death during solo practice. Hypoxyphilia: arousal from oxygen deprivation. Consensual BDSM activities are not considered pathological. Disorder is diagnosed when the behavior causes clinically significant distress, impairment, or risk of harm. Treatment: CBT and SSRIs.

Sexual Sadism Disorder

– A paraphilic disorder characterized by recurrent, intense sexual arousal from the physical or psychological suffering of another person, lasting ≥ 6 months and causing distress or impairment or involving acting on these urges with a nonconsenting person. In the context of BDSM with consenting adults, sadistic acts alone do not constitute a disorder. Diagnosis requires that the individual has acted on these urges with a nonconsenting person or the urges cause significant distress or interpersonal difficulty. The most severe form is associated with serial sexual homicide. Treatment: CBT, SSRIs, antiandrogens, and GnRH agonists for severe cases.

Sleep Hygiene

– A set of behavioral and environmental practices designed to promote consistent, uninterrupted, and restorative sleep. Key elements include maintaining a regular sleep schedule, creating a cool, dark, and quiet sleep environment, avoiding caffeine and electronic screens before bedtime, and engaging in relaxing pre-sleep routines. Poor sleep hygiene is a common contributor to insomnia, and adopting these habits is often the first-line recommendation for improving sleep quality without medication.

Social Anxiety Disorder

– Marked fear or anxiety about one or more social situations in which the individual may be scrutinized by others. The individual fears acting in a way or showing anxiety symptoms that will be negatively evaluated. The social situations almost always provoke fear or anxiety, are avoided or endured with intense anxiety, and are disproportionate to the actual threat. The fear, anxiety, or avoidance is

persistent, typically lasting six months or more.

Somatic Symptom Disorder

– Characterized by one or more somatic symptoms that are distressing or result in significant disruption of daily life, accompanied by excessive thoughts, feelings, or behaviors related to the somatic symptoms. The individual experiences persistent high levels of worry about the seriousness of symptoms, an excessive amount of time and energy devoted to health concerns, or disproportionate and persistent concern about the medical implications of symptoms. The problematic symptoms are not better explained by another medical or psychiatric condition. Somatic symptom disorder is common, with prevalence of approximately 5-7 percent in the general population. It is associated with high healthcare utilisation and functional impairment. Diagnosis is clinical using DSM-5 criteria, after appropriate medical evaluation to exclude underlying organic pathology. Treatment includes establishing a consistent therapeutic relationship with a single primary care provider, CBT, graded exercise, and antidepressants (SSRIs, TCAs) for comorbid depression or pain. Prognosis is variable, but most patients improve with appropriate management that avoids unnecessary investigations and procedures.

Specific Learning Disorder

– Persistent difficulties in reading, written expression, or mathematics, despite adequate intelligence and educational opportunity. Diagnosis requires academic skills significantly below expected for age, difficulties for at least six months, and no better explained by intellectual disability, sensory impairment, or neurological condition. Subtypes include dyslexia (reading), dysgraphia (writing), and dyscalculia (mathematics).

Specific Phobia

– Marked fear or anxiety about a specific object or situation that is out of proportion to the actual danger posed. Exposure to the phobic stimulus almost invariably provokes an immediate anxiety response. The object or situation is actively avoided or endured with intense anxiety. The fear, anxiety, or avoidance persists for six months or more. Subtypes include animal, natural environment, blood-injection-injury, situational, and other.

Splitting

– A primitive defense mechanism in which objects or self-representations are viewed as entirely good or entirely bad, with no integration of positive and negative qualities. It is a core feature of borderline personality disorder and contributes to idealization-devaluation patterns in relationships. It reflects impaired object relations.

Stimulant Use Disorder

– A problematic pattern of stimulant use (cocaine, amphetamines, methamphetamine, MDMA) leading to significant impairment. Stimulants increase dopamine and norepinephrine activity. Withdrawal is characterized by fatigue, depression, increased appetite, hypersomnia, psychomotor retardation, and vivid unpleasant dreams. Methamphetamine use is associated with severe dental disease, paranoia, and hallucinations. Treatment is primarily behavioral as no FDA-approved medications exist.

Stress

– A physiological and psychological response to perceived threats or demands that activates the sympathetic nervous system and the hypothalamic-pituitary-adrenal axis. Acute stress can enhance focus and performance in challenging situations, but chronic stress contributes to the development or exacerbation of numerous health conditions, including hypertension, anxiety disorders, depression, gastrointestinal problems, and immunosuppression. Effective stress management techniques include regular physical activity, mindfulness meditation, adequate sleep, social support, and professional counseling when needed.

Substance Abuse Psychiatry

– The subspecialty focused on the evaluation and treatment of substance use disorders and co-occurring psychiatric conditions. Dual diagnosis patients require integrated treatment addressing both disorders simultaneously. Psychopharmacology includes medication-assisted treatment (methadone, buprenorphine, naltrexone for opioid use disorder; acamprosate, disulfiram, naltrexone for alcohol use disorder) alongside psychotherapy including motivational interviewing and CBT.

Substance Use Disorder

– A problematic pattern of substance use leading to

clinically significant impairment or distress, manifested by at least two of eleven criteria within a twelve-month period. Criteria include taking the substance in larger amounts or over a longer period than intended, persistent desire or unsuccessful efforts to cut down, great deal of time spent obtaining or recovering from the substance, craving, failure to fulfill obligations, continued use despite social problems, giving up activities, recurrent use in hazardous situations, continued use despite physical or psychological problems, tolerance, and withdrawal. Severity is graded as mild (2-3 criteria), moderate (4-5), or severe (6 or more). Diagnosis is clinical using DSM-5 criteria. Treatment involves motivational interviewing to enhance motivation for change, CBT, contingency management, 12-step facilitation, and medication-assisted treatment where available (methadone, buprenorphine, naltrexone for opioid use disorder; acamprosate, disulfiram, naltrexone for alcohol use disorder). Relapse rates are high, and recovery often requires multiple treatment episodes and long-term support.

Substance/Medication-Induced Sexual Dysfunction

– Sexual dysfunction directly caused by substance use or medication effects. Common culprits: SSRIs/SNRIs (decreased desire, delayed ejaculation/anorgasmia, erectile dysfunction — most common cause of drug-induced sexual dysfunction), antipsychotics (hyperprolactinemia causing decreased desire and ED), antihypertensives (beta-blockers, thiazides, alpha-blockers), hormonal contraceptives (decreased desire, vaginal dryness), antiandrogens (spironolactone, finasteride), opioids (decreased desire, ED, delayed ejaculation), and alcohol (acute: erectile difficulty; chronic: decreased desire and testicular atrophy). Management: identify the culprit, dose reduction, drug holiday, switch to alternative (bupropion, mirtazapine for depression; PDE5 inhibitors for ED), and add-on therapy (buspirone for SSRI-induced sexual dysfunction). Bupropion has the lowest rate of sexual side effects among antidepressants.

Suicidal Ideation

– Thoughts about killing oneself, ranging from passive (wish to be dead, wishes to fall asleep and not wake) to active (thoughts of killing oneself with

varying degrees of intent, plan, and means). The C-SSRS grades severity from 1 (wish to be dead) to 5 (active suicidal ideation with specific plan and intent). Assessment of suicidal ideation must include questions about plan, intent, means, and history of attempts.

Suicide

– The intentional act of taking one's own life. Suicide is a major public health problem worldwide, causing 700,000 deaths annually. Risk factors: psychiatric disorders (major depression—most common contributor, bipolar disorder, schizophrenia, borderline personality disorder, PTSD, substance use disorders—especially alcohol), previous suicide attempt (strongest predictor), family history of suicide, access to means (firearms—most common method in the US; hanging, pesticide poisoning—common globally), male sex (3–4:1 ratio of completed suicide vs attempts), older age (peaks in middle-aged and older adults), chronic physical illness, social isolation, unemployment, financial stress, history of childhood abuse/trauma, and LGBTQ+ identity (increased risk in the context of minority stress). Assessment: direct questioning about suicidal thoughts, plans, intent, and means (does not increase risk—contrary to myth). The SAFE-T (Suicide Assessment Five-step Evaluation and Triage) framework. Acute management: ensure safety—remove means, hospitalisation (voluntary or involuntary if imminent risk), suicide watch (1:1 observation), and pharmacological treatment of underlying psychiatric condition. Long-term management: psychotherapy (CBT, dialectical behaviour therapy—DBT for borderline personality disorder), pharmacotherapy (antidepressants—SSRIs, lithium—reduces suicide risk in mood disorders, clozapine—for schizophrenia), and psychosocial interventions (safety planning, crisis hotlines—988 in the US, 111 option 2 in the UK). Postvention: support for bereaved family and friends (suicide bereavement). Prevention: restricting access to means, responsible media reporting, school-based programmes, and gatekeeper training (GPs, teachers, police).

Tardive Dyskinesia

– Involuntary, repetitive, purposeless movements caused by prolonged use of antipsychotic medications, typically developing after months to years

of exposure. Movements include choreoathetoid movements of the tongue, face, and extremities (lip smacking, tongue protrusion, grimacing, choreiform movements of limbs). It is caused by dopamine receptor supersensitivity. It may be irreversible. VMAT2 inhibitors (valbenazine, deutetrabenazine) are FDA-approved treatments. Risk is lower with atypical antipsychotics (especially clozapine and quetiapine) compared to typical antipsychotics. Prevention involves using the lowest effective dose, regular screening using the Abnormal Involuntary Movement Scale (AIMS) every 6-12 months, and switching to an atypical antipsychotic with lower D2 affinity if emerging dyskinesia is detected. Patients should be warned about the risk prior to starting antipsychotic treatment.

Therapeutic Alliance

- The collaborative, trusting relationship between therapist and patient that is foundational to effective psychotherapy. It includes agreement on goals, tasks, and the bond between therapist and patient. It is the strongest predictor of psychotherapy outcome across all therapeutic modalities.

Therapeutic Drug Monitoring

- The clinical practice of measuring specific drug concentrations in blood or plasma to individualize drug dosing and ensure therapeutic effectiveness while minimizing toxicity. See [pharmacology](#).

Therapeutic Hypothermia

- Controlled cooling of the body temperature used in psychiatric practice for severe catatonia and neuroleptic malignant syndrome. In NMS, cooling is a key treatment alongside discontinuation of the offending agent and dantrolene administration. Body temperature is reduced to below 38 degrees Celsius using cooling blankets, ice packs, or intravascular cooling catheters.

Thought Blocking

- An abrupt interruption in the train of thought before it is completed, as if the thought was removed or pushed out of the patient's mind. The patient may pause mid-sentence, appear confused, and report that the thought was "taken out" or "blocked." It is a formal thought disorder seen in schizophrenia.

Tourette Disorder

- A neurodevelopmental disorder characterized by

multiple motor tics and one or more vocal tics lasting >1 year, with onset before age 18. Motor tics: eye blinking, head jerking, shoulder shrugging, facial grimacing. Vocal tics: throat clearing, sniffing, grunting, barking, coprolalia (obscene words, occurs in <10%). Premonitory urge precedes tics. Comorbidities: ADHD (60%), OCD (30-50%), anxiety. Course: waxing and waning severity; most improve by late adolescence. Diagnosis: clinical DSM-5 criteria. Treatment: CBIT (habit reversal training), alpha-2 agonists (clonidine, guanfacine), antipsychotics (haloperidol, pimozide) for severe tics.

Tourette Syndrome

- A neurodevelopmental disorder characterized by multiple motor tics and at least one vocal tic occurring over at least one year. Tics are sudden, rapid, recurrent, stereotyped movements or vocalizations. They are often preceded by premonitory urges. Tics typically worsen in adolescence and may improve in adulthood. Comorbidities include ADHD, OCD, and anxiety disorders. Treatments include behavioral therapy and antipsychotics for severe tics.

Tranquillisers

- A class of drugs that have a calming or sedative effect, reducing anxiety, tension, and agitation. See [pharmacology](#).

Transference

- A psychoanalytic concept in which feelings, attitudes, and expectations originally directed toward a significant figure from childhood are unconsciously redirected onto the therapist. In psychodynamic therapy, transference is a therapeutic tool for understanding the patient's relational patterns and resolving conflicts.

Transvestic Disorder

- A paraphilic disorder characterized by recurrent, intense sexual arousal from cross-dressing, lasting ≥ 6 months and causing marked distress or impairment. Almost exclusively in heterosexual males. Transvestic disorder is distinguished from gender dysphoria by the primary motivation: sexual arousal (transvestic) vs. identity incongruence (gender dysphoria). Many cross-dressers do not experience distress and therefore do not meet disorder criteria. Treatment: CBT for distress or guilt, and SSRIs for

compulsive behavior. No treatment is indicated for cross-dressing without distress.

Trichotillomania

- Recurrent pulling out of one's hair, resulting in hair loss. The individual has made repeated attempts to decrease or stop hair pulling. The hair pulling causes clinically significant distress or impairment. It is not attributable to another medical condition. The pulling can occur from any body region and may be focused or focused-pulling. It is classified under obsessive-compulsive and related disorders.

Tricyclic Antidepressants

- Older antidepressants that non-selectively inhibit the reuptake of serotonin and norepinephrine. They include amitriptyline, nortriptyline, imipramine, clomipramine, and desipramine. TCAs are effective but have more side effects than SSRIs, including anticholinergic effects (dry mouth, urinary retention, constipation), orthostatic hypotension, weight gain, and cardiac conduction delays. Lethal in overdose due to cardiac arrhythmias. They are used for depression, neuropathic pain, migraine prophylaxis, and off-label for insomnia and anxiety. TCAs have significant anticholinergic, antihistaminergic, and alpha-adrenergic blocking properties. Nortriptyline has the least anticholinergic side effects and is preferred in elderly patients. Due to their narrow therapeutic index and cardiotoxicity in overdose, TCAs are used less frequently than SSRIs but remain important for treatment-resistant depression. Monitoring of ECG and serum drug levels is recommended.

Vagus Nerve Stimulation

- A neuromodulation treatment involving electrical stimulation of the left vagus nerve via an implanted device. It is FDA-approved for treatment-resistant depression and epilepsy. It requires surgical implantation and delivers intermittent stimulation. Improvement may take months to develop. Non-invasive transcutaneous vagus nerve stimulation is being investigated.

Voyeuristic Disorder

- A paraphilic disorder involving recurrent, intense sexual arousal from observing an unsuspecting person who is naked, disrobing, or engaging in sexual activity. The individual has acted on these urges

or they cause marked distress or interpersonal difficulty. Duration ≥ 6 months. Most common in males with onset in adolescence. Treatment: CBT and SSRIs.

Word Salad

- Severe disorganized speech consisting of a jumble of words and phrases that lack meaning or logical connection. It is a hallmark of formal thought disorder in schizophrenia and represents the most severe form of disorganized speech. It reflects profound disruption of language processing.

Psychosis

- A syndrome characterized by loss of contact with shared reality, commonly involving delusions, hallucinations, disorganized thought or behavior, and negative symptoms. Causes include primary psychotic disorders, mood disorders, substances, medications, neurologic disease, and systemic illness.

Positive Symptoms

- Symptoms reflecting an excess or distortion of normal mental functions, such as hallucinations, delusions, disorganized speech, or grossly disorganized behavior. They are contrasted with negative symptoms, which reflect loss or reduction of function.

Negative Symptoms

- Reduced or absent normal emotional, motivational, cognitive, or social functions, including affective flattening, alogia, avolition, anhedonia, and asociality. Persistent negative symptoms can substantially impair functional recovery.

Delusion

- A fixed belief that is not consistent with available evidence or the person's sociocultural context and is not readily changed by reasoned discussion. Delusions may be persecutory, grandiose, referential, somatic, nihilistic, or erotomanic.

First-Episode Psychosis

- The first clinically recognized episode of psychosis, regardless of eventual diagnosis. It requires urgent assessment for substance exposure, medication effects, mood symptoms, neurologic disease, systemic illness, safety risk, and functional decline.

Differential Diagnosis

- A structured list and evaluation of conditions that could explain a patient's symptoms. Psychiatric di-

agnosis requires consideration of medical, neurologic, substance-related, medication-induced, developmental, cultural, and psychosocial explanations.

Suicide Risk Assessment

- A clinical evaluation of suicidal thoughts, intent, plan, access to means, past attempts, self-harm, psychiatric and medical illness, substance use, protective factors, and immediate safety. It informs but does not replace ongoing clinical judgment and safety planning.

Safety Plan

- A collaboratively written, practical plan for responding to escalating suicidal thoughts or emotional crisis. It identifies warning signs, internal coping strategies, supportive contacts, professional resources, and methods to restrict access to lethal means.

Lethal-Means Counseling

- A preventive intervention that reduces access to firearms, medications, toxic substances, or other methods of self-harm during periods of elevated risk. It is conducted collaboratively and is an important component of suicide prevention.

Decision-Making Capacity

- The clinical ability to understand relevant information, appreciate its consequences, reason about options, and communicate a stable choice regarding a specific decision. Capacity is decision-specific and may fluctuate; it is distinct from legal competence.

Involuntary Psychiatric Treatment

- Assessment, hospitalization, or treatment without the patient's consent under applicable law when serious mental disorder creates a substantial risk of harm or severe inability to meet basic needs. The least restrictive alternative, due process, and ongoing reassessment are required.

Acute Agitation

- A state of heightened motor activity, emotional tension, irritability, and impaired behavioral control that may threaten the patient or others. Management begins with de-escalation and assessment for delirium, intoxication, withdrawal, medical illness, and psychosis.

De-Escalation

- A set of verbal and nonverbal techniques used to re-

duce agitation and prevent violence while preserving dignity and safety. It includes calm communication, appropriate personal space, clear limits, environmental modification, and offering choices.

Substance Intoxication

- A reversible substance-specific syndrome caused by recent use that produces clinically significant behavioral or physiologic changes. Diagnosis requires assessing timing, dose or exposure, expected pharmacology, co-ingestants, and medical complications.

Substance Withdrawal

- A substance-specific syndrome occurring after reduction or cessation of heavy or prolonged use. Withdrawal can range from discomfort to life-threatening complications such as seizures, delirium tremens, severe autonomic instability, or respiratory depression depending on the substance.

Harm Reduction

- Evidence-based strategies that decrease health, social, and legal harms associated with substance use without requiring immediate abstinence. Examples include naloxone access, sterile injecting equipment, drug-checking where available, safer-use education, and linkage to treatment.

Opioid Agonist Treatment

- Treatment of opioid use disorder with a prescribed opioid agonist or partial agonist, most commonly methadone or buprenorphine, together with psychosocial and medical support. It reduces withdrawal, craving, illicit opioid use, overdose, and mortality.

Akathisia

- A medication-associated movement disorder characterized by subjective inner restlessness and an objective need to move, commonly caused by dopamine-receptor-blocking drugs. It can be mistaken for anxiety or agitation and may increase distress and suicide risk.

Antipsychotic-Induced Parkinsonism

- Drug-induced bradykinesia, rigidity, tremor, or postural instability caused by dopamine-receptor blockade, usually from antipsychotic treatment. Management involves reviewing the medication, dose, alternatives, and symptomatic treatment

when appropriate. **Adjustment disorder with anxiety**

- An emotional or behavioral response to an identifiable stressor that causes distress or impairment but does not meet criteria for another mental disorder. **Postnatal depression**

- A depressive episode occurring after childbirth, with persistent low mood, anhedonia, sleep or appetite disturbance, guilt, impaired bonding, or suicidal thoughts. **Puerperal psychosis**

- A rare psychiatric emergency beginning soon after childbirth, characterized by rapidly changing mood, confusion, delusions, hallucinations, or disorganized behavior. **Bereavement reaction**

- A normal emotional response to the death of a loved one, involving grief that generally follows a variable course without necessarily indicating a mental disorder.

Functional Neurological Symptom Disorder

- A condition in which neurological symptoms such as weakness, abnormal movement, sensory loss, or episodes resembling seizures are incompatible with recognized neurological disease patterns and cause significant distress or impairment. Diagnosis requires positive clinical findings of inconsistency or incongruence, not merely normal imaging or tests.

Hallucinations

- Perceptions occurring without an external sensory stimulus, such as hearing voices, seeing images, or feeling sensations that are not present. They may result from psychiatric illness, neurological disease, delirium, substance exposure, sensory loss, or severe sleep disruption.

Irregular Sleep-Wake Syndrome

- A circadian rhythm sleep-wake disorder with multiple irregular periods of sleep and wakefulness across the 24-hour day rather than one consolidated nighttime sleep period. It is associated with neurological disease, dementia, aging, and reduced exposure to environmental time cues.

Chapter 34

Public Health

Long COVID

- Persistent or recurrent symptoms following acute SARS-CoV-2 infection, lasting at least several weeks and sometimes months or years. Common manifestations include fatigue, post-exertional malaise, cognitive difficulty, breathlessness, dysautonomia, and altered smell or taste.

Middle East Respiratory Syndrome

- A severe respiratory infection caused by Middle East respiratory syndrome coronavirus, usually acquired through close contact with infected camels or people. It can cause pneumonia, respiratory failure, and renal or multiorgan complications.

Air Quality

- Measurement of air pollutants. Examples: particulate matter, ozone, nitrogen dioxide, sulfur dioxide.

Airborne Precautions

- For diseases spread by small particles. Examples: tuberculosis, measles, varicella. N95 respirator required, negative pressure room.

AMR (Antimicrobial Resistance)

- Bacteria resisting antibiotic effects. See [antibiotic resistance](#).

Antibiotic Resistance

- Bacteria resisting antibiotic effects. Mechanisms: enzymatic degradation, target modification, efflux pumps, membrane permeability. Driven by antibiotic overuse.

Antibiotic Stewardship

- Program to optimize antibiotic use. Goals: improve outcomes, reduce resistance, decrease costs.

Attributable Risk

- Difference in risk between exposed and unexposed.

$AR = \text{incidence exposed} - \text{incidence unexposed}$.

Public Health Research Bias

- Systematic error in a population-health study, including selection bias, information bias, and confounding.

Bioethics

- Ethical issues in medicine and biology. Examples: research ethics, end-of-life care, resource allocation.

Blinding

- Concealing group assignment. Single-blind: participants. Double-blind: participants and investigators. Triple-blind: participants, investigators, analysts.

Carrier

- Person harboring pathogen without symptoms. Can transmit disease. Examples: Typhoid Mary, pneumococcal carriers.

Case-Control Study

- Compares cases with disease to controls without. Retrospective. Measures odds ratio.

Case-Fatality Rate

- Proportion of cases dying from disease. Formula: $\text{deaths} / \text{cases}$. Measures severity.

Clinical Guideline

- Systematically developed statements to assist practice. Examples: CDC guidelines, WHO guidelines, specialty society guidelines.

Clinical Practice Guideline

- Systematically developed statements to assist practice. See [clinical guideline](#).

Cohort Study

- Follows exposed and unexposed groups over time. Prospective or retrospective. Measures incidence, relative risk.

Community Health Worker

- Lay health worker from community. Bridges community and healthcare. Examples: promotoras, CHWs.

Confounding

- Distortion of association by third variable. Examples: age confounding relationship between exposure and disease. Controlled by matching, stratification, regression.

Contact Precautions

- For highly contagious or multidrug-resistant organisms. Examples: C. difficile, MRSA, VRE. Gloves and gown required.

Contact Tracing

- Identifying and monitoring persons exposed to infectious disease. Critical for outbreak control. Examples: COVID-19, Ebola, TB.

Cross-Sectional Study

- Measures exposure and outcome at same time. Prevalence study. Cannot establish temporality.

Disaster Preparedness

- Planning for disasters. Examples: hurricane, earthquake, pandemic, terrorism. Components: response, recovery, mitigation.

Droplet Precautions

- For diseases spread by large droplets. Examples: influenza, pertussis, bacterial meningitis. Surgical mask required.

Emerging Infectious Disease

- New or reemerging infectious diseases. Examples: COVID-19, Zika, Ebola, MERS.

Endemic

- Disease constantly present in population. Examples: malaria in tropics, influenza in winter.

Environmental Health

- Study of environmental factors affecting health. Examples: air pollution, water quality, occupational hazards, climate change.

Epidemic

- Sudden increase in disease cases above expected level. Examples: cholera outbreak, measles outbreak.

Epidemiology

- Study of distribution and determinants of health-related states in populations. Branches: descriptive (who, when, where), analytic (why, how), experimental (intervention trials). Measures: incidence, prevalence, mortality rates, case-fatality rate.

Evidence-Based Medicine

- Integration of best research evidence with clinical expertise and patient values. Foundation for clinical guidelines.

Global Health

- Health issues transcending national boundaries. Examples: pandemics, health disparities, climate change.

Hand Hygiene

- Most important infection control measure. Methods: handwashing with soap and water, alcohol-based hand rub.

Health Behavior

- Actions affecting health. Examples: diet, exercise, smoking, alcohol, sexual behavior, medication adherence.

Health Disparity

- Difference in health outcomes between populations. Examples: racial disparities, socioeconomic disparities, geographic disparities.

Health Equity

- Attainment of highest possible health for all people. Requires addressing disparities.

Health Information Technology

- Use of technology for health information. Examples: electronic health records, telemedicine, mobile health, decision support.

Health Literacy

- Ability to obtain, process, understand health information. Examples: reading labels, following instructions, communicating with providers.

Health Promotion

- Process enabling people to control and improve health. Components: healthy public policy, supportive environments, community action, personal skills, reorient health services.

Health Surveillance

- Ongoing collection, analysis, interpretation of

health data. See [surveillance](#).

Herd Immunity

- Resistance of population to invasion by infectious agent when sufficient proportion immune. Threshold varies by disease (measles 95)

Incidence

- Number of new cases of disease in a population during specified time period. Measures risk. Formula: $\text{new cases} / \text{population at risk} \times \text{time unit}$.

Infection Control

- Prevention of healthcare-associated infections. Examples: hand hygiene, isolation precautions, environmental cleaning, antibiotic stewardship.

Isolation

- Separation of sick persons with contagious disease. Examples: tuberculosis isolation, airborne infection isolation rooms.

Isolation Precautions

- Measures for disease transmission. Types: contact, droplet, airborne. PLUS standard precautions.

Meta-Analysis

- Statistical combination of results from multiple studies. Increases power, precision. Forest plot visualization.

Mobile Health (mHealth)

- Use of mobile devices for health. Examples: health apps, text message reminders, wearable devices.

Mortality Rate

- Deaths from disease in population. Crude: $\text{total deaths} / \text{total population}$. Specific: $\text{disease-specific deaths} / \text{population at risk}$.

Negative Predictive Value

- Probability that negative test indicates no disease. $\text{NPV} = \text{true negatives} / \text{all negatives}$.

Notifiable Disease

- Disease required by law to be reported to health authorities. Examples: tuberculosis, measles, HIV, COVID-19.

Occupational Health

- Health of workers. Examples: workplace safety, occupational diseases, ergonomics.

Odds Ratio

- Ratio of odds of exposure in cases vs. controls.

Used in case-control studies. OR approximates RR for rare diseases.

One Health

- Approach recognizing health connections between humans, animals, environment. Examples: zoonotic diseases, antibiotic resistance, food safety.

Outbreak

- Similar to epidemic but more localized. Examples: foodborne outbreak, school outbreak.

Pandemic

- Epidemic spread across multiple countries/continents. Examples: COVID-19, Spanish flu, HIV/AIDS.

Patient Safety

- Prevention of harm from healthcare. Examples: medication errors, healthcare-associated infections, surgical errors. Strategies: checklists, hand hygiene, barcoding.

Patient-Centered Care

- Care respecting patient preferences, needs, values. Examples: shared decision-making, communication, coordination.

Personal Protective Equipment (PPE)

- Equipment for protection. Examples: gloves, gown, mask, goggles, respirator.

Population Attributable Risk

- Proportion of disease in population attributable to exposure. $\text{PAR} = (\text{incidence total} - \text{incidence unexposed}) / \text{incidence total}$.

Positive Predictive Value

- Probability that positive test indicates disease. Depends on prevalence. $\text{PPV} = \text{true positives} / \text{all positives}$.

Prevalence

- Total number of cases (new and existing) in population at given time. Formula: $\text{all cases} / \text{total population}$. $\text{Prevalence} = \text{incidence} \times \text{duration}$.

Primary Prevention

- Preventing disease before onset. Examples: vaccination, smoking cessation, safe sex, seat belts.

Primordial Prevention

- Preventing the emergence of disease risk factors

by addressing social, economic, behavioural, and environmental conditions early. Examples: promoting healthy diets and physical activity in children, reducing tobacco exposure, and creating safe environments for exercise.

Protective Factor

- Attribute decreasing probability of disease. Examples: exercise (cardiovascular disease), vaccination (infectious disease).

Public Health Emergency

- Event threatening public health. Examples: pandemic, bioterrorism, natural disaster. Declaration enables special powers.

Quality Improvement

- Systematic efforts to improve healthcare. Methods: PDSA cycles, Lean, Six Sigma. Outcomes: safety, effectiveness, patient-centeredness.

Quarantine

- Separation of exposed individuals to prevent disease spread.

Randomized Controlled Trial (RCT)

- Gold standard for intervention studies. Participants randomly assigned to intervention or control. Minimizes bias.

Reemerging Disease

- Previously controlled disease increasing. Examples: tuberculosis, measles, drug-resistant infections.

Relative Risk

- Ratio of disease risk in exposed vs. unexposed. $RR = (a/(a+b)) / (c/(c+d))$. $RR > 1$: increased risk. $RR < 1$: protective.

Reservoir

- Host where pathogen lives and multiplies. Examples: animals (zoonoses), humans (human reservoirs), environment (soil, water).

Risk Factor

- Attribute increasing probability of disease. Examples: smoking (lung cancer), hypertension (stroke), obesity (diabetes).

Secondary Prevention

- Early detection and treatment. Examples: screening (mammography, colonoscopy, blood pressure), self-examination.

Sensitivity

- Proportion of true positives correctly identified. High sensitivity: few false negatives. Screening tests should be sensitive.

Specificity

- Proportion of true negatives correctly identified. High specificity: few false positives. Confirmatory tests should be specific.

Standard Precautions

- Precautions for all patient care. Examples: hand hygiene, PPE, safe injection, respiratory hygiene.

Surveillance

- Systematic collection, analysis, interpretation of health data. Types: passive (reporting), active (proactive case finding), sentinel (selected sites).

Systematic Review

- Comprehensive summary of research on specific question. Uses explicit methods to minimize bias. Cochrane reviews example.

Telemedicine

- Remote delivery of healthcare using technology. Examples: video visits, remote monitoring, store-and-forward. Increases access.

Tertiary Prevention

- Reducing complications from established disease. Examples: rehabilitation, chronic disease management, palliative care.

Vaccination

- Administration of vaccine to stimulate immunity. Types: live attenuated, inactivated, subunit, mRNA, viral vector. Schedule varies by country.

Vector

- Organism transmitting pathogen. Examples: mosquitoes (malaria, dengue), ticks (Lyme disease), fleas (plague).

Vector Control

- Reduction of vector populations. Examples: insecticides, larvicides, environmental modification, personal protection.

Vector-Borne Disease

- Disease transmitted by vectors. Examples: malaria, dengue, Lyme disease, Zika virus.

Zoonosis

- Disease transmitted from animals to humans. Examples: rabies, Lyme disease, avian influenza, COVID-19.

Attack Rate

- The proportion of an at-risk population that develops a specified illness during a defined outbreak or exposure period. It is a cumulative incidence measure commonly used for foodborne and other localized outbreaks.

Secondary Attack Rate

- The proportion of susceptible contacts who develop infection after exposure to a primary case within a defined period. It helps estimate transmissibility in households, schools, healthcare settings, and other close-contact groups.

Basic Reproduction Number (R_0)

- The expected number of secondary infections generated by one typical infectious person in a completely susceptible population, under specified conditions. It is a population and context parameter, not a fixed biological constant.

Effective Reproduction Number (R_t)

- The average number of secondary infections caused by an infectious person at a particular time, accounting for existing immunity, behavior, interventions, and population structure. Sustained transmission generally requires R_t above 1.

Case Definition

- Standardized clinical, laboratory, and epidemiologic criteria used to classify a person as a suspected, probable, or confirmed case for surveillance or outbreak investigation. It may differ from the criteria used for individual clinical diagnosis.

Sentinel Surveillance

- Ongoing collection of health data from selected reporting sites, providers, or populations chosen to represent trends rather than enumerate every event. It can provide early warning and monitor changes in disease activity.

Syndromic Surveillance

- Monitoring of symptoms, clinical encounters, laboratory requests, or other near-real-time signals before definitive diagnoses are available. It sup-

ports early detection of outbreaks and public-health threats but may have lower specificity.

Screening Program

- An organized public-health service that systematically invites a defined population to undergo testing for an asymptomatic condition, with quality-assured follow-up, diagnosis, treatment, and evaluation of benefits and harms.

Lead-Time Bias

- The appearance of improved survival after screening because diagnosis occurs earlier, even when the time of death is unchanged. It can make screening appear beneficial without reducing mortality.

Length-Time Bias

- The tendency of screening to preferentially detect slower-growing or less aggressive disease because it remains detectable for a longer preclinical period. It can exaggerate the apparent benefit of screening.

Number Needed to Treat (NNT)

- The number of people who must receive an intervention for one additional person to experience the specified beneficial outcome compared with the control over a defined time. It is the reciprocal of absolute risk reduction.

Number Needed to Harm (NNH)

- The number of people exposed to an intervention for one additional person to experience a specified adverse outcome compared with the control over a defined time. It is the reciprocal of absolute risk increase.

Disability-Adjusted Life Year (DALY)

- A population-health measure combining years of life lost because of premature mortality with years lived with disability. One DALY represents one lost year of healthy life under the chosen methods and disability weights.

Quality-Adjusted Life Year (QALY)

- A health-economic measure combining length of life with health-related quality of life on a scale where 1 represents full health and 0 represents death. It is used to compare cost-effectiveness across interventions.

Age-Standardized Rate

- A rate adjusted to a specified standard population age distribution so that populations with different age structures can be compared more fairly. It is commonly used for mortality, cancer, and disease-incidence comparisons.

Health Inequity

- A systematic, avoidable, and unjust difference in health or access to health resources between social groups. It differs from health variation that is not preventable or not linked to unfair social conditions.

Population Attributable Fraction

- The proportion of cases or disease burden in the total population that would theoretically be prevented if the exposure were eliminated, assuming the exposure is causal and other conditions remain unchanged.

Positive Predictive Value in Surveillance

- The proportion of reported signals or alerts that represent true events meeting the surveillance case definition. It is influenced by the specificity of the signal and the underlying prevalence of the condition.

Chapter 35

Pulmonology

Atypical Pneumonia

- Pneumonia with a gradual onset, relatively mild chest findings, and prominent systemic or extrapulmonary symptoms. Common causes include *Mycoplasma pneumoniae*, *Chlamydia pneumoniae*, and respiratory viruses.

Collapsed Lung

- A common description of pneumothorax, in which air enters the pleural space and partially or completely collapses the lung. It may cause sudden chest pain and shortness of breath and can be life-threatening when tension develops. See also Pneumothorax.

Intercostal Retractions

- Inward movement of the skin between the ribs during inspiration, indicating increased work of breathing. It is commonly seen in infants and children with airway obstruction, bronchiolitis, asthma, pneumonia, or respiratory failure.

Pulmonary Arteriovenous Fistula

- An abnormal direct connection between a pulmonary artery and vein that bypasses the capillary bed. It can cause hypoxemia, cyanosis, dyspnea, paradoxical emboli, or brain abscess.

Silicosis

- Fibrotic lung disease caused by inhalation of crystalline silica dust, typically in mining, quarrying, construction, or stone-cutting work. It causes progressive breathlessness and increases the risk of tuberculosis, chronic airflow limitation, and lung cancer.

Acute Cough

- Cough lasting < 3 weeks. Most common causes: URI, acute bronchitis, pneumonia. Usually self-limited.

Acute Respiratory Distress Syndrome

- ARDS: a syndrome of acute, diffuse inflammatory lung injury causing severe hypoxemic respiratory failure with bilateral infiltrates not due to cardiogenic pulmonary edema ($\text{PaO}_2/\text{FiO}_2$ ratio ≤ 300). Causes: sepsis (most common), pneumonia, trauma, aspiration, pancreatitis, massive transfusion. Pathology: endothelial/alveolar injury, protein-rich edema, surfactant dysfunction, hyaline membranes; three phases—exudative, proliferative, fibrotic. Features: severe dyspnea, hypoxemia, refractory hypoxemia; diagnosis by Berlin criteria. Management: lung-protective ventilation (low tidal volume 6 mL/kg, plateau pressure ≤ 30), PEEP, prone positioning, conservative fluids, neuromuscular blockade; steroids controversial. Mortality 30-40 percent.

Airway Clearance Techniques

- Physical therapies to mobilize and remove secretions from the airways. Techniques include postural drainage, percussion, vibration, active cycle of breathing, autogenic drainage, positive expiratory pressure, oscillating PEP, and high-frequency chest wall oscillation. They are essential in CF, bronchiectasis, and neuromuscular disease.

Allergen Immunotherapy

- Gradual desensitization to specific allergens through repeated subcutaneous or sublingual exposure. It reduces allergic asthma symptoms and medication needs. Treatment requires 3–5 years for full benefit. It is indicated for allergic asthma with identified specific allergens not controlled by standard therapy.

Allergic Bronchopulmonary

Aspergillosis

- A hypersensitivity reaction to *Aspergillus fumigatus* in asthma or CF patients. Causes central bronchiectasis, elevated total IgE, and eosinophilia. Treatment includes corticosteroids and itraconazole.

Alpha-1 Antitrypsin Deficiency

- An autosomal codominant genetic disorder caused by mutations in the SERPINA1 gene. It predisposes to early-onset panlobular emphysema (lower lobes), liver disease, and panniculitis. PiZZ genotype is most severe. Treatment includes AAT augmentation therapy and smoking avoidance.

Anti-IgE Therapy

- Omalizumab is a monoclonal antibody that binds free IgE, preventing it from binding to mast cells and basophils. It reduces allergic inflammation and is approved for moderate-to-severe persistent allergic asthma. It reduces exacerbations and the need for oral corticosteroids. It is administered by subcutaneous injection every 2–4 weeks.

Anti-IL4 Receptor Therapy

- Dupilumab is a monoclonal antibody blocking the IL-4 receptor alpha subunit, inhibiting both IL-4 and IL-13 signaling. It is approved for moderate-to-severe asthma with eosinophilic phenotype or oral corticosteroid dependence. It reduces exacerbations and improves lung function.

Anti-IL5 Therapy

- Monoclonal antibodies targeting interleukin-5, a key cytokine in eosinophil production and survival. Mepolizumab, reslizumab, and benralizumab (anti-IL-5 receptor) are approved for severe eosinophilic asthma. They reduce exacerbations and oral corticosteroid requirements in patients with blood eosinophils ≥ 300 .

ARDS

- Acute respiratory distress syndrome; see Acute Respiratory Distress Syndrome. Acute diffuse inflammatory lung injury causing severe hypoxemia ($\text{PaO}_2/\text{FiO}_2 \leq 300$), bilateral infiltrates, and non-cardiogenic pulmonary edema. Common causes: sepsis, pneumonia, trauma, aspiration. Management: lung-protective ventilation (6 mL/kg tidal volume, low plateau pressure), PEEP, prone positioning, conservative fluid strategy, and treatment of

the underlying cause. Complications: barotrauma, VAP, multi-organ failure; mortality 30–40 percent.

Asbestosis

- See public_health.

Aspirin-Exacerbated Respiratory Disease

- A triad of asthma, nasal polyps, and aspirin sensitivity due to COX-1 inhibition. It involves overproduction of cysteinyl leukotrienes. Leukotriene receptor antagonists are specifically effective.

Asthma

- A chronic inflammatory disorder of the airways characterized by recurrent episodes of wheezing, breathlessness, chest tightness, and cough. Airflow limitation is often reversible. It involves eosinophilic inflammation, mucus hypersecretion, and smooth muscle hypertrophy.

Asthma-COPD Overlap

- Features of both asthma and COPD in the same patient. Characterized by persistent airflow limitation with features of both diseases: airway inflammation (eosinophilic and neutrophilic), bronchial hyperresponsiveness, and partially reversible obstruction. Treatment: inhaled corticosteroids plus long-acting bronchodilators. Distinguished from pure asthma (usually atopic, reversible) and pure COPD (smoking history, fixed obstruction).

Brittle Asthma

- Rare phenotype of severe asthma characterized by wide, chaotic, unpredictable peak expiratory flow variability ($> 40\%$ diurnal variation over weeks), classified as type 1 (chronic, persistent chaotic variability maintained over months despite maximal therapy) and type 2 (sudden onset of severe, life-threatening attacks against a background of apparently well-controlled asthma with normal pulmonary function between attacks; can be triggered by allergens, stress, or anaphylaxis). Most cases have type 1 brittle asthma; risk factors include atopy, food sensitivities, psychosocial factors, female sex, and severe airway hyperresponsiveness. Management: supervised high-dose inhaled corticosteroids and long-acting β_2 -agonists; consider monoclonal antibodies (omalizumab, mepolizumab, benralizumab, dupilumab) for type 2-mediated disease; rapid-action bronchodilators with written action

plan; autoinjector epinephrine for those with anaphylaxis comorbidity; consider subcutaneous terbutaline infusion or nocturnal noninvasive ventilation for refractory cases. High mortality risk if mismanaged.

Bagassosis

- An occupational hypersensitivity pneumonitis (extrinsic allergic alveolitis) caused by inhalation of dust from moldy bagasse—the fibrous residue of sugarcane after extraction. Caused by thermophilic actinomycetes (*Saccharopolyspora rectivirgula*) that colonize stored bagasse. Presents with fever, cough, dyspnea, and malaise 4–8 hours after exposure. Acute episodes resolve with corticosteroid treatment and avoidance; chronic exposure leads to pulmonary fibrosis.

Berylliosis

- A granulomatous lung disease from beryllium exposure. Chronic berylliosis resembles sarcoidosis. Diagnosis requires beryllium lymphocyte proliferation test.

BiPAP

- Bilevel Positive Airway Pressure, a form of non-invasive ventilation delivering two levels of pressure: IPAP (inspiratory) for ventilation and EPAP (expiratory) for alveolar recruitment. It is particularly effective for COPD exacerbations with hypercapnic respiratory failure. It reduces work of breathing and improves gas exchange.

Bird Fancier's Lung

- HP from avian proteins in bird droppings or feathers. Common among pigeon breeders. Chronic exposure leads to progressive fibrosis.

Blue Bloater

- A clinical phenotype of chronic bronchitis in COPD. Patients present with chronic cough, sputum production, cyanosis, right heart failure, and airway-centric inflammation. They tend to be younger, have more hypercapnia, and less emphysema on imaging.

Bradypnea

- Abnormally slow respiratory rate (adult <12 breaths/min). Causes: opioid/benzodiazepine/sedative overdose, central nervous system depression (stroke, trauma, increased ICP), hypothyroidism, hypothermia,

and metabolic (e.g., hypokalemia). May lead to hypoventilation, hypercapnia, and respiratory failure. Management: airway protection, ventilation support, reversal of depressants (naloxone, flumazenil), and treatment of the cause. Contrast with apneustic/Cheyne-Stokes patterns in specific CNS lesions.

Bronchial Carcinoid

- Pulmonary neuroendocrine tumor arising from Kulchitsky cells of the bronchial mucosa; subclassified as typical carcinoid (TC, low-grade, < 3 mitoses/2 mm², no necrosis, excellent prognosis with > 90% 5-year survival) and atypical carcinoid (AC, intermediate-grade, 2-10 mitoses or necrosis present, higher recurrence/ metastasis). Typical are 3-4× more common; patients typically young adults (40s), more common in women, non-smoking association. Presentations: central tumors cause cough, hemoptysis, wheeze, post-obstructive pneumonia; peripheral tumors typically asymptomatic. Cushing syndrome from ectopic ACTH in ~ 2% of typical, up to 40 – 50% of atypical. Carcinoid syndrome rare unless hepatic metastases. Diagnosis: CT chest, bronchoscopy with biopsy (cautious due to hemorrhage risk); octreotide scan/SSTR PET for staging. Treatment: anatomical surgical resection (lobe or segment) with lymphadenectomy; bronchial-sparing sleeve resection for central typical; radiation, chemotherapy, and somatostatin analogs for metastatic disease.

Bronchial Biopsy

- Tissue sampling of the bronchial wall during bronchoscopy. It is used to diagnose inflammatory conditions (sarcoidosis, eosinophilic bronchitis), infections, and malignancy. Endobronchial biopsy of visible lesions and transbronchial biopsy of parenchymal lesions provide complementary diagnostic information.

Bronchiectasis

- Permanent, abnormal dilation of bronchi caused by destruction of the bronchial wall from chronic airway inflammation and infection. Causes include CF, immune deficiency, primary ciliary dyskinesia, and post-infectious damage. Features include chronic cough, copious purulent sputum, and recurrent hemoptysis.

Bronchitis

- Inflammation of the bronchial mucosa. Acute bronchitis is typically viral, presents with cough (often productive), and resolves spontaneously. Cough with sputum production for at least 3 months in 2 consecutive years, often due to smoking. Treatment: supportive for acute; bronchodilators, smoking cessation, and pulmonary rehabilitation for chronic.

Bronchoalveolar Lavage

- Diagnostic procedure during bronchoscopy where saline is instilled and aspirated. Analyzed for cell counts, microbiology, and cytology. Useful for *Pneumocystis pneumonia*, pulmonary alveolar proteinosis, and sarcoidosis diagnosis.

Bronchodilator Reversibility

- Improvement in FEV1 > 12% and > 200 mL after short-acting bronchodilator. Supports asthma diagnosis. Some COPD patients show partial reversibility.

Bronchopleural Fistula

- An abnormal communication between the bronchial tree and pleural space. It is a complication of pneumonectomy, lung surgery, or empyema. It causes persistent air leak, subcutaneous emphysema, and respiratory compromise. Treatment includes chest tube drainage, bronchoscopic intervention, and surgical repair.

Centriacinar Emphysema

- A subtype of emphysema in which destruction begins in the respiratory bronchioles and extends peripherally. It predominantly affects the upper lobes and is strongly associated with cigarette smoking. It is the most common form of emphysema and often coexists with chronic bronchitis.

Chest Physiotherapy

- Techniques to mobilize and clear secretions from the lungs, including postural drainage, percussion, vibration, and huffing. It is used in bronchiectasis, CF, and post-operative patients. Positive expiratory pressure devices and oscillating PEP devices are also used.

Chronic Bronchitis

- Defined clinically as a productive cough for at least three months in each of two consecutive years, after excluding other causes. It is characterized

by hypertrophy of mucus-secreting glands in the bronchi (Reid index > 0.5), goblet cell hyperplasia, and chronic airway inflammation.

Chronic Cough

- Cough lasting > 8 weeks. Top 3 causes in non-smokers with normal CXR: upper airway cough syndrome, asthma, GERD. ACE inhibitor use is another common cause.

Chronic Obstructive Pulmonary Disease

- COPD is a preventable lung disease characterized by persistent respiratory symptoms and airflow limitation due to airway and/or alveolar abnormalities, usually caused by significant exposure to noxious particles or gases (primarily tobacco smoke). Includes emphysema and chronic bronchitis. Diagnosis: spirometry with post-bronchodilator FEV1/FVC < 0.70. Management: smoking cessation, bronchodilators, inhaled corticosteroids, pulmonary rehabilitation, oxygen therapy, and lung volume reduction.

Chronic Obstructive Pulmonary Disease (COPD)

- COPD is a progressive lung disease characterized by persistent airflow limitation due to chronic bronchitis and emphysema, most commonly caused by cigarette smoking. Symptoms include dyspnea, chronic cough, sputum production, and frequent respiratory infections. Treatment involves bronchodilators, inhaled corticosteroids, pulmonary rehabilitation, supplemental oxygen, and smoking cessation to reduce exacerbations and improve quality of life.

Coal Worker's Pneumoconiosis

- Pneumoconiosis from coal dust. Simple CWP shows upper lobe macules. Complicated CWP (progressive massive fibrosis) involves coalescent macules. May be associated with Caplan syndrome.

Coarse Crackles

- Lower-pitched, longer-duration crackles heard throughout inspiration, caused by fluid or secretions in larger airways. They are heard in COPD, bronchiectasis, pneumonia, and pulmonary edema. They are less specific than fine crackles.

Combination Inhalers

- Inhalers containing both an inhaled corticosteroid and a long-acting bronchodilator.

teroid and a long-acting beta-2 agonist. Examples include fluticasone/salmeterol (Advair), budesonide/formoterol (Symbicort), and fluticasone furoate/vilanterol (Breo Ellipta). They simplify asthma and COPD maintenance therapy and improve adherence.

Crackles (Rales)

- Discontinuous, non-musical adventitious lung sounds produced by the sudden explosive opening of collapsed small airways and alveoli during inspiration or the bubbling of air through fluid in the bronchioles. Fine crackles: high-pitched, short duration, late inspiratory; characteristic of interstitial lung disease (idiopathic pulmonary fibrosis) and early congestive heart failure. Coarse crackles: low-pitched, moist, early inspiratory/expiratory; characteristic of pulmonary edema, pneumonia, bronchitis, and bronchiectasis.

Cryobiopsy

- A bronchoscopic technique using rapid freezing to obtain larger lung tissue samples than conventional transbronchial biopsy. It provides better histopathological specimens for diagnosing interstitial lung diseases. It requires general anesthesia and bronchoscopic expertise. It is less invasive than surgical lung biopsy.

Dead Space Ventilation

- Ventilation of alveoli without perfusion ($V/Q = \text{infinity}$). Anatomic dead space is the conducting airways (≈ 150 mL). Physiologic dead space includes alveoli without perfusion. Increased in PE, hypotension, and emphysema. Measured by the Bohr equation.

Desquamative Interstitial Pneumonia

- A rare ILD characterized by uniform filling of alveoli with macrophages containing brown pigment (hemosiderin-laden). It is strongly associated with smoking. HRCT shows bilateral ground-glass opacities with lower lobe predominance. Smoking cessation and corticosteroids are the main treatments.

Diffusing Capacity (DLCO)

- Ability of lungs to transfer gas from alveoli to blood. Reduced in emphysema, ILD, and anemia. Increased in pulmonary hemorrhage and left-to-right shunts.

Digital Clubbing

- Bulbous enlargement of distal phalanges with loss of nail-bed angle (> 180 degrees). Associated with lung cancer, ILD, bronchiectasis, and cyanotic heart disease.

Dyspnoea

- The subjective sensation of difficult or labored breathing, also known as shortness of breath (SOB). It is a symptom common to many cardiopulmonary and systemic conditions. Causes: respiratory (asthma, COPD, pneumonia, pulmonary embolism, pneumothorax, interstitial lung disease), cardiac (heart failure, myocardial ischemia, arrhythmia, valvular disease), and others (anemia, deconditioning, anxiety, metabolic acidosis, thyrotoxicosis). Assessed using the Borg Scale or modified Medical Research Council (mMRC) scale. Acute dyspnea is a medical emergency requiring rapid assessment of airway, breathing, and circulation; immediate oxygen supplementation and treatment of the underlying cause (bronchodilators, diuretics, anticoagulation, etc.). Chronic dyspnea requires systematic evaluation with pulmonary function testing, echocardiography, and imaging.

Emphysema

- A form of COPD characterized by permanent, abnormal enlargement of airspaces distal to the terminal bronchioles, accompanied by destruction of their walls. Centriacinar emphysema affects the respiratory bronchioles and is associated with smoking. Panlobular emphysema involves the entire acinus and is associated with alpha-1 antitrypsin deficiency.

Endobronchial Foreign Body

- A foreign object lodged in a bronchus, causing partial or complete airway obstruction. It may cause localized wheezing, atelectasis, and post-obstructive pneumonia. It is most common in children and may be initially misdiagnosed as asthma. Bronchoscopy is both diagnostic and therapeutic.

Endobronchial Valve

- A one-way valve placed bronchoscopically in a target airway to achieve lobar atelectasis in emphysema. It allows air and secretions to exit but prevents air from entering. It is used for bronchoscopic lung volume reduction in selected patients with heterogeneous emphysema and intact fissures.

Exacerbation of COPD

- An acute worsening of respiratory symptoms beyond normal day-to-day variations, requiring change in medication. It is commonly triggered by respiratory infections (viral, bacterial), air pollution, or non-compliance. Treatment includes increased bronchodilators, systemic corticosteroids, antibiotics if indicated, and oxygen therapy.

Exercise-Induced Bronchoconstriction

- Airway narrowing during or after exercise, presenting with cough, wheeze, and dyspnea. It occurs in up to 90% of asthmatics and is triggered by heat and water loss from the airways. Prevention includes pre-exercise SABA.

Exhaled Nitric Oxide

- A non-invasive measure of airway eosinophilic inflammation. FeNO > 25 ppb in adults suggests eosinophilic airway inflammation and predicts response to inhaled corticosteroids. It is useful for diagnosing eosinophilic asthma, monitoring treatment response, and differentiating asthma from other causes of cough.

Expectoration

- The act of coughing up and spitting out mucus, sputum, or phlegm from the respiratory tract; sputum production. Sputum characteristics aid diagnosis: purulent (bacterial infection), frothy pink (pulmonary edema), rust-colored (pneumococcal pneumonia), green (*Pseudomonas*, COPD exacerbation), bloody (hemoptysis—TB, malignancy, bronchiectasis), mucoid (asthma). Assessment includes quantity, color, viscosity, and microbiologic studies (Gram stain, culture). Treatment targets the underlying cause; mucolytics/expectorants and hydration may help.

FEV1/FVC Ratio

- Fraction of air exhaled in first second relative to total. < 0.70 post-bronchodilator indicates obstruction. Normal or elevated in restrictive disease.

Fine Crackles

- High-pitched, brief, discontinuous sounds heard at the end of inspiration, caused by opening of small airways. They are characteristic of ILD, pulmonary fibrosis, and heart failure. They are also called

Velcro crackles due to their resemblance to the sound of Velcro being pulled apart.

Flutter Valve

- A handheld device combining PEP therapy with oscillations during exhalation. The oscillations create shear forces that loosen mucus from airway walls, while the PEP keeps airways open. It is used for airway clearance in bronchiectasis, CF, and COPD.

Forced Oscillation Technique

- Similar to impulse oscillometry, applying small pressure oscillations at various frequencies during tidal breathing to measure respiratory resistance and reactance. It provides information about airway mechanics without requiring forced expiratory maneuvers. It is useful for detecting small airway dysfunction and monitoring treatment response in asthma and COPD.

Forced Vital Capacity

- Total air exhaled after maximal inspiration. Reduced in both obstructive and restrictive disease. In restrictive disease, FVC reduced with preserved ratio.

Haemoptysis

- Coughing up blood or blood-stained sputum from the lower respiratory tract. See [hematology](#).

Hemoptysis

- Expectoration of blood from the lower respiratory tract. Must be differentiated from hematemesis and epistaxis. Causes: bronchitis, pneumonia, TB, bronchiectasis, lung cancer, PE.

Hypersensitivity Pneumonitis

- An immune-mediated lung disease from environmental antigen inhalation (molds, bird proteins). Acute, subacute, and chronic forms exist. HRCT shows ground-glass opacities, air trapping, and centrilobular nodules. Chronic HP progresses to fibrosis.

Hypertonic Saline Inhalation

- Nebulized 3–7% sodium chloride solution that draws water into the airway surface liquid by osmosis, improving mucociliary clearance. It is used in CF and bronchiectasis. It may cause bronchospasm and should be preceded by a bronchodilator. It reduces exacerbations in CF.

Hypoxia

– Reduced oxygen availability at the tissue level, defined as arterial partial pressure of oxygen (PaO_2) < 60 mmHg or arterial oxygen saturation (SpO_2) $< 90\%$ on room air. Five types: (1) Hypoxic hypoxia (low arterial PO_2)—caused by low inspired oxygen (high altitude), hypoventilation, V/Q mismatch, shunt, or diffusion impairment (pneumonia, COPD, pulmonary edema, ARDS). (2) Anaemic hypoxia (reduced oxygen-carrying capacity)—anemia, carbon monoxide poisoning, methaemoglobinaemia. (3) Stagnant/hypoperfusion hypoxia (reduced blood flow)—heart failure, shock, peripheral vascular disease. (4) Histotoxic hypoxia (impaired tissue utilisation)—cyanide poisoning (blocks cytochrome c oxidase), sepsis. (5) Demand hypoxia (increased O_2 requirement)—exercise, hypermetabolic states (thyrotoxicosis, malignant hyperthermia). Assessment: ABG, pulse oximetry, and calculation of alveolar-arterial (A-a) gradient. Consequences: cellular anaerobic metabolism, lactic acidosis, ATP depletion, and cell death. Treatment: supplemental oxygen (high-flow nasal cannula, non-invasive ventilation, mechanical ventilation), treat underlying cause. The hypoxic ventilatory response is mediated by peripheral chemoreceptors (carotid and aortic bodies).

Idiopathic Pulmonary Fibrosis

– A chronic, progressive fibrosing interstitial pneumonia of unknown cause. Histopathology shows usual interstitial pneumonia (UIP). Features include exertional dyspnea, dry cough, bibasilar crackles, and digital clubbing. Median survival is 3–5 years.

Impulse Oscillometry

– A pulmonary function testing technique that measures respiratory impedance by applying small pressure oscillations during tidal breathing. It assesses large airway resistance (R_5), small airway resistance (R_5 – R_{20}), and reactance. It is more sensitive than spirometry for detecting early small airway disease and is useful in patients who cannot perform spirometry (young children, elderly).

Incentive Spirometry

– A device that encourages deep breathing to prevent atelectasis after surgery. The patient inhales slowly and deeply through the device, maintaining maximal

inspiration for several seconds. It promotes alveolar recruitment and prevents mucus plugging. It is standard post-operative care.

Induced Sputum Analysis

– A non-invasive method of assessing airway inflammation by examining sputum cell counts and differentials obtained after hypertonic saline inhalation. Sputum eosinophils $> 3\%$ indicate eosinophilic airway inflammation (asthma, EGPA). Neutrophilic inflammation suggests infection, COPD, or bronchiectasis. It guides anti-inflammatory therapy decisions.

Inhaled Corticosteroids

– Anti-inflammatory medications delivered directly to the airways, reducing airway inflammation, mucus production, and bronchial hyperresponsiveness. Examples include fluticasone, budesonide, beclomethasone, and mometasone. They are the cornerstone of asthma maintenance therapy. Side effects include oral candidiasis and dysphonia.

Inspiratory Crackles

– Fine, discontinuous sounds heard during inspiration, caused by the sudden opening of collapsed airways. They are a hallmark of interstitial lung disease (bibasilar, Velcro-like crackles) and pulmonary fibrosis. They are also heard in pneumonia, atelectasis, and heart failure.

Interstitial Lung Disease

– A heterogeneous group of disorders with inflammation and fibrosis of lung parenchyma, causing restrictive physiology (reduced FVC and TLC with normal or elevated FEV1/FVC ratio).

Interstitial Pneumonia

– Inflammation centered on the interstitium. Caused by Mycoplasma, Chlamydophila, Legionella, and viruses. Presents with dry cough and diffuse crackles.

Ipratropium Bromide

– An inhaled anticholinergic (antimuscarinic) bronchodilator that blocks acetylcholine at airway smooth muscle muscarinic receptors. It reduces bronchospasm and mucus secretion. It is used in COPD and acute asthma exacerbations. It is less effective than beta-2 agonists in asthma but more effective in COPD.

Kartagener Syndrome

- A subset of primary ciliary dyskinesia with situs inversus, chronic sinusitis, and bronchiectasis. Caused by dynein defects impairing both mucociliary clearance and embryonic nodal cilia rotation.

Kartagener Triad

- The classic triad of situs inversus, chronic sinusitis, and bronchiectasis, occurring in approximately 50% of patients with primary ciliary dyskinesia. It is caused by dynein defects impairing both mucociliary clearance and embryonic nodal cilia rotation.

Lfgren Syndrome

- Acute sarcoidosis with bilateral hilar lymphadenopathy, erythema nodosum, and ankle polyarthralgia. Excellent prognosis with spontaneous resolution. Associated with HLA-DR3.

Long-Acting Beta-2 Agonists

- Bronchodilators that provide sustained airway smooth muscle relaxation for 12–24 hours. Examples include salmeterol, formoterol, indacaterol, and olodaterol. They are used for maintenance therapy in asthma and COPD, always in combination with inhaled corticosteroids in asthma.

Lower Airway Obstruction

- Narrowing of airways below the carina, causing expiratory wheezing and airflow obstruction on spirometry. Causes include asthma, COPD, bronchiectasis, and foreign body. It is characterized by scooped-out expiratory limb on flow-volume loops and reduced FEV1/FVC ratio.

Lung Disease

- Lung disease encompasses disorders affecting the airways, parenchyma, pleura, pulmonary vasculature, and chest wall. Major categories: obstructive (asthma, COPD—chronic bronchitis and emphysema), restrictive (pulmonary fibrosis, sarcoidosis, asbestosis), infectious (pneumonia, tuberculosis), pulmonary vascular (pulmonary embolism, pulmonary arterial hypertension), and neoplastic (lung cancer, the leading cause of cancer death). Common symptoms: dyspnea, cough (dry or productive), wheezing, hemoptysis, chest pain, and weight loss. Diagnosis: pulmonary function tests (spirometry, DLCO), chest imaging (X-ray, CT), bronchoscopy, and biopsy. Management: smoking cessa-

tion (most effective intervention), bronchodilators (beta-agonists, antimuscarinics), inhaled corticosteroids, oxygen therapy, pulmonary rehabilitation, antimicrobials for infection, and lung transplantation for end-stage disease.

Lung Transplant

- Surgical replacement of one or both lungs from a donor for end-stage lung disease: COPD (most common), idiopathic pulmonary fibrosis, cystic fibrosis, pulmonary hypertension, and other advanced conditions. Types: single, bilateral, heart-lung. Evaluation: multidisciplinary, age, comorbidities, functional status, infection; waiting list allocation by severity. Immunosuppression (calcineurin inhibitors, mycophenolate, steroids) prevents rejection. Complications: primary graft dysfunction, acute/chronic rejection (bronchiolitis obliterans), infection (CMV, fungal), airway anastomotic complications, and malignancy. Survival 50-90 percent at 5 years by indication.

Lung Transplantation

- Surgical replacement of a diseased lung with a healthy lung from a donor. Indications include IPF, COPD, CF, PAH, and bronchiectasis. Options include single lung transplant, double lung transplant, or heart-lung transplant. Post-transplant immunosuppression is required lifelong. Complications include rejection and infection.

Lymphocytic Interstitial Pneumonia

- A rare ILD characterized by diffuse polyclonal lymphocytic infiltration of the lung parenchyma. It is strongly associated with Sjgren syndrome and HIV. HRCT shows ground-glass opacities, thin-walled cysts, and lymphadenopathy. Treatment is corticosteroids for symptomatic disease.

Metered-Dose Inhaler

- A pressurized inhaler delivering a metered dose of medication. Requires proper technique for effective delivery. Spacer devices improve drug delivery and reduce oropharyngeal deposition. Most common delivery device for asthma and COPD maintenance.

Methacholine Challenge Test

- See medical_tests.

Middle Lobe Syndrome

- Chronic or recurrent atelectasis and infection of the right middle lobe due to bronchial obstruction. The long, narrow right middle lobe bronchus is susceptible to compression by lymph nodes, tumors, or mucous plugging. It may be caused by bronchiectasis, malignancy, or granulomatous disease. Treatment depends on the underlying cause.

Mucolytic Therapy

- Medications that reduce mucus viscosity and elasticity, facilitating clearance. N-acetylcysteine (NAC) breaks disulfide bonds in mucus glycoproteins. Dornase alfa (Pulmozyme) cleaves extracellular DNA in CF sputum. Hypertonic saline aerosol draws water into the airway surface liquid. They are used in CF, bronchiectasis, and chronic bronchitis.

Mucus Plugging

- Accumulation of thick, tenacious mucus within airways causing obstruction. It is common in asthma, CF, bronchiectasis, and chronic bronchitis. It impairs gas exchange, promotes infection, and causes atelectasis. Treatment includes airway clearance techniques, mucolytics, and bronchodilators.

Nebulizer

- A device that converts liquid medications into a mist for inhalation. Used for bronchodilators (albuterol, ipratropium) and corticosteroids in acute exacerbations. More effective than MDI in patients with severe obstruction.

Non-Asthmatic Eosinophilic Bronchitis

- Chronic cough with airway eosinophilia (induced sputum eosinophils > 3%) but without bronchial hyperresponsiveness. It is a common cause of chronic cough and does not respond to bronchodilators. It responds well to inhaled corticosteroids. It is distinct from asthma in the absence of variable airflow obstruction.

Non-Invasive Ventilation

- Positive pressure ventilation delivered via a face mask or nasal mask without endotracheal intubation. BiPAP (bilevel positive airway pressure) is most commonly used for acute hypercapnic respiratory failure (COPD exacerbation) and cardiogenic pulmonary edema. It reduces the need for intuba-

tion and improves outcomes in selected patients.

Nonspecific Interstitial Pneumonia

- A pattern with uniform, temporally homogeneous inflammation and/or fibrosis. Most common ILD associated with connective tissue disease. HRCT shows bilateral ground-glass opacities with subpleural sparing.

Occupational Asthma

- Asthma from workplace exposures to sensitizers (isocyanates, flour, latex) or irritants. Improves away from work and worsens at work. Serial peak flow monitoring supports diagnosis.

Occupational COPD

- COPD from workplace dust, chemical, or fume exposure independent of smoking. Accounts for 15–20% of COPD cases. High-risk occupations: mining, construction, farming.

Orthopnoea

- Shortness of breath that occurs when lying flat and is relieved by sitting or standing upright. Orthopnoea is a classic symptom of left-sided heart failure (elevated pulmonary venous pressure worsens pulmonary congestion in the supine position). Other causes: severe COPD, asthma exacerbation, diaphragmatic paralysis, ascites, and obesity. It is quantified by the number of pillows required to sleep comfortably (e.g., two-pillow orthopnoea). Pathophysiology: supine position increases venous return (preload) and reduces lung volumes (cephalad displacement of the diaphragm and abdominal contents), worsening V/Q mismatch and increasing pulmonary capillary pressure. Orthopnoea may develop acutely in pulmonary edema (cardiac asthma) or gradually in worsening chronic heart failure. Related: paroxysmal nocturnal dyspnoea (PND—sudden breathlessness during sleep, relieved by sitting up, also CHF). Management: treat the underlying cause—diuretics, vasodilators, and optimisation of heart failure therapy.

Oxygen Saturation

- The percentage of hemoglobin saturated with oxygen in arterial blood; normal 95–100 percent. Measured noninvasively by pulse oximetry (SpO₂) and invasively by co-oximetry (SaO₂). Target levels vary by context: >94 percent general; 88–92 percent in patients with hypercapnic respiratory failure

(COPD); permissive targets in ARDS. Reductions indicate hypoxemia from ventilation-perfusion mismatch, shunt, hypoventilation, or reduced inspired oxygen. False readings from poor perfusion, anemia, carboxyhemoglobin. Guides oxygen therapy.

Panlobular Emphysema

- A subtype involving diffuse destruction of the entire acinus. It predominantly affects the lower lobes and is classically associated with alpha-1 antitrypsin deficiency. The destruction is more uniform compared to centriacinar emphysema.

Paraseptal Emphysema

- A form of emphysema characterized by destruction of alveoli adjacent to the pleura. It typically affects young adults and predisposes to spontaneous pneumothorax due to rupture of subpleural blebs. It may be associated with Marfan syndrome.

Peak Expiratory Flow Rate (PEFR)

- The maximum flow rate achieved during a forced expiratory manoeuvre after maximal inspiration, measured in litres per minute (L/min) using a peak flow meter. PEFR reflects the degree of airflow obstruction and is effort-dependent. Normal values are predicted based on age, sex, and height (e.g., healthy adult male 600 L/min, female 400 L/min). Uses: diagnosis and monitoring of asthma (diurnal variability >20% supports asthma diagnosis), assessment of exacerbation severity (PEFR <50% of predicted indicates severe exacerbation—NICE/BTS guidelines), and guiding asthma action plans (personal best, zone system). PEFR <33% of predicted is life-threatening. Limitations: effort-dependent, poor technique, less reproducible than FEV₁.

Percussion Note

- The sound produced by percussing the chest wall. Normal lung produces a resonant note. Dullness suggests consolidation or fluid. Hyperresonance suggests pneumothorax or emphysema. Stony dullness suggests pleural effusion. Tympany suggests large pneumothorax.

Persistent Asthma

- Asthma requiring daily controller therapy. Mild persistent: symptoms > 2 days/week but not daily. Moderate persistent: daily symptoms, nighttime awakenings > 1/week. Severe persistent: symptoms

throughout the day, frequent nighttime awakenings, SABA use several times/day, extremely limited activity.

Pink Puffer

- A clinical phenotype of emphysema in COPD. Patients present with severe dyspnea, minimal cough, thin habitus, pursed-lip breathing, accessory muscle use, and relatively normal PaO₂ with late hypercapnia. They tend to be older and have more extensive emphysema.

Pneumoconiosis

- ILDs from mineral dust inhalation (silicosis, asbestosis, coal worker's, berylliosis). They share interstitial fibrosis and risk of infection and malignancy.

Pneumomediastinum

- Air in the mediastinum, often from alveolar rupture with air tracking along bronchovascular sheaths. Causes include asthma exacerbation, trauma, Valsalva maneuver, and esophageal rupture (Boerhaave syndrome). It presents with chest pain, subcutaneous emphysema, and Hamman's crunch (mediastinal crunch synchronous with heartbeat). Usually self-limited.

Positive Pressure Ventilation

- Mechanical ventilation that delivers air/oxygen under positive pressure to support or replace spontaneous breathing. Noninvasive (NIV): CPAP (continuous) and BiPAP (two levels) via mask for obstructive sleep apnea, cardiogenic pulmonary edema, and hypercapnic COPD. Invasive: endotracheal tube/tracheostomy delivering volume- or pressure-controlled breaths. Modes: assist-control, SIMV, pressure support, PRVC. Benefits: improved oxygenation, reduced work of breathing, alveolar recruitment. Complications: barotrauma/pneumothorax, VAP, hemodynamic compromise, hyperinflation. Requires monitoring and lung-protective settings.

Post-Operative Atelectasis

- Collapse of alveoli after surgery, the most common post-operative pulmonary complication. Risk factors include general anesthesia, abdominal surgery, obesity, smoking, and pre-existing lung disease. Prevention includes incentive spirometry, early ambulation, and adequate pain control.

Primary Ciliary Dyskinesia

- An autosomal recessive disorder of ciliary structure, most commonly caused by dynein arm defects. Leads to impaired mucociliary clearance, chronic sinopulmonary infections, bronchiectasis, and situs inversus (50% of cases).

Pulmonary Fibrosis

- Scarring replacing normal alveolar architecture. Causes: IPF, connective tissue disease, asbestos, radiation, drugs (bleomycin, methotrexate). Features: progressive dyspnea, dry cough, digital clubbing.

Pulse Oximetry

- A noninvasive method measuring oxygen saturation by spectrophotometry: light at two wavelengths (red and infrared) passes through a pulsatile vascular bed (finger, ear, toe); absorption difference estimates oxyhemoglobin fraction (SpO₂). Normal 95-100 percent. Used widely in monitoring (perioperative, emergency, sleep, home oxygen). Limitations: inaccurate with poor perfusion, motion, nail polish, anemia (despite adequate O₂ content), and elevated carboxyhemoglobin (falsely normal in CO poisoning); does not assess ventilation (PaCO₂).

Respiratory Acidosis

- Acid-base disturbance due to accumulation of CO₂ from hypoventilation, lowering pH (acidemia). Causes: respiratory depression (opioids, sedatives, CNS disease), airway obstruction, neuromuscular weakness (GBS, myasthenia), chest wall restriction, severe COPD/asthma, and ventilation-perfusion mismatch. Compensation: renal bicarbonate retention (slow, days). Diagnosis: ABG—elevated PaCO₂ (>45 mmHg), low pH, increased HCO₃ if chronic. Management: treat cause, airway support, noninvasive/invasive ventilation; avoid over-correction; chronic compensation protects pH.

Respiratory Alkalosis

- Acid-base disturbance from excessive elimination of CO₂ by hyperventilation, raising pH (alkalemia). Causes: anxiety/hyperventilation, hypoxia, pulmonary embolism, sepsis, fever, pain, salicylate toxicity, liver failure, pregnancy, high altitude. Compensation: renal bicarbonate excretion (days). Features: paresthesias, lightheadedness, tetany, carpopedal spasm (hypocalcemia symptoms). Diagnosis: ABG—low PaCO₂ (<35 mmHg), high pH.

Management: treat underlying cause, rebreathing/calming for anxiety; avoid over-sedation; check for causes like PE/ARDS which are dangerous.

Respiratory Failure

- Inadequate gas exchange resulting in hypoxemia (PaO₂ <60 mmHg), hypercapnia (PaCO₂ >50 mmHg), or both. Type 1 (hypoxemic): V/Q mismatch, shunt, diffusion impairment. Type 2 (hypercapnic): hypoventilation from neuromuscular disease, COPD exacerbation, or opioid overdose. Management: oxygen therapy, non-invasive ventilation, mechanical ventilation, and treatment of the underlying cause.

Respiratory Health

- The proper functioning of the lungs and airways, enabling efficient gas exchange and oxygen delivery to the body. Maintaining respiratory health involves avoiding tobacco smoke, minimizing exposure to air pollutants and occupational hazards, and receiving vaccinations against respiratory infections like influenza and pneumococcal disease. Regular exercise strengthens respiratory muscles and improves lung capacity, while prompt treatment of infections and management of chronic conditions such as asthma or COPD help preserve lung function over a lifetime.

Respiratory Infections

- Illnesses caused by pathogens including viruses, bacteria, and fungi that affect the airways and lungs. Common upper respiratory infections include the common cold, sinusitis, and pharyngitis, while lower respiratory infections such as bronchitis and pneumonia can be more serious, particularly in older adults and immunocompromised individuals. Treatment varies by cause, with viral infections often managed symptomatically and bacterial infections requiring antibiotics; prevention through hand hygiene and vaccination is key.

Respiratory System

- The anatomical and physiological system responsible for gas exchange—delivering oxygen to the blood and removing carbon dioxide. Components: (1) Upper respiratory tract—nose, nasal cavity, paranasal sinuses, pharynx (nasopharynx, oropharynx, laryngopharynx). The nose warms, humidifies, and filters inspired air; the nasal mucosa contains olfactory receptors. (2) Lower respiratory tract—larynx

(voice production, airway protection—epiglottis, vocal cords), trachea (C-shaped cartilage rings, 10–12 cm long), bronchi (right main bronchus—wider, shorter, more vertical—common site of aspiration), bronchioles (no cartilage, smooth muscle—asthma), alveolar ducts, and alveoli (300–500 million, total surface area 70–100 m²), where gas exchange occurs across the thin alveolar-capillary membrane (0.2–0.5 μm). (3) Lungs—right lung (three lobes: upper, middle, lower) and left lung (two lobes: upper, lower—the cardiac notch accommodates the heart). The pleura (visceral and parietal) lines the lungs and chest wall; the pleural cavity contains a thin layer of surfactant-rich fluid for lubrication. (4) Chest wall and muscles of respiration—diaphragm (primary inspiratory muscle, innervated by phrenic nerve C3–C5), intercostal muscles (external—inspiration; internal—expiration), and accessory muscles (sternocleidomastoid, scalenes—used in respiratory distress). Ventilation: the rhythmic contraction of the diaphragm and intercostal muscles creates negative intrapleural pressure, drawing air into the lungs. Control: the respiratory center in the medulla oblongata generates the breathing rhythm, modulated by chemoreceptors (central—CO₂/pH; peripheral—O₂, CO₂, pH in carotid and aortic bodies).

Respiratory Tract Infections

– Infections affecting any part of the respiratory tract, classified by anatomical location into upper respiratory tract infections (URTIs) and lower respiratory tract infections (LRTIs). URTIs: common cold (rhinovirus, coronavirus, adenovirus), pharyngitis (Group A Streptococcus—bacterial, adenovirus, EBV), tonsillitis (Streptococcus pyogenes), sinusitis (Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalis, viruses), otitis media (S. pneumoniae, H. influenzae), laryngitis (viruses, vocal strain). LRTIs: acute bronchitis (viruses—influenza, RSV; Bordetella pertussis), bronchiolitis (RSV—infants), pneumonia (community-acquired—S. pneumoniae, H. influenzae, Mycoplasma pneumoniae, Legionella, Chlamydia psittaci, viruses; hospital-acquired—Pseudomonas aeruginosa, MRSA, Enterobacteriaceae; aspiration—anaerobes). Risk factors: extremes of age, smoking, COPD, asthma, immunocompromise, cystic fibrosis, structural lung disease,

and institutionalisation. Antibiotic resistance is a growing concern (MRSA, ESBL-producing Enterobacteriaceae, multidrug-resistant S. pneumoniae). Diagnosis: clinical (cough, sputum, fever, dyspnoea, chest pain), chest X-ray (consolidation in pneumonia), sputum culture, blood culture, nasopharyngeal swab (viral PCR), and urinary antigen testing (S. pneumoniae, Legionella). Prevention: hand hygiene, vaccination (influenza, pneumococcal, pertussis, RSV—maternal, palivizumab for high-risk infants), and smoking cessation.

Rhonchi

– Low-pitched, continuous adventitious sounds heard primarily during expiration, caused by secretions in the large airways. They may clear with coughing. They are heard in COPD, bronchitis, and bronchiectasis. They are different from wheezes in their lower pitch and coarser quality.

Small Airway Disease

– Disease affecting airways with diameter < 2 mm (bronchioles). It is the earliest site of damage in COPD and is often subclinical until advanced. It is characterized by narrowing, mucus plugging, and inflammation of small airways. PFTs may show air trapping (increased RV/TLC) before FEV1 decline.

Spirometry

– Most common PFT measuring air volume and flow during forced breathing. Key measurements: FVC, FEV1, FEV1/FVC ratio. Used to diagnose and classify obstructive and restrictive diseases.

Status Asthmaticus

– A severe, life-threatening asthma exacerbation unresponsive to standard bronchodilator therapy. Characterized by severe airflow obstruction, hypoxemia, and hypercapnia. Treatment includes continuous nebulized albuterol, IV magnesium sulfate, systemic corticosteroids, and possibly intubation.

Subcutaneous Emphysema

– Air in the subcutaneous tissues, often from pneumothorax, pneumomediastinum, or chest trauma. It causes a characteristic crepitus on palpation. It is usually benign and resolves when the underlying air leak is treated. Severe cases may cause skin necrosis and compartment syndrome.

Supplemental Oxygen Therapy

- Administration of oxygen above atmospheric concentration. Indicated for hypoxemia ($\text{PaO}_2 < 60$ mmHg or $\text{SpO}_2 < 90\%$). Delivered via nasal cannula (1–6 L/min), simple mask, non-rebreather mask, or mechanical ventilation. Target SpO_2 88–92% in COPD patients to avoid CO_2 retention.

Tachypnea

- Abnormally rapid respiratory rate (adult >20 breaths/min). Physiologic (exercise, anxiety) or pathologic: hypoxia, fever, sepsis, metabolic acidosis (Kussmaul), pulmonary embolism, pneumonia, heart failure, pain, and compensation for metabolic derangement. Combined with other signs aids diagnosis; persistent tachypnea with distress suggests significant illness. Neonates and infants normally breathe faster. Evaluation: oxygen saturation, ABG, imaging, and treatment of the underlying cause.

Tachypnoea

- Abnormally rapid breathing, defined as a respiratory rate >20 breaths per minute in adults (age-dependent: >60 in neonates, >40 in 1–12 months, >30 in 1–5 years, >20 in >5 years). Tachypnoea is a non-specific sign of respiratory or metabolic distress. Causes: (1) Respiratory—hypoxia (pneumonia, asthma/COPD exacerbation, pulmonary embolism, pneumothorax, pulmonary edema, ARDS, interstitial lung disease), airway obstruction, and hypercapnia (COPD, respiratory muscle weakness). (2) Cardiac—heart failure (pulmonary congestion stimulates vagal irritant receptors). (3) Metabolic—metabolic acidosis (diabetic ketoacidosis—Kussmaul breathing, uraemia, lactic acidosis, salicylate poisoning), fever (respiratory rate increases 2–4 breaths/min per 1°C rise). (4) Other—anxiety (panic attack—psychogenic hyperventilation), pain, anemia, hyperthyroidism, pregnancy (progesterone stimulates respiratory center), exercise, and high altitude. (5) Drugs: salicylates, theophylline, β -agonists, and other stimulants. Tachypnoea is often accompanied by shallow breathing (low tidal volume). Assessment: respiratory rate, SpO_2 , ABG, chest X-ray, ECG, and focused history. Persistent tachypnoea with hypoxia is a sign of serious illness requiring urgent investigation and treatment.

Talcosis

- Pneumoconiosis from talc dust inhalation or IV injection of crushed oral medications. Causes upper lobe nodular fibrosis. HRCT may show “galaxy sign” of calcified nodules.

Thermoplasty

- A bronchoscopic procedure that uses radiofrequency energy to ablate smooth muscle in the airways, reducing bronchospasm. It is approved for severe, persistent asthma in adults not controlled with ICS/LABA. It reduces exacerbations and emergency department visits but does not improve lung function.

Tiotropium Bromide

- A long-acting muscarinic antagonist (LAMA) bronchodilator used for maintenance therapy in COPD. Once-daily dosing provides sustained bronchodilation. It reduces exacerbations and improves lung function. It is often combined with a LABA for additive bronchodilation.

Tracheal Stenosis

- Narrowing of the trachea, often a complication of prolonged endotracheal intubation or tracheostomy. It presents with progressive dyspnea, stridor, and wheezing that may be mistaken for asthma. Diagnosis is by bronchoscopy or CT. Treatment is balloon dilation, stenting, or surgical resection.

Transbronchial Biopsy

- Bronchoscopic biopsy of lung parenchyma obtained through the bronchial wall. It is used to diagnose interstitial lung diseases (sarcoidosis, HP), reject lung transplant rejection, and sample peripheral lung lesions. It carries a higher risk of pneumothorax than endobronchial biopsy.

Usual Interstitial Pneumonia

- The histopathological pattern in IPF with temporal heterogeneity, fibroblast foci, and honeycombing. HRCT shows basal-predominant, subpleural reticular opacities with traction bronchiectasis.

Ventilation-Perfusion Mismatch

- The most common cause of hypoxemia. Areas of lung are ventilated but not perfused (dead space) or perfused but not ventilated (shunt). It is the mechanism of hypoxemia in COPD, pneumonia, and PE.

Vocal Cord Dysfunction

- Abnormal adduction of the vocal cords during inspiration, causing inspiratory stridor and dyspnea. It may mimic asthma but does not respond to bronchodilators. It is often misdiagnosed as refractory asthma. Diagnosis is by laryngoscopy showing paradoxical vocal cord motion. Treatment is speech therapy and avoiding triggers.

Wheezes

- High-pitched, continuous, musical sounds heard primarily during expiration, caused by airway narrowing. They are a hallmark of asthma and COPD. Expiratory wheezing indicates intrathoracic airway obstruction; inspiratory wheezing indicates extrathoracic obstruction. A silent chest (absent wheezing) in severe asthma indicates critical obstruction.

Wheezing

- A continuous, high-pitched, musical adventitious lung sound produced by turbulent airflow through narrowed or compressed lower airways during expiration (and occasionally inspiration). Pathophysiology: bronchospasm, mucosal edema, airway inflammation, or intraluminal secretions. Most common causes: Asthma, Chronic Obstructive Pulmonary Disease (COPD), Anaphylaxis, Heart Failure ("cardiac asthma"), and foreign body aspiration (focal monophonic wheeze).

A-a Gradient

- PAO_2 minus PaO_2 , reflecting gas transfer efficiency. Normal approximately 15 mmHg (increases with age: $< 15 + \text{age}/4$). Elevated in V/Q mismatch, shunt, and diffusion impairment. Normal gradient in hypoventilation.

Absent Breath Sounds

- Complete absence of air movement sounds in a lung field, indicating complete airway obstruction, pneumothorax, or large pleural effusion. It is a medical finding requiring urgent evaluation and intervention.

Alveolar Gas Equation

- $PAO_2 = (FiO_2 \times (P_{\text{atm}} - P_{H_2O})) - (PaCO_2 / R)$. $P_{\text{atm}} = 760$ mmHg, $P_{H_2O} = 47$ mmHg, $R = 0.8$. Allows calculation of A-a gradient.

Anaphylactic Shock

- See immunology.

Anoxia

- Complete absence of oxygen supply to tissues, distinguished from hypoxia (reduced oxygen). Anoxia causes rapid cell death, particularly in highly aerobic tissues (brain, heart, kidneys). Causes: airway obstruction (complete—foreign body, laryngeal edema, anaphylaxis), respiratory arrest, severe drowning, carbon monoxide poisoning (carboxyhaemoglobin $> 50\%$), and high-altitude exposure. Irreversible brain damage occurs within 4–6 minutes of complete anoxia (cerebral cortex most vulnerable, followed by hippocampus, basal ganglia, and cerebellum). EEG may show isoelectric activity. Hypoxic-ischemic encephalopathy (HIE) is the clinical syndrome following cardiac arrest or perinatal asphyxia. Treatment: immediate restoration of oxygenation (ABC, oxygen, ventilation), therapeutic hypothermia for HIE (reduces neurological injury), and supportive care.

Apnea-Hypopnea Index

- Number of apneas plus hypopneas per hour of sleep. Apnea = airflow cessation > 10 seconds. Hypopnea = partial obstruction with desaturation or arousal. AHI < 5 normal, 5–14 mild, 15–29 moderate, ≥ 30 severe.

Apneustic Breathing

- A breathing pattern characterized by a prolonged inspiratory pause, seen in brainstem lesions (particularly the pons). It indicates damage to the apneustic center and is a poor prognostic sign in neurological injury. It may require mechanical ventilation.

Apnoea

- Temporary cessation of breathing, defined as complete cessation of airflow for ≥ 10 seconds. Obstructive apnea: airway collapse despite respiratory effort (common in obstructive sleep apnea). Central apnea: absence of respiratory effort (Cheyne–Stokes respiration in heart failure, high-altitude periodic breathing, opioid-induced central apnea, brainstem stroke). Mixed apnea: features of both. Physiologic apnea: breath-holding, voluntary apnea. Pathological apnea in infants: apnea of prematurity (seen in preterm infants < 37 weeks, due to immature respiratory control, treated with caffeine), apparent life-threatening events (ALTEs, now termed brief resolved unexplained events—BRUE). Diagnosis: polysomnography (sleep study). See also [Sleep](#)

apnea.

Aspiration Pneumonia

- Lung infection from aspiration of oropharyngeal or gastric contents. Risk factors include impaired consciousness and dysphagia. Right lower lobe is most commonly affected.

Assist-Control Ventilation

- Ventilator delivers a set tidal volume at a set rate. Every breath receives the full set volume. Guarantees minimum rate and minute ventilation. Risk of respiratory alkalosis and auto-PEEP.

Ataxic Breathing

- An irregular, unpredictable breathing pattern with random variations in rate and depth, seen in medullary lesions. It is the most dangerous respiratory pattern and often precedes respiratory arrest. It requires mechanical ventilation.

Atelectasis

- Complete or partial collapse of lung tissue, resulting in loss of aeration. It may be caused by airway obstruction (resorption atelectasis), pleural disease (compressive atelectasis), surfactant dysfunction (dissolution atelectasis), or scarring (cicatrization atelectasis). It impairs gas exchange and may predispose to infection.

Autogenic Drainage

- A breathing technique using controlled breathing at different lung volumes to mobilize secretions from peripheral to central airways. It involves breathing at low lung volumes (collect), mid lung volumes (loosen), and high lung volumes (evacuate). It requires patient training and cooperation.

Azygos Vein

- A vein that drains the posterior intercostal veins and empties into the superior vena cava. It forms an important collateral pathway when the SVC is obstructed. On chest imaging, enlargement of the azygos vein may indicate SVC obstruction, heart failure, or portal hypertension.

Barotrauma

- Lung injury from excessive pressure during ventilation, causing alveolar rupture (pneumothorax, pneumomediastinum). Risk factors: high pressures, high PEEP. Prevented by lung-protective ventilation.

Biot Breathing

- An irregular breathing pattern with random periods of normal breathing interspersed with apneic episodes, seen in brainstem lesions. It is less organized than Cheyne-Stokes breathing and indicates medullary damage.

Biotrauma

- Inflammatory response to ventilator-induced lung injury with systemic cytokine release. Can lead to multi-organ dysfunction. Minimized by lung-protective ventilation strategies.

Body Plethysmography

- Technique for measuring lung volumes (TLC, RV, FRC) using a sealed chamber. Gold standard for TLC measurement. Useful for diagnosing restriction and hyperinflation.

Breath Sounds

- The sounds produced by airflow through the respiratory tract during breathing, assessed by auscultation with a stethoscope over the chest wall. Normal breath sounds are classified by location and quality: tracheal (loud, harsh, high-pitched heard over the trachea), bronchial (loud, tubular, heard over the manubrium and large airways, with a gap between inspiration and expiration), bronchovesicular (intermediate pitch and intensity, heard over the mainstem bronchi, equal inspiratory and expiratory duration).

Breath Stacking

- A technique using a manual resuscitation bag or glossopharyngeal breathing to deliver successive breaths without exhaling, stacking tidal volumes to achieve higher lung volumes. It improves cough effectiveness and secretion clearance in patients with weak respiratory muscles.

Bronchial Stenosis

- Narrowing of a bronchus from trauma, infection, inflammation, or prior intervention. It causes localized wheezing, recurrent infections, and impaired secretion clearance. Diagnosis is by bronchoscopy. Treatment includes balloon dilation, stenting, or surgical resection.

Bronchogenic Cyst

- A congenital cyst derived from abnormal budding of the ventral foregut. It is typically found in the

middle mediastinum or near the carina. It is usually asymptomatic but may cause compression of adjacent structures. Treatment is surgical resection if symptomatic.

Bronchophony

- Increased transmission of spoken sounds to the stethoscope over consolidated lung tissue. It is normally heard over the central airways. Excessive bronchophony over peripheral lung fields indicates consolidation. It is part of the constellation of physical examination findings in pneumonia.

Bronchopneumonia

- Patchy consolidation centered on bronchioles across multiple lobes. Caused by *S. aureus*, gram-negative bacteria, and *Pseudomonas*.

Bronchoscopy

- See `medical_tests`.

Carina

- The ridge at the base of the trachea where it bifurcates into the right and left main bronchi. It is a landmark for endotracheal tube placement and bronchoscopy. The right main bronchus is wider, shorter, and more vertical than the left, making it the preferred path for aspirated foreign bodies.

Central Sleep Apnea

- Apneas from variability in respiratory effort without airway obstruction. Associated with heart failure (Cheyne-Stokes respiration), high altitude, and opioid use.

CFTR Modulator Therapy

- Targeted therapies correcting the defective CFTR protein. Elexacaftor-tezacaftor-ivacaftor (Trikafta) is the most effective combination for patients with at least one F508del mutation. These therapies have dramatically changed CF prognosis.

Chest Tube Insertion

- Placement of a thoracostomy tube in the safe triangle (latissimus dorsi, pectoralis major, nipple level) to drain air, fluid, or blood from the pleural space. Connected to underwater seal drainage.

Chest Wall Deformity

- Abnormalities of the chest wall that can affect lung function. Pectus excavatum (sunken sternum) may compress the heart and lungs. Pectus carinatum (protruding sternum) is usually cosmetic. Scolio-

sis can cause restrictive lung disease. These may require surgical correction if severe.

Cheyne-Stokes Respiration

- Crescendo-decrescendo breathing pattern with periods of apnea, seen in heart failure and stroke. It is a form of central sleep apnea.

Chlamydophila Pneumonia

- Atypical pneumonia with mild presentation: sore throat, hoarseness, cough. Treatment is macrolides or tetracyclines.

Chylothorax

- Pleural effusion with chyle from thoracic duct disruption. Triglycerides > 110 mg/dL. Treatment includes dietary modification, octreotide, and surgical ligation if refractory.

Community-Acquired Pneumonia

- See `infectious_disease`.

Compressive Atelectasis

- Atelectasis caused by external compression of the lung by pleural fluid, air, or a mass. The lung volume is reduced by the external force. It is reversible when the compressing force is relieved (e.g., drainage of pleural effusion).

Cor Pulmonale

- Right ventricular hypertrophy and dilation from pulmonary hypertension due to lung disease. Features include peripheral edema, JVD, and hepatomegaly.

Cough

- A complex reflex arc protecting the airway by clearing secretions, irritants, and foreign material from the tracheobronchial tree. The cough reflex involves sensory receptors (rapidly adapting irritant receptors, C-fibers, and mechanoreceptors) in the larynx, trachea, and bronchi, afferent pathways (vagus nerve, superior laryngeal nerve, trigeminal nerve), the cough center in the medulla oblongata, efferent pathways (recurrent laryngeal nerve, phrenic nerve, spinal motor nerves), and effector muscles (diaphragm, abdominal wall, intercostals, and laryngeal muscles) for the coordinated cough response.

Cough Augmentation

- Techniques to improve cough effectiveness in patients with neuromuscular disease or chest wall weakness. Methods include manually assisted cough

(abdominal thrust timed with cough), mechanical insufflation-exsufflation (CoughAssist device), and breath stacking with a resuscitation bag. They are essential in Duchenne muscular dystrophy and spinal cord injury.

CPAP

- Continuous Positive Airway Pressure, first-line for OSA. Delivers constant pressure through a mask to prevent airway collapse. Eliminates apneas and improves outcomes. Adherence is the main challenge.

Crazy Paving Pattern

- A HRCT finding characterized by ground-glass opacification with superimposed interlobular septal thickening and intralobular lines. It is seen in pulmonary alveolar proteinosis, lipoid pneumonia, ARDS, pulmonary hemorrhage, and Pneumocystis pneumonia. Despite its name, it is not specific to any single diagnosis.

Cryptogenic Organizing Pneumonia

- An inflammatory lung disease with granulation tissue within alveolar ducts. May be idiopathic or secondary to infection, drugs, or connective tissue disease. Responds well to corticosteroids.

CT Pulmonary Angiography

- Gold standard for PE diagnosis, showing thrombi as filling defects. Sensitivity > 95%, specificity > 97% for central emboli.

CURB-65 Score

- One point each for: Confusion, Urea > 7 mmol/L, RR > 30, BP < 90/60, age ≥ 65. 0–1: outpatient. 2: consider hospitalization. 3–5: severe.

D-Dimer

- See medical_tests.

Decreased Breath Sounds

- Diminished air movement heard on auscultation, indicating decreased ventilation. Causes include pneumothorax, pleural effusion, atelectasis, and mucus plugging. Unilateral decreased breath sounds may indicate tension pneumothorax or large effusion.

Directly Observed Therapy

- Supervision of medication ingestion to ensure adherence. Standard of care for TB treatment. Ensures completion of the full treatment course and reduces

development of drug resistance.

Dornase Alfa

- A recombinant human DNase that cleaves extracellular DNA in airway secretions, reducing sputum viscosity. It is used in CF to improve lung function and reduce exacerbations. It is administered as a nebulized solution once or twice daily. It has become a standard part of CF airway clearance regimens.

Dry Powder Inhaler

- A breath-actuated inhaler delivering powdered medication. Does not require hand-breath coordination. Requires adequate inspiratory flow. Examples include Advair Diskus and Spiriva HandiHaler.

Egophony

- An abnormal vocal sound heard during auscultation in which spoken “E” sounds are heard as “A” (the “E-to-A” change). It is a sign of lung consolidation, as in lobar pneumonia. The consolidated lung tissue conducts high-frequency sounds better than air-filled lung.

Electromagnetic Navigation Bronchoscopy

- A guidance system for bronchoscopy that uses electromagnetic fields to navigate to peripheral lung lesions. It allows biopsy of lesions not visible on standard bronchoscopy. It is more accurate than conventional transbronchial biopsy for peripheral lesions. It may reduce the need for CT-guided biopsy.

Empyema

- Pus in the pleural space. CT shows peripheral enhancement (split pleura sign). Treatment requires chest tube drainage, intrapleural fibrinolytics, or VATS decortication.

Empyema Necessitans

- Extension of pleural empyema through the chest wall. Presents as a painful, fluctuant mass. Requires drainage and antibiotics.

Endobronchial Tumor

- A tumor growing within the bronchial lumen, causing obstruction, atelectasis, and post-obstructive pneumonia. It may be malignant (lung cancer, carcinoid tumor) or benign (hamartoma, papilloma). Symptoms include cough, hemoptysis, and wheezing. Treatment is bronchoscopic removal or debulking plus definitive therapy.

Endobronchial Ultrasound

- Bronchoscopy with ultrasound guidance for trans-bronchial needle aspiration of mediastinal and hilar lymph nodes. Essential for lung cancer staging. Less invasive than mediastinoscopy.

Endothelin Receptor Antagonists

- Medications that block endothelin-1, a potent vasoconstrictor implicated in pulmonary arterial hypertension. Bosentan (dual ERA), ambrisentan (selective ETA), and macitentan are used for PAH. Side effects include hepatotoxicity (bosentan), anemia, and teratogenicity.

Endotracheal Intubation

- Placement of a tube through the mouth into the trachea for mechanical ventilation. Gold standard for airway management. Confirmation by end-tidal CO₂ detection and bilateral breath sounds.

Expiratory Grunting

- A forced exhalation against a partially closed glottis, creating an audible sound. It is an end-expiratory maneuver that generates intrinsic PEEP, helping to maintain alveolar recruitment and improve oxygenation. It is commonly seen in children with respiratory distress.

Extensively Drug-Resistant TB

- TB resistant to isoniazid, rifampin, fluoroquinolones, and at least one injectable agent. Very limited treatment options and poor outcomes.

Exudative Pleural Effusion

- From local pleural disease. Causes include pneumonia, malignancy, TB, and PE. Elevated protein, LDH, and cell count.

Farmer's Lung

- The most common HP, caused by thermophilic actinomycetes in moldy hay. Presents acutely 4–8 hours after exposure with fever, cough, and dyspnea.

Flail Chest

- A clinical condition caused by three or more consecutive ribs fractured in two or more places, creating a free-floating segment of chest wall. The segment moves paradoxically inward during inspiration and outward during expiration. It causes severe pain, impaired ventilation, and may require mechanical ventilation. It is often associated with pulmonary contusion.

Flow-Volume Loop

- Graphical representation of airflow during forced breathing. Obstructive: scooped expiratory limb. Restrictive: narrowed loop with preserved shape. Variable extrathoracic obstruction: flattening of inspiratory limb.

Foreign Body Aspiration

- See emergency_medicine.

Hamman's Sign

- A crunching or crackling sound heard on auscultation synchronized with the heartbeat, caused by air in the mediastinum (pneumomediastinum). It is a rare but specific finding. It is also described as a mediastinal crunch heard in spontaneous pneumomediastinum.

Hampton Hump

- Wedge-shaped opacification with its base abutting the pleura on chest radiography, representing pulmonary infarction secondary to Pulmonary Embolism. *See Pulmonary Embolism (PE).*

Hampton's Hump

- Wedge-shaped, pleural-based opacity on CXR representing pulmonary infarction distal to PE.

Hemothorax

- Blood in pleural space from trauma. Initial chest tube output > 1500 mL or persistent bleeding > 200 mL/hour indicates need for surgery.

Hereditary Hemorrhagic Telangiectasia

- An autosomal dominant vascular disorder (also called Osler-Weber-Rendu syndrome) characterized by telangiectasias on skin and mucous membranes, pulmonary AVMs, hepatic AVMs, and cerebral AVMs. Pulmonary AVMs can cause hypoxemia and paradoxical emboli. Treatment is embolization of pulmonary AVMs.

High-Flow Nasal Cannula

- A device delivering heated and humidified oxygen at flow rates up to 60 L/min through a nasal cannula. It provides a modest amount of PEEP, reduces dead space ventilation, and improves patient comfort compared to non-invasive ventilation. It is used for acute hypoxemic respiratory failure and post-extubation support.

Hospital-Acquired Pneumonia

- Pneumonia developing > 48 hours after hospital admission. Common pathogens include *Pseudomonas* and MRSA. Empiric treatment covers resistant organisms.

Hypercyanotic Tetralogy

- A complex congenital heart defect with four features: ventricular septal defect, overriding aorta, right ventricular outflow tract obstruction (pulmonary stenosis), and right ventricular hypertrophy. It causes right-to-left shunting and cyanosis. Treatment is surgical repair, typically in infancy.

Hyperventilation

- Breathing in excess of metabolic requirements, resulting in decreased partial pressure of arterial carbon dioxide (PaCO_2) and respiratory alkalosis. Acute hyperventilation causes: perioral and digital paraesthesiae (numbness, tingling of lips, hands, feet), carpopedal spasm (tetany due to decreased ionised calcium from alkalosis—Chvostek and Trousseau signs), lightheadedness, dizziness, chest tightness, palpitations, anxiety, panic, and rarely loss of consciousness. Causes: anxiety and panic disorder (most common, acute or chronic hyperventilation syndrome), pain, fever, sepsis, pulmonary embolism (tachypnoea, hypoxia, hyperventilation), head injury (lesions affecting the respiratory center), metabolic acidosis (Kussmaul breathing as compensatory hyperventilation, e.g., DKA), drugs (salicylate overdose), pregnancy (progesterone stimulates the respiratory center), and neurological disorders (stroke, brainstem lesions). Diagnosis: clinical (typical symptoms, normal oxygen saturation, history of anxiety/panic), arterial blood gas (decreased PaCO_2 < 35 mmHg, elevated pH > 7.45, normal PO_2). Hyperventilation can be distinguished from pathological tachypnoea by the absence of hypoxia and underlying cause. Management: (1) Acute: reassurance, rebreathing into a paper bag (controversial and risk of hypoxia safer to use slow breathing technique), breathing retraining (5-second inhale, 5-second hold, 5-second exhale), treatment of underlying cause. (2) Chronic: cognitive behavioural therapy (CBT), breathing exercises, management of anxiety/panic disorder (SSRI, buspirone, relaxation techniques).

Hypoxemia

- PaO_2 < 80 mmHg on room air. Causes: hypoventilation, V/Q mismatch, shunt, diffusion impairment, low FiO_2 . A-a gradient helps distinguish causes.

Influenza

- A contagious respiratory illness caused by influenza A or B viruses, characterized by sudden onset of fever, myalgia, headache, malaise, nonproductive cough, sore throat, and nasal congestion. Seasonal epidemics occur annually. Complications: pneumonia (primary viral or secondary bacterial), exacerbation of underlying conditions. Diagnosis: PCR or rapid antigen testing. Treatment: supportive care, neuraminidase inhibitors (oseltamivir). Prevention: annual vaccination.

Inhaled Nitric Oxide

- A selective pulmonary vasodilator used in acute settings (acute respiratory failure, right heart failure, post-cardiac surgery). It reduces pulmonary vascular resistance and improves oxygenation by dilating well-ventilated pulmonary vessels (improving V/Q matching). It has a short half-life and requires continuous delivery.

Interferon-Gamma Release Assay

- Blood tests measuring IFN-gamma release in response to *M. tuberculosis* antigens (ESAT-6, CFP-10). More specific than PPD and unaffected by BCG. Cannot distinguish latent from active TB.

Intrapulmonary Shunt

- Perfusion of alveoli without ventilation ($\text{V}/\text{Q} = 0$). Blood passes through the pulmonary circulation without gas exchange, mixing with oxygenated blood and causing hypoxemia. It is seen in ARDS, pneumonia, and atelectasis. It is refractory to supplemental oxygen.

IVC Filter

- A device in the IVC to prevent DVT from reaching the lungs. Indications include recurrent PE despite anticoagulation and absolute contraindication to anticoagulation.

Klebsiella Pneumonia

- Severe, necrotizing pneumonia in alcoholic or debilitated patients. Upper lobe involvement with “bulging fissure sign” and “currant jelly” sputum.

Kussmaul Breathing

- A deep, rapid breathing pattern seen in severe metabolic acidosis (diabetic ketoacidosis, lactic acidosis, uremia). It represents the body's attempt to compensate by blowing off CO₂. The increased respiratory rate and depth create the characteristic labored breathing.

Kyphoscoliosis

- An abnormal curvature of the spine in both the coronal (scoliosis) and sagittal (kyphosis) planes. Severe forms cause restrictive lung disease by reducing chest wall compliance and lung volumes. It can lead to chronic respiratory failure and pulmonary hypertension. Treatment includes bracing, surgical correction, and non-invasive ventilation.

Lambert-Eaton Myasthenic Syndrome

- Autoantibodies against presynaptic calcium channels at the neuromuscular junction, associated with SCLC. Proximal weakness, reduced reflexes, facilitation with exercise.

Large Airway Obstruction

- Obstruction of airways with diameter > 2 mm (trachea and main bronchi). It causes significant symptoms including stridor, dyspnea, and impaired secretion clearance. It may be fixed (stenosis, tumor) or variable (tracheomalacia, vocal cord dysfunction). Flow-volume loops show characteristic patterns.

Latent Tuberculosis Infection

- Persistent immune response to *M. tuberculosis* without active disease. Asymptomatic and non-infectious. 5–10% of immunocompetent individuals develop active TB without treatment. Treatment reduces risk by 60–90%.

Legionella Pneumonia

- From *Legionella pneumophila* in water systems. Presents with high fever, diarrhea, confusion, and hyponatremia. Diagnosis by urinary antigen test. Treatment is fluoroquinolones or macrolides.

Light's Criteria

- An effusion is exudative if any one is met: pleural protein/serum protein > 0.5, pleural LDH/serum LDH > 0.6, or pleural LDH > 2/3 upper limit of normal serum LDH.

Lipoid Pneumonia

- Lung inflammation caused by accumulation of lipid-laden macrophages in the alveoli. Exogenous lipoid pneumonia results from aspiration of mineral oil, petroleum jelly, or oil-based nose drops. Endogenous lipoid pneumonia occurs distal to bronchial obstruction. HRCT shows ground-glass opacities with low-attenuation areas (fat density).

Lobar Pneumonia

- Consolidation involving an entire lobe. Most commonly caused by *S. pneumoniae*. Classic progression: congestion, red hepatization, gray hepatization, resolution.

Low-Dose CT Scan

- CT protocol using reduced radiation for lung cancer screening. Detects small nodules at earlier stages. False positives require follow-up per Fleischner guidelines.

Lung Abscess

- Localized necrosis with cavitation containing purulent material. Causes include aspiration and anaerobic bacteria. CXR shows thick-walled cavity with air-fluid level.

Lung Function Tests

- A group of physiological tests that assess the function and capacity of the lungs. See [Pulmonary Function Tests](#).

Lung Protective Ventilation

- A ventilation strategy using low tidal volumes (6 mL/kg ideal body weight), plateau pressure < 30 cmH₂O, appropriate PEEP, and permissive hypercapnia to minimize ventilator-induced lung injury. It is the standard of care for ARDS and is used in all mechanically ventilated patients to reduce barotrauma, volutrauma, and biotrauma.

Lymphangioleiomyomatosis

- A rare, progressive cystic lung disease caused by proliferation of abnormal smooth muscle-like cells (LAM cells) in the lungs, lymphatics, and kidneys. It occurs almost exclusively in women of childbearing age. HRCT shows thin-walled cysts throughout both lungs. It may be associated with tuberous sclerosis complex. Treatment includes sirolimus (mTOR inhibitor) and lung transplantation.

Massive Hemoptysis

- > 600 mL in 24 hours or causing hemodynamic compromise. Medical emergency. Treatment: airway protection, bronchial artery embolization (first-line), or surgery.

Mechanical Insufflation-Exsufflation

- A device that delivers positive pressure (insufflation) followed by rapid negative pressure (exsufflation) to simulate a cough. It is used in neuromuscular disease (Duchenne muscular dystrophy, spinal cord injury, ALS) to augment cough effectiveness and clear secretions.

Mediastinoscopy

- Surgical procedure to sample mediastinal lymph nodes through a small incision above the sternum. Gold standard for mediastinal lymph node staging in lung cancer. Being replaced by EBUS in many centers.

Miliary TB

- Hematogenous dissemination of *M. tuberculosis* causing innumerable 1–3 mm granulomas throughout lungs and other organs. CXR shows “millet seed” pattern. More common in immunocompromised patients.

Minute Ventilation

- The total volume of air breathed in one minute (tidal volume x respiratory rate). Normal is 6–8 L/min. Elevated in increased metabolic demand, pain, anxiety, and sepsis. Reduced in neuromuscular disease and sedation.

Multidrug-Resistant TB

- TB resistant to at least isoniazid and rifampin. Requires second-line drugs for 18–24 months. Worse outcomes and higher mortality than drug-susceptible TB.

Mycoplasma Pneumonia

- Atypical pneumonia most common in ages 5–35. Dry cough, low-grade fever, headache. Patchy infiltrates on CXR disproportionate to symptoms (“walking pneumonia”).

Negative Pressure Ventilation

- Ventilation using negative pressure applied around the chest wall to expand the lungs, as opposed to positive pressure applied to the airway. The “iron

lung” is a historical example. Modern negative pressure ventilators include the cuirass and wrap. They are rarely used today but may be useful in neuromuscular disease.

Obesity Hypoventilation Syndrome

- Chronic daytime hypercapnia in obese individuals without other causes. Reduced chest wall compliance and blunted respiratory drive. Often coexists with OSA. Treatment: weight loss and BiPAP.

Obstructive Sleep Apnea

- Repetitive upper airway obstruction during sleep. Presents with snoring, witnessed apneas, daytime sleepiness. AHI quantifies severity: 5–14 mild, 15–29 moderate, ≥ 30 severe. Treatment: CPAP, oral appliances, weight loss, surgery.

Orthopnea

- Dyspnea that occurs when lying flat and is relieved by sitting upright. It is measured by the number of pillows the patient needs to sleep (two-pillow orthopnea). It is a hallmark of left heart failure and is caused by redistribution of fluid from the lower extremities to the lungs in the supine position.

Pancoast Tumor

- Superior sulcus tumor invading brachial plexus, subclavian vessels, and sympathetic chain. Causes Horner syndrome, shoulder/arm pain, and hand muscle atrophy. Treated with chemoradiation followed by surgery.

Parapneumonic Effusion

- Pleural effusion complicating pneumonia. Simple effusions resolve with antibiotics. Complicated effusions (pH < 7.2, glucose < 60 mg/dL) require chest tube drainage.

Paroxysmal Nocturnal Dyspnea

- Episodes of severe dyspnea that awaken the patient from sleep, typically occurring 1–2 hours after lying down. It is a classic symptom of left heart failure, caused by progressive pulmonary congestion during sleep. It is different from orthopnea in its delayed onset and nocturnal presentation.

PE Anticoagulation

- Initial heparin (LMWH or UFH), followed by warfarin (INR 2–3) for 3–6 months. DOACs are first-line for most patients. Duration depends on pro-

voked vs. unprovoked status.

Permissive Hypercapnia

- A ventilator strategy that allows PaCO₂ to rise above normal (and pH to fall) in exchange for lung-protective ventilation with lower tidal volumes and airway pressures. It is used in severe ARDS when achieving normal PaCO₂ would require harmful ventilation parameters.

Phosphodiesterase-5 Inhibitors

- Medications that inhibit PDE-5, increasing cGMP and causing smooth muscle relaxation and vasodilation. Sildenafil and tadalafil are used for PAH and erectile dysfunction. In PAH, they reduce pulmonary vascular resistance and improve exercise capacity.

Platypnea

- Dyspnea that occurs in the upright position and is relieved by lying down. It is the opposite of orthopnea. It is rare and may be associated with hepatopulmonary syndrome, intracardiac shunting, or pulmonary arteriovenous malformations.

Pleural Effusion

- Abnormal fluid in the pleural space. Transudates result from altered pressures; exudates from inflammation, infection, or malignancy. Light's criteria differentiate the two.

Pleural Fluid Glucose

- Low pleural fluid glucose (< 60 mg/dL) suggests bacterial empyema, rheumatoid pleurisy, or tuberculosis. It indicates high metabolic activity in the pleural space consuming glucose. Very low glucose is characteristic of empyema and parapneumonic effusions requiring drainage.

Pleural Fluid pH

- Pleural fluid pH < 7.20 indicates a complicated parapneumonic effusion or empyema requiring drainage. Normal pleural fluid pH is approximately 7.60. Low pH reflects high metabolic activity and anaerobic metabolism in the pleural space. It is a key decision point in managing parapneumonic effusions.

Pleural Friction Rub

- A grating, leathery sound heard on auscultation caused by inflamed pleural surfaces rubbing against each other during breathing. It is a sign of pleurisy

and may be heard in pneumonia, PE, and pleural effusion. It disappears when fluid accumulates and separates the pleural surfaces.

Pleural Plaque

- Circumscribed fibrous tissue on parietal pleura, hallmark of asbestos exposure. Bilateral, often calcified. Does not indicate asbestosis.

Pleurisy

- Pleural inflammation causing sharp, breathing-related chest pain. Causes: pneumonia, PE, autoimmune disease, malignancy. Treatment addresses the underlying cause.

Pleuritis

- Inflammation of the pleural membranes (visceral and parietal pleura). Presents with pleuritic chest pain: sharp, stabbing pain exacerbated by deep breathing, coughing, or sneezing. Common causes: viral pleurisy (most common), bacterial pneumonia with parapneumonic effusion, pulmonary embolism, tuberculosis, connective tissue diseases (SLE, rheumatoid arthritis), uremia, and malignancy. May be accompanied by pleural friction rub on auscultation. Diagnosis: clinical history, chest X-ray (evaluate for effusion, infiltrates, or pneumothorax), ultrasound, and laboratory evaluation (CBC, CRP, D-dimer to rule out PE). Treatment: addressing the underlying cause; NSAIDs for pain relief; corticosteroids for severe inflammatory pleuritis (e.g., SLE).

Pleurodesis

- Fusion of visceral and parietal pleura to prevent recurrence of effusions or pneumothorax. Chemical pleurodesis uses talc, doxycycline, or bleomycin.

Pneumatocele

- Thin-walled, air-filled cystic spaces in the lung, often in staphylococcal pneumonia. Typically self-resolving.

Pneumocystis Pneumonia

- Opportunistic pneumonia from *P. jirovecii* in immunocompromised patients (CD4 < 200). Progressive dyspnea, dry cough, bilateral ground-glass opacities. Elevated LDH. Treatment is TMP-SMX.

Pneumonia

- Infection of the lung parenchyma, classified as community-acquired (CAP), hospital-

acquired (HAP), or ventilator-associated (VAP). Common pathogens: *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Mycoplasma pneumoniae*, viruses. Presents with cough, fever, dyspnea, and consolidation on imaging. Severity assessment: CURB-65 or PSI. Treatment: empiric antibiotics based on setting and local resistance patterns.

Pneumothorax

- Air in the pleural space causing lung collapse. Primary spontaneous occurs in tall, thin young men. Secondary occurs with underlying lung disease. Tension is a medical emergency.

Positive End-Expiratory Pressure

- Pressure maintained at end-expiration to prevent alveolar collapse. Improves oxygenation by recruiting alveoli and increasing FRC. Balances oxygenation with hemodynamic effects.

Post-Infectious Cough

- A chronic cough persisting 3–8 weeks after a URI, caused by transient bronchial hyperresponsiveness and airway inflammation. It is self-limited and usually resolves without treatment. Inhaled corticosteroids, antitussives, and time are the mainstays of management.

Post-Obstructive Pneumonia

- Pneumonia occurring distal to a bronchial obstruction caused by tumor, foreign body, mucus plug, or stenosis. The obstruction prevents clearance of secretions, creating a favorable environment for infection. It does not resolve with antibiotics alone until the obstruction is relieved.

Post-Pneumonectomy Syndrome

- A rare complication following pneumonectomy where the remaining lung herniates across the mediastinum, causing compression of airways and vessels. It presents with dyspnea, stridor, and recurrent infections. Treatment is surgical correction with mediastinal repositioning and prosthetic implant placement.

Pott Disease

- TB of the spine involving thoracic or lumbar vertebrae. Causes vertebral destruction, kyphosis (gibbus deformity), and paravertebral abscess. May cause spinal cord compression.

Pressure Support Ventilation

- Spontaneous breathing mode with ventilator-provided pressure support above PEEP for each breath. Reduces work of breathing. Used for weaning from mechanical ventilation.

Primary Tuberculosis

- Initial *M. tuberculosis* infection causing Ghon focus in lower lobes with hilar lymph node involvement (Ghon complex). Most infections are contained, resulting in latent TB.

Prone Positioning

- Turning supine patients to prone for > 12 hours daily in severe ARDS. Improves oxygenation by recruiting dorsal lung segments. Reduces mortality when $\text{PaO}_2/\text{FiO}_2 < 150$.

Prostacyclin Analogs

- Medications that mimic prostacyclin (PGI_2), causing vasodilation and inhibiting platelet aggregation in the pulmonary vasculature. They include epoprostenol (continuous IV), treprostinil (subcutaneous, IV, inhaled, oral), and iloprost (inhaled). They are used for severe PAH.

Pulmonary Alveolar Hemorrhage

- Bleeding into the alveolar spaces from disruption of the alveolar-capillary membrane. Causes include vasculitis (GPA, MPA, Goodpasture), connective tissue disease, medications, and coagulopathy. It presents with hemoptysis, falling hemoglobin, diffuse bilateral infiltrates, and serially bloody returns on BAL.

Pulmonary Alveolar Microlithiasis

- A rare genetic disease caused by *SLC34A2* mutations, leading to accumulation of calcium phosphate microliths within the alveoli. HRCT shows diffuse bilateral calcified nodules with a “sandstorm” appearance. It is usually diagnosed in the third to fourth decade. Treatment is supportive; lung transplantation may be needed for progressive disease.

Pulmonary Alveolar Proteinosis

- A rare disease characterized by accumulation of surfactant-like material within the alveoli due to impaired clearance by alveolar macrophages. Most cases are autoimmune (anti-GM-CSF antibodies). Presents with progressive dyspnea and cough. HRCT shows bilateral ground-glass opacities with

“crazy paving” pattern. Treatment is whole lung lavage.

Pulmonary Arteriovenous Malformation

– An abnormal direct communication between a pulmonary artery and vein, causing a right-to-left shunt. It may be idiopathic or associated with hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome). It can cause hypoxemia, paradoxical emboli (stroke, brain abscess), and hemoptysis. Treatment is embolization or surgical resection.

Pulmonary Artery Catheter

– A catheter inserted through the right heart into the pulmonary artery to measure hemodynamic parameters (PA pressure, PAWP, cardiac output). Used for diagnosis and management of pulmonary hypertension, heart failure, and critical illness.

Pulmonary Contusion

– Bruising of the lung parenchyma from blunt chest trauma, causing hemorrhage and edema without lung laceration. It impairs gas exchange and can progress to ARDS. It is often associated with rib fractures and flail chest. Treatment is supportive with lung-protective ventilation.

Pulmonary Edema

– Accumulation of fluid in the pulmonary interstitium and alveoli, most commonly due to left-sided heart failure (cardiogenic). Causes increased hydrostatic pressure leads to transudation. Presents with acute dyspnea, orthopnea, crackles, and S3 gallop. Non-cardiogenic causes include ARDS, renal failure, and high altitude. Treatment: diuretics, afterload reduction, oxygen, and positive pressure ventilation if severe.

Pulmonary Embolism

– See emergency_medicine.

Pulmonary Hemosiderosis

– Iron deposition in the lungs from repeated alveolar hemorrhage. It presents with hemoptysis, anemia, and diffuse bilateral infiltrates on imaging. Causes include Goodpasture syndrome, granulomatosis with polyangiitis, and idiopathic pulmonary hemosiderosis. The classic triad is hemoptysis, anemia, and diffuse pulmonary infiltrates.

Pulmonary Infarction

– Lung necrosis from PE when bronchial supply is compromised. Causes pleuritic pain, hemoptysis, and wedge-shaped opacity. Most PE do not cause infarction due to dual blood supply.

Pulmonary Sequestration

– A congenital malformation of non-functioning lung tissue that lacks normal communication with the tracheobronchial tree and receives its blood supply from a systemic artery (usually the descending aorta). Intralobar sequestration is within the normal pleural investment; extralobar is outside. It may present with recurrent infections or be incidental.

Pulmonary Vasodilator Therapy

– Medications that reduce pulmonary vascular resistance and pulmonary artery pressure. Used for WHO Group 1 PAH. Includes endothelin receptor antagonists (bosentan), PDE-5 inhibitors (sildenafil), prostacyclin analogs (epoprostenol), and soluble guanylate cyclase stimulators (riociguat).

Pulmonary Wedge Pressure

– The pressure measured by a balloon-tipped pulmonary artery catheter when the balloon is inflated, occluding a branch of the pulmonary artery. It approximates left atrial pressure. Normal is 6–12 mmHg. Elevated in left heart failure (PCWP > 18 mmHg). Low in hypovolemia.

Reactivation Tuberculosis

– Reactivation of latent infection, typically years later. Characteristically affects apical and posterior upper lobe segments. Features include chronic cough, hemoptysis, night sweats, weight loss, and cavitation.

Relapsing Polychondritis

– A systemic autoimmune disorder causing inflammation and destruction of cartilage throughout the body. Airway involvement can cause tracheal and bronchial stenosis. Other features include auricular chondritis, nasal chondritis, ocular inflammation, and arthritis. Treatment is corticosteroids and immunosuppressants.

Resorption Atelectasis

– Atelectasis caused by complete obstruction of an airway, leading to absorption of trapped air by the

pulmonary capillaries. Common causes include mucus plugging, foreign body, tumor, and post-surgical shallow breathing. The affected area appears as increased density on CXR with volume loss.

RIPE Therapy

- Standard 4-drug regimen for active TB: Rifampin, Isoniazid, Pyrazinamide, Ethambutol. Intensive phase 2 months, continuation phase 4 months (total 6 months). Pyridoxine prevents isoniazid-induced neuropathy.

Round Pneumonia

- Pneumonia appearing as a round opacity on CXR rather than typical consolidation. More common in children and elderly. May mimic lung mass.

Siderosis

- Benign pneumoconiosis from iron dust, seen in welders. Causes small opacities on CXR but minimal impairment. Reversible with removal of exposure.

Situs Inversus

- A congenital condition in which the thoracic and abdominal organs are reversed or mirrored from their normal positions. Complete situs inversus (situs inversus totalis) involves all organs. It is usually asymptomatic but may be associated with primary ciliary dyskinesia (Kartagener syndrome), congenital heart disease, and polysplenia or asplenia.

Sleep Apnea (Obstructive Sleep Apnea - OSA)

- A sleep disorder characterized by repeated episodes of partial or complete upper airway obstruction during sleep (obstructive sleep apnea—OSA, most common) or cessation of respiratory drive (central sleep apnea—CSA), causing intermittent hypoxia, hypercapnia, and sleep fragmentation. OSA affects 13% of men and 6% of women (moderate–severe). Risk factors: obesity (BMI ≥ 30 —strongest risk factor, 60–90% of OSA patients), male sex, age >40 , menopause, craniofacial abnormalities (retrognathia, macroglossia, tonsillar hypertrophy), smoking, alcohol, and hypothyroidism. Pathophysiology: loss of pharyngeal muscle tone during sleep leads to collapse of the pharyngeal airway (velopharynx, oropharynx, hypopharynx). Clinical: loud snoring, witnessed apnoeas (by bed partner), choking/gasping arousals, unrefreshing

sleep, excessive daytime sleepiness (Epworth Sleepiness Scale ≥ 10), morning headache, nocturia, and cognitive impairment. Consequences: hypertension (dose-dependent, 40% of OSA patients have hypertension), cardiovascular disease (MI, stroke, atrial fibrillation, heart failure), type 2 diabetes, and increased all-cause mortality. Diagnosis: polysomnography (apnea-hypopnoea index—AHI: mild 5–15, moderate 15–30, severe >30 events/hour). Home sleep apnea testing (HSAT) is an alternative for high-risk patients. Treatment: continuous positive airway pressure (CPAP—first-line, splints the airway open, AHI reduction $>90\%$), mandibular advancement devices (MAD—for mild–moderate OSA, $<25\%$ of CPAP efficacy), weight loss (5–10% weight loss reduces AHI by 30–50%), positional therapy (for supine-dependent OSA), and surgery (uvulopalatopharyngoplasty, maxillo-mandibular advancement, hypoglossal nerve stimulation/Inspire—for moderate–severe OSA who fail CPAP). Untreated severe OSA: 5-year mortality 10–15%.

Snoring and Sleep Apnea

- Snoring is the sound produced by vibrating soft tissues in the upper airway during sleep, often resulting from partial airway obstruction. Sleep apnea is a more serious condition characterized by repeated episodes of complete or partial airway collapse during sleep, leading to intermittent hypoxia, frequent arousal, and fragmented sleep. Obstructive sleep apnea, the most common form, is associated with obesity, hypertension, and cardiovascular disease; treatment includes continuous positive airway pressure therapy, oral appliances, weight loss, and positional therapy.

Solitary Pulmonary Nodule

- Single, well-circumscribed lesion < 3 cm surrounded by normal lung. Differential includes granuloma, hamartoma, and carcinoma. PET-CT and tissue sampling help determine etiology.

Spontaneous Breathing Trial

- A period of unsupported breathing to assess a patient's readiness for extubation. The patient breathes through a T-piece or with minimal pressure support for 30–120 minutes. Successful SBT predicts successful extubation.

Spontaneous Pneumothorax

- Pneumothorax without trauma. Primary in healthy individuals; secondary with underlying lung disease. Treatment depends on size.

Staphylococcal Pneumonia

- Severe pneumonia from *S. aureus*, often post-influenza. May cause necrotizing pneumonia, lung abscess, and empyema.

Stridor

- A high-pitched, monophonic, adventitious sound heard primarily during inspiration, caused by narrowing of the extrathoracic or proximal intrathoracic airway. It is a medical emergency when severe. Causes include foreign body aspiration, croup, epiglottitis, and tracheal stenosis.

SVC Syndrome

- Obstruction of the superior vena cava causing facial swelling, plethora, and distended neck veins. Commonly from lung cancer (SCLC, squamous) and lymphoma. Oncologic emergency.

Tactile Fremitus

- Vibrations transmitted through the lung to the chest wall, felt during palpation. It is increased in consolidation (pneumonia) due to better sound transmission through solid tissue. It is decreased in pleural effusion, pneumothorax, and atelectasis due to impaired transmission.

Tension Pneumothorax

- See emergency_medicine.

Thoracentesis

- Removal of pleural fluid via needle insertion through the chest wall. Performed for diagnosis and symptom relief. Ultrasound guidance improves safety.

Thrombolysis for PE

- Systemic thrombolytics (alteplase) for massive PE with hemodynamic instability. Rapid clot dissolution but significant bleeding risk.

Total Lung Capacity

- Total lung air volume after maximal inspiration. Measured by body plethysmography. Increased in obstructive disease, decreased in restrictive disease. TLC < 80% confirms restriction.

Tracheal Foreign Body

- A foreign object lodged in the trachea, causing severe respiratory distress, stridor, and complete airway obstruction. It is a medical emergency requiring immediate bronchoscopic removal. In complete obstruction, emergency cricothyrotomy may be needed.

Tracheitis

- Inflammation of the tracheal mucosa. Acute bacterial tracheitis: a rare but life-threatening cause of upper airway obstruction in children, typically presenting as a superinfection following viral croup (parainfluenza). Caused by *Staphylococcus aureus* (most common), *Streptococcus pneumoniae*, *Haemophilus influenzae* type b (now rare due to Hib vaccine), and *Moraxella catarrhalis*. Presents with high fever, stridor (biphasic, worsening), barking cough, hoarseness, respiratory distress, toxic appearance, and copious purulent tracheal secretions. Diagnosis: lateral neck X-ray—tracheal narrowing ('steeple sign' similar to croup, but with irregular tracheal margins and pseudomembrane), bronchoscopy (definitive—shows inflammation, ulceration, and thick purulent secretions/ pseudomembranes). Treatment: hospitalisation, IV antibiotics (anti-staphylococcal—flucloxacillin or cefuroxime, plus metronidazole for anaerobes), humidified oxygen, and intubation if severe respiratory distress (airway protection, suction of thick secretions). Endotracheal intubation may be required for 5–7 days. Complications: airway obstruction, pneumonia, septic shock, and post-intubation stenosis.

Tracheobronchomalacia

- Abnormal softening of the trachea and/or bronchi causing excessive airway collapse during breathing. It may be congenital or acquired. Symptoms include chronic cough, recurrent infections, and expiratory airflow obstruction. Diagnosis is by dynamic CT or bronchoscopy. Treatment includes CPAP, stenting, or surgical reconstruction.

Tracheomalacia

- Softening of the tracheal cartilage causing excessive collapse of the trachea during expiration. It may be congenital or acquired (prolonged intubation, relapsing chondritis). Symptoms include expiratory stridor and difficulty clearing secretions. Diagnosis

is by dynamic CT or bronchoscopy. Treatment may require tracheal stenting or surgery.

Tracheostomy

- Surgical creation of an airway opening in the anterior neck into the trachea. Indications include prolonged ventilation (> 10–14 days), upper airway obstruction, and airway protection.

Transudative Pleural Effusion

- From systemic factors altering hydrostatic/oncotic pressures. Most commonly from heart failure. Low protein, low LDH. Treatment addresses the underlying cause.

Trepopnea

- Dyspnea that occurs in one lateral decubitus position but not the other. It is typically worse when lying on the side of the affected lung. It may be caused by unilateral lung disease, pleural effusion, or mediastinal mass.

Upper Airway Obstruction

- Narrowing of the airway above the carina, causing inspiratory stridor, dyspnea, and characteristic changes on flow-volume loops (flattening of the inspiratory limb). Causes include tumors, stenosis, goiter, and vocal cord dysfunction. It is a medical emergency when severe.

Ventilator-Associated Pneumonia

- Pneumonia > 48 hours after intubation. Most common ICU-acquired infection. Diagnosis uses quantitative BAL or protected specimen brush cultures.

Vocal Resonance

- The transmission of vocal sounds to the chest wall, assessed by having the patient speak while auscultating. It is increased in consolidation and decreased in pleural effusion or pneumothorax. It correlates with bronchophony and whispered pectoriloquy.

Volutrauma

- Lung injury from excessive tidal volume causing alveolar overdistension. Prevented by low tidal volume ventilation (6 mL/kg IBW). Key component of ARDS management.

Westermarck Sign

- Focal area of oligemia (decreased vascularity) distal to an occluded pulmonary artery segment on chest radiography in acute Pulmonary Embolism. *See*

Pulmonary Embolism (PE).

Whispered Pectoriloquy

- The ability to hear whispered words clearly through the stethoscope over consolidated lung tissue. It is a sign of pulmonary consolidation. Normally, whispered words are barely audible over the lung fields. It is one of the classic signs of pneumonia on physical examination.

Windpipe

- The windpipe, a 10–12 cm fibrocartilaginous tube from the larynx (C6) to the carina (T4/T5) where it bifurcates into main bronchi. *See Trachea.*

Pulmonary Hypertension

- Abnormally increased pressure in the pulmonary circulation, confirmed by right-heart catheterization when mean pulmonary artery pressure exceeds 20 mmHg at rest. Classification by cause guides treatment and includes pulmonary arterial, left-heart, lung-disease/hypoxia, chronic thromboembolic, and multifactorial groups.

Pulmonary Arterial Hypertension (PAH)

- A precapillary pulmonary hypertension syndrome caused by increased pulmonary vascular resistance from pulmonary arteriolar disease. It may be idiopathic, heritable, drug-associated, or associated with conditions such as connective-tissue disease, congenital heart disease, portal hypertension, or HIV.

Chronic Thromboembolic Pulmonary Hypertension (CTEPH)

- Pulmonary hypertension caused by organized, persistent thromboembolic obstruction and secondary pulmonary-vessel remodeling after pulmonary embolism. It is potentially curable in selected patients by pulmonary endarterectomy or balloon pulmonary angioplasty.

Acute Hypoxemic Respiratory Failure

- Inability of the respiratory system to maintain adequate arterial oxygenation, usually manifested by low arterial oxygen or oxygen saturation despite appropriate inspired oxygen. Causes include pneumonia, pulmonary edema, ARDS, atelectasis, and

pulmonary embolism.

Acute Hypercapnic Respiratory Failure

- Inability to eliminate carbon dioxide, producing elevated arterial PaCO_2 and often respiratory acidemia. Causes include COPD exacerbation, severe asthma, neuromuscular weakness, central respiratory depression, and chest-wall restriction.

Respiratory Drive

- The neural output that stimulates respiratory muscles and determines ventilation. It is generated by brainstem networks and modified by chemoreceptor input, mechanoreceptors, wakefulness, metabolic state, medications, and behavioral control.

Respiratory Quotient (RQ)

- The ratio of carbon dioxide production to oxygen consumption for a particular substrate or metabolic state. It differs from the respiratory exchange ratio measured at the mouth and is used in metabolic and ventilatory physiology.

Alveolar Ventilation Equation

- The relationship between alveolar ventilation and arterial carbon-dioxide tension, approximately $\text{PaCO}_2 = 0.863$ times carbon-dioxide production divided by alveolar ventilation. It explains why reduced effective ventilation causes hypercapnia.

Bronchodilator Response

- The change in spirometric airflow after administration of a short-acting bronchodilator. A significant response can support variable airflow limitation, but a negative response does not exclude asthma and a positive response is not specific to one disease.

Cystic Fibrosis

- An autosomal recessive multisystem disorder caused by pathogenic CFTR variants that impair epithelial chloride and bicarbonate transport. Thick secretions cause chronic sinopulmonary infection, bronchiectasis, pancreatic insufficiency, intestinal obstruction, infertility, and abnormal sweat chloride.

Sarcoidosis

- A multisystem inflammatory disease characterized by noncaseating granulomas in affected tissues. It commonly involves the lungs and intrathoracic lymph nodes but may affect skin, eyes, heart, ner-

vous system, and other organs; diagnosis requires compatible findings and exclusion of other granulomatous causes.

Acute Exacerbation of Asthma

- A progressive increase in dyspnea, cough, wheezing, or chest tightness with reduced expiratory airflow compared with the patient's baseline. Severe attacks may cause exhaustion, silent chest, hypercapnia, respiratory failure, and need for urgent treatment.

COPD Exacerbation

- Acute worsening of respiratory symptoms beyond normal day-to-day variation in a patient with COPD that leads to additional therapy. Common triggers include viral or bacterial infection, air pollution, and cardiopulmonary comorbidity.

Pulmonary Rehabilitation

- A supervised, multidisciplinary program combining exercise training, education, behavioral support, and self-management for chronic respiratory disease. It improves exercise capacity, dyspnea, functional status, and quality of life.

Sleep-Related Hypoventilation

- Inadequate ventilation during sleep causing elevated carbon dioxide, oxygen desaturation, or both. Causes include obesity, neuromuscular disease, chest-wall disorders, chronic lung disease, medications, and central respiratory-control abnormalities.

Ventilator-Induced Lung Injury (VILI)

- Lung injury caused or amplified by mechanical ventilation, including volutrauma, barotrauma, atelectrauma, and biotrauma. Lung-protective ventilation limits tidal volume and excessive airway pressures while maintaining appropriate oxygenation and carbon-dioxide targets. **Air bronchogram**

- A radiographic sign showing air-filled bronchi visible against opacified lung parenchyma, indicating that the airways remain patent while the surrounding alveoli are filled with fluid, pus, or cells. **Chronic eosinophilic pneumonia**

- An idiopathic inflammatory lung disease characterized by eosinophilic infiltration of the

pulmonary parenchyma, presenting with fever, cough, dyspnea, and peripheral airspace opacities on imaging. **Eosinophilic bronchitis**

- Inflammation of the bronchial airways with eosinophilic infiltration causing chronic cough, with normal spirometry and no airway hyperresponsiveness, distinguishing it from asthma.

Hydropneumothorax

- The simultaneous presence of both fluid and air in the pleural space, causing respiratory distress and dullness to percussion with absent breath sounds, typically requiring chest tube drainage.

Mycoplasma pneumoniae-associated mucositis

- Inflammatory lesions of the oral, ocular, or genital mucosa occurring as an extrapulmonary manifestation of *Mycoplasma pneumoniae* infection, often presenting with target-like skin lesions. **Oleothorax**

- Historical surgical obliteration of the pleural space using infused oil to collapse the lung, once used for tuberculosis treatment before effective chemotherapy, now largely obsolete. **Plastic bronchitis**

- A rare condition producing large, branching mucous casts that form in the airways, causing life-threatening airway obstruction, often associated with congenital heart disease or post-fontan circulation. **Pleural perforation**

- A breach in the pleural lining allowing air or fluid to enter the pleural space, potentially causing pneumothorax or hydropneumothorax, often from trauma, procedures, or underlying lung disease.

Pneumocephalus

- The presence of air or gas within the cranial cavity, most commonly following trauma, surgery, or sinus disease, and potentially causing increased intracranial pressure if tension develops.

Reexpansion pulmonary edema

- Noncardiogenic pulmonary edema developing rapidly after rapid reexpansion of a collapsed lung, typically following chest tube drainage of a large or long-standing pneumothorax. **Asthma exacerbation**

- An acute or subacute worsening of asthma symp-

toms and airflow limitation, typically causing increased wheeze, cough, chest tightness, or breathlessness.

Hyperventilation Syndrome

- Recurrent or persistent overbreathing that exceeds metabolic requirements, usually producing reduced arterial carbon dioxide and respiratory alkalosis in the absence of primary pulmonary disease. Symptoms may include breathlessness, chest tightness, dizziness, palpitations, paraesthesia, and carpopedal spasm. It is a diagnosis of exclusion after serious cardiopulmonary and metabolic causes have been assessed.

Bronchiolitis Obliterans

- An uncommon, often irreversible obstructive small-airway disease caused by inflammation and fibrotic narrowing or obliteration of the bronchioles. Causes include severe infection, inhalational injury, autoimmune disease, and complications after lung or bone-marrow transplantation. It presents with progressive breathlessness, dry cough, wheezing, and fixed airflow obstruction; diagnosis relies on clinical history, pulmonary-function testing, and chest CT.

Acute Bronchitis

- Acute inflammation of the tracheobronchial tree, usually caused by a viral respiratory infection and characterized by cough, with or without sputum production, lasting up to several weeks. Wheeze, chest discomfort, and low-grade fever may occur; persistent high fever, hypoxaemia, focal findings, or severe illness should prompt assessment for pneumonia or another cause.

Apnea

- See *Apnoea*.

Clubbing

- Bulbous enlargement of the distal fingers or toes with increased nail curvature and loss of the normal nail-fold angle. It reflects proliferation of connective tissue in the distal digits and may be associated with chronic pulmonary disease, cyanotic heart disease, inflammatory bowel disease, or malignancy.

Hypercapnia

- An abnormally elevated arterial partial pressure of carbon dioxide, usually caused by alveolar hypoventilation. It may produce headache, somnolence,

confusion, asterixis, respiratory acidosis, and, when severe or rapidly developing, coma.

Intercostal Retraction

- Inward movement of the skin and soft tissues between the ribs during inspiration, indicating increased work of breathing. It is common in infants and children with respiratory distress and may accompany airway obstruction, bronchiolitis, pneumonia, asthma, or other pulmonary disease.

Lymphangiectasis

- Abnormal dilatation of lymphatic vessels. It may be congenital or acquired and can cause lymph leakage, oedema, protein-losing enteropathy, chylous effusions, or pulmonary and pleural complications depending on the affected site.

Radiation Pneumonitis

- An inflammatory lung injury occurring weeks to months after thoracic radiation. It may cause dry cough, fever, dyspnea, and hypoxemia within the irradiated field and can progress to radiation fibrosis.

Tracheobronchomegaly

- Abnormal enlargement of the trachea and main bronchi, usually associated with connective-tissue weakness. It may cause recurrent lower-respiratory infection, bronchiectasis, ineffective cough, dyspnea, and difficulty clearing airway secretions.

Chemical Pneumonitis

- Inflammation and lung injury caused by inhalation or aspiration of irritating chemicals, gastric contents, hydrocarbons, or other toxic substances. It may cause cough, dyspnea, hypoxemia, wheezing, and diffuse pulmonary infiltrates.

Exercise-Induced Asthma

- Bronchoconstriction occurring during or shortly after physical exertion, causing cough, wheezing, chest tightness, or shortness of breath. It is associated with airway hyperresponsiveness and may occur in people with or without persistent asthma.

Chapter 36

Radiology

Abdominal Aortic Aneurysm

- See vascular surgery.

Abdominal Aortic Ultrasound

- Screening for abdominal aortic aneurysm. One-time screening in men 65-75 who smoked.

Abdominal CT

- First-line imaging for acute abdominal pain. Evaluates appendicitis, diverticulitis, bowel obstruction, trauma, renal stones, liver masses. Oral and IV contrast often used.

Ablation Therapy

- Image-guided destruction of tissue. Radiofrequency ablation, cryoablation, microwave ablation. Used for tumors, arrhythmias, pain.

Accreditation

- Formal recognition of compliance with standards. ACR accreditation for facilities.

Aliasing Artifact

- Ultrasound artifact from high velocities. Reduced by increasing scale, using lower frequency transducer.

Angiography

- X-ray imaging of blood vessels after contrast injection. Digital subtraction angiography (DSA) gold standard. Used for diagnosing and treating vascular diseases.

Angioplasty

- Image-guided balloon dilation of stenosis. Coronary, peripheral, renal, carotid. Often combined with stenting.

Anorectal Manometry

- Measurement of anal pressures. Evaluates fecal incontinence, constipation.

Aortic Dissection

- A tear in the intima of the aorta allowing blood to dissect through the media, creating a false lumen. See emergency medicine.

Aortography

- Contrast imaging of aorta. Evaluates aneurysm, dissection, occlusion. Largely replaced by CTA/MRA.

Appendicitis

- Inflammation of appendix. CT diagnosis. May present atypically. Surgical emergency.

Arthrography

- Contrast injected into joint for imaging. Used for shoulder, knee, hip evaluation. MR arthrography more common now.

Artifacts

- Image distortions not representing true anatomy. Types: motion, beam hardening, metal, aliasing, partial volume. Recognition important for accurate interpretation.

Ascites

- Fluid in peritoneal cavity detected on imaging. Causes: cirrhosis, malignancy, heart failure, nephrotic syndrome. Ultrasound sensitive.

Atelectasis

- Collapse of lung tissue detected on imaging. Plate-like, lobar, or total lung collapse. Causes: obstruction, compression, scarring.

Barium Enema

- X-ray imaging of colon using barium enema. Evaluates polyps, tumors, diverticula, inflammatory bowel disease.

Barium Study

- X-ray imaging using barium sulfate contrast. Bar-

ium swallow, barium enema, upper GI series. Evaluates GI tract morphology and function.

Beam Hardening Artifact

- CT artifact from dense structures. Reduced by beam hardening correction algorithms.

BI-RADS

- Breast Imaging-Reporting and Data System. Standardizes mammography reporting. Categories: 0 (incomplete), 1 (negative), 2 (benign), 3 (probably benign), 4 (suspicious), 5 (highly suggestive of malignancy), 6 (known biopsy-proven malignancy).

Bladder Cancer

- Urothelial carcinoma. See [urology](#).

Board Certification

- Formal recognition of radiology expertise. American Board of Radiology.

Bone Scan

- Nuclear medicine imaging using Tc-99m MDP. Detects bone metastases, fractures, infection. Sensitive but not specific. Whole body imaging.

Bosniak Classification

- System classifying renal cysts by CT features. Categories I-II benign, IIF follow-up, III-IV likely malignant.

Bowel Obstruction

- Blockage of intestinal lumen. X-ray, CT diagnosis. Differentiate small vs. large bowel obstruction. Mechanical vs. paralytic ileus.

Brachytherapy

- Internal radiation therapy. Sources placed inside or near tumor. Used for prostate, cervical, breast cancer.

Breast Cancer

- Most common cancer in women. See [oncology](#).

Breast MRI

- MRI of breast for high-risk screening, implant evaluation, staging breast cancer. High sensitivity, lower specificity.

Bronchiectasis

- Permanent dilation of bronchi detected on imaging. CT diagnosis. Causes: infection, obstruction, immunodeficiency.

Carbon Ion Therapy

- Radiation using carbon ions. Higher biological effectiveness. Limited availability.

Cardiac CT

- CT imaging of heart and coronary arteries. Coronary calcium scoring, coronary CT angiography, cardiac function assessment.

Cardiac Gated SPECT

- SPECT imaging synchronized with ECG. Assess ventricular function, wall motion, viability.

Carotid Duplex

- Ultrasound combining B-mode and Doppler imaging of carotid arteries. Assesses stenosis, plaque characterization.

Cerebral Angiography

- Contrast imaging of cerebral vessels. Evaluates aneurysms, AVMs, stenosis. Invasive procedure.

Chelation Study

- Nuclear medicine study using chelating agents. Evaluates renal function, obstruction.

Chest X-ray

- Initial imaging for respiratory symptoms. PA and lateral views. Evaluates pneumonia, pneumothorax, pleural effusion, heart size, mediastinal masses. Limited sensitivity for early disease.

Cholangiography

- Contrast imaging of bile ducts. Intraoperative, percutaneous, or ERCP approach. Evaluates biliary obstruction, stones, strictures.

Cholangitis

- Infection of bile ducts. CT, MRCP diagnosis. Charcot triad: fever, jaundice, right upper quadrant pain.

Cholecystitis

- Inflammation of gallbladder. Ultrasound diagnosis. Stone, wall thickening, pericholecystic fluid.

Clinical Trials

- Research study testing new cancer treatments. See [clinical trial](#).

Colorectal Cancer

- Third most common cancer. See [oncology](#).

Comparison

- Reference to prior imaging in radiology report.

Compression Ultrasound

- Ultrasound technique applying pressure. Used for DVT diagnosis, testicular evaluation.

Computed Tomography (CT)

- Cross-sectional imaging using rotating X-ray tube and detectors. Produces axial images, reconstructable into sagittal, coronal, 3D. CT number measured in Hounsfield units (HU): water = 0, air = -1000, bone = +1000. Contrast: iodine-based, enhances vascular structures and perfused organs. Speed: seconds. Radiation dose: higher than plain X-ray.

Conclusion

- Summary of key findings and recommendations in radiology report. See [impression](#).

Consolidation

- Lung parenchyma filled with fluid, detected on imaging. Pneumonia, edema, hemorrhage, malignancy.

Continuing Medical Education

- Postgraduate education that maintains and updates a clinician's knowledge, skills, and professional competence.

Contrast Agent

- Substance enhancing image visibility. X-ray/CT: iodine-based (positive contrast). MRI: gadolinium-based (shortens T1, bright on T1). Ultrasound: microbubble agents. Barium sulfate for GI studies.

Contrast Reaction

- Adverse reaction to contrast agent. Mild: nausea, urticaria. Severe: anaphylaxis, bronchospasm. Pre-medication for prior reactions.

Contrast-Enhanced Ultrasound

- Ultrasound using microbubble contrast agents. Improves lesion characterization, perfusion assessment.

Contrast-Induced Nephropathy

- Acute kidney injury after iodinated contrast administration. Risk factors: pre-existing renal impairment, diabetes, dehydration. Prevention: hydration, lowest contrast volume, N-acetylcysteine controversial.

Core Needle Biopsy

- Biopsy using core needle. CT, ultrasound, or MRI guidance.

Coronary Angiography

- Invasive X-ray imaging of coronary arteries. Gold standard for diagnosing coronary artery disease.

Coronary Calcium Scoring

- Non-contrast CT measuring calcified plaque in coronary arteries. Agatston score predicts cardiovascular risk.

Critical Findings

- Findings requiring immediate communication. Examples: pneumothorax, brain herniation, aortic dissection.

Critical Results

- Unexpected significant findings require immediate notification. See [critical findings](#).

Cryoablation

- Image-guided destruction of tissue. See [ablation therapy](#).

CT Angiography (CTA)

- CT imaging of blood vessels after IV contrast. Fast, non-invasive. Used for pulmonary embolism, aortic dissection, coronary artery disease, peripheral arterial disease.

CT Chest

- Detailed lung and mediastinal imaging. High-resolution CT (HRCT) for interstitial lung disease. CT pulmonary angiography (CTPA) for pulmonary embolism. Lung cancer screening with low-dose CT.

CT Colonography

- CT imaging of colon after bowel preparation and insufflation. Detects polyps and masses. Alternative to colonoscopy for screening. False positives common.

CT Contrast

- Substance enhancing image visibility. See [contrast agent](#).

CT Coronary Angiography

- CT imaging of coronary arteries after contrast. Detects stenosis, plaque. Alternative to invasive angiography in low-intermediate risk.

CT Perfusion

- CT technique measuring brain or organ perfusion. Used for acute stroke, tumor evaluation.

Cystography

- Contrast imaging of bladder. Evaluates trauma, fistulas, vesicoureteral reflux.

Dacryocystography

- Contrast imaging of lacrimal drainage system. Evaluates obstruction.

Defecography

- X-ray imaging of defecation using barium. Evaluates pelvic floor dysfunction, rectocele, intussusception.

DEXA (Dual-Energy X-ray Absorptiometry)

- Measures bone mineral density (BMD) at spine and hip. T-score compares to young adult reference. Osteoporosis: T-score ≤ -2.5 . Osteopenia: -1.0 to -2.5 . Low radiation dose.

Diagnostic Radiology

DICOM

- Digital Imaging and Communications in Medicine. Standard for medical image exchange.

Diffusion-Weighted Imaging (DWI)

- MRI technique measuring water molecule diffusion. Restricted diffusion bright. Used for stroke, abscess, tumor characterization.

Digital Subtraction Angiography (DSA)

- Technique subtracting pre-contrast images from post-contrast images to visualize blood vessels. Gold standard for vascular imaging. Used for diagnosing and treating vascular diseases.

Discography

- Contrast injection into intervertebral disc. Evaluates disc pathology. Controversial, limited use.

Disofenin Scan

- Hepatobiliary imaging using Tc-99m disofenin. Similar to mebrofenin scan.

Diverticulitis

- Inflammation of colonic diverticula. CT diagnosis. Complications: abscess, perforation, fistula.

Doppler Ultrasound

- Ultrasound technique measuring blood flow velocity

and direction. Color Doppler, spectral Doppler, power Doppler. Used for vascular studies, cardiac evaluation, organ perfusion.

Doppler Velocimetry

- Ultrasound measuring blood flow velocity in umbilical and fetal vessels. Assesses fetal well-being.

Drainage Procedures

- Image-guided drainage of fluid collections. Abscess, hematoma, biloma, urinoma. CT or ultrasound guidance.

Dual-Energy CT

- CT using two different energy spectra. Material differentiation, virtual non-contrast images, gout detection.

Echocardiography

- Ultrasound of heart. Transthoracic (TTE) and transesophageal (TEE) approaches. Evaluates cardiac structure, function, valves, pericardium. Doppler assesses blood flow.

Effective Dose

- Dose measure accounting for tissue sensitivity. Measured in millisieverts (mSv).

EHR

- Electronic Health Record. Broader than EMR, includes population health.

Elastography

- Imaging tissue stiffness. Used for liver fibrosis assessment, breast lesion characterization, thyroid nodule evaluation.

Electroencephalography (EEG)

- Recording of electrical activity from scalp electrodes. Used for seizure disorders, encephalopathy, brain death.

Electromyography (EMG)

- Recording of electrical activity from muscles. Used for neuropathy, myopathy, radiculopathy.

Embolization Therapy

- Image-guided occlusion of vessels. Used for hemorrhage control, tumor devascularization, aneurysm treatment, varices.

Emphysema

- Destruction of lung parenchyma detected on imaging. Centriacinar, panacinar. CT sensitive for de-

tection.

EMR

- Electronic Medical Record. Patient medical records.

Enhancement Artifact

- Ultrasound artifact from fluid-filled structures. Enhanced by harmonic imaging.

Esophageal Manometry

- Measurement of esophageal pressures. Evaluates motility disorders.

Event Monitor

- Extended ECG monitoring for infrequent symptoms. Worn for weeks to months.

Evidence-Based Medicine

- Practice informed by best available evidence.

Evoked Potentials

- Measurement of electrical responses to stimuli. Visual, auditory, somatosensory. Used for demyelinating diseases.

Excisional Biopsy

- Surgical removal of entire lesion. Diagnosis and treatment.

Exercise Stress Test

- ECG monitoring during exercise. Detects coronary artery disease.

External Beam Radiation Therapy

- Radiation from outside body. 3D conformal, IMRT, stereotactic body radiation therapy (SBRT).

Extravasation

- Contrast leakage into surrounding tissue during injection. Pain, swelling, potential tissue necrosis.

Fetal Echocardiography

- Ultrasound imaging of fetal heart. Evaluates congenital heart disease.

Findings

- Detailed description of imaging observations in radiology report.

Fine Needle Aspiration

- Biopsy using fine needle. Cytology diagnosis. Ultrasound or CT guidance.

Fludeoxyglucose F-18

- See [nuclear medicine](#).

Fluoroscopy

- Real-time X-ray imaging. Used for barium studies, angiography, catheter placement, joint injections. Continuous or pulsed radiation. Radiation dose higher than plain X-ray.

Follow-Up Recommendations

- Recommendations for further imaging or evaluation. Based on guidelines (Fleischner Society for lung nodules).

Four-Dimensional Ultrasound

- Real-time 3D ultrasound. Used in obstetrics for fetal imaging.

Functional MRI (fMRI)

- MRI measuring brain activity by detecting blood flow changes. Used for pre-surgical planning, research.

Gadolinium-Induced Nephrogenic Systemic Fibrosis

- Rare but serious condition in patients with severe renal impairment receiving gadolinium-based MRI contrast. Causes skin thickening, organ fibrosis. Risk reduced with macrocyclic agents.

Gallium Scan

- Nuclear medicine imaging using Ga-67. Detects inflammation, infection, tumors. Largely replaced by FDG-PET.

Gastrografin Study

- X-ray imaging using water-soluble contrast. Used when barium contraindicated (perforation risk). Less detailed than barium.

Gastrointestinal Stromal Tumor (GIST)

- Mesenchymal tumor of GI tract. CT diagnosis. KIT mutation common.

Ground-Glass Opacity

- Hazy lung opacity on CT without obscuring vessels. Non-specific, may represent inflammation, edema, fibrosis, malignancy.

Hepatic Trauma

- Liver injury from trauma. CT staging guides management. Grades I-V based on injury severity.

Hepatomegaly

- Enlarged liver detected on imaging. Causes: fatty liver, hepatitis, congestion, infiltration, malignancy.

High-Intensity Focused Ultrasound (HIFU)

- Ultrasound ablation using focused energy. Used for uterine fibroids, prostate cancer, bone metastases.

Holter Monitoring

- Continuous ECG recording for 24-48 hours. Detects arrhythmias, ischemia.

Hounsfield Units (HU)

- CT number scale referencing water (0 HU) and air (-1000 HU). Fat: -50 to -100 HU. Water: 0 HU. Soft tissue: +20 to +50 HU. Bone: +400 to +3000 HU. Blood: +40 to +60 HU (acute), +20 to +40 HU (chronic).

Hydronephrosis

- Dilation of renal pelvis and calyces due to obstruction. Diagnosis: ultrasound, CT, MRI. Causes: stones, stricture, tumor, pregnancy.

Hysterosalpingo-Contrast-Sonography (HyCoSy)

- Ultrasound evaluation of tubal patency using contrast. Alternative to hysterosalpingography.

Hysterosalpingography

- Contrast imaging of uterus and fallopian tubes. Evaluates infertility, uterine anomalies, tubal patency.

Image Quality

- Assessment of diagnostic adequacy. Factors: resolution, contrast, noise, artifacts.

Image-Guided Ablation

- Image-guided destruction of tissue. See [ablation therapy](#).

Image-Guided Biopsy

- Biopsy performed under imaging guidance. CT, ultrasound, MRI, or fluoroscopy. Improves accuracy, safety.

Image-Guided Therapy

- Image-guided minimally invasive procedures. See [interventional radiology](#).

Iminoacetic Acid Scan

- Renal imaging using Tc-99m iminodiacetic acid. Evaluates renal function, secretion.

Implantable Loop Recorder

- Subcutaneous ECG monitor for years. Detects

infrequent arrhythmias.

Impression

- Summary of key findings and recommendations in radiology report.

Incidental Finding

- Incidental imaging finding of uncertain significance. See [incidentaloma](#).

Incidental Findings

- See [incidental finding](#).

Incidentaloma

- Incidental imaging finding of uncertain significance. May require further evaluation.

Incisional Biopsy

- Surgical removal of part of lesion. Diagnosis before definitive treatment.

Indication

- Clinical reason for imaging in radiology report.

Indium-111 Scan

- Nuclear medicine imaging using In-111. Used for WBC labeling, octreotide scanning.

Infiltrate

- Patchy lung opacity detected on imaging. Non-specific, may represent infection, edema, hemorrhage, inflammation.

Informed Consent

- Autonomous voluntary authorization given by a competent patient to undergo a specific medical intervention, procedure, or clinical trial.

Intensity-Modulated Radiation Therapy (IMRT)

- Radiation therapy modulating beam intensity. Improves conformity, spares normal tissue.

Interstitial Lung Disease

- Group of diseases affecting lung interstitium. CT patterns: usual interstitial pneumonia, nonspecific interstitial pneumonia, cryptogenic organizing pneumonia.

Interventional Procedures

- Image-guided treatments: angioplasty, stenting, embolization, ablation, biopsy, drain placement. Advantages: minimally invasive, faster recovery, lower complication rates.

Interventional Radiologist

- Physician performing image-guided procedures.

Interventional Radiology

- Image-guided minimally invasive procedures. Examples: angioplasty, stenting, embolization, biopsy, ablation, drain placement. Reduces need for open surgery.

Kyphoplasty

- Similar to vertebroplasty but uses balloon to create cavity before cement injection.

Leukemia

- A group of hematological malignancies characterized by the clonal proliferation of abnormal white blood cells (blasts) in the bone marrow and peripheral blood. See oncology.

LI-RADS

- Liver Imaging-Reporting and Data System. Standardizes reporting of liver imaging in patients with cirrhosis. Used for hepatocellular carcinoma diagnosis.

Liver Cancer

- Hepatocellular carcinoma, often in cirrhosis. See oncology.

Liver Mass

- Abnormality in liver detected on imaging. Benign: hemangioma, focal nodular hyperplasia, adenoma. Malignant: hepatocellular carcinoma, metastasis, cholangiocarcinoma.

Lower Extremity Venous Doppler

- Ultrasound assessing deep vein thrombosis. Compression ultrasound, Doppler flow assessment.

Lung Cancer

- Leading cancer death worldwide. See oncology.

Lymphangiography

- Contrast imaging of lymphatic vessels. Evaluates lymphatic obstruction, fistulas. Largely replaced by MRI/CT.

Lymphoma

- A malignancy of lymphocytes, divided into Hodgkin lymphoma (HL—Reed-Sternberg cells, cervical/supraclavicular nodes, B symptoms, younger adults) and non-Hodgkin lymphoma (NHL—heterogeneous, more common, aggressive or indolent). See oncology.

Lymphoscintigraphy

- Nuclear medicine imaging of lymphatic system. Uses Tc-99m nanocolloid. Sentinel lymph node biopsy, lymphedema evaluation.

Magnetic Resonance Cholangiopancreatography (MRCP)

- MRI technique visualizing biliary and pancreatic ducts without contrast. Non-invasive alternative to ERCP. Used for choledocholithiasis, biliary strictures, pancreatic pathology.

Magnetic Resonance Imaging (MRI)

- Uses strong magnetic field and radiofrequency pulses to generate images from hydrogen protons. Excellent soft tissue contrast. No ionizing radiation. Sequences: T1-weighted (fat bright, fluid dark), T2-weighted (fluid bright), FLAIR (suppresses CSF), DWI (diffusion restriction). Contrast: gadolinium-based. Contraindications: pacemaker, certain implants, claustrophobia.

Magnetic Resonance Spectroscopy (MRS)

- MRI technique measuring metabolic compounds. Used for tumor characterization, metabolic disorders.

Mammography

- Breast X-ray for cancer screening. Digital mammography standard. Tomosynthesis (3D mammography) improves detection. BI-RADS classification system. Screening: annual or biennial for women 40-74.

Mass

- Large lung lesion detected on imaging. Differentiate nodule (small) from mass (large). Malignancy more likely with mass.

Mebrofenin Scan

- Hepatobiliary imaging using Tc-99m mebrofenin. Evaluates liver function, biliary obstruction.

Medical Physicist

- Expert in radiation physics and safety.

Medical Physics

- Physics of radiation imaging and therapy. See [radiation physics](#).

Mesenteric Ischemia

- Reduced blood flow to intestines. Acute: embolism, thrombosis. Chronic: atherosclerosis. CT angiography diagnosis.

Metal Artifact

- Image degradation from metal implants. Reduced by metal artifact reduction sequences (MRI), iterative reconstruction (CT).

Metastasis

- Spread of cancer cells from primary site to distant locations. See oncology.

MIBG Scan

- Nuclear medicine imaging using I-123 or In-111 MIBG. Detects pheochromocytoma, neuroblastoma.

Microwave Ablation

- Image-guided destruction of tissue. See [ablation therapy](#).

Motion Artifact

- Image degradation from patient movement. Reduced by faster acquisition, breath-hold, sedation.

MR Angiography (MRA)

- Vascular imaging using MRI without ionizing radiation. Time-of-flight (TOF) or contrast-enhanced (CE-MRA). Used for cerebral aneurysms, renal artery stenosis, peripheral arterial disease.

MR Enterography

- MRI technique evaluating small bowel. Uses oral contrast to distend bowel. Used for Crohn disease, small bowel tumors, bleeding.

MR Neurography

- MRI technique visualizing peripheral nerves. See [neurography](#).

MRI Brain

- Excellent for brain pathology: tumors, stroke, demyelination, infection, degeneration. Sequences: T1, T2, FLAIR, DWI, SWI, contrast-enhanced. DWI detects acute ischemia within minutes.

MRI Contrast

- Substance enhancing image visibility. See [contrast agent](#).

MRI Joint

- Evaluation of musculoskeletal structures: cartilage, ligaments, tendons, menisci, labrum. Knee: ACL,

meniscus tears. Shoulder: rotator cuff, labrum. Hip: labral tears, FAI.

MRI Sequences

- T1-weighted: anatomy, fat bright. T2-weighted: pathology, fluid bright. FLAIR: suppresses CSF, lesions bright. DWI: restricted diffusion bright (acute stroke, abscess). STIR: fat suppression, fluid bright. Post-contrast T1: enhancement bright.

Myelography

- Contrast injected into subarachnoid space for spinal imaging. Used when MRI contraindicated. CT myelography more common now.

Myocardial Perfusion Imaging

- Nuclear medicine imaging of heart muscle blood flow. Stress-rest protocol. Detects ischemia and infarction.

Nephrogenic Systemic Fibrosis

- See [gadolinium-induced nephrogenic systemic fibrosis](#).

Nerve Conduction Studies

- Measurement of nerve conduction velocity and amplitude. Used for peripheral neuropathy, entrapment neuropathies.

Neuroendocrine Tumor

- Tumor from neuroendocrine cells. CT, PET diagnosis. Octreotide scan useful.

Neurography

- MRI technique visualizing peripheral nerves. Used for nerve tumors, entrapment, trauma.

Nodule

- Small lung mass detected on imaging. Solitary pulmonary nodule evaluation: size, morphology, growth rate, PET avidity.

Nuclear Medicine

- A medical specialty that uses small amounts of radioactive substances (radiotracers) to diagnose, stage, and treat various diseases, including cancer and heart disease.

Nuclear Stress Test

- Myocardial perfusion imaging during stress. Detects coronary artery disease.

Obstetric Ultrasound

- Ultrasound imaging during pregnancy. First

trimester: dating, viability. Second trimester: anatomy survey. Third trimester: growth, position.

Octreoscan

- Nuclear medicine imaging using In-111 octreotide. Detects neuroendocrine tumors.

PACS

- Picture Archiving and Communication System. Digital image storage and retrieval.

Pancreatic Cancer

- Aggressive malignancy with pancreatic ductal adenocarcinoma accounting for approximately eighty-five percent of cases. See oncology.

Pancreatic Mass

- Abnormality in pancreas detected on imaging. Pancreatic adenocarcinoma most common malignancy. Neuroendocrine tumors also important.

Pancreatic Trauma

- Pancreatic injury from trauma. CT diagnosis. May require surgery.

Pancreatitis

- Inflammation of pancreas. CT diagnosis. Edematous vs. necrotizing.

Pancreatography

- Contrast imaging of pancreatic duct. ERCP approach. Evaluates pancreatic duct abnormalities.

Partial Volume Artifact

- CT artifact from voxel containing multiple tissues. Reduced by thinner slices.

Patient Communication

- Exchange of information between provider and patient. See [clinical communication](#).

Percutaneous Biopsy

- Biopsy performed under imaging guidance. See [image-guided biopsy](#).

Percutaneous Drainage

- Image-guided drainage of fluid collections. See [drainage procedures](#).

Perfusion Imaging

- Imaging tissue blood flow. CT perfusion, MR perfusion, PET perfusion. Used for stroke, tumor characterization.

PET Tracers

- 18F-FDG: glucose metabolism (cancer, infection,

inflammation). 18F-fluoride: bone turnover. 11C-metionine: protein synthesis. 68Ga-DOTATATE: somatostatin receptors. 68Ga-PSMA: prostate cancer.

PET/CT

- Combined PET and CT imaging. See [nuclear medicine](#).

PET/MRI

- Combined PET and MRI. See [nuclear medicine](#).

pH Monitoring

- Measurement of esophageal pH. Evaluates gastroesophageal reflux disease.

Pharmacological Stress Test

- Stress testing using medications (dobutamine, adenosine, regadenoson). For patients unable to exercise.

Phlebography

- Contrast imaging of veins. Evaluates deep vein thrombosis, venous obstruction. Largely replaced by Doppler ultrasound.

PI-RADS

- Prostate Imaging-Reporting and Data System. Standardizes multiparametric MRI reporting for prostate cancer detection and staging.

Pleural Effusion

- Fluid in pleural space detected on imaging. Chest X-ray, ultrasound, CT. Transudative vs. exudative.

Pneumography

- Contrast imaging of body cavities. Pneumoencephalography obsolete. Pneumoperitoneum for laparoscopy.

Pneumothorax

- Air in pleural space detected on imaging. Chest X-ray, ultrasound, CT. Tension pneumothorax emergency.

Polysomnography

- Sleep study measuring brain activity, breathing, oxygen saturation, muscle activity. Diagnoses sleep apnea, parasomnias.

Positron Emission Mammography (PEM)

- PET imaging of breast. Higher sensitivity than mammography for dense breasts. Limited availabil-

ity.

Positron Emission Tomography (PET)

- Functional imaging using positron-emitting radio-tracers. FDG-PET most common. Metabolic activity visualized. Combined with CT (PET/CT) for anatomical correlation. Used in oncology, neurology, cardiology.

Prostate Cancer

- Common cancer in men. See [oncology](#).

Proton Therapy

- Radiation using protons instead of photons. Bragg peak allows precise dose delivery. Used for pediatric tumors, skull base tumors.

Pulmonary Angiography

- Contrast imaging of pulmonary arteries. Gold standard for pulmonary embolism diagnosis. Largely replaced by CTPA.

Pulmonary Embolism

- See [emergency medicine](#).

Pyelonephritis

- Kidney infection. CT may show striated nephrogram, perinephric stranding.

Quality Assurance

- Systematic efforts to enhance care. See [quality improvement](#).

Quality Control

- Systematic efforts to enhance care. See [quality improvement](#).

Radiation Biology

- Biological effects of radiation. Deterministic vs. stochastic effects.

Radiation Dose

- Principles: time, distance, shielding. See [radiation safety](#).

Radiation Emergency

- Planning for disasters. See [disaster preparedness](#).

Radiation Monitoring

- Measurement of radiation exposure. Personal dosimeters, area monitors.

Radiation Oncologist

- Physician providing radiation therapy.

Radiation Oncology

- A medical specialty that uses high-energy radiation (such as X-rays or gamma rays) to shrink tumors and destroy cancer cells.

Radiation Physics

- Physics of radiation imaging and therapy.

Radiation Protection

- Principles: time, distance, shielding. See [radiation safety](#).

Radiation Safety

- ALARA principle: As Low As Reasonably Achievable. Time, distance, shielding. Pregnancy screening before imaging. Pediatric considerations: lower doses, alternative imaging when possible.

Radiofrequency Ablation

- Image-guided destruction of tissue. See [ablation therapy](#).

Radiologic Technologist

- Professional performing imaging examinations.

Radiologist

- Physician interpreting imaging studies.

Radiology Report

- Document describing imaging findings and interpretation. Structure: indication, technique, findings, impression. Clear, concise language essential. Critical findings require immediate communication.

Radiopharmaceutical

- Radioactive compound used for diagnostic or therapeutic purposes. See [nuclear medicine](#).

Red Blood Cell Labeling

- Nuclear medicine technique labeling RBCs with Tc-99m. Used for GI bleeding detection, cardiac blood pool imaging.

Renal Abscess

- Collection of pus in kidney. CT diagnosis. May require drainage.

Renal Artery Doppler

- Ultrasound assessing renal artery stenosis. Screening for renovascular hypertension.

Renal Cell Carcinoma

- See [urology](#).

Renal Colic

- Pain from urinary stone. CT diagnosis. Stone

location, size, obstruction assessment.

Renal Mass

- Abnormality in kidney detected on imaging. Solid masses may be renal cell carcinoma. Cystic masses classified by Bosniak system.

Renal Scan

- Nuclear medicine imaging using Tc-99m compounds. Evaluates renal function, obstruction, blood flow. MAG3 for function, DTPA for GFR.

Renal Trauma

- Kidney injury from trauma. CT staging guides management. Grades I-V based on injury severity.

Renography

- Nuclear medicine imaging of kidneys. Evaluates function, obstruction, blood flow.

Renovascular Hypertension

- Hypertension due to renal artery stenosis. Diagnosis: Doppler ultrasound, CTA, MRA, renography. Treatment: angioplasty, stenting, surgery.

Reporting Standards

- Standards for structured reporting. ACR guidelines, BI-RADS, LI-RADS, PI-RADS.

Research

- The systematic investigation and scientific study of new materials, methods, or clinical trials to advance medical knowledge and patient care.

Resolution

- Ability to distinguish small structures. Spatial, temporal, contrast resolution.

Response Assessment

- Evaluation of treatment response. RECIST criteria for solid tumors. PET response criteria for lymphoma.

Reverberation Artifact

- Ultrasound artifact from multiple reflections. Reduced by changing angle, using tissue harmonic imaging.

RIS

- Radiology Information System. Workflow management for radiology department.

Saline Infusion Sonohysterography

- Ultrasound evaluation of uterus using saline contrast. Evaluates intrauterine pathology.

Salpingography

- Contrast imaging of fallopian tubes. Part of hysterosalpingography.

Second Opinion

- Review by another radiologist. Common for difficult cases, cancer staging.

Shadowing Artifact

- Ultrasound artifact from attenuating structures. Enhanced by harmonic imaging.

Sialography

- Contrast imaging of salivary ducts. Evaluates obstruction, stricture, tumors. Rarely performed now.

Signal-to-Noise Ratio

- Measure of image quality. Higher SNR = better image.

Single Photon Emission Computed Tomography (SPECT)

- Nuclear medicine imaging using gamma-emitting radiotracers (99mTc most common). Rotating gamma camera acquires images. Less resolution than PET but more widely available and cheaper. Used for cardiac perfusion, bone scans, brain imaging.

Small Bowel Follow-Through

- Extended upper GI series tracking barium through small bowel.

Small Bowel Series

- X-ray imaging of small intestine using barium. Evaluates Crohn disease, tumors, obstructions.

Spinal Angiography

- Contrast imaging of spinal vessels. Evaluates vascular malformations.

Splenic Rupture

- Traumatic or spontaneous splenic injury. CT diagnosis. May require splenectomy.

Splenomegaly

- Enlarged spleen detected on imaging. Causes: portal hypertension, hematologic disorders, infections, infiltrative diseases.

Standard of Care

- Accepted medical practice for a particular clinical circumstance. See [clinical guideline](#).

Stent Placement

- Image-guided deployment of stent. Vascular, biliary, ureteral, esophageal. Maintains patency.

Stereotactic Biopsy

- Biopsy using stereotactic guidance. Breast, brain, lung.

Stereotactic Radiosurgery

- Single high-dose radiation to small target. Used for brain metastases, AVMs, acoustic neuroma.

Stress Echocardiography

- Echocardiography during exercise or pharmacological stress. Detects coronary artery disease by identifying wall motion abnormalities.

Structured Reporting

- Reporting using standardized templates. Improves consistency, completeness.

Sulfur Colloid Scan

- Nuclear medicine imaging using Tc-99m sulfur colloid. Evaluates liver, spleen, bone marrow, lymph nodes.

Surveillance Imaging

- Repeat imaging to detect recurrence. Protocol varies by cancer type, stage, treatment.

Swallow Study

- X-ray imaging of swallowing using barium. Evaluates dysphagia, aspiration, structural abnormalities.

Synovigraphy

- Contrast imaging of joint cavity. Evaluates synovial pathology.

Technetium-99m

- Most widely used radionuclide in nuclear medicine. See [nuclear medicine](#).

Technique

- Description of imaging protocol in radiology report.

Tele radiology

- Remote interpretation of imaging studies.

Thallium Scan

- Nuclear medicine imaging using Tl-201. Myocardial perfusion, tumor detection. Largely replaced by Tc-99m agents.

Three-Dimensional Ultrasound

- Ultrasound creating 3D images. Used in obstetrics, gynecology.

Thrombectomy

- Image-guided removal of thrombus. Mechanical, pharmacological, or combined. Used for stroke, DVT, PE.

Thyroid Scan

- Nuclear medicine imaging using I-123 or Tc-99m. Evaluates thyroid function and nodules. Hot nodules rarely malignant. Cold nodules require further evaluation.

Transcranial Doppler

- Ultrasound measuring blood flow velocity in cerebral arteries. Used for vasospasm detection, stroke risk assessment.

Tubography

- Contrast imaging of fallopian tubes. Evaluates patency.

Tumor Staging

- See oncology.

Ultrasound

- Real-time imaging using high-frequency sound waves. No ionizing radiation. Useful for abdominal organs, obstetrics, vascular studies, musculoskeletal. Doppler assesses blood flow. Limited by bone and air.

Ultrasound Contrast

- Substance enhancing image visibility. See [contrast agent](#).

Upper Extremity Venous Doppler

- Ultrasound assessing upper extremity DVT. Common in catheter-related thrombosis.

Upper GI Series

- X-ray imaging of esophagus, stomach, duodenum using barium. Evaluates motility, ulcers, masses, strictures.

Urethrography

- Contrast imaging of urethra. Evaluates urethral strictures, trauma, anomalies.

Urolithiasis

- Stone formation in the urinary tract (kidneys, ureters, bladder, urethra). See [urology](#).

Venography

- Contrast imaging of veins. Evaluates deep vein thrombosis, venous obstruction.

Ventilation-Perfusion (V/Q) Scan

- Lung imaging assessing ventilation and perfusion. Mismatch indicates pulmonary embolism. Alternative to CTPA in renal impairment or contrast allergy.

Ventriculography

- Imaging ventricular function. Radionuclide ventriculography (MUGA scan) accurately measures ejection fraction. Cardiac MRI also accurate.

Vertebroplasty

- Percutaneous injection of bone cement into fractured vertebra. Provides pain relief, stabilization.

Videofluoroscopic Swallow Study

- Real-time X-ray imaging of swallowing. Detailed assessment of oropharyngeal phase.

Voiding Cystourethrogram (VCUG)

- Fluoroscopic study of bladder and urethra during voiding. Evaluates vesicoureteral reflux, posterior urethral valves.

White Blood Cell Labeling

- Nuclear medicine technique labeling WBCs with Tc-99m. Used for infection localization.

Windowing

- Adjusting CT image brightness and contrast to optimize visualization of specific tissues. Bone window: wide window width, high level. Soft tissue window: narrow width, mid level. Lung window: wide width, low level.

X-ray (Radiography)

- Projectional imaging using ionizing radiation. Dense structures (bone, contrast) appear white; air appears black. Fast, inexpensive, widely available. Two-dimensional projection of three-dimensional structures. Mammography: specialized breast X-ray for screening.

Xanthogranulomatous Pyelonephritis

- Chronic destructive renal infection with replacement of parenchyma by lipid-laden macrophages. See [urology](#).

Iodinated Contrast Media

- Contrast agents containing iodine used primarily for radiography, CT, angiography, and some fluoro-

scopic procedures. Important risks include immediate hypersensitivity-like reactions, extravasation, thyroid effects, and kidney injury in susceptible patients.

Gadolinium-Based Contrast Agent

- A paramagnetic contrast agent used in MRI to alter tissue signal and improve lesion conspicuity or vascular assessment. Agent selection and dosing consider kidney function, pregnancy, prior reactions, and the rare risk of nephrogenic systemic fibrosis.

Contrast-Associated Acute Kidney Injury (CA-AKI)

- Acute worsening of kidney function occurring after administration of contrast, whether or not contrast is causal. Risk assessment includes baseline kidney function, hemodynamic status, diabetes, nephrotoxins, urgency, and the need to avoid unnecessary contrast exposure.

Magnetic Resonance Safety

- The practices used to prevent injury from the static magnetic field, gradient fields, radiofrequency energy, and implanted or ferromagnetic objects in the MRI environment. Screening must address implants, foreign bodies, devices, pregnancy, burns, hearing protection, and projectile risk.

Ionizing Radiation

- Radiation with enough energy to remove electrons from atoms and create ions, including X-rays, gamma rays, and certain particulate emissions. It can cause deterministic tissue effects at sufficient doses and stochastic cancer risk at lower doses.

ALARA Principle

- Radiation-protection principle requiring exposure to be kept as low as reasonably achievable while obtaining the necessary diagnostic or therapeutic information. Justification, optimization, collimation, shielding, time reduction, and increased distance support ALARA.

Radiopaque

- Describing a material that attenuates X-rays strongly and therefore appears relatively white on a radiograph or CT image. Bone, metal, and some contrast agents are radiopaque.

Radiolucent

- Describing a material that allows relatively greater

passage of X-rays and therefore appears darker on a radiograph or CT image. Air is highly radiolucent; some stones, foreign bodies, and lesions may also be radiolucent.

CT Dose-Length Product (DLP)

- A CT dose metric calculated from the volume CT dose index and scan length. It estimates the total scanner output for an examination and is used for protocol optimization and dose monitoring, not as a direct patient-specific risk estimate.

Magnetic Resonance Angiography (MRA)

- MRI techniques used to depict arteries or veins, with or without contrast. It may evaluate stenosis, aneurysm, dissection, thrombosis, and vascular malformation without ionizing radiation.

Diffusion Restriction

- Reduced movement of water molecules detected by diffusion-sensitive MRI sequences, usually appearing bright on DWI with corresponding low ADC. It may indicate acute ischemia but can also occur with abscess, hypercellular tumor, seizure, and other processes.

Radiologic-Pathologic Correlation

- Integration of imaging findings with gross and microscopic pathology to explain lesion location, extent, tissue composition, and sampling adequacy. It is important for discordant biopsy and imaging results.

Imaging-Guided Biopsy

- Tissue acquisition directed by ultrasound, CT, MRI, or fluoroscopy to target a lesion while avoiding critical structures. The procedure requires appropriate specimen handling, informed consent, bleeding-risk assessment, and post-procedure monitoring.

Image-Guided Drainage

- Placement of a catheter or needle under imaging guidance to evacuate fluid, pus, blood, or bile from a pathologic collection. Indications include abscess, biloma, urinoma, pleural collection, and symptomatic cysts.

Embolization

- Deliberate occlusion of a blood vessel or vascular malformation using materials such as coils, particles, glue, or plugs. It is used to control hemorrhage,

treat aneurysms or malformations, reduce tumor vascularity, or induce organ infarction in selected therapies.

Radiology-Patient Identification

- Verification of the correct patient, examination, body site, indication, pregnancy status when relevant, allergies, renal function, and prior imaging before image acquisition or intervention. It is a core diagnostic and procedural safety step.

Mammogram

- See [Mammography](#).

Abdominal Radiography

- Plain projectional X-ray imaging of the abdomen, sometimes obtained in supine, erect, or decubitus positions. It can demonstrate bowel gas patterns, obstruction, perforation-related free air, abnormal calcification, foreign bodies, and selected urinary or skeletal findings, but cross-sectional imaging is often more sensitive for acute abdominal disease.

Chapter 37

Rehabilitation Medicine

Acute Rehabilitation

- Intensive inpatient rehabilitation (3+ hours therapy/day) for acute conditions: stroke, spinal cord injury, traumatic brain injury, major trauma. Length of stay: 1-4 weeks.

Adaptive Equipment

- Devices that help individuals with disabilities perform daily activities independently. Examples: reachers, dressing sticks, button hooks, ergonomic utensils, grab bars, shower chairs, wheelchairs, walkers, canes. Selection based on individual needs and goals. Occupational therapy assessment recommended.

Adherence

- Patient following treatment plan. Barriers: cost, side effects, complexity, beliefs. Strategies: simplification, education, motivational interviewing.

ADL Training

- Training for activities of daily living: dressing, bathing, grooming, feeding, toileting. Adaptive techniques, equipment.

Agility

- Ability to change direction quickly. Essential for sports, functional mobility.

Amputation

- Surgical removal of body part. Types: partial/complete, above/below knee, transhumeral/transradial. Indications: trauma, vascular disease, malignancy, infection. Rehabilitation: prosthetic fitting, gait training, strength, ADL independence, psychological support. Phantom limb pain common.

Animal-Assisted Therapy

- Use of animals for therapeutic purposes. Reduces stress, improves mood, motivates exercise.

Aquatic Therapy

- Exercise in water using buoyancy, resistance, warmth. See [hydrotherapy](#).

Art Therapy

- Use of art-making for therapeutic purposes. Emotional expression, coping, self-awareness.

Assistive Device Training

- Training for walkers, canes, crutches: fitting, gait patterns, stair negotiation, safety.

Assistive Devices

- Tools enhancing mobility and independence. Categories: mobility (walkers, crutches, canes, wheelchairs), ADL (reachers, dressing aids, adaptive utensils), communication (sign language, communication boards), environmental (retractable showerheads, raised toilet seats). Prescription by PT/OT.

Balance Assessment

- Tests: Berg Balance Scale, Tinetti, timed up and go, Romberg. Identifies fall risk.

Balance Training

- Exercises improving postural stability and preventing falls. Components: static balance, dynamic balance, reactive balance. Techniques: weight shifting, tandem stance, single-leg stance, perturbations, balance boards. Essential for elderly, neurological conditions.

Barthel Index

- Standardized measure of functional independence in activities of daily living (ADL). See [geriatrics](#).

Behavioral Rehabilitation

- Behavioral interventions for chronic conditions: pain management, addiction, adjustment.

Biomechanics

- Study of movement mechanics. Gait analysis, joint

forces, muscle activation. Applied to rehabilitation device design.

Bladder Retraining

- See [urology](#).

Bowel Program

- See [gastroenterology](#).

Cardiac Rehabilitation

- Supervised program for cardiac patients post-MI, PCI, CABG, heart failure. Phases: inpatient (early mobilization), outpatient (supervised exercise, education), maintenance. Components: exercise training, risk factor modification, psychological support, return to work counseling. Reduces mortality, hospitalizations.

Care Coordination

- Coordination of rehabilitation services across settings, providers.

Case Management

- See [geriatrics](#).

Cerebral Palsy

- Non-progressive motor disorder from brain injury before, during, or after birth. Types: spastic (most common), dyskinetic, ataxic, mixed. Symptoms: impaired movement, posture, muscle tone. Associated: intellectual disability, epilepsy, speech/language disorders. Management: multidisciplinary—PT, OT, speech therapy, medications, orthotics, surgery.

Chronic Fatigue Syndrome

- See [myalgic encephalomyelitis](#).

Cognitive Rehabilitation

- See [neurology](#).

Community Rehabilitation

- Rehabilitation services in community settings.

Community Reintegration

- Return to community roles: work, leisure, social. Vocational rehabilitation, accessibility modifications.

Concussion

- Mild traumatic brain injury causing transient neurological dysfunction. Symptoms: headache, confusion, memory problems, dizziness, nausea, sensitivity to light/noise. Management: physical and cognitive rest, gradual return to activity, symptom-

limited exercise. Most recover within 7-10 days.

Constraint-Induced Movement Therapy

- CIMT: restrain unaffected limb, force use of affected limb. Based on neuroplasticity. Effective for stroke hemiparesis.

Contracture Prevention

- Positioning, stretching, splinting, orthotics, serial casting, surgery.

Coordination

- Smooth, efficient movement. Tests: finger-to-nose, heel-to-shin, rapid alternating movements.

COPD Rehabilitation

- Comprehensive intervention for COPD patients including exercise training, education, behavior change. Components: aerobic exercise, strength training, breathing techniques, nutrition, psychosocial support. Improves exercise capacity, quality of life, reduces hospitalizations.

Disability Evaluation

- Assessment of functional limitations for legal, insurance, or benefits purposes. Objective measures, standardized tests.

Discharge Planning

- Planning for post-hospitalization care. Early identification of needs, arrangements.

Driving Evaluation

- Assess driving fitness after neurological, musculoskeletal conditions. On-road testing, vehicle modifications.

Driving Rehabilitation

- Training for adaptive driving: hand controls, left-foot accelerator, other modifications.

Dysphagia Rehabilitation

–

Early Intervention

- Rehabilitation for infants, toddlers with developmental delays or disabilities.

Electrical Stimulation

- TENS, NMES for pain, muscle re-education, spasticity.

Electromyography

- EMG: measurement of muscle electrical activity.

Used for diagnosis, biofeedback, device control.

End-Stage Renal Disease

- The final stage of chronic kidney disease (CKD stage 5), defined by GFR <15 mL/min/1.73 m² or the need for renal replacement therapy. See nephrology.

Endurance

- Aerobic capacity, muscular endurance. Cardiorespiratory fitness testing.

Ergonomics

- Design for human use. Workstation setup, tool design, injury prevention.

Evidence-Based Practice

- Integration of best research evidence, clinical expertise, patient values. Rehabilitation guidelines based on systematic reviews.

Fall Prevention

- See [geriatrics](#).

Family Involvement

- Family support crucial for rehabilitation success. Training family as therapists, addressing caregiver burden.

Flexibility

- Tissue extensibility. Stretching programs improve flexibility.

Follow-Up

- Post-rehabilitation follow-up. Monitor progress, adjust treatment, prevent complications.

Force Plates

- Measure ground reaction forces during gait. Assess balance, symmetry, loading.

Functional Independence Measure

- FIM: standardized assessment of disability. Scores 18 (total assistance) to 7 (independent). 18 items: self-care, sphincter control, transfers, locomotion, communication, social cognition.

Gait Training

- Teaching or retraining walking pattern. Techniques: parallel bars, walker, cane, stair training. Addresses abnormalities: limping, antalgic gait, hemiplegic gait, parkinsonian gait. Goals: safety, efficiency, independence.

Geriatric Rehabilitation

- See [geriatrics](#).

Goal Setting

- SMART goals: Specific, Measurable, Achievable, Relevant, Time-bound. Patient-centered goals improve adherence.

Health Literacy

- Patient ability to understand health information. Teach-back method, plain language.

Hippotherapy

- Therapeutic horseback riding for neurological, musculoskeletal conditions. Improves balance, posture, coordination.

Home Health Rehabilitation

- Therapy provided at home. For patients unable to travel. Home exercise program emphasized.

Home Rehabilitation

- Therapy provided at home. See [home health rehabilitation](#).

Hospice Rehabilitation

- Rehabilitation in hospice setting. Symptom management, positioning, caregiver education.

Hydrotherapy

- Exercise in water using buoyancy, resistance, warmth. Benefits: reduced weight-bearing, improved circulation, pain relief, increased range of motion. Used for arthritis, spinal cord injury, amputation, neurological conditions.

IADL Training

- Training for instrumental ADLs: cooking, cleaning, shopping, managing medications, finances.

ICF Framework

- International Classification of Functioning, Disability and Health. Biopsychosocial model: body functions/structures, activities, participation, environmental factors, personal factors.

Inpatient Rehabilitation

- Intensive inpatient rehabilitation (3+ hours therapy/day) for acute conditions: stroke, spinal cord injury, traumatic brain injury, major trauma. See [acute rehabilitation](#).

Integrative Rehabilitation

- Combination of conventional and complementary

therapies: acupuncture, massage, yoga, meditation.

Intensive Care Rehabilitation

- Early rehabilitation in ICU setting. Early mobilization, positioning, passive range of motion. Improves outcomes, reduces complications.

Isokinetic Exercise

- Muscle contraction at constant speed throughout range of motion. Uses specialized equipment. Assesses and improves strength.

Job Modification

- Adjust job duties, equipment, schedule for disability.

Joint Replacement Rehabilitation

- See [orthopedics](#).

Katz Index

- Assessment of ADLs: bathing, dressing, toileting, transferring, continence, feeding.

Kinesio Taping

- See physical therapy.

Kinesiology

- Study of human movement. Applied to rehabilitation, sports, ergonomics.

Language Therapy

- See speech-language pathology.

Lawton IADL Scale

- Instrumental ADLs: phone use, shopping, food preparation, housekeeping, laundry, transportation, medication management, finance management.

Light Therapy

- Phototherapy for skin conditions, seasonal affective disorder, jaundice.

Long-Term Rehabilitation

- Chronic condition management. Focus on maintaining function, preventing complications.

Lymphedema Management

- See [geriatrics](#).

Magnetic Therapy

- PEMF for bone healing, pain. Evidence mixed.

Mirror Therapy

- Mirror reflection of unaffected limb movement creates visual illusion of affected limb moving. Reduces phantom limb pain, improves stroke recovery.

Motion Analysis

- Assessment of movement patterns. 3D gait analysis, video analysis. Identifies abnormalities, guides treatment.

Rehabilitation Motivation

- Patient factors that influence participation in rehabilitation, including intrinsic and extrinsic motivation and engagement with therapeutic goals.

Multidisciplinary Team

- Rehabilitation team includes: physiatrist, physical therapist, occupational therapist, speech-language pathologist, psychologist, social worker, case manager, nursing, recreation therapist.

Music Therapy

- Use of music for therapeutic purposes. Pain reduction, emotional expression, cognitive stimulation.

Myalgic Encephalomyelitis/Chronic Fatigue Syndrome

- ME/CFS: debilitating condition characterized by profound fatigue, post-exertional malaise, unrefreshing sleep, cognitive impairment. Diagnosis: exclusion. Treatment: pacing, symptom management, graded exercise therapy controversial.

Neurological Rehabilitation

- Rehabilitation for stroke, spinal cord injury, traumatic brain injury, Parkinson disease, multiple sclerosis. Goals: maximize function, independence, quality of life. Multidisciplinary team: physiatrist, PT, OT, speech therapy, psychology.

Neuroplasticity

- Brain's ability to reorganize by forming new neural connections. Basis for rehabilitation after neurological injury. Use-dependent plasticity: repetitive practice drives recovery.

Occupational Rehabilitation

- See [occupational medicine](#).

Occupational Therapy

- OT helps patients perform daily activities (ADLs, IADLs) through therapeutic activities, adaptive equipment, environmental modification. Focus on upper extremity function, cognition, sensory integration.

Occupational Therapy Assessment

- OT helps patients perform daily activities (ADLs, IADLs) through therapeutic activities, adaptive equipment, environmental modification. See [occupational therapy](#).

Oncology Rehabilitation

- Cancer rehabilitation: fatigue, pain, neuropathy, lymphedema, functional impairment. Pre- and post-treatment support.

Orthopedic Rehabilitation

- See [orthopedics](#).

Orthotic Training

- Training for brace users: donning/doffing, skin care, gait training with brace.

Outcome Measurement

- Standardized tools: FIM, Barthel, MRC, ASIA (spinal cord), NIHSS (stroke), etc. Track progress, adjust treatment.

Outcome Research

- Study of rehabilitation outcomes. Effectiveness, cost-effectiveness, patient-reported outcomes.

Outpatient Rehabilitation

- Therapy sessions 2-3 times per week. For conditions requiring ongoing therapy: post-surgical, chronic pain, neurological conditions.

Pain Management

- Multimodal pain management: medications, physical modalities, cognitive-behavioral therapy, intervention.

Palliative Rehabilitation

- Rehabilitation for patients with terminal illness. Focus on comfort, function, quality of life.

Patient Education

- Teach patient and family about condition, exercises, equipment, prevention. Improves adherence, outcomes.

Patient-Centered Care

- Care respecting patient preferences, needs, values. Shared decision-making.

Pediatric Rehabilitation

- Rehabilitation for children with congenital or acquired disabilities. Developmental considerations, family-centered care, school collaboration.

Physiatrist

- Physician specialty focusing on function, quality of life for patients with impairment, disability. See [rehabilitation medicine](#).

Physical Therapy Assessment

- Comprehensive evaluation: history, observation, ROM, strength, sensation, coordination, balance, gait, functional tasks.

Post-Surgical Rehabilitation

- Recovery program after surgery. Phases: acute (pain control, wound care), subacute (range of motion, strengthening), functional (return to activities). Protocols vary by procedure.

Pressure Ulcer Prevention

- See [geriatrics](#).

Prosthesis

- Artificial replacement for missing body part. Types: upper extremity, lower extremity. Components: socket, suspension, joint, pylon, terminal device. Fitting: certified prosthetist. Training: physical therapy.

Prosthetic Training

- Training for amputees: stump care, donning/doffing, gait training, balance, stair negotiation, community ambulation.

Psychological Support

- Counseling, therapy for patients with chronic illness, disability, pain. Address depression, anxiety, adjustment difficulties, coping strategies.

Psychosocial Rehabilitation

- Support for mental illness recovery: skills training, supported employment, peer support.

Pulmonary Rehabilitation

- See [pulmonology](#).

Quality Improvement

- Continuous improvement of rehabilitation services.

Quality of Life

- Perception of well-being including physical, psychological, social, spiritual domains. See [geriatrics](#).

Range of Motion

- ROM: joint movement capacity. Goniometer measurement. Restrictions from contracture, pain, swelling.

Reaction Time

- Time from stimulus to response. Declines with age, neurological disease.

Recreational Therapy

- Use of recreation for therapeutic purposes. Improves quality of life, socialization, coping.

Rehabilitation Clinic

- Outpatient rehabilitation facility.

Rehabilitation Engineering

- Technology development for disability: prosthetics, orthotics, assistive devices, environmental control.

Rehabilitation Hospital

- Inpatient facility specializing in rehabilitation.

Rehabilitation Medicine

- Physician specialty focusing on function, quality of life for patients with impairment, disability. Also called physiatry.

Rehabilitation Unit

- Hospital ward dedicated to rehabilitation.

Respiratory Rehabilitation

- See pulmonology.

Robot-Assisted Rehabilitation

- Robotic devices for repetitive task training. Upper extremity, lower extremity, gait training. Objective measurement, high repetition.

School-Based Rehabilitation

- Rehabilitation services in schools for children.

Self-Efficacy

- Patient belief in ability to manage condition. Influences adherence, outcomes.

Self-Management

- Patient managing own condition. Education, skills, support.

Sexual Rehabilitation

- Address sexual function after injury, illness. Counseling, devices, medications.

Spasticity Management

- See neurology.

Speech Therapy

- See speech-language pathology.

Speech-Language Pathology

Assessment

- Evaluate communication, swallowing, cognition. Standardized tests, clinical observation.

Spinal Cord Injury

- Spinal cord injury: ASIA impairment scale (A-E). See neurology.

Sports Rehabilitation

- See sports medicine.

Strength Testing

- Manual muscle testing, dynamometry, isokinetic testing. Quantifies weakness, tracks progress.

Subacute Rehabilitation

- Less intensive than acute rehab. For patients needing continued therapy but not as intensive. Skilled nursing facility setting.

Swallowing Therapy

- See speech-language pathology.

Tele-Rehabilitation

- Remote rehabilitation via technology. Video consultations, remote monitoring, home exercise programs. Increases access, especially rural.

Therapeutic Alliance

- Collaboration between therapist and patient. Foundation for successful rehabilitation.

Therapeutic Exercise

- Exercise prescribed to improve function, reduce pain, prevent disability. Types: stretching, strengthening, aerobic, balance, functional. Progression: low to high intensity.

Thermal Therapy

- Heat and cold therapy. Heat: relax muscles, increase circulation. Cold: reduce inflammation, pain.

Transfer Training

- Teaching safe transfer techniques: bed to chair, chair to toilet, floor to standing. Use of transfer boards, lift equipment.

Transition to Adulthood

- Support for youth with disabilities transitioning to adult services.

Transitional Care

- See [geriatrics](#).

Ultrasound Therapy

- Therapeutic ultrasound for tissue healing, pain,

scar tissue.

Urinary Retraining

- See [urology](#).

Vestibular Rehabilitation

- See [neurology](#).

Virtual Reality

- Immersive technology for rehabilitation. Engaging, motivates exercise. Used for balance, coordination, cognitive training.

Walking Speed

- Gait speed: important functional marker. <0.8 m/s indicates disability risk.

Wheelchair

- Mobility device for patients with walking difficulties. Types: manual, power. Components: seat, backrest, wheels, footrests, armrests. Assessment: seating evaluation, pressure relief, posture. Training: mobility, transfers, safety.

Wheelchair Skills

- Training for wheelchair users: propulsion, maneuvering, obstacles, slopes, stairs, transfers.

Activities of Daily Living (ADLs)

- Basic self-care activities such as bathing, dressing, toileting, eating, grooming, and transferring. ADL performance is a core measure of independence and rehabilitation need.

Instrumental Activities of Daily Living (IADLs)

- More complex activities required for independent community living, including medication management, shopping, cooking, finances, communication, transportation, and household tasks.

Functional Capacity

- The maximum level of physical, cognitive, communication, or self-care performance a person can safely achieve under specified conditions. It is assessed in relation to activities, participation, environment, and personal goals.

Rehabilitation Potential

- The expected capacity to improve function, independence, participation, or quality of life through rehabilitation. It depends on diagnosis, prognosis, cognition, motivation, comorbidity, social support, and environmental resources.

Goal Attainment Scaling

- An individualized outcome method in which patient-specific goals are defined with graded levels of expected attainment and scored after intervention. It captures meaningful changes that standardized measures may miss.

Patient-Reported Outcome Measure (PROM)

- A validated questionnaire completed directly by a patient to assess symptoms, function, health status, or quality of life without clinician interpretation of the response.

Motor Learning

- A relatively lasting change in the ability to perform a motor skill resulting from practice, experience, feedback, and adaptation. Rehabilitation uses task-specific repetition and meaningful practice to promote motor learning.

Energy Conservation

- Strategies that reduce unnecessary energy expenditure and fatigue during daily activities, such as pacing, prioritizing, planning, positioning, and using adaptive equipment.

Pacing

- Planned regulation of activity, rest, and intensity to avoid symptom exacerbation while gradually increasing tolerance. It is used in fatigue, chronic pain, cardiopulmonary disease, and post-viral conditions.

Orthosis

- An externally applied device that supports, aligns, prevents deformity, protects, or assists movement of a body segment. It differs from a prosthesis, which replaces a missing body part.

Residual Limb

- The portion of a limb remaining after amputation. Care includes edema control, skin inspection, shaping, strengthening, desensitization, contracture prevention, and prosthetic preparation.

Wheelchair Seating and Positioning

- Assessment and configuration of a wheelchair, cushion, supports, and posture to optimize stability, propulsion, comfort, function, pressure distribution, and prevention of musculoskeletal deformity.

Pressure Injury

- Localized damage to skin and underlying tissue, usually over a bony prominence, caused by pressure or pressure combined with shear. Prevention requires risk assessment, repositioning, skin care, nutrition, and pressure redistribution.

Contracture

- Permanent or semi-permanent limitation of passive joint range of motion caused by shortening or structural change in muscle, tendon, capsule, fascia, skin, or other periarticular tissue. Prevention and treatment depend on cause and stage.

Spasticity

- A velocity-dependent increase in muscle tone caused by hyperexcitability of the stretch reflex after an upper motor-neuron lesion. It may impair movement, hygiene, positioning, comfort, gait, and function.

Functional Electrical Stimulation (FES)

- Application of electrical impulses to peripheral nerves or muscles to produce purposeful contraction during a functional task, such as foot clearance during gait or cycling after neurologic injury.

Chapter 38

Rheumatology

Achilles Tendinopathy

- Degeneration/inflammation of Achilles tendon. Symptoms: posterior heel pain, thickening, stiffness. Risk factors: running, improper footwear, tight calf muscles. Treatment: eccentric exercises, heel raises, orthotics, shockwave therapy, surgery if refractory.

Adult-Onset Still Disease

- AOSD: a rare systemic autoinflammatory disorder characterized by daily high-spiking fevers, evanescent salmon-pink rash, arthritis/arthralgia, sore throat, lymphadenopathy, hepatosplenomegaly, and markedly elevated ferritin (with low glycosylated ferritin), ESR/CRP. Complications: macrophage activation syndrome, pericarditis, DIC. Diagnosis: Yamaguchi criteria; exclude infection, malignancy, other rheumatic disease. Management: NSAIDs, corticosteroids (first-line for moderate-severe), methotrexate, IL-1 inhibitors (anakinra, canakinumab), IL-6 inhibitor (tocilizumab), and TNF inhibitors.

ANCA-Associated Vasculitis

- A group of small-vessel vasculitides associated with antineutrophil cytoplasmic antibodies. Includes granulomatosis with polyangiitis (c-ANCA/PR3), microscopic polyangiitis (p-ANCA/MPO), and eosinophilic granulomatosis with polyangiitis (p-ANCA/MPO with asthma/eosinophilia). Treatment: glucocorticoids plus rituximab or cyclophosphamide for induction, rituximab or azathioprine for maintenance.

Ankylosing Spondylitis

- A chronic inflammatory disease primarily affecting the axial skeleton, causing fusion of vertebrae (bamboo spine) and sacroiliitis. Associated with HLA-B27 in 90

Anterior Cruciate Ligament Tear

- ACL tear: common knee injury, often non-contact pivoting sports. Symptoms: popping sound, swelling, instability, inability to continue play. Diagnosis: Lachman test, anterior drawer, MRI. Treatment: surgical reconstruction (autograft/allograft), rehabilitation.

Anterior/Posterior Drawer Test

- Knee ligament testing. Anterior (ACL), posterior (PCL). **Anti-CCP**
 - Anti-cyclic citrullinated peptide antibody: an autoantibody against citrullinated proteins, highly specific (90-95 percent) for rheumatoid arthritis and predictive of erosive disease. Positive anti-CCP is a key component of ACR/EULAR RA classification; may be present years before clinical onset. Used with rheumatoid factor; anti-CCP-positive, RF-negative and vice versa occur. Useful in early/inflammatory arthritis to identify patients needing aggressive DMARD therapy. Does not correlate directly with disease activity over time.

Antinuclear Antibody

- ANA: autoantibodies against nuclear components (DNA, histones, ribonucleoproteins, etc.), detected by immunofluorescence (HEp-2 cells), reported with pattern (homogeneous, speckled, nucleolar, centromere) and titer. ANA is a screening test for systemic autoimmune disease: high positive in SLE (99 percent), also in drug-induced lupus, Sjogren, scleroderma, MCTD, RA, and in healthy individuals (low titers). Positive ANA requires specific antibody testing based on pattern/suspicion (anti-dsDNA, anti-Smith—SLE; anti-SSA/SSB—Sjogren; anti-Scl-70, centromere—scleroderma; anti-RNP—MCTD). ANA is not diagnostic alone.

Antiphospholipid Antibodies

- Include lupus anticoagulant (prolongs phospholipid-dependent coagulation tests), anticardiolipin antibodies (IgG/IgM), and anti-beta-2-glycoprotein I antibodies. Detected on ≥ 2 occasions 12 weeks apart. Clinical criteria: vascular thrombosis or pregnancy morbidity. Can be transient (infection, drugs) or persistent.

Antiphospholipid Syndrome

- A thrombophilic disorder with arterial/venous thrombosis and/or pregnancy morbidity, with persistent antiphospholipid antibodies (lupus anticoagulant, anticardiolipin, anti-beta-2-glycoprotein I). Can be primary or secondary to SLE. Management: anticoagulation with warfarin (target INR 2-3 for venous thrombosis, 2-3 or 3-4 for arterial); antiplatelet therapy for pregnancy.

Antisynthetase Syndrome

- Defined by the presence of anti-aminoacyl-tRNA synthetase antibodies (anti-Jo-1 most common, 75

Aphthous Ulcer

- Recurrent, painful, round or oval ulcers of the oral mucosa, commonly called canker sores. See dentistry.

Arthritis

- Inflammation of one or more joints, characterized by joint pain, swelling, warmth, and stiffness. Arthritis is classified into several major categories: osteoarthritis (degenerative, the most common form, characterized by articular cartilage loss, subchondral sclerosis, and osteophyte formation, typically affecting weight-bearing joints such as knees, hips, and spine as well as hands); rheumatoid arthritis (autoimmune, symmetric polyarthritis affecting small joints of hands and feet with pannus formation causing marginal erosions and periarticular osteopenia); spondyloarthritis (including ankylosing spondylitis, psoriatic arthritis, reactive arthritis, and enteropathic arthritis, typically presenting with inflammatory back pain, asymmetric oligoarthritis, enthesitis, and association with HLA-B27); crystal arthropathies (gout and calcium pyrophosphate deposition disease); septic arthritis (bacterial infection of the joint, a medical emergency requiring urgent drainage and antibiotics); and other arthritides associated with connective tissue diseases, infection,

or haemochromatosis.

Autoimmune Hepatitis

- Chronic hepatitis caused by immune-mediated destruction of hepatocytes characterized by interface hepatitis with lymphoplasmacytic infiltrate, elevated transaminases, hypergammaglobulinemia, and autoantibodies. See [gastroenterology](#).

Avascular Necrosis

- See vascular surgery. Osteonecrosis of bone due to interrupted blood supply. Common sites: femoral head, humeral head, talus. Risk factors: steroids, alcohol, trauma, sickle cell, SLE. Treatment: core decompression, joint replacement.

Baker Cyst

- Popliteal cyst behind knee, often associated with knee pathology (OA, meniscal tear, RA). May rupture causing calf pain/swelling (pseudothrombophlebitis). Diagnosis: ultrasound/MRI. Treatment: treat underlying condition, aspiration if symptomatic.

Bankart Lesion

- Injury to inferior glenohumeral ligament/labrum from shoulder dislocation. Associated with recurrent instability. Treatment: surgical repair (arthroscopic/open).

Bechterew Disease

- Historical eponym for ankylosing spondylitis (also known as Marie-Strümpell disease), describing the chronic inflammatory arthritis of the axial skeleton first reported by Vladimir Bekhterev (Russian, 1892) and Adolf Strümpell (German, 1884). Characterized by inflammatory back pain, sacroiliitis, syndesmophyte formation, eventual "bamboo spine" with ankylosis, and association with HLA-B27 in approximately 90% of cases. Modern usage prefers ankylosing spondylitis / axial spondyloarthritis; "Bechterew disease" remains in some European (Russian, German) medical literature. See [Ankylosing Spondylitis](#).

Biologic Therapy

- Treatment with biologic agents targeting specific immune pathways, used in autoimmune and inflammatory disease. Types: TNF inhibitors (infliximab, etanercept, adalimumab), IL-6 inhibitors (tocilizumab), IL-1 inhibitors (anakinra), IL-17/IL-

23 inhibitors (secukinumab, ustekinumab), B-cell depletion (rituximab), T-cell costimulation blockade (abatacept), JAK inhibitors (tofacitinib—small molecule), and others. Indications: rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, SLE, vasculitis, IBD, psoriasis. Benefits: targeted efficacy with steroid-sparing. Risks: infection (TB, opportunistic), malignancy (rare), immunogenicity (anti-drug antibodies), and injection reactions. Requires screening and monitoring.

Bursitis

– Inflammation of the bursa (fluid-filled sac reducing friction between tissues). Common sites: subacromial (shoulder), olecranon (elbow), prepatellar (knee), trochanteric (hip). Causes: repetitive stress, trauma, infection, crystal deposition (gout, pseudogout), autoimmune disease. Treatment: rest, ice, NSAIDs, corticosteroid injection, aspiration if septic.

Calcium Pyrophosphate Deposition Disease

– A crystal arthropathy caused by deposition of calcium pyrophosphate dihydrate crystals in articular cartilage (chondrocalcinosis). Presents with acute pseudogout (most common): acute monoarticular inflammation of the knee or wrist, mimicking gout but less painful. Chronic CPPD: degenerative arthritis-like with OA pattern (knee, wrist, MCP joints). Pseudo-rheumatoid: symmetric polyarticular inflammation. Associated with aging, OA, hemochromatosis, hyperparathyroidism, hypomagnesemia, hypothyroidism. Diagnosis: joint aspiration shows weakly positively birefringent rhomboid crystals. Treatment: NSAIDs, colchicine, intra-articular corticosteroids for acute flares; low-dose colchicine for prophylaxis.

Carpal Tunnel Syndrome

– Median nerve compression at wrist. Symptoms: numbness/tingling in thumb, index, middle, radial half of ring finger. Night symptoms common. Diagnosis: clinical, nerve conduction studies. Treatment: splinting, corticosteroid injection, surgical decompression.

Chondrocalcinosis

– Calcification of cartilage visible on X-ray. Associated with CPPD disease. Found in knees, wrists, pu-

bic symphysis. May be incidental or symptomatic.

Chronic Fatigue Syndrome

– ME/CFS: debilitating condition characterized by severe fatigue lasting >6 months, post-exertional malaise, unrefreshing sleep, cognitive impairment, orthostatic intolerance. Diagnosis: clinical, exclude other causes. Treatment: symptom management, pacing, graded exercise therapy controversial.

Collateral Ligament Injury

– MCL (medial) or LCL (lateral) knee ligament injury. MCL more common, often from valgus stress. Treatment: braces, physical therapy, surgical repair if severe.

Complex Regional Pain Syndrome

– CRPS: chronic pain condition, usually after trauma/surgery. Type I (no nerve injury), Type II (nerve injury). Symptoms: pain disproportionate to injury, allodynia, swelling, color/temperature changes, decreased range of motion. Treatment: physical therapy, medications (bisphosphonates, gabapentin, corticosteroids), sympathetic blocks.

Connective Tissue Disease

– Autoimmune diseases affecting connective tissue. Examples: SLE, scleroderma, RA, Sjogren syndrome, mixed connective tissue disease. Overlap syndromes common.

CREST Syndrome

– Limited cutaneous form of systemic sclerosis (scleroderma), characterized by the eponymic features: Calcinosis cutis (multiple subcutaneous calcium deposits, often in extremities — can cause pain, inflammation, ulceration), Raynaud phenomenon (usually long-standing; often precedes other features by years), Esophageal dysmotility (lower two-thirds smooth muscle, causes dysphagia, reflux, strictures), Sclerodactyly (thickening and tightening of skin distal to MCP joints — fingers become tapered, immobile), Telangiectasias (mat-like, on face, lips, palms, finger pads). Anti-centromere antibodies (anti-CENP-B) positive in 70-80% of cases (highly specific for limited scleroderma; less specific in diffuse disease — anti-Scl-70 (anti-topoisomerase I) is more associated with diffuse). Clinical course: relatively indolent compared with diffuse systemic sclerosis (skin thickening limited to distal extremities and face, lung involvement later and slower;

pulmonary arterial hypertension (PAH) in 10-15%), unlike diffuse disease where early ILD and renal crisis predominate. Diagnosis: ACR/EULAR 2013 classification (skin thickening of fingers extending proximal to MCP joints suffices); nailfold capillaroscopy; antibody testing. Management: Raynaud — calcium channel blockers (amlodipine, nifedipine), phosphodiesterase type 5 inhibitors (sildenafil), prostacyclin analogs, digital sympathectomy for severe digital ischemia; PPI for reflux; vasodilator therapy for PAH (bosentan, ambrisentan, macitentan, sildenafil, riociguat); immunosuppression generally limited in limited cutaneous SSc; periodic surveillance echocardiography, PFTs, ECG.

Cryopyrin-Associated Periodic Syndromes

– Autosomal dominant autoinflammatory disorders (NLRP3 mutations, gain-of-function) causing constitutive inflammasome activation and IL-1 β overproduction. Spectrum: familial cold autoinflammatory syndrome (FCAS, cold-induced urticaria, fever, conjunctivitis), Muckle-Wells syndrome (MWS, progressive sensorineural hearing loss, amyloidosis risk), neonatal-onset multisystem inflammatory disease (NOMID/CINCA, severe CNS involvement, bony overgrowth, chronic meningitis, cognitive impairment). Diagnosis is clinical with genetic confirmation. Treatment: IL-1 inhibitors (anakinra, canakinumab, rilonacept) are dramatically effective, suppressing inflammation and preventing disease progression.

Crystal Arthropathy

– Joint disease caused by crystal deposition. Gout (monosodium urate) and pseudogout (calcium pyrophosphate). Diagnosis by joint aspiration and polarized microscopy.

Cubital Tunnel Syndrome

– Ulnar nerve compression at elbow. Symptoms: numbness/tingling in little finger, medial hand. Elbow flexion exacerbates. Treatment: elbow padding, splinting, surgical decompression/transposition.

Dactylitis

– Inflammation of an entire digit (finger or toe), producing a diffuse, fusiform swelling often described as sausage-shaped. Most commonly associated with psoriatic arthritis and reactive arthritis (enthesitis-

related), but also occurs in sickle cell disease (hand-foot syndrome in young children, caused by dactylitis from vaso-occlusive crises in the small bones of the hands and feet) and tuberculous dactylitis (spina ventosa—bony expansion from granulomatous infection). Diagnosis based on clinical appearance and underlying condition.

De Quervain Tenosynovitis

– Tenosynovitis of first dorsal compartment tendons (abductor pollicis longus, extensor pollicis brevis). Finkelstein test positive. Treatment: splinting, corticosteroid injection, surgical release.

Dermatomyositis

– An inflammatory myopathy with characteristic skin manifestations: Gottron papules (over knuckles), heliotrope rash (purple periorbital), shawl/V sign erythema, and proximal muscle weakness; associated with interstitial lung disease, and in adults an increased risk of malignancy (ovary, lung, GI). Antibodies: anti-Mi-2, anti-Jo-1 (antisynthetase with ILD, mechanic's hands), anti-MDA5 (rapidly progressive ILD). Diagnosis: elevated CK, EMG, muscle biopsy (perifascicular atrophy), skin biopsy, MRI. Management: corticosteroids, methotrexate/azathioprine, IVIG, rituximab; cancer screening at diagnosis. Juvenile dermatomyositis variant in children.

Drug-Induced Autoimmunity

– Drug-induced lupus (DIL): procainamide, hydralazine, isoniazid, minocycline, TNF inhibitors, anti-TNF; anti-histone antibodies, positive ANA, negative anti-dsDNA/anti-Smith; symptoms resolve after drug cessation. Drug-induced ANCA vasculitis: propylthiouracil, hydralazine, minocycline, allopurinol; MPO-ANCA positive, pauci-immune GN, pulmonary hemorrhage. Drug-induced subacute cutaneous lupus: hydrochlorothiazide, calcium channel blockers, TNF inhibitors; anti-Ro/SSA positive, annular/papulosquamous photosensitive rash. Diagnosis is clinical with drug history and serology. Management is withdrawal of the offending drug with supportive care; symptoms typically resolve over weeks to months.

Dupuytren Contracture

– Progressive fibrosis of palmar fascia causing flexion contracture of fingers (ring, little). More common in

men, Northern European descent, diabetes, epilepsy. Treatment: observation, collagenase injection, fasciectomy, needle aponeurotomy.

Ehlers-Danlos Syndrome

- Group of connective tissue disorders affecting collagen. Types: hypermobile, classical, vascular, arthrochalasic, kyphoscoliotic, dermatosparaxis. Features: joint hypermobility, skin hyperextensibility, tissue fragility. Vascular type: arterial/intestinal/uterine rupture risk. Diagnosis: clinical criteria, genetic testing. Management: multidisciplinary, avoid contact sports, genetic counseling.

Enteropathic Arthritis

- Spondyloarthritis associated with inflammatory bowel disease (Crohn disease, ulcerative colitis), affecting 10-20

Enthesitis

- Inflammation at the site where a tendon, ligament, or joint capsule inserts into bone (enthesitis), a hallmark of spondyloarthritis (ankylosing spondylitis, psoriatic arthritis, reactive arthritis, IBD-associated). Affects Achilles tendon, plantar fascia, patellar, and costochondral junctions. Features: localized pain and tenderness at insertion sites, morning stiffness, sometimes swelling; plantar fasciitis and Achilles enthesitis are common. Diagnosis: clinical, ultrasound/MRI (enthesal thickening, vascularity, erosions). Management: NSAIDs, physiotherapy, and in spondyloarthritis—biologics (TNF inhibitors, IL-17 inhibitors) for refractory enthesitis.

Eosinophilic Granulomatosis with Polyangiitis

- EGPA (formerly Churg-Strauss syndrome): an ANCA-associated vasculitis characterized by asthma, peripheral and tissue eosinophilia, and necrotizing vasculitis. Features: late-onset asthma, allergic rhinitis, eosinophilic pneumonia, mononeuritis multiplex, skin lesions, cardiac involvement (myocarditis—major cause of death), and glomerulonephritis (less common); p-ANCA (anti-MPO) in 40-50 percent. Diagnosis: clinical, eosinophilia (>10 percent/1500), biopsy (eosinophilic vasculitis), ANCA. Management: corticosteroids (mainstay), cyclophosphamide or rituximab for severe/organ-threatening; treat asthma and eosinophilia; relapse common.

Erythrocyte Sedimentation Rate

- ESR: a nonspecific inflammatory marker measuring the rate of red blood cell sedimentation in a vertical tube over 1 hour (mm/h), elevated by inflammation, infection, malignancy, and anemia. Extremely elevated (>100 mm/h): myeloma, giant cell arteritis/polymyalgia rheumatica, infection, SLE, malignancy. Used with CRP to monitor inflammation (RA, GCA) and in diagnosis (temporal arteritis). Affected by age, sex, anemia (increases), polycythemia (decreases), fibrinogen, and pregnancy. Not specific—combination with clinical findings and CRP is standard.

Familial Mediterranean Fever

- An autosomal recessive autoinflammatory disorder (MEFV gene mutations, pyrin/inflammasome dysregulation) causing recurrent self-limited febrile attacks with serositis (peritonitis, pleuritis, synovitis), erysipelas-like erythema, lasting 12-72 hours. Predominantly affects Mediterranean populations (Armenians, Turks, Arabs, Sephardic Jews). Complication: AA amyloidosis (renal, hepatic, splenic) from chronic inflammation if untreated. Diagnosis: Tel-Hashomer criteria: major (typical attacks with peritonitis, pleuritis, synovitis, or erysipelas-like erythema) plus minor (incomplete attacks). Treatment: colchicine is highly effective for preventing attacks and AA amyloidosis; IL-1 inhibitors (anakinra, canakinumab) for colchicine-resistant cases.

Fasciitis

- Inflammation of fascia. Examples: plantar fasciitis (heel pain), eosinophilic fasciitis (Shulman disease—skin thickening, eosinophilia). Treatment: NSAIDs, corticosteroids, physical therapy.

Felty Syndrome

- Triad of rheumatoid arthritis, splenomegaly, and neutropenia (ANC <2000). Complication of longstanding, severe, seropositive RA. Increased infection risk. Treatment: DMARDs (methotrexate, TNF inhibitors), G-CSF for neutropenia, splenectomy in refractory cases.

Fibromyalgia

- A chronic centralized pain syndrome characterized by widespread musculoskeletal pain (>3 months), fatigue, sleep disturbance, cognitive dysfunction (fibro fog), and somatic symptoms, affecting 2-4

Finkelstein Test

- Wrist deviation test for De Quervain tenosynovitis. Pain over radial styloid.

Frozen Shoulder

- Adhesive capsulitis: progressive shoulder pain and stiffness. Stages: freezing (pain), frozen (stiffness), thawing (recovery). Associated with diabetes, thyroid disease, immobilization. Treatment: physical therapy, corticosteroid injection, manipulation under anesthesia, arthroscopic capsular release.

Giant Cell Arteritis

- A large-vessel vasculitis of adults >50 (peak 70-80) affecting cranial branches of carotid arteries, with risk of permanent vision loss from anterior ischemic optic neuropathy. Clinical: new-onset headache (temporal), scalp tenderness, jaw claudication, visual disturbances (amaurosis fugax, diplopia), polymyalgia rheumatica symptoms. Diagnosis: temporal artery biopsy (gold standard, skip lesions reduce sensitivity), ultrasound (halo sign), PET-CT (large-vessel involvement (aorta, subclavian). Treatment: high-dose glucocorticoids (prednisolone 40-60 mg/day) promptly to prevent blindness; tocilizumab (IL-6 inhibitor) as steroid-sparing agent; low-dose aspirin for thromboprophylaxis. Methotrexate, azathioprine as alternatives.

Gout

- A crystal deposition disease caused by monosodium urate (MSU) crystal formation in joints and tissues due to chronic hyperuricemia (serum urate >6.8 mg/dL). Pathophysiology: urate overproduction (10

Granulomatosis with Polyangiitis

- GPA (formerly Wegener granulomatosis): an ANCA-associated small-vessel necrotizing vasculitis affecting the upper and lower respiratory tract and kidneys. Features: sinonasal disease (crusting, epistaxis, saddle-nose deformity), pulmonary nodules/cavitation, alveolar hemorrhage, glomerulonephritis (RPGN), and constitutional symptoms; c-ANCA (anti-PR3) positive in most. Diagnosis: clinical, ANCA serology, biopsy (necrotizing granulomas, vasculitis). Management: induction with rituximab or cyclophosphamide + high-dose corticosteroids, then maintenance (rituximab, azathioprine); treat renal failure aggressively; relapses re-

quire re-treatment. Untreated: rapidly fatal.

Henoch-Schonlein Purpura

- IgA vasculitis: palpable purpura on buttocks/legs, abdominal pain, arthralgia, renal involvement (IgA nephropathy), most common in children. Self-limited in most cases; corticosteroids for severe GI/renal involvement.

Hill-Sachs Lesion

- Impaction fracture of posterolateral humeral head from anterior shoulder dislocation. Associated with Bankart lesion.

HLA-B27

- Human leukocyte antigen B27, a class I MHC molecule strongly associated with spondyloarthropathies. Present in 90

Hydroxychloroquine

- An antimalarial DMARD used in SLE (first-line for skin/joint/mild disease, reduces flares and improves survival), rheumatoid arthritis, and antiphospholipid syndrome. Mechanisms: interference with antigen processing, Toll-like receptor inhibition, immunomodulation. Well tolerated; side effects: GI upset, rash, retinal toxicity (cumulative dose-related—require ophthalmologic screening), cardiomyopathy (rare), and myopathy. Monitor for retinopathy annually after 5 years or risk factors. Generally safe in pregnancy. Avoid with QT-prolonging drugs and in G6PD deficiency.

IgG4-Related Disease

- A fibro-inflammatory condition characterized by tumefactive lesions in multiple organs, dense lymphoplasmacytic infiltrate with >10 IgG4+ plasma cells/HPF and IgG4+/IgG+ ratio >40

Iliotibial Band Syndrome

- Lateral knee pain from IT band friction over lateral femoral epicondyle. Common in runners. Treatment: rest, stretching, strengthening, biomechanical correction.

Immune-Mediated Necrotizing Myopathy

- A subacute severe proximal myopathy with very high CK (often >10,000), minimal inflammation on biopsy, necrotic fibers. Two major autoantibodies: anti-HMGCR (3-hydroxy-3-methylglutaryl-CoA reductase, statin-associated or spontaneous) and anti-

SRP (signal recognition particle). Anti-HMGCR: older, statin exposure, severe; anti-SRP: younger, more cardiac/respiratory involvement, worse prognosis. Treatment: high-dose glucocorticoids + rituximab or IVIG as first-line; additional immunosuppressants (methotrexate, azathioprine, mycophenolate) and physical therapy for rehabilitation.

Inclusion Body Myositis

- The most common acquired myopathy after age 50, characterized by asymmetric distal and proximal weakness (finger flexors, quadriceps), rimmed vacuoles, 15-18 nm tubulofilaments, TDP-43 pathology, endomysial inflammation with CD8+ T cells invading non-necrotic fibers. Refractory to immunotherapy. Clinical: dysphagia (40

Interferonopathies

- Type I interferonopathies: Aicardi-Goutieres syndrome (TREX1, RNASEH2, SAMHD1 mutations, neonatal encephalopathy, calcifications, chilblains, SLE-like); STING-associated vasculopathy with onset in infancy (SAVI, TMEM173 mutations, severe interstitial lung disease, digital ischemia); Proteasome-associated autoinflammatory syndromes (PRAAS, PSMB8 mutations, CANDLE syndrome: lipodystrophy, fever, skin lesions, joint contractures). Treatment: JAK inhibitors (baricitinib, ruxolitinib) target IFN signalling. Baricitinib approved for SAVI and CANDLE. hematopoietic stem cell transplantation in severe Aicardi-Goutieres syndrome.

Janus Kinase Inhibitors

- JAK inhibitors (tofacitinib, baricitinib, upadacitinib, filgotinib, abrocitinib) block JAK-STAT signaling downstream of cytokine receptors (IL-6, IFN-gamma, IL-2, IL-7, IL-15, IL-21, GM-CSF, erythropoietin, thrombopoietin). Selectivity: JAK1/JAK3 (tofacitinib), JAK1/JAK2 (baricitinib), JAK1 (upadacitinib, filgotinib, abrocitinib). Indications: RA, PsA, axial SpA, UC, AD, alopecia areata. Safety: herpes zoster (vaccinate Shingrix before), VTE (risk factors: age, obesity, prior VTE), infections, lipid elevation, transaminitis, neutropenia, anemia, GI perforation. Drug interactions: CYP3A4 (tofacitinib, upadacitinib). Dose adjustment for renal impairment.

Juvenile Arthritis

- The most common chronic rheumatic disease of childhood (onset <16 years), encompassing 7 subtypes: systemic JIA (Still disease of childhood, quotidian fever, salmon rash, arthritis, hepatosplenomegaly, serositis, macrophage activation syndrome risk), oligoarticular JIA (4 or fewer joints in first 6 months, high risk of chronic anterior uveitis, ANA positive), polyarticular JIA (5 or more joints, RF-negative or RF-positive), psoriatic JIA (arthritis + psoriasis), enthesitis-related JIA (HLA-B27, male > female, enthesitis, acute uveitis), and undifferentiated JIA. See [juvenile idiopathic arthritis](#).

Juvenile Dermatomyositis

- Juvenile dermatomyositis (JDM) presents with proximal weakness, heliotrope rash, Gottron papules, calcinosis (20-30

Juvenile Idiopathic Arthritis

- The most common chronic rheumatic disease of childhood (onset <16 years), encompassing 7 subtypes: systemic JIA (Still disease of childhood, quotidian fever, salmon rash, arthritis, hepatosplenomegaly, serositis, macrophage activation syndrome risk), oligoarticular JIA (4 or fewer joints in first 6 months, high risk of chronic anterior uveitis, ANA positive), polyarticular JIA (5 or more joints, RF-negative or RF-positive), psoriatic JIA (arthritis + psoriasis), enthesitis-related JIA (HLA-B27, male > female, enthesitis, acute uveitis), and undifferentiated JIA. Treatment: NSAIDs, intra-articular corticosteroids, methotrexate, TNF inhibitors, IL-6 inhibitors (tocilizumab), IL-1 inhibitors (anakinra) for systemic JIA. Uveitis screening essential (ANA-positive, oligoarticular).

Kawasaki Disease

- Acute febrile vasculitis of childhood (peak 6 months-5 years), affecting medium-sized arteries, especially coronary arteries. Criteria: fever ≥ 5 days plus 4 of 5: conjunctival injection, oral changes (strawberry tongue, cracked lips), cervical lymphadenopathy (>1.5 cm), polymorphous rash, extremity changes (erythema/edema of hands/feet, periungual desquamation). Treatment: IVIG (2 g/kg single infusion) + high-dose aspirin within 10 days of fever onset reduces coronary aneurysm risk from 25

Lachman Test

- ACL integrity test. Knee 20-30 degrees flexed, anterior drawer. Positive = ACL tear.

Latarjet Procedure

- Surgical procedure for shoulder instability using coracoid process transfer. Provides bony block to prevent recurrent dislocation.

Lupus Erythematosus (Systemic Lupus Erythematosus - SLE)

- A chronic multisystem autoimmune disease predominantly affecting women (9:1 female:male) of childbearing age, characterized by autoantibody production (ANA 98)

Lupus Nephritis

- Renal involvement in SLE, classified into 6 classes by ISN/RPS: Class I (minimal mesangial), II (mesangial proliferative), III (focal proliferative, <50

Macrophage Activation Syndrome

- A life-threatening complication of rheumatic diseases (especially systemic JIA and SLE) characterized by uncontrolled cytokine release and hemophagocytosis. Criteria: fever, splenomegaly, cytopenias (≥ 2 lineages), hypertriglyceridemia or hypofibrinogenemia, hyperferritinemia (>684 mcg/L), elevated soluble CD25, low/absent NK cell activity. Treatment: high-dose corticosteroids, etoposide, anakinra, cyclosporine.

Marfan Syndrome

- Autosomal dominant connective tissue disorder (fibrillin-1 mutation). Features: tall stature, long limbs, arachnodactyly, pectus deformity, lens subluxation, aortic root dilation, mitral valve prolapse. Diagnosis: Ghent criteria. Management: beta-blockers, ARBs, elective aortic repair, regular cardiac monitoring.

McMurray Test

- Meniscal tear test. Knee flexed, rotated, extended. Click/pain indicates tear.

Meniscal Tear

- Tear of knee meniscus. Types: longitudinal, radial, flap, bucket handle, horizontal. Symptoms: knee pain, swelling, catching, locking. Diagnosis: clinical (McMurray, Thessaly), MRI. Treatment: conservative, arthroscopic partial meniscectomy, meniscal repair.

Microscopic Polyangiitis

- A necrotizing vasculitis affecting small blood vessels (capillaries, venules, arterioles) with few or no immune deposits (pauci-immune). Part of the ANCA-associated vasculitis group. Strongly associated with MPO-ANCA (p-ANCA, 80

Mixed Connective Tissue Disease

- An overlap syndrome with features of systemic lupus erythematosus, systemic sclerosis, and polymyositis/dermatomyositis. Highly associated with anti-U1 RNP antibodies. Presents with Raynaud phenomenon (nearly universal), puffy hands, arthritis, myositis, esophageal dysmotility, and serositis. Renal disease is less common than in SLE. Diagnosis: clinical + anti-U1 RNP positivity without sufficient criteria for other CTDs. Treatment: hydroxychloroquine, corticosteroids, and immunosuppressants (mycophenolate, methotrexate). Prognosis varies with predominant disease manifestation.

Myositis

- Inflammation of skeletal muscle. Includes polymyositis, dermatomyositis, inclusion body myositis, immune-mediated necrotizing myopathy. Diagnosis: CK elevation, EMG, muscle MRI, muscle biopsy. Treatment: immunosuppression with corticosteroids, methotrexate, azathioprine, mycophenolate, IVIG, rituximab.

Nonsteroidal Anti-Inflammatory Drug

- NSAID: drugs inhibiting cyclooxygenase (COX-1/COX-2), reducing prostaglandin synthesis—anti-inflammatory, analgesic, antipyretic. Types: non-selective (ibuprofen, naproxen, diclofenac, indomethacin, ketorolac) and COX-2 selective (celecoxib, etoricoxib). Uses: arthritis, musculoskeletal pain, gout, dysmenorrhea, postoperative pain. Adverse effects: GI ulceration/bleeding (reduce with PPI, COX-2), renal impairment (reduced GFR), cardiovascular risk (hypertension, fluid retention, increased MI risk—especially diclofenac), and asthma exacerbation. Avoid in renal disease, heart failure, GI bleeding, and late pregnancy; caution with anticoagulants. Use lowest effective dose/shortest duration.

Osgood-Schlatter Disease

- Traction apophysitis of tibial tubercle in adolescents. Pain/swelling at knee. Self-limiting, resolves with skeletal maturity. Treatment: rest, ice, NSAIDs.

Osteoarthritis

- The most common joint disease, characterized by progressive cartilage loss, subchondral bone sclerosis, osteophyte formation, and synovial inflammation, affecting knees, hips, hands (DIP/PIP Heberden/Bouchard nodes), spine. Risk factors: age, obesity, joint injury, malalignment, genetics, female sex. Clinical: activity-related pain, brief morning stiffness (<30 min), crepitus, bony enlargement, functional limitation. Diagnosis: clinical + radiographic (joint space narrowing, osteophytes, subchondral sclerosis, cysts). Management: non-pharmacological (weight loss, exercise, physiotherapy, joint protection), pharmacological (paracetamol, NSAIDs topical/oral, intra-articular corticosteroids, hyaluronic acid injections), and surgical (joint replacement) for end-stage disease.

Osteogenesis Imperfecta

- Hereditary disorder of collagen type I, causing brittle bones. Types I-VIII. Features: recurrent fractures, blue sclerae, hearing loss, dentinogenesis imperfecta, short stature. Diagnosis: clinical, genetic testing. Management: bisphosphonates, orthopedic surgery, physical therapy.

Osteomalacia

- Softening of bones due to defective mineralization, usually from vitamin D deficiency. Adults; rickets in children. Features: bone pain, muscle weakness, fractures. Diagnosis: low calcium/phosphate, high alkaline phosphatase, low vitamin D, radiographic changes (Looser zones). Treatment: vitamin D supplementation, calcium.

Osteomyelitis

- Bone infection, usually bacterial (*Staphylococcus aureus*). Acute: fever, pain, swelling. Chronic: sinus tracts, sequestrum, involucrum. Diagnosis: MRI, bone scan, biopsy. Treatment: antibiotics (prolonged), surgical debridement.

Osteonecrosis (Avascular Necrosis)

- Osteonecrosis (AVN) is bone death from vascular

compromise, affecting femoral head (most common), humeral head, femoral condyles, talus. Risk factors: glucocorticoids (high dose, cumulative), alcohol, trauma, sickle cell disease, SLE, antiphospholipid syndrome, pancreatitis, decompression sickness, radiation, organ transplantation. ARCO classification: stage 0 (normal X-ray, MRI+), I (normal X-ray, MRI+), II (crescent sign), III (subchondral collapse), IV (joint space narrowing, OA). Treatment: core decompression for early stages, osteotomy, and joint replacement for advanced collapse. Bisphosphonates may reduce risk in high-dose glucocorticoid therapy.

Overlap Myositis

- Patients with features of inflammatory myopathy (DM/PM/IMNM) plus another systemic autoimmune disease (SLE, SSc, MCTD, Sjogren). Anti-PM-Scl (Scl/PM overlap, limited SSc + myositis, good prognosis); anti-Ku (SLE/PM overlap); anti-U1-RNP (MCTD with myositis). Treatment: tailored to predominant organ involvement; often requires combination immunosuppression.

Paget Disease of Bone

- Chronic bone disorder with excessive bone breakdown and formation, leading to enlarged/deformed bones. Features: bone pain, deformity, fractures, hearing loss (skull involvement), high alkaline phosphatase. Diagnosis: radiographic (cotton wool skull, flame-shaped lytic lesions), bone scan. Treatment: bisphosphonates (alendronate, zoledronic acid), calcitonin.

Palindromic Rheumatism

- Characterized by recurrent, self-limited attacks of mono- or oligoarthritis (hours to days), periarticular soft tissue swelling, no radiographic erosions between attacks. 30-50

Patellofemoral Pain Syndrome

- Anterior knee pain from patellar maltracking. Common in runners, cyclists. Symptoms: pain with stairs, squatting, prolonged sitting. Treatment: quadriceps strengthening, patellar taping, orthotics.

Phalen Test

- Wrist flexion test for carpal tunnel syndrome. Symptoms reproduced within 60 seconds.

Piriformis Syndrome

- Sciatic nerve compression by piriformis muscle. Buttock pain, radiating down leg. Diagnosis: clinical, exclude disc herniation. Treatment: stretching, injection, surgical release.

Plantar Fasciitis

- Inflammation of plantar fascia causing heel pain, worse with first steps in morning. Risk factors: obesity, tight calf muscles, prolonged standing. Treatment: stretching, orthotics, night splints, corticosteroid injection, shockwave therapy, surgery if refractory.

Polyarteritis Nodosa

- Necrotizing inflammation of medium-sized muscular arteries, spares lungs. Associated with hepatitis B (10-30)

Polymyalgia Rheumatica

- An inflammatory syndrome of older adults (age >50, peak 70-80) causing bilateral shoulder and pelvic girdle pain and stiffness lasting >45 minutes, with elevated inflammatory markers (ESR >40, CRP elevated). Strongly associated with giant cell arteritis (15-20)

Polymyositis

- An idiopathic inflammatory myopathy characterized by symmetric, proximal muscle weakness (shoulders, hips) with elevated muscle enzymes (CK, aldolase, LDH). More common in women, peaks at 30-50 years. Diagnosis: EMG (myopathic units with fibrillations), muscle MRI (edema), and muscle biopsy (CD8+ T cell infiltration of MHC-I expressing muscle fibers). Autoantibodies: anti-Jo-1 (antisynthetase syndrome with interstitial lung disease, arthritis, mechanic's hands). Treatment: high-dose corticosteroids, methotrexate, azathioprine, mycophenolate, and IVIG for refractory disease.

Posterior Cruciate Ligament Tear

- PCL tear: less common, usually from direct blow to tibia (dashboard injury). Symptoms: knee pain, swelling, instability. Diagnosis: posterior drawer test, MRI. Treatment: usually conservative, surgical if combined injuries.

Posterior Drawer Test

- PCL integrity test. Knee flexed 90 degrees, posterior tibial translation.

Pseudogout

- Calcium pyrophosphate deposition disease (CPPD): deposition of calcium pyrophosphate dihydrate crystals in joints, causing acute arthritis resembling gout (pseudogout) or chronic osteoarthritis-like disease. Affects knees, wrists, and metacarpophalangeal joints; associated with aging, hemochromatosis, hyperparathyroidism, hypomagnesemia, hypothyroidism. Acute attacks: swelling, pain, effusion with weakly positively birefringent (rhomboid) crystals on polarized microscopy, chondrocalcinosis on X-ray. Management: NSAIDs, colchicine, intra-articular corticosteroids for acute; treat associated metabolic disease. Distinguish from gout (monosodium urate, negatively birefringent).

Psoriatic Arthritis

- An inflammatory arthritis associated with psoriasis (precedes arthritis in 70)

Pyoderma Gangrenosum

- A neutrophilic dermatosis causing rapidly expanding, painful ulcers with violaceous undermined borders, pathergy phenomenon. Associated with IBD (50)

Raynaud Syndrome

- A vasospastic disorder causing episodic digital color changes (white -> blue -> red) triggered by cold or stress, due to exaggerated vasoconstriction of digital arteries. Primary Raynaud: benign, symmetric, in young women, no underlying disease. Secondary Raynaud: associated with scleroderma, SLE, mixed connective tissue disease, vasculitis, and cryoglobulins—often asymmetric, severe, with digital ulcers/gangrene. Diagnosis: clinical; nailfold capillaroscopy and autoantibody testing to detect secondary causes. Management: avoid cold, smoking cessation, calcium channel blockers (nifedipine), prostacyclin analogs (iloprost) for severe; treat underlying disease; avoid sympathomimetics.

Reactive Arthritis

- A post-infectious spondyloarthritis occurring 1-4 weeks after genitourinary (Chlamydia trachomatis) or gastrointestinal (Salmonella, Shigella, Campylobacter, Yersinia) infection. Classic triad (Reiter syndrome): arthritis, conjunctivitis/uveitis, urethritis/cervicitis (only 1/3 have full triad). HLA-B27 positive in 60-80

Remitting Seronegative Symmetrical Synovitis with Pitting Edema

- RS3PE: an acute-onset, symmetric polyarthritides (usually in elderly) with pitting edema of the hands/feet, negative rheumatoid factor and anti-CCP, and marked response to low-dose corticosteroids. Distinct from RA—tends to be severe but responds dramatically to steroids and often remits; some cases progress to RA or other rheumatic disease (polymyalgia rheumatica, spondyloarthritis, or paraneoplastic). Features: symmetric tenosynovitis of wrist/hands with edema. Management: corticosteroids (rapid response), NSAIDs; assess for underlying malignancy or connective tissue disease.

Rheumatoid Arthritis

- A chronic, symmetric, erosive inflammatory polyarthritis primarily affecting small joints of the hands and feet, with a female-to-male ratio of 3:1 and peak onset 40-60 years. Pathogenesis involves genetic susceptibility (HLA-DRB1 shared epitope), environmental triggers (smoking, periodontal disease), and immune dysregulation (citruination of proteins, anti-CCP antibody production, rheumatoid factor, cytokine-driven synovial inflammation with TNF, IL-6, IL-1). Clinical: symmetric small joint polyarthritis (MCP, PIP, MTP), morning stiffness >1 hour, rheumatoid nodules, extra-articular manifestations (Sjogren, interstitial lung disease, pericarditis, vasculitis, Felty syndrome). Diagnosis: 2010 ACR/EULAR criteria: joint involvement (0-5), serology (RF and anti-CCP, 0-3), acute phase reactants (0-1), symptom duration (0-1). Treatment: treat-to-target strategy with methotrexate as anchor DMARD, plus short-term glucocorticoids; early use of TNF inhibitors, IL-6 inhibitors (tocilizumab), abatacept, JAK inhibitors (tofacitinib, baricitinib, upadacitinib) for inadequate response; rituximab for seropositive disease. Intensive disease management reduces joint damage and disability.

Rheumatoid Factor

- RF: an autoantibody (usually IgM) directed against the Fc portion of IgG, positive in 70-80 percent of rheumatoid arthritis (seropositive RA) but also in other conditions: Sjogren, SLE, chronic infection (TB, endocarditis, hepatitis C), cryoglobulinemia, sarcoidosis, and healthy elderly. High titers cor-

relate with more severe, erosive RA. Used with anti-CCP (more specific for RA) for diagnosis and classification (ACR/EULAR criteria). Serial monitoring not generally recommended. Negative RF does not exclude RA (seronegative RA).

Rickets

- See osteomalacia. Pediatric form with growth plate changes, bowing of legs, craniotabes, rachitic rosary.

Sarcoidosis

- A multisystem granulomatous disorder of unknown etiology characterized by non-caseating granulomas, predominantly affecting lungs (90

Scleroderma

- Systemic sclerosis: an autoimmune connective tissue disease of skin and internal organs due to fibrosis, vasculopathy, and autoantibodies. Limited cutaneous (CREST—calcinosis, Raynaud, esophageal dysmotility, sclerodactyly, telangiectasia) and diffuse cutaneous forms. Features: skin thickening (sclerodactyly, skin tightness), Raynaud phenomenon, digital ulcers, pulmonary fibrosis, pulmonary hypertension, renal crisis (hypertension, renal failure—emergency), GI dysmotility. Diagnosis: clinical, ANA, anti-Scl-70 (diffuse), anti-centromere (limited), anti-RNA polymerase III. Management: immunosuppression (mycophenolate, methotrexate, cyclophosphamide), vasodilators (pulmonary hypertension—endothelin antagonists, PDE5 inhibitors), ACE inhibitors for renal crisis, symptom control.

Septic Arthritis

- Joint infection, usually bacterial (Staph, Strep, Gonorrhea). Emergency: fever, severe joint pain, swelling, inability to bear weight. Diagnosis: joint aspiration (WBC >50,000, positive culture). Treatment: antibiotics, joint drainage (arthroscopy/open).

Seronegative Arthritis

- Arthritis with negative rheumatoid factor and anti-CCP. Includes spondyloarthropathies, psoriatic arthritis, reactive arthritis.

Sever Disease

- Calcaneal apophysitis in children/adolescents. Heel pain, worse with activity. Treatment: rest, heel cups, stretching.

Shoulder Impingement

- Compression of rotator cuff tendons beneath acromion. Symptoms: shoulder pain with overhead activity, weakness. Diagnosis: clinical (Neer, Hawkins tests), ultrasound/MRI. Treatment: physical therapy, corticosteroid injection, surgical decompression.

Sicca Syndrome

- Dry eyes and dry mouth due to decreased tear and saliva production. Primary: Sjogren syndrome. Secondary: associated with RA, SLE, scleroderma, graft-versus-host disease, hepatitis C, sarcoidosis, HIV, medications (anticholinergics, antidepressants). Diagnosis: Schirmer test (<5 mm/5 min), rose bengal staining, salivary gland biopsy. Treatment: artificial tears, pilocarpine, cevimeline, dental care.

Sinding-Larsen-Johansson Syndrome

- Traction apophysitis of inferior patellar pole in adolescents. Similar to Osgood-Schlatter but at knee. Treatment: rest, activity modification.

Sjogren Syndrome

- Primary Sjogren syndrome (pSS) is a chronic autoimmune exocrinopathy characterized by lymphocytic infiltration of lacrimal and salivary glands causing dry eyes (keratoconjunctivitis sicca) and dry mouth (xerostomia), with female predominance (9:1) and peak onset 40-60. Secondary SS occurs with RA, SLE, SSc. 2016 ACR/EULAR criteria: anti-Ro/SSA positive (3 points) OR focal lymphocytic sialadenitis with focus score ≥ 1 (3 points) OR ocular staining score ≥ 5 (1 point) OR Schirmer test ≤ 5 mm/5 min (1 point). Treatment: symptomatic (artificial tears, saliva substitutes, pilocarpine, cevimeline); systemic immunosuppression (hydroxychloroquine, methotrexate, azathioprine, mycophenolate, rituximab) for extraglandular manifestations (arthritis, ILD, vasculitis, nephritis, neuropathy). Lymphoma risk (3-5 percent, MALT in parotid) requires long-term surveillance.

SLAP Lesion

- Superior labrum anterior to posterior tear. Associated with overhead activities, trauma. Treatment: rest, physical therapy, surgical repair if symptomatic.

Snapping Hip Syndrome

- Hip pain/clicking from tendon snapping over bony prominence. Internal (iliopsoas), external (IT band), intra-articular (labral tear). Treatment: physical therapy, injection, surgery if refractory.

Soft Tissue Rheumatism

- Pain conditions affecting muscles, tendons, ligaments, bursae. Examples: frozen shoulder, lateral epicondylitis, rotator cuff tendinopathy. Treatment: rest, physiotherapy, injections, surgery if refractory.

Spondyloarthritis

- Group of inflammatory arthritis associated with HLA-B27. Includes ankylosing spondylitis, psoriatic arthritis, reactive arthritis, enteropathic arthritis. Features: axial involvement, enthesitis, dactylitis.

Sulfasalazine

- A DMARD combining sulfapyridine and 5-aminosalicylic acid, used in rheumatoid arthritis, psoriatic arthritis, and inflammatory bowel disease (ulcerative colitis). Slows disease progression in RA; onset over 1-3 months. Adverse effects: GI upset, rash, headache, myelosuppression (monitor CBC), hepatotoxicity, male infertility (reversible), and sulfa allergy. Contraindicated in sulfonamide allergy and G6PD deficiency; use folate supplementation. Useful in combination DMARD therapy and for patients intolerant to methotrexate.

Sweet Syndrome

- Sweet syndrome (acute febrile neutrophilic dermatosis) presents with fever, neutrophilia, and tender erythematous plaques/nodules with dense dermal neutrophilic infiltrate. Classical (idiopathic), malignancy-associated (AML, solid tumors), drug-induced (G-CSF, granulocyte colony-stimulating factor). Associated with VEXAS syndrome. Treatment: systemic corticosteroids (rapid response); colchicine, dapsone, indomethacin as steroid-sparing; treat underlying malignancy.

Synovitis

- Inflammation of the synovial membrane lining a joint, causing swelling, pain, warmth, and joint effusion. Causes: inflammatory arthritis (RA, psoriatic, gout, reactive, septic), autoimmune (SLE), and trauma/overuse. Diagnosis: clinical (joint swelling, effusion), ultrasound (synovial hypertro-

phy, Doppler signal), MRI, and joint aspiration for septic vs. crystal arthritis (gout—urate crystals, pseudogout—CPPD). Chronic synovitis causes cartilage and bone destruction. Management: treat underlying cause—NSAIDs, corticosteroids, DMARDs/biologics for inflammatory arthritis, antibiotics for septic arthritis (emergency—urgent aspiration and antibiotics), and intra-articular steroid injection.

Systemic Juvenile Idiopathic Arthritis

– sJIA: a subtype of juvenile idiopathic arthritis with prominent systemic inflammation—daily spiking fevers, evanescent salmon-pink rash, arthritis, lymphadenopathy, hepatosplenomegaly, and elevated inflammatory markers (ferritin). Complications: macrophage activation syndrome (MAS—emergency with cytopenias, coagulopathy, very high ferritin), growth impairment, uveitis. Diagnosis: clinical; exclude infection/malignancy. Management: NSAIDs, corticosteroids, methotrexate, IL-1 inhibitors (anakinra, canakinumab), IL-6 inhibitor (tocilizumab); early aggressive treatment improves outcomes.

Systemic Lupus Erythematosus

– Multisystem autoimmune disease, more common in women. Features: malar rash, photosensitivity, oral ulcers, arthritis, serositis, renal disorder, neurologic disorder, hematologic disorder, immunologic disorder. Diagnosis: ANA positive plus clinical/immunologic criteria. Treatment: hydroxychloroquine, corticosteroids, immunosuppressants (mycophenolate, cyclophosphamide, azathioprine), biologics (belimumab, anifrolumab).

Systemic Sclerosis

– Systemic sclerosis: an autoimmune connective tissue disease of skin and internal organs due to fibrosis, vasculopathy, and autoantibodies. See [scleroderma](#).

Takayasu Arteritis

– Large-vessel vasculitis affecting the aorta and its major branches, predominantly in young Asian women (<40 years). Early stage: constitutional symptoms, arthralgia. Late stage: pulselessness, blood pressure discrepancy (>10 mmHg between arms), claudication, bruits, hypertension (renal artery stenosis), visual symptoms. Angiogra-

phy shows wall thickening, stenosis, aneurysms. Treatment: corticosteroids, steroid-sparing agents (methotrexate, azathioprine, mycophenolate), TNF inhibitors; angioplasty/stenting for severe stenosis.

Tarsal Tunnel Syndrome

– Tibial nerve compression at ankle. Symptoms: burning pain, tingling in foot sole. Tinel sign at ankle. Treatment: orthotics, corticosteroid injection, surgical decompression.

Tendinitis

– Inflammation of tendon. Common sites: rotator cuff, patellar, Achilles, lateral epicondyle (tennis elbow), medial epicondyle (golfer's elbow). Treatment: rest, ice, NSAIDs, physical therapy, corticosteroid injection, surgery if refractory.

Tendonitis

– Tendinopathy: inflammation or degeneration of a tendon from overuse, repetitive strain, or trauma, causing localized pain, swelling, and tenderness with activity. Common sites: rotator cuff (supraspinatus), lateral elbow (tennis elbow), medial elbow (golfer's elbow), Achilles, patellar (jumper's knee), biceps, and De Quervain. Diagnosis: clinical; ultrasound/MRI for severity or rupture. Management: relative rest, ice, NSAIDs, physiotherapy (eccentric exercises), corticosteroid injection (caution—may weaken tendon), platelet-rich plasma; surgical repair for rupture (e.g., Achilles). Avoid prolonged immobilization; gradual return to activity.

Tenosynovitis

– Inflammation of a tendon and its synovial sheath, causing pain, swelling, and crepitus along the tendon. Causes: overuse/repetitive activity (De Quervain—first dorsal compartment, trigger finger), infection (septic tenosynovitis—emergency, especially flexor sheaths of hand, gonococcal), inflammatory arthritis (RA, psoriatic, gout, reactive arthritis), and trauma. Features: tenderness along tendon, swelling, pain with movement, and in infection: fusiform swelling, pain on passive extension, tenderness along sheath. Diagnosis: clinical; ultrasound/MRI; culture for infection. Management: rest, NSAIDs, splinting, corticosteroid injection, treat underlying disease; surgical drainage for septic tenosynovitis.

Thoracic Outlet Syndrome

- Compression of neurovascular bundle at thoracic outlet. Types: neurogenic (most common), venous, arterial. Symptoms: neck/shoulder/arm pain, paresthesia, weakness, vascular symptoms. Diagnosis: clinical, imaging, nerve conduction. Treatment: physical therapy, surgical decompression.

Tinel Sign

- Tapping over nerve produces tingling in distribution. Indicates nerve irritation/regeneration. Used for carpal tunnel, cubital tunnel, tarsal tunnel.

Tophus

- Deposits of monosodium urate crystals in soft tissues, characteristic of chronic gout. Appear as subcutaneous nodules over joints, ears, olecranon, Achilles tendon. Can erode through skin, forming draining sinus tracts. Radiographically: punched-out erosions with overhanging edges. Treatment with urate-lowering therapy causes tophi to dissolve over months to years.

Trigger Finger

- Stenosing tenosynovitis of flexor tendon, causing locking/catching. Treatment: splinting, corticosteroid injection, surgical release.

Tumor Necrosis Factor Inhibitor

- TNF inhibitor (biologic): monoclonal antibodies/fusion proteins blocking TNF-alpha—infliximab, adalimumab (monoclonals), etanercept (soluble receptor), certolizumab, golimumab. Used in rheumatoid arthritis (after methotrexate failure), ankylosing spondylitis, psoriatic arthritis, psoriasis, IBD (Crohn, UC). Advantages: rapid, effective control of inflammation and joint damage. Risks: infection (tuberculosis—screen before starting, hepatitis B reactivation, fungal), lymphoma (rare), demyelination, heart failure worsening, and injection/infusion reactions. Screening (TB, HBV) and live vaccine avoidance required; contraindicated in active infection.

Valgus/Varus Stress Test

- Collateral ligament integrity. Valgus (MCL), varus (LCL).

Vasculitis

- Inflammation of blood vessels causing tissue ischemia and necrosis. Classification by vessel size.

Large vessel: giant cell arteritis, Takayasu arteritis. Medium vessel: polyarteritis nodosa (PAN), Kawasaki disease. Small vessel: ANCA-associated vasculitis (microscopic polyangiitis, granulomatosis with polyangiitis, eosinophilic granulomatosis with polyangiitis), IgA vasculitis (Henoch-Schonlein purpura), and anti-GBM disease. Diagnosis: clinical presentation, ANCA, ANA, complement, and tissue biopsy. Treatment: corticosteroids and immunosuppressants (cyclophosphamide, rituximab for ANCA-associated).

Vasculitis (Systemic)

- See vasculitis. Large vessel (GCA, Takayasu), medium vessel (PAN, Kawasaki), small vessel (ANCA-associated, IgA vasculitis).

VEXAS Syndrome

- VEXAS (Vacuoles, E1 ubiquitin-activating enzyme, X-linked, Autoinflammatory, Somatic) syndrome is an adult-onset autoinflammatory disorder caused by somatic UBA1 mutations in hematopoietic stem cells, affecting men >50. Clinical: recurrent fever, chondritis (relapsing polychondritis-like), vasculitis (Sweet-like, polyarteritis-like), macrocytic anemia, thrombocytopenia, vacuoles in myeloid/erythroid precursors. High mortality from infections, thrombosis, hematologic progression (MDS, AML). Treatment: high-dose corticosteroids for acute inflammation; JAK inhibitors (ruxolitinib, tofacitinib); azacitidine for MDS; supportive care for cytopenias. hematopoietic stem cell transplantation is the only potential cure.

Synovial Fluid Analysis

- Laboratory examination of aspirated joint fluid for appearance, viscosity, leukocyte count and differential, crystals under polarized light, Gram stain, and culture. It helps distinguish noninflammatory, inflammatory, crystal-associated, and septic arthritis.

Arthrocentesis

- Aspiration of synovial fluid from a joint using a needle for diagnosis or symptom relief. Sterile technique is essential, and suspected septic arthritis requires prompt fluid analysis and culture before or alongside treatment.

C-Reactive Protein (CRP)

- An acute-phase protein synthesized by the liver in response primarily to interleukin-6 and other

inflammatory signals. It is useful for assessing inflammatory activity and response to treatment but is nonspecific and should not be interpreted in isolation.

Treat-to-Target Strategy

- A management approach in which treatment is adjusted at regular intervals toward a predefined goal such as remission or low disease activity. It requires validated disease-activity measures, shared decisions, monitoring, and timely escalation or modification.

Disease-Modifying Antirheumatic Drug (DMARD)

- A medication that reduces inflammatory disease activity and helps prevent structural damage or disability rather than providing only symptomatic relief. Conventional synthetic, biologic, and targeted synthetic DMARDs are used according to disease and patient factors.

Glucocorticoid-Sparing Therapy

- Use of a non-glucocorticoid treatment strategy to control inflammation while reducing cumulative corticosteroid exposure. It aims to limit osteoporosis, infection, diabetes, hypertension, adrenal suppression, and other glucocorticoid complications.

Gout Flare

- An acute inflammatory response to monosodium urate crystal deposition in or around a joint. It commonly causes abrupt severe pain, swelling, warmth, and erythema, often involving the first metatarsophalangeal joint; aspiration can confirm crystals and exclude infection.

Urate-Lowering Therapy

- Long-term treatment that reduces serum urate to dissolve monosodium urate deposits and prevent gout flares and structural damage. Xanthine oxidase inhibitors and uricosuric medicines are selected according to renal function, comorbidity, and treatment goals.

Pseudogout Flare

- Acute crystal-induced arthritis caused by calcium pyrophosphate dihydrate deposition, often affecting the knee or wrist. Identification of positively birefringent rhomboid crystals in synovial fluid supports the diagnosis.

Giant Cell Arteritis Emergency

- Suspected giant cell arteritis with visual symptoms, jaw or tongue claudication, or neurologic ischemia requires immediate glucocorticoid treatment to reduce risk of irreversible visual loss while diagnostic evaluation proceeds.

Immunosuppression Screening

- Pre-treatment evaluation for latent or active infection, vaccination status, malignancy risk, and organ dysfunction before immunosuppressive therapy. Testing commonly includes tuberculosis, hepatitis B and C, HIV, blood counts, liver and kidney function, and pregnancy when relevant.

Raynaud Phenomenon

- Episodic vasospasm of digital arteries triggered by cold or emotional stress, producing sequential color changes and altered sensation. Primary disease is usually benign; secondary Raynaud phenomenon may signal systemic sclerosis, lupus, vasculitis, or another connective-tissue disease.

Inflammatory Back Pain

- A pattern of chronic back pain characterized by insidious onset, improvement with exercise, lack of improvement with rest, nocturnal pain, and prolonged morning stiffness. It suggests axial spondyloarthritis but is not diagnostic without supportive clinical, laboratory, and imaging findings. **Cryoglobulinemic vasculitis**

- Systemic vasculitis caused by cryoglobulin-containing immune complexes that deposit in small and medium vessels, classically presenting with purpura, arthralgia, and glomerulonephritis. Most cases are associated with hepatitis C virus infection. **Cutaneous lupus**

- A form of lupus erythematosus limited to the skin, manifesting as discoid lesions, subacute cutaneous plaques, or acute malar erythema. It may occur in isolation or as a feature of systemic lupus erythematosus. **Jaccoud's arthropathy**

- A non-erosive, reducible deformity of the metacarpophalangeal joints caused by chronic periarticular fibrosis and tendon laxity, most commonly associated with systemic lupus

erythematosus. **Lupus pernio**

– A chronic, violaceous skin lesion of the face and extremities associated with sarcoidosis, indicating a higher risk of systemic involvement and chronic disease. **Polychondritis**

– Relapsing inflammatory disorder targeting cartilage throughout the body, causing pain, swelling, and destruction of the ears, nose, larynx, trachea, and joints. May lead to airway collapse and hearing loss. **Primary hypertrophic osteoarthropathy**

– A rare inherited syndrome characterized by digital clubbing, periostosis of long bones, and pachydermia, presenting with joint pain, skin thickening, and visible nail-bed enlargement.

Anti-citrullinated peptide antibody

– An autoantibody highly specific for rheumatoid arthritis that may precede clinical disease and is associated with erosive joint damage.

Sacroiliitis

– Inflammation of one or both sacroiliac joints, causing pain in the lower back, buttock, or posterior thigh that may worsen with prolonged rest. Causes include axial spondyloarthritis, psoriatic or enteropathic arthritis, infection, trauma, and degenerative disease. Diagnosis combines clinical assessment with inflammatory markers and sacroiliac imaging, particularly magnetic resonance imaging when early inflammation is suspected.

Heberden Node

– A firm bony enlargement of the distal interphalangeal joint, usually caused by hand osteoarthritis. It may be tender during progression and can produce deformity, reduced fine-motor function, or restricted finger movement.

Calcium Pyrophosphate Arthritis

– Acute or chronic inflammatory arthritis caused by deposition of calcium pyrophosphate crystals in cartilage and joints. Acute attacks, often called pseudogout, commonly affect the knee or wrist and are diagnosed by identifying weakly positively birefringent crystals in synovial fluid.

Gonococcal Arthritis

– A disseminated infection of joints caused by Neis-

seria gonorrhoeae, often with fever, migratory joint or tendon pain, skin pustules, and tenosynovitis. It requires prompt antimicrobial treatment and evaluation for concomitant sexually transmitted infection.

IgA Vasculitis

– An immune-complex small-vessel vasculitis characterized by palpable purpura, joint pain, abdominal symptoms, and kidney involvement. It is common in children and may follow an infection; renal disease determines long-term risk.

Joint Swelling

– Enlargement of a joint caused by excess synovial fluid, blood, inflammation, infection, trauma, or structural disease. It may be accompanied by pain, warmth, stiffness, or restricted movement and can indicate inflammatory or septic arthritis.

Chapter 39

Surgery

Acute Pancreatitis

- Inflammation of pancreas with potential systemic effects. See [gastroenterology](#).

Adrenal Tumors

- Adrenal incidentaloma: >1cm on imaging. Workup: hormonal (cortisol after 1mg DST, metanephrines, aldosterone/renin if hypertensive, DHEAS/androgens if virilizing), imaging (CT washout: adenoma >60% absolute washout or >40% relative; MRI chemical shift). Size >4cm or suspicious imaging -> surgery. Pheochromocytoma: catecholamine excess (episodic hypertension, headache, diaphoresis, palpitations); 10% bilateral, 10% malignant, 10% extra-adrenal (paraganglioma), 10% familial (MEN2, VHL, NF1, SDHx). Biochemical confirmation: plasma free metanephrines (elevated). Pre-operative: alpha-blockade (phenoxybenzamine 10 mg TDS for 7-14 days before surgery, starting at 10 mg TDS and titrating up to 20-30 mg TDS to achieve blood pressure control and prevent intraoperative hypertensive crisis, followed by beta-blockade after alpha-blockade to control reflex tachycardia or arrhythmia, such as propranolol 10-20 mg TDS starting on day 3 of alpha-blockade). Surgery: laparoscopic adrenalectomy (gold standard for pheochromocytoma and other adrenal masses; partial/cortical-sparing adrenalectomy if bilateral disease or genetic syndrome). Cortical-sparing adrenalectomy is preferred for hereditary pheochromocytoma syndromes (MEN2, VHL) to avoid lifelong steroid dependence. Criteria for surgery: tumors >4 cm or any functioning or suspicious mass in a patient who is a good surgical candidate. Adrenocortical carcinoma (ACC): usually >6cm, irregular, heterogeneous with central necrosis, invasion of adjacent structures, venous tumor thrombus; worst

prognosis; treatment is open radical en bloc resection with lymphadenectomy and complete tumor excision achieving R0 resection margins. Mitotane therapy for advanced or metastatic ACC. Adjuvant mitotane therapy after resection reduces recurrence when there is a high risk of recurrence (tumor size >6 cm, Ki-67 >10 percent, positive margins, capsular invasion, or tumor rupture at the time of surgery).

Amputation

- Surgical removal of a limb or part of a limb. Levels: toe, partial foot (transmetatarsal), below-knee (BKA, preserves knee function, 40-60% walk with prosthesis), through-knee, above-knee (AKA), hip disarticulation, and hemipelvectomy. Upper extremity: digit, ray, transradial, transhumeral, and shoulder disarticulation. Indications: peripheral arterial disease with gangrene (most common), trauma (crush, degloving), infection (necrotizing fasciitis, osteomyelitis refractory), malignancy (sarcoma), and severe deformity. Prosthetic fitting: post-operative rigid dressing, early weight-bearing for BKA. Complications: stump pain, phantom limb pain (80-100%), phantom sensation, surgical site infection, and deconditioning.

Anti-Reflux Surgery

- Surgical procedures designed to restore the anti-reflux barrier at the gastroesophageal junction, primarily indicated for gastroesophageal reflux disease (GERD) refractory to medical therapy, patient preference to discontinue lifelong medication, or large hiatal hernias. The most common procedure is laparoscopic Nissen fundoplication, a 360-degree wrap of the gastric fundus around the distal esophagus, restoring the lower esophageal sphincter pressure and preventing transient lower esophageal sphinc-

ter relaxation and reducing the volume of refluxate. The wrap is typically 2-3 cm in length and is performed laparoscopically. Pre-operative evaluation includes esophageal manometry to confirm normal peristalsis (essential before a 360-degree wrap), 24-hour pH monitoring to confirm the diagnosis of GERD, upper endoscopy to assess for oesophagitis, Barrett esophagus, and stricture, and a barium swallow to evaluate esophageal anatomy and identify hiatal hernia. Alternatives to Nissen fundoplication include partial wraps (Toupet 270-degree posterior fundoplication for patients with poor esophageal motility, Dor 180-200-degree anterior fundoplication) and the LINX magnetic sphincter augmentation device, which consists of a ring of titanium beads with magnetic cores placed around the gastroesophageal junction. Crural closure of the diaphragmatic hiatus is performed to prevent recurrence of the hiatal hernia. Post-operative complications include dysphagia (common initially, resolves in most cases, may require pneumatic dilation if persistent), gas-bloat syndrome (inability to belch, leading to abdominal distension and discomfort, usually improves over weeks to months), and recurrence of reflux symptoms due to wrap disruption or slippage. Outcomes are excellent, with 85-95 percent patient satisfaction at 10 years.

Appendectomy

– Surgical removal of the appendix, the most common emergency surgical procedure performed worldwide. Appendectomy is indicated for acute appendicitis, the most common surgical emergency with a lifetime risk of 7-8 percent and peak incidence between 10 and 30 years. Laparoscopic appendectomy is the preferred approach, offering lower wound infection rates, faster recovery, less postoperative pain, and better cosmetic outcomes compared to open appendectomy. The procedure involves placement of three to four ports (umbilical camera port, suprapubic and right lower quadrant working ports), identification of the base of the appendix, division of the mesoappendix using cautery or a vessel-sealing device, and ligation of the appendiceal base using endoloops (two proximal and one distal) or a stapler. The appendix is placed in a retrieval bag and removed through the umbilical port. In cases of perforated appendicitis with peritonitis, conversion to

open appendectomy may be required for adequate peritoneal lavage. Intravenous antibiotics covering Gram-negative and anaerobic organisms are given pre-operatively. For uncomplicated appendicitis, no post-operative antibiotics are needed beyond 24 hours. For perforated appendicitis, antibiotics are continued for 3-5 days or until the patient is clinically improving. Complicated appendicitis (perforation, abscess, or gangrene) has a higher risk of wound infection and intra-abdominal abscess, which may require percutaneous drainage. The complication rate for laparoscopic appendectomy is approximately 5-10 percent, with wound infection being the most common (1-5 percent). Post-operative recovery is rapid, with most patients discharged within 24 hours and returning to normal activity within 1-2 weeks.

Appendiceal Tumors

– Appendiceal neoplasms: carcinoid (most common, 50%, tip of appendix, <1cm: appendectomy alone; >2cm or positive margins/lymphovascular invasion: right hemicolectomy), mucinous neoplasm (low-grade appendiceal mucinous neoplasm LAMN, high-grade appendiceal mucinous neoplasm HAMN), appendiceal adenocarcinoma (treated like colon cancer: right hemicolectomy), goblet cell carcinoid (adenocarcinoid, amphicrine, right hemicolectomy if >2cm or nodal involvement). Pseudomyxoma peritonei (PMP): disseminated mucinous tumor throughout the peritoneal cavity from ruptured mucinous neoplasm; treatment: cytoreductive surgery (CRS) + hyperthermic intraperitoneal chemotherapy (HIPEC) with mitomycin C. Prognosis: 5-year survival 70% for low-grade, 20-50% for high-grade.

Appendicitis

– Inflammation of appendix. See [gastroenterology](#).

Arterial Line (A-Line)

– A catheter inserted into a peripheral artery (most commonly radial, also femoral, brachial, dorsalis pedis) for continuous blood pressure monitoring and arterial blood gas sampling. Allen test: assesses ulnar collateral flow before radial artery cannulation. Indications: hemodynamic instability (shock, vasopressors), need for frequent ABGs, and advanced hemodynamic monitoring (pulse pressure variation SVV for fluid responsiveness). Transducer: zeroed

at the phlebostatic axis (4th intercostal space, midaxillary line), leveled to the patient's heart. Damping: underdamped (overestimates systolic, normal waveform) or overdamped (underestimates systolic, sluggish upstroke). Complications: thrombosis, ischemia (rare if collateral flow is adequate), infection, hematoma, and pseudoaneurysm.

Arterial Ulcer

– A chronic wound caused by arterial insufficiency (peripheral artery disease). Located on distal extremities: toes, heels, lateral malleolus, and sites of pressure. Presents with punched-out, deep, well-demarcated wound with pale or necrotic base, minimal exudate, and cool, hairless, shiny skin. Pain is severe, worse with elevation and night. Associated with claudication and rest pain. Diagnosis: ABI (<0.5 suggests severe ischemia), toe pressure (<30 mmHg), vascular duplex. Treatment: revascularization (endovascular or surgical bypass) is essential for healing. Wound care: debridement, moist healing, infection control. Avoid compression. Amputation if non-salvageable.

Arthroscopy

– Minimally invasive joint visualization and intervention via a rigid arthroscope inserted through small portals, used for meniscal and ligamentous repair, chondroplasty, loose body removal, and synovectomy. Knee, shoulder, and hip are commonly arthroscoped; complications include infection, chondral injury, and deep venous thrombosis, with faster recovery than open arthrotomy.

Aseptic Technique

– A set of laboratory practices preventing contamination of sterile sites, cultures, and specimens by unwanted microorganisms. See microbiology.

Bariatric Surgery

– Weight loss procedures and surgery, collectively known as bariatric surgery, are invasive interventions for severe obesity that produce substantial and sustained weight loss by altering gastrointestinal anatomy and physiology. Common procedures include Roux-en-Y gastric bypass, sleeve gastrectomy, and adjustable gastric banding, which restrict food intake, reduce nutrient absorption, or both. Bariatric surgery is typically reserved for individuals with a body mass index of 40 or greater, or 35

or greater with significant obesity-related complications, and requires lifelong nutritional monitoring and lifestyle adherence.

Benign Prostatic Hyperplasia

– Non-malignant enlargement of the prostate gland due to hyperplasia of stromal and glandular elements, affecting $>50\%$ of men by age 60 and $>90\%$ by age 85. Presents with lower urinary tract symptoms (LUTS): hesitancy, weak stream, intermittency, straining, incomplete emptying, urgency, frequency, and nocturia. Complications: acute urinary retention, bladder stones, recurrent UTIs, and renal impairment. Diagnosis: digital rectal exam, PSA, AUA symptom index, post-void residual, and uroflowmetry. Treatment: watchful waiting for mild symptoms, alpha-blockers (tamsulosin), 5-alpha-reductase inhibitors (finasteride), combination therapy, and surgical options (TURP, laser prostatectomy, and open prostatectomy for large glands).

Biliary Tract Injuries

– Bile duct injury (BDI) occurs in 0.3-0.5% of laparoscopic cholecystectomies. Strasberg classification: A (cystic duct leak/minor hepatic duct leak), B (occlusion of aberrant right hepatic duct), C (transection of aberrant right hepatic duct without ligation), D (lateral injury to major duct), E (major duct injury: E1-E5 based on level). Recognition: intraoperative (bile leak, visualization) or postoperative (bilious drain output, pain, fever, jaundice). Intraoperative management: if recognized, primary repair over T-tube (if $>50\%$ intact wall) or Roux-en-Y hepaticojejunostomy (if transection, ligation, or significant resection of the bile duct). If recognized postoperatively, ERCP with sphincterotomy and stenting (Strasberg A, D) or percutaneous transhepatic cholangiography (PTC) with drainage (Strasberg B, C) may be attempted. Strasberg E injuries require surgical repair via Roux-en-Y hepaticojejunostomy, preferably performed by a hepatobiliary surgeon at a tertiary referral center. The timing of repair is critical: early repair (<72 hours) is acceptable for clean, well-vascularised tissue; otherwise, delayed repair (4-6 weeks) after resolution of inflammation and sepsis is preferred. Pre-operative optimisation includes biliary drainage (ERCP, PTC, or percutaneous transhepatic biliary drainage), control of sepsis with antibiotics (piperacillin-tazobactam or

meropenem), and nutritional support (enteral nutrition via nasojejun tube if possible). Prevention: critical view of safety (CVS) technique during cholecystectomy, low threshold for cholangiography (indocyanine green fluorescence imaging, intraoperative cholangiography, or laparoscopic ultrasound) when anatomy is unclear. Outcomes: Strasberg A and D have excellent outcomes; Strasberg E has a 10-20% stricture rate after repair. Long-term complications include anastomotic stricture (treated with balloon dilation or revision), cholangitis, secondary biliary cirrhosis, and portal hypertension.

Blood Loss

– The volume of blood lost during surgery or trauma, estimated by weighing swabs, suction contents, and hemodynamic monitoring, guiding fluid and transfusion management. ATLS classes range from I (up to 15 percent loss) to IV (over 40 percent, requiring aggressive resuscitation); massive transfusion uses packed cells, plasma, and platelets with tranexamic acid.

Blunt Abdominal Trauma

– Trauma to the abdomen without penetrating injury. Mechanisms: motor vehicle collisions (most common), falls, assaults. Commonly injured organs: spleen (most common, left upper quadrant), liver (right upper quadrant), kidneys (flank), bowel (seat-belt sign, delayed perforation), and pancreas (epigastric). Diagnosis: FAST (Focused Assessment with Sonography in Trauma) for free intraperitoneal fluid; CT scan (gold standard in hemodynamically stable patients). Management: hemodynamically unstable with positive FAST → exploratory laparotomy. Stable: CT for grading; non-operative management of solid organ injuries (spleen/liver) if hemodynamically stable. Bowel and pancreatic injuries often require surgical repair.

BPH

– Abbreviation for Benign Prostatic Hyperplasia.

Breast Surgery

– Breast cancer surgery: breast-conserving therapy (BCT: lumpectomy + radiation) equivalent survival to mastectomy for early stage. Margins: "no ink on tumor" for invasive cancer; 2mm for DCIS. Sentinel lymph node biopsy (SLNB): dual mapping (blue dye + radioisotope); if positive (macrometastasis

>2mm): completion ALND (historical) or radiation (ACOSOG Z0011: 1-2 positive SLN + BCT + whole breast RT → no ALND; AMAROS: ALND vs axillary RT equivalent). Mastectomy types: simple, skin-sparing, nipple-sparing (NSM), and radical modified (Patey: breast + axillary lymph node dissection - ALND). Nipple-areola complex (NAC) is spared if tumor is >2cm from the nipple and no Paget disease of the breast. Oncoplastic techniques integrate plastic surgery principles with oncological resection for improved aesthetic outcomes. Adjuvant therapy: radiation (post-BCT, post-mastectomy if T3/T4 or 4+ positive nodes), endocrine (tamoxifen pre-menopausal, aromatase inhibitor post-menopausal if ER+), HER2-targeted (trastuzumab/pertuzumab if HER2+), chemotherapy (high-risk: triple-negative, HER2+, high-grade, node-positive). BRCA mutation carriers: bilateral mastectomy (risk-reducing) + RRSO (risk-reducing salpingo-oophorectomy) recommended.

Burn Surgery

– Burn assessment: rule of 9s (adult), Lund-Browder (children). Depth: superficial (epidermis), superficial partial (dermis, blanch, blister, painful), deep partial (deeper dermis, white, sluggish capillary refill, less painful), full thickness (all dermis, white/charred, anesthetic). TBSA >20%: IV resuscitation (Parkland: 4 mL/kg/%TBSA LR, half in first 8h, half in next 16h; modified Brooke: 2 mL/kg/%TBSA). Inhalation injury: bronchoscopy, carboxyhemoglobin, cyanide level. Escharotomy: circumferential full-thickness burns of chest (impaired ventilation), extremities (compartment syndrome), neck, or penis. Fasciotomy for compartment syndrome (burn deep to fascia). Tangential excision (within 24-72 hours) with split-thickness skin grafting (STSG: 0.008-0.012 inch), meshed (1:1 to 1:4 for larger surface area) or sheet graft (face, hands, joints). Biological dressings: allograft (cadaver), xenograft (porcine), amniotic membrane, synthetic (Biobrane, Integra, Apligraf, and artificial dermal regeneration template). Scar management: pressure garments, silicone sheeting, laser therapy (pulsed dye laser for hypertrophic scars, fractional CO2 laser for contracture release and scar texture improvement).

Bypass Surgery

- A surgical conduit that reroutes flow around an obstructed or diseased segment, applied to coronary arteries (CABG), peripheral arteries (autologous vein or prosthetic bypass), and the gastrointestinal tract (gastric bypass). Principal long-term concerns are conduit patency, graft infection, and anastomotic stenosis.

CABG (Coronary Artery Bypass Grafting)

- Open heart surgery to bypass stenotic coronary arteries using autologous grafts. On-pump: cardiopulmonary bypass, cardioplegic arrest. Off-pump (OP-CAB): beating heart, no bypass machine. Grafts: left internal mammary artery (LIMA to LAD, best patency 95% at 10 years), saphenous vein graft (SVG, patency 60-80% at 10 years), and radial artery (patency between LIMA and SVG). Indications: left main CAD ($\geq 50\%$), three-vessel CAD, two-vessel CAD with proximal LAD and EF $< 50\%$, and failed PCI. Complications: bleeding, AF, stroke, infection (sternal wound), renal failure, and graft failure.

Carotid Endarterectomy

- Surgical removal of atherosclerotic plaque from the carotid bifurcation to prevent stroke. Indications: symptomatic carotid stenosis $\geq 50\%$ (NASCET criteria: TIA or non-disabling stroke) and asymptomatic stenosis $\geq 70\%$ (if perioperative risk $< 3\%$). Pre-operative: CTA or MRA, antiplatelet therapy. Complications: stroke (2-5%), cranial nerve injury (hypoglossal, vagus, facial marginal mandibular, recurrent laryngeal: 5-10%, most temporary), hematoma, restenosis. Alternative: carotid artery stenting (CAS, for high surgical risk).

Cesarean Section (C-section)

- Surgical delivery of a fetus through incisions in the abdominal wall (laparotomy) and uterus (hysterotomy). Indications: failure to progress, non-reassuring fetal heart tracing, malpresentation (breech, transverse), placenta previa, placental abruption, prior classical C-section, maternal infection (HSV, HIV), and elective (maternal request). Incisions: low transverse (Kerr, most common, heals best for future VBAC), classical (vertical, high risk of rupture in labor). Steps: Pfannenstiel incision, bladder flap, hysterotomy, delivery of the baby,

placental removal, closure. Complications: hemorrhage, infection, thromboembolism, bladder/bowel injury, and uterine rupture in future pregnancies (VBAC).

Cholecystectomy

- Surgical removal of the gallbladder. Laparoscopic cholecystectomy (gold standard, $> 95\%$): 4 small incisions, short stay. Open cholecystectomy: for severe inflammation, cirrhosis, or failed laparoscopy. Indications: symptomatic cholelithiasis (biliary colic), acute cholecystitis, gallstone pancreatitis, and gallstone ileus. Intraoperative cholangiogram (IOC): assess for CBD stones. Critical view of safety (CVS): before clipping the cystic artery and duct. Complications: bile duct injury (0.3-0.5%), bile leak, bleeding, and retained CBD stones.

Cholecystitis

- Inflammation of the gallbladder, most commonly caused by obstruction of the cystic duct by a gallstone, which occurs in approximately 95 percent of cases. See [pathology](#).

Chronic Pancreatitis

- Progressive irreversible inflammatory condition characterized by permanent structural damage causing exocrine and endocrine impairment. See [gastroenterology](#).

Cleft Lip and Palate

- A congenital anomaly caused by failure of fusion of the facial prominences during embryonic development (4-10 weeks gestation). Cleft lip: failure of maxillary and medial nasal processes to fuse. Cleft palate: failure of palatal shelves to fuse. Can occur together or separately. Incidence: 1 in 700 live births, more common in Asians and Native Americans. Multifactorial: genetic (IRF6, FGFR1) and environmental (maternal smoking, folate deficiency, alcohol). Associated syndromes: Pierre Robin sequence, Van der Woude syndrome, 22q11 deletion. Presents with cosmetic deformity, feeding difficulties, speech abnormalities, and ear infections. Management: multidisciplinary team (ENT, plastic surgery, speech therapy, orthodontics). Surgical repair: cleft lip at 3-6 months, cleft palate at 9-18 months.

Cleft Palate

- A congenital malformation characterized by an opening (cleft) in the palate (roof of the mouth)

due to failure of fusion of the palatal shelves during embryonic development (weeks 6–9 of gestation). Incidence: 1 in 1,500–2,500 live births. Cleft palate may occur in isolation or with cleft lip (cleft lip and palate—CLP). Classification: incomplete (soft palate only) vs complete (soft and hard palate), unilateral vs bilateral, and associated with Pierre Robin sequence (micrognathia, glossoptosis, airway obstruction). Risk factors: genetics (multiple genes implicated—IRF6, MSX1, TBX22, FGFR1), maternal smoking, alcohol, diabetes, and folate deficiency. Diagnosis: antenatal ultrasound (around 20-week anomaly scan) or postnatal clinical examination (inspect palate with a tongue depressor). Complications: feeding difficulties (nasal regurgitation, poor weight gain), recurrent otitis media (Eustachian tube dysfunction—hearing loss), speech delay (velopharyngeal insufficiency—hypernasal speech, articulation errors), dental abnormalities (missing or malpositioned teeth), and maxillary hypoplasia. Management: multidisciplinary team (plastic surgeon, ENT, speech therapist, orthodontist, paediatrician, psychologist). Primary palatoplasty (repair of the palate) is performed at 9–12 months (before speech development); techniques: Furlow double-opposing Z-plasty, Bardach two-flap palatoplasty. Secondary surgery for velopharyngeal insufficiency (pharyngeal flap, sphincter pharyngoplasty). Alveolar bone grafting at 6–9 years. Orthognathic surgery for maxillary hypoplasia in adolescence. Speech therapy, audiology, and orthodontic treatment throughout childhood. Long-term outcomes: good speech and feeding outcomes, normal intelligence, and good quality of life with appropriate multidisciplinary care.

Colectomy

– Surgical resection of part or all of the colon. Right hemicolectomy: for cecal/ascending colon cancer. Left hemicolectomy: for descending/sigmoid cancer. Sigmoidectomy: for diverticulitis or sigmoid cancer. Total colectomy: for FAP, UC, or Lynch syndrome. Low anterior resection (LAR): for rectal cancer with anastomosis (coloanal anastomosis). Abdominoperineal resection (APR): for distal rectal cancer, permanent colostomy. Indications: colon cancer, diverticulitis, IBD (UC, Crohn), and

ischemic colitis. Complications: anastomotic leak (most feared), hemorrhage, wound infection, and ileus.

Colorectal Surgery

– Colon cancer: right hemicolectomy (cecum to transverse), extended right (to mid-transverse), transverse colectomy, left hemicolectomy (splenic flexure to sigmoid), sigmoid colectomy, anterior resection (low anterior resection - LAR for upper/mid rectal), abdominoperineal resection (APR for low rectal with sphincter involvement), total mesorectal excision (TME) standard for rectal cancer. Lymphadenectomy: minimum 12 nodes. Rectal cancer: neoadjuvant chemoradiation (5-FU/capecitabine + 50.4 Gy) for T3/T4 or node-positive; total neoadjuvant therapy (TNT: induction chemotherapy followed by chemoradiation) for locally advanced; watch-and-wait for complete clinical response (cCR) after TNT. Anal cancer: squamous cell carcinoma; Nigro protocol (mitomycin C + 5-FU + 55-60 Gy radiation); surgery (APR) only for residual/recurrent disease. Diverticulitis: Hinchey classification (I: pericolic abscess, antibiotics, percutaneous drainage if >4cm; II: pelvic abscess, percutaneous drainage; III: purulent peritonitis, Hartmann or resection with anastomosis + defunctioning stoma; IV: fecal peritonitis, Hartmann procedure). Elective sigmoid resection after 2 episodes of uncomplicated or 1 episode of complicated diverticulitis (current guidelines have shifted towards a more conservative, individualised approach, with surgery considered on a case-by-case basis for recurrent attacks, persistent complications, or immunosuppression).

Colostomy

– A surgically created stoma formed by bringing the colon to the abdominal wall for fecal diversion, indicated for distal obstruction, trauma, perforation, or abdominoperineal resection. Types include end, loop, and double-barrel. Complications include parastomal hernia, prolapse, retraction, and high-output dehydration.

Complication

– Any adverse event arising during or after a surgical procedure, graded by the Clavien-Dindo classification from minor deviation (Grade I) through organ failure (Grade IV) to death (Grade V). Common

types include surgical site infection, hemorrhage, wound dehiscence, anastomotic leak, ileus, and venous thromboembolism.

Conscious Sedation

- A drug-induced depression of consciousness in which patients respond purposefully to verbal or tactile stimulation, maintain a patent airway, and retain protective reflexes. Typical agents include midazolam, fentanyl, or low-dose propofol. Indications include endoscopic and minor surgical procedures. Reversal agents and airway equipment must be available.

Craniotomy

- Surgical opening of the skull (bone flap) for access to intracranial contents. Indications: brain tumor resection (glioblastoma, meningioma, mets), hematoma evacuation (SDH, EDH, ICH), aneurysm clipping, AVM resection, and epilepsy surgery (lobectomy). Stereotactic craniotomy: frameless neuronavigation (Stealth, BrainLab) for precise localization. Awake craniotomy: speech/language mapping for tumors in eloquent cortex. Complications: cerebral edema, hemorrhage (epidural, subdural, intraparenchymal), infection (osteomyelitis, meningitis), CSF leak, seizures, and neurologic deficits.

Cryptorchidism

- Failure of one or both testes to descend into the scrotum, the most common congenital genitourinary anomaly in boys (3% at birth, 1% at 1 year). 70% of undescended testes are palpable (inguinal), 30% non-palpable (intra-abdominal, absent, or atrophic). Spontaneous descent by 6 months occurs in about one-third. Complications: impaired fertility (bilateral: 75% reduced, unilateral: 50% reduced), testicular cancer risk (seminoma, 4-5x increased, even after orchiopexy), and psychological effects. Diagnosis: physical exam; ultrasound or laparoscopy for non-palpable. Treatment: orchiopexy (surgical placement in scrotum) between 6-18 months of age. Hormonal therapy (hCG) is less effective. Atrophic or absent testis: orchiectomy. Follow-up: annual exam and testicular self-exam.

Debridement

- The surgical removal of dead, damaged, or infected tissue from a wound to promote healing and pre-

vent infection. Types: sharp/surgical debridement (scalpel, curette, scissors—most rapid and definitive), enzymatic debridement (collagenase, papain-urea), autolytic debridement (moist dressings allow the body's own enzymes to liquefy necrotic tissue), mechanical debridement (wet-to-dry dressings, irrigation, whirlpool), and biologic debridement (sterile maggots—*Lucilia sericata* larvae consume necrotic tissue). Selection depends on wound type, amount of necrotic tissue, infection status, and patient tolerance.

Diabetic Foot Ulcer

- A chronic wound of the foot in a patient with diabetes, resulting from peripheral neuropathy, peripheral artery disease, and impaired wound healing. Neuropathic ulcers: painless, at pressure points (plantar metatarsal heads, heel), punched-out appearance, surrounded by callus. Ischemic ulcers: painful, at toes or margins of foot, with pale, cool, hairless skin. Risk factors: poor glycemic control, long diabetes duration, prior amputation, neuropathy, PAD, and foot deformity. Diagnosis: monofilament testing, ankle-brachial index, vascular duplex ultrasound, and wound assessment. Treatment: offloading (total contact cast, CAM boot, wheelchair), debridement, infection control (antibiotics, surgical drainage for osteomyelitis), revascularization for ischemic ulcers, and advanced wound care (negative pressure, growth factors, bioengineered skin). Prevention: daily foot inspection, proper footwear, glycemic control, and podiatry referral.

Dilation and Curettage (D&C)

- Surgical dilation of the cervix and curettage (scraping) of the uterine lining. Indications: incomplete or missed abortion (miscarriage management), therapeutic abortion, endometrial sampling (abnormal uterine bleeding, postmenopausal bleeding, endometrial hyperplasia/cancer), and removal of retained products of conception (RPOC). Complications: uterine perforation (1-3%, higher in postmenopausal, retroverted uterus), cervical laceration, hemorrhage, infection, and Asherman syndrome (intrauterine adhesions from overzealous curettage). Now often replaced by hysteroscopy-guided procedures.

Discectomy

– Surgical removal of a herniated intervertebral disc fragment compressing a nerve root. Microscopic discectomy (most common): small incision, microscope, minimal muscle dissection. Indications: radicular pain (sciatica, cervical radiculopathy) refractory to 6-12 weeks of conservative therapy, progressive motor deficit, and cauda equina syndrome (surgical emergency). Success rate: 85-95% for leg pain relief. Also performed via endoscopic, minimally invasive (Tubular/METRx, MIS-TLIF for associated instability), and open (rarely). Complications: dural tear (3-5%), infection, hematoma, recurrent herniation, and nerve root injury.

Drowning

– Respiratory impairment from submersion/immersion in liquid. Drowning can be fatal or non-fatal. Pathophysiology: laryngospasm followed by aspiration of fluid, surfactant washout, pulmonary edema, and hypoxemia. Fresh water: washes out surfactant, causes alveolar collapse. Salt water: draws fluid into alveoli (pulmonary edema). Both cause severe hypoxemia, metabolic acidosis, and multiorgan failure. Risk factors: children 1-4 (bathtubs, pools), alcohol use, lack of supervision, and seizure disorders. Management: immediate rescue, CPR with rescue breaths (most important intervention), ICU care with ventilation, and treatment of aspiration pneumonia and ARDS. Prognosis: associated with submersion time, CPR delay, water temperature, and neurologic status on arrival.

Electrical Injury

– Tissue damage caused by passage of electrical current through the body. Severity depends on voltage, current (alternating vs. direct), pathway, duration, and resistance. High-voltage (>1000V): extensive internal tissue damage (muscle necrosis, compartment syndrome, rhabdomyolysis) with relatively small skin burns (entry/exit wounds). Cardiopulmonary effects: arrhythmias (ventricular fibrillation, asystole), cardiac arrest. Neurologic effects: spinal cord injury, peripheral nerve damage, cognitive deficits. Complications: acute kidney injury (myoglobinuria), compartment syndrome, fractures from falls, and delayed neurologic deficits. Diagnosis: ECG, CK, urine myoglobin, CT/MRI. Treatment: ABCs, car-

diac monitoring, IV fluids with alkalization (bicarbonate), surgical fasciotomy/debridement for compartment syndrome. Tetanus prophylaxis.

Esophageal Surgery

– GERD surgery: Nissen fundoplication (360° wrap, gold standard), partial wraps (Toupet 270°, Dor anterior 180-200°) for dysmotility. LINX device (magnetic sphincter augmentation) alternative. Achalasia: Heller myotomy (laparoscopic/robotic) + partial fundoplication (Dor); POEM (peroral endoscopic myotomy) endoscopic alternative; pneumatic dilation (recurrence 30-50%). Esophageal cancer: adenocarcinoma (distal, Barrett's), squamous (proximal/mid, smoking/alcohol). Staging: EUS, PET-CT, laparoscopy for peritoneal disease. Neoadjuvant chemoradiation (CROSS regimen: carboplatin + paclitaxel + 41.4 Gy) for locally advanced (T2N+ or T3-4 any N). Surgery: Ivor Lewis (right thoracotomy + laparotomy, for mid/distal), McKeown (right thoracotomy + laparotomy + cervical, for proximal), transhiatal (blunt dissection, for distal, higher anastomotic leak rate). Reconstruction: gastric conduit (greater curve based on right gastroepiploic artery, most common), colon interposition (when stomach unavailable). Three-field lymphadenectomy (cervical, mediastinal, abdominal) for squamous cell carcinoma at or above the carina. Anastomotic techniques: stapled (EEA, 21-25 mm, end-to-side) or hand-sewn (two-layer running or interrupted, anastomotic leak rate 5-15%). Wait time of 8-12 weeks after neoadjuvant therapy for surgical resection. Outcomes: 5-year survival for esophageal cancer is 15-25% overall; 40-50% for patients who achieve a pathological complete response (pCR) after neoadjuvant chemoradiation. Salvage oesophagectomy for persistent or recurrent disease after definitive chemoradiation (50.4 Gy + chemotherapy) has higher morbidity (30-50% complication rate, especially anastomotic leak and pulmonary complications).

Evisceration

– Protrusion of viscera through a dehiscence abdominal wound, typically occurring 5-8 days postoperatively and constituting a surgical emergency. Risk factors include obesity, wound infection, and inadequate fascial closure. Management requires sterile coverage, broad-spectrum antibiotics, and emergent operative

reclosure. The term is distinct from ophthalmologic evisceration.

Excision

– The surgical removal of a piece of tissue, an organ, or a lesion. Excisional biopsy removes the entire lesion with a margin of normal tissue, used for definitive diagnosis and treatment of small tumors (suspected melanoma, breast lump, lymph node). Wide local excision removes the lesion with an additional margin of healthy tissue for oncologic clearance. In biochemistry, excision repair: the removal of damaged DNA segments. Surgical principles: hemostasis, closure method (primary, secondary, or tertiary intention), and specimen orientation for pathology. Margin status (clear, close, or involved) is the most important prognostic factor for local recurrence in cancer surgery.

Fasciotomy

– Surgical incision through the fascia to relieve compartment syndrome. Indications: acute compartment syndrome (trauma, reperfusion, burns, crush injury). Classic signs: pain out of proportion, pain with passive stretch, paresthesias, pallor, pulselessness (late). Diagnosis: clinical, compartment pressure >30 mmHg OR delta pressure (diastolic BP minus compartment pressure) <30 mmHg. Leg: 4 compartments (anterior, lateral, superficial posterior, deep posterior) via two incisions. Forearm: volar (Henry approach) and dorsal. Foot, thigh, hand, abdomen (for abdominal compartment syndrome) also possible. Fasciotomy wounds are left open for 48-72 hours, then delayed primary closure or skin grafting.

Femoral Hernia

– A hernia of abdominal contents through the femoral ring, into the femoral canal, medial to the femoral vessels and below the inguinal ligament. More common in women (3:1) and more prone to strangulation (40%) than inguinal hernias due to narrow, rigid femoral ring. Presents as a small, non-reducible mass below and lateral to the pubic tubercle (distinguishing from inguinal hernia). Diagnosis: clinical; ultrasound/CT for equivocal cases. Treatment: surgical repair (McVay, mesh plug, or laparoscopic TEP/TAPP) due to high strangulation risk. Emergency surgery for strangulated or incarcerated

femoral hernia.

Frostbite

– Tissue injury caused by freezing of skin and underlying tissues. Severity grading: first degree (superficial, numbness, erythema), second degree (blisters, clear fluid, pain), third degree (hemorrhagic blisters, necrosis, full-thickness skin loss), fourth degree (deep tissue necrosis, mummification, autoamputation). Common sites: fingers, toes, nose, ears, cheeks. Predisposing factors: cold exposure, wind chill, vasoconstriction, immobility, alcohol, smoking, diabetes. Pathophysiology: ice crystal formation, endothelial injury, thrombosis, and reperfusion injury upon rewarming. Diagnosis: clinical. Treatment: rapid rewarming in water $37-39^{\circ}\text{C}$ ($100-104^{\circ}\text{F}$) for 15-30 minutes; ibuprofen, tetanus prophylaxis, wound care, and delayed amputation (march of demarcation). Thrombolytic therapy (tPA) within 24 hours for severe cases to reduce amputation rate.

Gallbladder Cancer

– Aggressive, often diagnosed incidentally after cholecystectomy for cholelithiasis (1-2% of cholecystectomies). Risk factors: gallstones (chronic inflammation), porcelain gallbladder (calcified wall, 10-25% cancer risk), anomalous pancreaticobiliary junction, gallbladder polyps $>1\text{cm}$, typhoid carrier state. T staging: T1a (lamina propria), T1b (muscularis), T2 (perimuscular connective tissue), T3 (perforates serosa or invades liver/adjacent organ), T4 (main portal vein/hepatic artery, extensive). Lymphatic spread: cystic, pericholedochal, hilar, peripancreatic, periduodenal, celiac, retroperitoneal nodes. Surgical management: T1a: simple cholecystectomy alone is sufficient (no lymphadenectomy required, 5-year survival $>95\%$); T1b: extended cholecystectomy (cholecystectomy + en bloc wedge resection of liver segments IVb and V + portal lymphadenectomy) is the minimum recommended operation (5-year survival 80-85%); T2: extended cholecystectomy + portal lymphadenectomy (5-year survival 50-60%); T3: extended cholecystectomy + portal lymphadenectomy $\pm$ bile duct resection/right hepatectomy (5-year survival 20-30%); T4: unresectable (palliative: biliary stenting, chemotherapy). Incidental gallbladder cancer discovered after simple cholecystectomy: refer to a hepatobiliary center for

completion radical cholecystectomy (wedge resection of gallbladder bed, portal lymphadenectomy, $\pm$ bile duct excision and reconstruction with Roux-en-Y hepaticojejunostomy) within 4 weeks of the initial cholecystectomy. Chemotherapy: gemcitabine + cisplatin for advanced disease (ABC-02 and BILCAP trials). Prognosis: overall 5-year survival 5-15%, worse if lymph node involvement (5-year survival $<10\%$ with nodal metastases). Adjuvant chemotherapy with capecitabine (BILCAP) or gemcitabine-based regimens may improve survival after curative resection.

Gastric Bypass

– Roux-en-Y gastric bypass creating a small proximal pouch drained by a Roux limb, combining restrictive and mildly malabsorptive mechanisms. Indicated for BMI over 40, or over 35 with obesity-related comorbidity. Mean excess weight loss approaches 60-70 percent. Complications include anastomotic leak, marginal ulcer, dumping syndrome, and nutritional deficiencies.

Gastric Surgery

– Gastric cancer: D2 lymphadenectomy standard (stations 1-12a, 12b). Gastrectomy types: total, distal subtotal (Billroth I gastroduodenostomy, Billroth II gastrojejunostomy, Roux-en-Y), proximal, pylorus-preserving. Reconstruction: Roux-en-Y preferred (prevents bile reflux). Early gastric cancer (T1a): ESD (endoscopic submucosal dissection) if no LVI, well-differentiated, $<2\text{cm}$ (expanded criteria). Neoadjuvant: FLOT (5-FU, leucovorin, oxaliplatin, docetaxel) superior to surgery alone. Palliative: systemic chemotherapy, palliative resection for bleeding/obstruction/perforation, stenting for GOO (gastric outlet obstruction). GIST: imatinib (neoadjuvant for downstaging, adjuvant if high risk: $>10\text{cm}$, mitotic $>10/\text{HPF}$, rupture), surgery (R0, avoid rupture). MALT lymphoma: H. pylori eradication first; only treat with surgery or chemoradiation if not responsive. Perforated peptic ulcer: omental patch repair (Graham patch: interrupted 2-0 silk sutures through the full thickness of each side of the perforation, tied over a pedicle of omentum, which is then secured in place with a second set of sutures), laparoscopic (preferred if hemodynamically stable, no contamination, surgeon experience), open if peritonitis. Intraoperative decision-making:

if the perforation is $>2\text{cm}$, there is a suspicion of malignancy, or the edges are oedematous and friable, a more extensive resection may be required (distal gastrectomy with Billroth II or Roux-en-Y reconstruction). Post-operative: PPI infusion (omeprazole 80 mg bolus + 8 mg/hour), H. pylori testing and eradication (triple therapy: PPI + amoxicillin + clarithromycin or metronidazole, 14-day course), return to oral intake after resolution of ileus.

Grafting

– The surgical transfer of tissue from one site to another, or from one individual to another. Types: (1) Autograft: same individual (gold standard, e.g., skin graft for burns, bone graft for non-union, saphenous vein graft for CABG). (2) Allograft: same species, different individual (cadaveric bone, cornea, heart valve, kidney). (3) Xenograft: different species (porcine heart valve, porcine/bovine skin for burns). (4) Isograft: identical twin (syngeneic). (5) Synthetic graft: prosthetic material (Dacron vascular graft, Gore-Tex, metal implants, polyethylene for joint replacement). Skin grafts: split-thickness (epidermis + part of dermis) or full-thickness (epidermis + full dermis). Flaps: tissue transferred with its blood supply intact (pedicled or free). Complications: graft rejection (allografts, xenografts), infection, haematoma, seroma, graft failure (ischemia), contracture. Immunosuppression (tacrolimus, mycophenolate, corticosteroids) is required for allograft organ transplantation.

Heimlich Manoeuvre

– An emergency procedure for relieving upper airway obstruction caused by a foreign body (choking). The maneuver is performed on a conscious, choking adult who cannot speak, cough effectively, or breathe. Technique: the rescuer stands behind the victim, wraps their arms around the victim's waist, makes a fist with one hand (thumb side against the victim's abdomen, midline above the navel and well below the xiphoid process), grasps the fist with the other hand, and performs upward, inward thrusts (abdominal thrusts). For obese or pregnant victims, chest thrusts (similar position but on the lower sternum) are used instead. The maneuver abruptly increases intra-abdominal and intrathoracic pressure, forcing air out of the lungs and creating a cough-like force to expel the obstructing object. For

a choking infant (under 1 year): hold the infant face-down along the rescuer's forearm, with the head lower than the trunk, and deliver 5 back blows between the shoulder blades, followed by 5 chest thrusts (face-up, two fingers on lower sternum). The Heimlich maneuver is contraindicated for: infants under 1 year (use back blows and chest thrusts), unconscious victims (start CPR), and cases where the obstruction is not complete (partial obstruction with good air exchange, encourage coughing). After successful expulsion, the patient should have a medical evaluation to exclude complications (esophageal rupture, gastric rupture, pneumothorax, abdominal organ injury).

Hemicolectomy

– Surgical resection of part or all of the colon. See [Colectomy](#).

Hemorrhagic Shock

– See [emergency_medicine](#).

Hemorrhoidectomy

– Surgical excision of symptomatic hemorrhoids. Indications: Grade III-IV internal hemorrhoids (prolapsed, irreducible), external hemorrhoids with uncontrolled bleeding or recurrent thrombosis, mixed hemorrhoids. Techniques: closed (Ferguson, primary closure), open (Milligan-Morgan, leave wounds open), and stapled hemorrhoidopexy (PPH, for circumferential prolapse, lower pain but higher recurrence). Laser, bipolar, and harmonic scalpel techniques also available. Postoperative pain is significant (particularly with open technique). Recovery: 2-4 weeks. Complications: pain, bleeding, urinary retention, anal stenosis, and incontinence.

Hepatic Surgery

– Liver resection: Couinaud segments. Indications: colorectal liver metastases (CRLM, up to 70% 5-year survival with R0), HCC (Child-Pugh A, portal pressure <10 mmHg, future liver remnant >20% normal, >40% cirrhotic), cholangiocarcinoma, benign tumors (adenoma >5cm, symptomatic hemangioma, FNH diagnostic uncertainty). Preoperative: PVE (portal vein embolization) for FLR <20%/40%; ALPPS (associating liver partition and portal vein ligation) for rapid hypertrophy (2 weeks). Techniques: open, laparoscopic, robotic. Pringle manoeuvre (clamp hepatoduode-

nal ligament, 15-20 min on, 5 min off, ischemic preconditioning may reduce ischemia-reperfusion injury). Low central venous pressure (CVP <5 mmHg) anesthesia. Parenchymal transection: crush-clamp (Kelly clamp), CUSA (cavitron ultrasonic surgical aspirator), LigaSure, Harmonic scalpel. Hepatic vein management: extrahepatic control (right, middle, left suprahepatic veins) or intrahepatic approach (anterior approach with hanging manoeuvre). Complications: bile leak (3-10%), PHLF (post-hepatectomy liver failure, defined by ISGLS peak bilirubin >50 $\mu\text{mol/L}$ + INR >1.5 on post-operative day 5; management: medical support, albumin, diuretics, TIPS, or liver transplantation in severe cases), hemorrhage, abscess, ascites. Non-resectional techniques: RFA (radiofrequency ablation), MWA (microwave ablation), IRE (irreversible electroporation), SBRT (stereotactic body radiotherapy), TACE (transarterial chemoembolization), and TARE (transarterial radioembolization with yttrium-90), each indicated for specific tumor types and locations where surgical resection is not feasible. Liver transplantation: Milan criteria for HCC (single ≤ 5 cm or up to 3 nodules each ≤ 3 cm, no extrahepatic disease, no major vascular invasion) with 5-year survival >70%.

Hernia

– The protrusion of an organ or tissue through an abnormal opening in the wall of the cavity that normally contains it. Most hernias occur in the abdominal wall. Types: (1) Inguinal hernia (most common): indirect (through the deep inguinal ring, lateral to inferior epigastric vessels, congenital or acquired, more common in younger men) vs direct (through Hesselbach triangle, medial to inferior epigastric vessels, acquired, older men). (2) Femoral hernia: through the femoral ring below the inguinal ligament, more common in women, higher risk of strangulation (40%) vs inguinal (10%). (3) Umbilical hernia: through the umbilical ring, common in infants (usually resolves spontaneously by age 2-4) and adults (obesity, pregnancy, ascites). (4) Incisional (ventral) hernia: through a surgical scar, risk factors: wound infection, obesity, smoking, COPD. (5) Hiatus hernia: see separate entry. (6) Epigastric hernia: through the linea alba. (7) Spigelian hernia: through the linea semilunaris. (8) Obturator hernia:

through the obturator foramen (rare, elderly thin women). (9) Lumbar hernia: through the lumbar triangle. (10) Diaphragmatic hernia: through the diaphragm. Diagnosis: history (lump or bulge, worse on standing/straining, cough impulse), examination (inspection: visible bulge; palpation: cough impulse; reducibility). Complications: irreducibility (cannot be reduced), obstruction (bowel obstruction), strangulation (vascular compromise–ischemia, gangrene, surgical emergency). Treatment: surgical repair (open or laparoscopic; tension-free mesh repair is standard–Lichtenstein for inguinal, laparoscopic transabdominal preperitoneal TAPP or totally extraperitoneal TEP). Watchful waiting is an option for minimally symptomatic inguinal hernias in men.

Hernia Repair (Herniorrhaphy)

– Surgical repair of a hernia (inguinal, femoral, umbilical, incisional, hiatal). Inguinal hernia repair: open (Lichtenstein tension-free mesh, Shouldice, Bassini) or laparoscopic (TEP: totally extraperitoneal, TAPP: transabdominal preperitoneal). Mesh reinforcement reduces recurrence (1-3% for mesh vs. 5-15% for primary tissue repair). Indications: symptomatic hernia, incarceration/strangulation risk, and groin pain. Emergency repair for strangulated hernia (bowel resection may be needed). Complications: recurrence, chronic groin pain (5-10%, especially open), mesh infection, seroma, hematoma, and cord injury (vas deferens, testicular vessels).

Hiatus Hernia

– The protrusion of part of the stomach through the esophageal hiatus of the diaphragm into the chest cavity. Types: (1) Sliding hernia (type I, 95%): the gastro-esophageal junction (GOJ) and a portion of the gastric cardia slide above the diaphragm through the hiatus. The GOJ is displaced cephalad, and the angle of His is lost, predisposing to GORD. Associated with: obesity, pregnancy, increased intra-abdominal pressure. (2) Para-esophageal hernia (type II): the GOJ remains in its normal position below the diaphragm, but a portion of the gastric fundus herniates alongside the esophagus. (3) Mixed (type III): both GOJ and fundus herniate. (4) Type IV: herniation of other abdominal organs (colon, omentum, spleen) through the hiatus. Para-esophageal hernias (types II-IV) can incarcerate or strangulate. Symptoms: many sliding hernias

are asymptomatic; associated with GORD (heartburn, regurgitation, dysphagia, chest pain, chronic cough). Large para-esophageal hernias may cause: postprandial fullness, chest pain, dyspnoea, dysphagia, vomiting, and rarely acute gastric volvulus (Borchardt triad: severe epigastric pain, retching without vomiting, inability to pass a nasogastric tube–surgical emergency). Diagnosis: barium swallow (GOJ above diaphragm), upper endoscopy (GOJ displacement, Los Angeles classification of oesophagitis), high-resolution manometry. Management: asymptomatic sliding hernias require no treatment; symptomatic GORD: PPI therapy, lifestyle measures; para-esophageal hernias with symptoms or risk of volvulus: laparoscopic Nissen fundoplication with hernia reduction and crural repair (hiatoplasty).

Hysterectomy

– See obstetrics_gynecology.

Ileostomy

– A surgically created stoma from the terminal ileum to the abdominal wall, performed after proctocolectomy for ulcerative colitis or familial adenomatous polyposis, or to protect a distal anastomosis. Output is liquid and enzyme-rich, requiring careful fluid and skin management. Complications include high-output stoma, hernia, and dehydration.

Incisional Hernia

– A hernia through a previous surgical incision scar, the most common long-term complication of abdominal surgery (10-20% of laparotomies). Risk factors: wound infection, obesity, smoking, malnutrition, COPD, and multiple previous surgeries. Present as a bulge at or near the incision site, worse with standing or straining. Can cause pain, obstruction, and strangulation. Diagnosis: clinical; CT for evaluation of size, number of defects, and contents. Treatment: surgical repair with mesh (open sublay, onlay, or laparoscopic IPOM) to reduce recurrence. Component separation for large/complex hernias.

Inguinal Hernia

– Protrusion of abdominal contents through the inguinal canal. Indirect (lateral to inferior epigastric vessels, through deep inguinal ring): congenital, patent processus vaginalis; most common overall (60-70%), male predominance. Direct (medial to

inferior epigastric vessels, through Hesselbach triangle): acquired, weakness of transversalis fascia; older men. Pantaloon: both indirect and direct. Femoral hernia (below inguinal ligament, through femoral canal): more common in women, right-sided predominance. Clinical: groin bulge (medial to pubic tubercle, below inguinal ligament, irreducible, may cause obstruction or strangulation). Imaging: ultrasound (sensitivity 95%, Valsalva enhancement increases sensitivity) or MRI if diagnosis uncertain. Management: elective repair (symptomatic; open or laparoscopic: TEP - totally extraperitoneal, TAPP - transabdominal preperitoneal). Mesh (polypropylene, lightweight macroporous) preferred over tissue repair (Bassini, Shouldice, McVay, Desarda, Lichtenstein) due to <5% recurrence. Lichtenstein: open tension-free mesh onlay repair, gold standard for open inguinal hernia repair. Laparoscopic: lower recurrence for bilateral and recurrent hernias, faster recovery, less chronic pain (in experienced hands, 1-2% for TEP). Emergency surgery for obstruction/strangulation: McBurney or Lotheissen approach (low midline incision for control of incarcerated bowel), viable bowel → herniorrhaphy, nonviable bowel → resection + herniorrhaphy. Femoral hernia repair: McEvedy approach (retroperitoneal, high approach, through a lower midline or transverse lower abdominal incision) or laparoscopic TEP/TAPP; locking sutures or mesh plug (Bard plug, PerFix plug) or open suture repair (Moschcowitz type, a suture repair of the femoral canal). Complications: recurrence (1-10%, higher with tissue repairs and laparoscopic learning curve), chronic groin pain (10-20%, higher with open, meshoma, nerve entrapment, triple neurectomy for refractory cases), seroma, haematoma, infection (mesh infection <1%, may require mesh removal), testicular atrophy or ischemic orchitis (1-2% during open repair for recurrent hernias or large scrotal hernias), and urinary retention (5-10%, transient) in older male patients after general or spinal anesthesia.

Jejunostomy

– Surgical or endoscopic placement of a feeding tube into the jejunum for enteral nutrition when upper gastrointestinal access is not feasible. See [Feeding Jejunostomy](#).

Laceration

– A wound caused by tearing of body tissue, typically caused by trauma from a sharp object (knife, glass, metal) or blunt force that splits the skin. Lacerations involve the skin and may extend into subcutaneous tissue, muscle, tendon, nerve, or blood vessels. Assessment: location, length, depth, contamination, foreign bodies, neurovascular status (sensation, motor function, capillary refill, distal pulses), and involvement of deeper structures (tendon function, bone exposure). Management: (1) hemostasis: direct pressure, elevation. (2) Wound cleaning: irrigation with normal saline (high-pressure, 250-500 mL, reduces bacterial load). (3) anesthesia: local infiltration with lidocaine 1-2% (with or without adrenaline, max 4.5 mg/kg plain, 7 mg/kg with adrenaline) or topical lidocaine-prilocaine cream for wound margins. (4) Exploration: assess for foreign bodies, tendon/nerve/vascular injury. (5) Debridement: excision of devitalised tissue, ragged wound edges (freshening). (6) Closure: primary closure (sutures—simple interrupted, continuous/mattress, subcuticular; tissue adhesive; adhesive strips; staples) for clean, non-infected wounds; delayed primary closure (3-5 days) for contaminated wounds; healing by secondary intention for infected or high-risk wounds. Tetanus prophylaxis: clean wound—tetanus toxoid if last dose >10 years; contaminated wound—tetanus toxoid + immunoglobulin if last dose >5 years or unknown. Antibiotics: not routinely indicated for simple lacerations; consider for contaminated wounds, human/animal bites, immunocompromised patients. Sutures removal timing: face 3-5 days, scalp 7 days, trunk/arms 7-10 days, legs 10-14 days. Complications: wound infection (2-5%), dehiscence, hypertrophic scarring/keloid, retained foreign body, nerve damage.

Laminectomy

– Surgical removal of the lamina (posterior vertebral arch) to decompress the spinal canal. Indications: spinal stenosis (lumbar and cervical), herniated disc (with central stenosis), and spinal tumor. Decompression of the entire spinal canal. Often combined with discectomy (lumbar) or foraminotomy (nerve root decompression). May require fusion if instability is present (laminectomy with fusion, PLF). Complications: CSF leak (dural tear), spinal instability

(post-laminectomy kyphosis), epidural hematoma, infection, and neurologic injury.

Large Bowel Obstruction

- Mechanical blockage of the colon most commonly caused by colorectal cancer, volvulus, or diverticular stricture. See [gastroenterology](#).

Ligature

- See [forensic_medicine](#).

Lobectomy

- Surgical removal of a lobe of an organ. Most commonly lung lobectomy (removal of one lobe of the lung, performed for lung cancer, bronchiectasis, abscess, or benign tumor) or temporal lobectomy (removal of the anterior temporal lobe for drug-resistant temporal lobe epilepsy). Lung lobectomy: the standard surgical treatment for early-stage (stage I-II) non-small cell lung cancer (NSCLC). Approaches: open thoracotomy (posterolateral) or video-assisted thoracoscopic surgery (VATS, minimally invasive, less post-operative pain, shorter hospital stay, equivalent oncologic outcomes). The remaining lung lobes expand to fill the thoracic cavity. Pulmonary function loss corresponds to the number of segments removed (each lobe contains 2-5 bronchopulmonary segments). Compensatory hyperinflation of remaining lung occurs over weeks. Temporal lobectomy: anterior temporal lobectomy (ATL) for epilepsy involves resection of 3-4 cm of the anterior temporal neocortex plus the amygdala and anterior 2-3 cm of the hippocampus. Seizure-free outcome: 60-70% in well-selected patients with mesial temporal sclerosis. Complications: visual field deficit (superior quadrantanopia, due to optic radiation Meyer loop injury, 50-80%), language deficits (dominant hemisphere), memory impairment. Other lobectomies: hepatic lobectomy (liver resection, for cancer or living donor), thyroid lobectomy (removal of one thyroid lobe, for thyroid nodule/cancer), and cerebral lobectomy (removal of a whole brain lobe, for severe trauma or tumor).

Local Anesthesia

- The reversible abolition of sensation in a circumscribed area by infiltration or topical application of local anesthetic agents (lidocaine, bupivacaine) without loss of consciousness. Maximum safe dosing must be observed to avoid systemic toxicity.

Epinephrine prolongs duration but is avoided in end-arterial territories.

Lumpectomy

- Breast-conserving surgery excising a malignant lesion with a margin of normal tissue, combined with whole-breast radiation to yield survival equivalent to mastectomy for early-stage cancer. An acceptable margin is no ink on tumor for invasive cancer and 2 mm for ductal carcinoma in situ. Sentinel lymph node biopsy is integrated for axillary staging.

Mastectomy

- Surgical removal of the breast. Total (simple) mastectomy: removal of breast tissue, areola, and nipple. Modified radical mastectomy (MRM): total mastectomy + axillary lymph node dissection (levels I-III), for invasive breast cancer. Skin-sparing mastectomy: preserves breast skin envelope for immediate reconstruction (implant or autologous). Nipple-sparing mastectomy: preserves nipple-areolar complex (for small, peripherally located tumors). Indications: breast cancer (locally advanced, multicentric, inflammatory), and risk-reducing in BRCA carriers (prophylactic bilateral mastectomy). Sentinel lymph node biopsy (SLNB) replaced ALND for node-negative patients. Reconstruction: implant-based or autologous (TRAM, DIEP, latissimus dorsi flap).

Necrotizing Fasciitis

- A life-threatening soft tissue infection characterized by rapid necrosis of the subcutaneous fascia and subcutaneous tissue, with relative sparing of the overlying skin in early stages. It is a surgical emergency requiring immediate wide surgical debridement and broad-spectrum antibiotics. Type I (polymicrobial, 60-75 percent of cases) occurs in diabetic, immunocompromised, or post-surgical patients and involves aerobic and anaerobic bacteria (*E. coli*, *Klebsiella*, *Bacteroides*, *Peptostreptococcus*, *Clostridium* species). Type II (monomicrobial, 15-30 percent) is caused by Group A *Streptococcus* (*Streptococcus pyogenes*) with or without *Staphylococcus aureus*, often in healthy individuals, and may present with toxic shock syndrome. Type III (gram-negative, marine-related: *Vibrio vulnificus*, *Aeromonas hydrophila*) occurs after exposure to seawater or freshwater, especially in pa-

tients with chronic liver disease. Type IV (fungal: *Candida*, *Mucor*, *Aspergillus*) occurs in severely immunocompromised patients and neutropenic patients. LRINEC score (Laboratory Risk Indicator for Necrotizing Fasciitis) stratifies risk: CRP >150 mg/L + WBC >15,000 + Hb <11 g/dL + Na <135 mmol/L + Cr >1.6 mg/dL + glucose >10 mmol/L, with a score ≥ 6 raising suspicion (positive predictive value 92%) and ≥ 8 strongly predictive (positive predictive value 93-99%). Management: aggressive IV fluid resuscitation, broad-spectrum antibiotics (piperacillin-tazobactam 4.5 g IV q6h or meropenem 1 g IV q8h + clindamycin 600-900 mg IV q8h to suppress toxin production, particularly for streptococcal toxic shock syndrome), urgent surgical debridement (fasciotomy with excision of all devitalised tissue, to the level of healthy bleeding muscle, re-exploration within 24-48 hours is mandatory). IVIG is used as adjunctive therapy for streptococcal toxic shock syndrome (2 g/kg loading dose, then 0.4 g/kg/day for 3-5 days). Hyperbaric oxygen (HBO) therapy is controversial but may be beneficial as an adjunct. Post-operative care includes repeat debridement such that the wound is thoroughly debrided within 24-72 hours, negative pressure wound therapy (NPWT) to promote granulation, and delayed primary closure or split-thickness skin grafting (STSG) once the wound is clean. Mortality: 20-40%, >50% if septic shock at presentation. Amputation rate is 15-25%. Poor prognostic factors include advanced age (>60), diabetes mellitus, delay in surgery (>24 hours from admission to first debridement), involvement of the trunk, and streptococcal toxic shock syndrome. Renal failure, immune compromise, LRINEC score ≥ 8 and the presence of bullae or skin necrosis are also poor prognostic signs.

Nephrectomy

– Surgical removal of a kidney. Radical nephrectomy: kidney + Gerota fascia + adrenal gland (for renal cell carcinoma). Partial nephrectomy (nephron-sparing): for small renal tumors (<7 cm, renal function preservation). Simple nephrectomy: for benign disease (non-functioning kidney, chronic infection, massive hydronephrosis). Laparoscopic/robotic approach is standard (less pain, shorter stay). Indications: renal cell carcinoma (most common),

trauma, and living donor nephrectomy. Complications: bleeding, infection, pneumothorax, splenic or pancreatic injury (left), and vascular injury.

Nephrostomy Tube

– A percutaneously placed catheter in the renal pelvis to drain urine, bypassing a ureteral obstruction. Indications: ureteral obstruction (calculus, tumor, stricture) causing hydronephrosis, pyonephrosis (infected, obstructed kidney — emergency drainage), and as a temporary measure before definitive surgery. Placed by interventional radiology under ultrasound/CT guidance. Sizes: 8-14 Fr. Output: normal 1-2 L/day. Tube is secured to the skin and connected to a drainage bag. Changed q6-12 weeks. Complications: bleeding (hematuria, perirenal hematoma), infection, tube dislodgement/obstruction, and adjacent organ injury (colon, pleura).

Open-Heart Surgery

– Any surgical procedure involving opening the chest wall (sternotomy or thoracotomy) and operating on the heart, usually with cardiopulmonary bypass (the heart-lung machine). Procedures: coronary artery bypass grafting (CABG—most common), valve repair/replacement (aortic, mitral), septal defect repair (ASD, VSD), heart transplantation, and ventricular assist device implantation. Cardiopulmonary bypass drains venous blood, oxygenates it, and returns it to the arterial system, allowing the surgeon to operate on a still, bloodless heart. Cardioplegia solution (high potassium) stops the heart in diastole, reducing myocardial oxygen demand during ischemia. Risks: bleeding, infection (mediastinitis, sternal wound), stroke (aortic manipulation—embolic), acute kidney injury, post-pericardiotomy syndrome, and cognitive dysfunction ('pump head'—typically transient). Minimally invasive approaches (mini-thoracotomy, robotic-assisted) reduce recovery time and blood loss. Off-pump CABG avoids cardiopulmonary bypass but has similar outcomes in selected patients.

Organ Transplants

– The surgical transfer of an organ from a donor to a recipient with end-stage organ failure. Solid organ transplants: kidney (most common, >90,000 per year worldwide), liver, heart, lung, pan-

creas, and intestine. Donor types: deceased donor (brainstem death or donation after circulatory death—DCD), living donor (kidney, partial liver, partial lung). Immunosuppression: induction (anti-thymocyte globulin, basiliximab) and maintenance (calcineurin inhibitors—tacrolimus, cyclosporine; antiproliferatives—mycophenolate mofetil; corticosteroids). Rejection: hyperacute (minutes—preformed antibodies, ABO incompatibility), acute (days to months—T-cell mediated, treatable with high-dose steroids), and chronic (months to years—multifactorial, progressive graft dysfunction). Organ allocation is managed by national bodies (NHSBT in the UK, UNOS in the US). Waiting list mortality is driven by organ shortage. Xenotransplantation (pig organs—genetically modified to reduce hyperacute rejection) is emerging as a potential solution.

Pancreatic Neuroendocrine Tumors

– Pancreatic neuroendocrine tumors (pNETs): functional (insulinoma, gastrinoma, glucagonoma, VIPoma, somatostatinoma) or non-functional (60-70%). WHO 2017 grading: NET G1 (Ki-67 <3%, mitotic <2/10 HPF), NET G2 (Ki-67 3-20%, mitotic 2-20/10 HPF), NEC G3 (Ki-67 >20%, mitotic >20/10 HPF). Functional: insulinoma (hypoglycemia, Whipple triad, 90% benign, enucleation/distal pancreatectomy), gastrinoma (Zollinger-Ellison syndrome, ulcers, diarrhea, MEN1 association, duodenal > pancreatic, surgery if localized and resectable, PPI (gastrinoma: high-dose PPI, 80 mg omeprazole daily, can be increased to 120 mg daily for symptom control), octreotide for symptom control), glucagonoma (necrolytic migratory erythema, diabetes, weight loss, DVT, distal pancreatectomy + octreotide), VIPoma (WDHA syndrome: watery diarrhea, hypokalaemia, achlorhydria, VIP levels >75 pmol/L, octreotide, surgery), somatostatinoma (diabetes, gallstones, steatorrhea, surgery). Non-functional: 60-70%, large >2cm at diagnosis, no hormonal syndrome, surgery (resection or enucleation if <2cm and favourable location). pNETs in MEN1: multiple, less aggressive, surgery for >2cm or functioning tumors in the pancreatic head; enucleation preferred for superficial tumors while deeper le-

sions may require pancreaticoduodenectomy; observation for small (<2cm) non-functioning pNETs with surveillance every 6-12 months (in MEN1 and sporadic cases). Syndromic associations: MEN1 (multiple pNETs, parathyroid adenomas, pituitary adenomas, carcinoid tumors), VHL (serous cystadenomas, pNETs, renal cell carcinoma, pheochromocytoma, retinal angiomas, cerebellar haemangioblastomas), tuberous sclerosis, NF1. Prognosis: 5-year survival 90% for well-differentiated localised NET, 30-50% for metastatic (grade-dependent; Ki-67 is the most important independent prognostic factor). WHO classification 2019: well-differentiated neuroendocrine tumor (NET G1, G2, G3) and poorly differentiated neuroendocrine carcinoma (NEC G3, small cell or large cell type), with significant difference in prognosis and management (NET G3 is treated as an indolent well-differentiated NET rather than aggressive NEC G3).

Pancreatic Surgery

– Pancreaticoduodenectomy (Whipple): pancreatic head, duodenum, gallbladder, distal stomach (pylorus-preserving standard), common bile duct; reconstruction: pancreaticojejunostomy (duct-to-mucosa or invagination), hepaticojejunostomy, gastrojejunostomy/duodenojejunostomy. Distal pancreatectomy: body/tail; spleen-preserving (Kimura, Warshaw) or splenectomy. Central pancreatectomy: neck tumors, preserve head and tail. Enucleation: small pNETs/insulinomas away from duct. Complications: POPF (pancreatic fistula; ISGPS definition: amylase >3x upper limit of normal in drain fluid on or after post-operative day 3; biochemical leak (grade A, no change in management) vs grade B (requires change in management, e.g., prolonged drainage, total parenteral nutrition, somatostatin analogues, antibiotics, percutaneous drainage) vs grade C (major change in management, ICU stay, reoperation, or death); management: NPO, TPN or enteral nutrition via nasojejunal tube if possible, octreotide (somatostatin 250-500 mcg subcutaneously TDS after gastrectomy or after Whipple procedure to reduce exocrine pancreatic secretion, though evidence is mixed and routine use is not recommended), ERCP with pancreatic duct stenting for persistent high-output fistula; percutaneous drainage of fluid collections; reoperation for uncon-

trolled fistula or bleeding), DGE (delayed gastric emptying, ISGPS definition: NGT >500 mL/day lasting beyond post-operative day 3; management: prokinetics, NGT decompression, enteral nutrition via surgical jejunostomy tube placed at the time of pancreaticoduodenectomy or by nasojejunal tube; most cases resolve spontaneously within 2-4 weeks; persistent DGE may require endoscopic dilation or stenting if there is mechanical obstruction at the gastrojejunostomy), post-pancreatectomy hemorrhage (PPH; early <24 hours, late >24 hours; ISGPS classification: grade A no intervention, grade B intervention without ICU, grade C ICU $\pm$ reoperation $\pm$ embolisation; management: resuscitation, endoscopy or angiography with embolisation, reoperation), and pancreatic ductal adenocarcinoma (PDAC) recurrence (locoregional, liver, peritoneal, distant). Adjuvant chemotherapy: FOLFIRINOX (modified) for 6 months after resection (PRODIGE 24 trial - median survival 54.4 months vs 35.0 months for gemcitabine) or gemcitabine + capecitabine (ESPAC-4 trial). Median survival for resected PDAC is 24-30 months; 5-year survival 15-25% (improving with modern multi-agent chemotherapy). Borderline resectable PDAC: neoadjuvant chemotherapy (FOLFIRINOX or gemcitabine + nab-paclitaxel) for 2-6 months, then restaging CT and CA 19-9; proceed to surgery if no progression and venous involvement is reconstructable. Arterial involvement (celiac axis, superior mesenteric artery, common hepatic artery) generally precludes resection unless a modified approach (e.g., Appleby procedure for celiac axis involvement) is considered in selected cases.

Parathyroid Surgery

– Primary hyperparathyroidism (PHPT): single adenoma (85%), hyperplasia (15%), double adenoma (2%), carcinoma (<1%). Criteria for surgery (NIH): age <50, calcium >1 above upper limit, creatinine clearance <60, BMD T-score <-2.5, vertebral fracture, nephrolithiasis, nephrocalcinosis. Localization: sestamibi scan (sensitivity 80-90%), US (sensitivity 70-80%), 4D-CT, MRI, PET-Choline. Minimally invasive parathyroidectomy (MIP) for single adenoma with concordant imaging; bilateral exploration for negative or discordant imaging. Intraoperative PTH monitoring (IOPTH): drop of >50% from baseline

10 minutes after gland excision confirms cure with 95% positive predictive value. Four-gland exploration: identify 4 glands, resect enlarged, biopsy normal. Auto-transplantation: implant parathyroid tissue (typically 10-15 fragments of 1-2mm each) into brachioradialis or sternocleidomastoid muscle if total parathyroidectomy is necessary (reoperative surgery, secondary/tertiary hyperparathyroidism, multiple gland hyperplasia, MEN1, familial hypocalciuric hypercalcaemia). Reoperative parathyroid surgery: persistent (never normocalcaemic) or recurrent (normocalcaemic for >6 months) PHPT; requires pre-operative imaging (4D-CT, sestamibi with SPECT/CT, MRI, PET-Choline) and intraoperative nerve monitoring (recurrent laryngeal nerve is at risk of injury in reoperative neck surgery). Complications: recurrent laryngeal nerve injury (<1% in primary surgery, 3-5% in reoperative), hypoparathyroidism (transient 10-20%, permanent <2%), haematoma (1-2%), infection, and hungry bone syndrome (severe, prolonged hypocalcaemia after resection of severe PHPT with high pre-operative calcium and ALP; management: IV calcium gluconate infusion, oral calcium carbonate 3-6 g/day, calcitriol 0.5-2 mcg/day, magnesium replacement if indicated; worst in patients with pre-operative calcium >3.0 mmol/L and markedly elevated PTH and alkaline phosphatase). Secondary hyperparathyroidism (renal failure): medical management (phosphate binders, vitamin D analogues, cinacalcet); subtotal parathyroidectomy (3.5 gland) or total parathyroidectomy with auto-transplantation for refractory symptomatic hyperparathyroidism with persistent hypercalcaemia despite maximal medical therapy, or for tertiary hyperparathyroidism after kidney transplantation with persistent hypercalcaemia >6 months post-transplant. Tertiary hyperparathyroidism: autonomous PTH secretion despite normal renal function after renal transplantation; parathyroidectomy indicated if hypercalcaemia persists beyond 6 months from transplantation.

Penetrating Abdominal Trauma

– Trauma to the abdomen caused by a missile (gun-shot wound) or sharp object (stab wound). GSWs: high energy transfer, produce blast cavity, high risk of intra-abdominal injury (90%), mandatory exploration. Stab wounds: lower energy, 30-50% do

not penetrate peritoneum; local wound exploration to determine peritoneal violation. Zones: anterior abdomen (xiphoid to pubis, costal margins), flank (midaxillary to posterior axillary line), and back (posterior to posterior axillary line). Diagnosis: CT with triple contrast (IV, oral, rectal) in stable patients; diagnostic laparoscopy for equivocal cases. Management: hemodynamic instability or peritonitis → laparotomy. Stable: serial exams, CT, and selective non-operative management.

PICC Line (Peripherally Inserted Central Catheter)

– A long, flexible catheter inserted into the basilic or cephalic vein and advanced so the tip sits in the superior vena cava. Inserted at the bedside, often by a specialized PICC nurse, with ultrasound and ECG or X-ray confirmation. Indications: long-term IV antibiotics (>2 weeks), TPN, chemotherapy, and frequent blood draws. Sizes: 4-6 Fr single, double, or triple lumen. Duration: weeks to months. Advantages over tunneled central lines: lower risk of pneumothorax, insertion by non-physicians. Complications: infection (line-related bloodstream infection), thrombosis, phlebitis, malposition, and catheter fracture.

Postoperative Care

– Structured post-surgical management encompassing pain control, fluid balance, wound care, early mobilization, and venous thromboembolism prophylaxis. Enhanced Recovery After Surgery pathways standardize care through multimodal opioid-sparing analgesia, goal-directed fluid therapy, and early feeding to reduce length of stay and complications.

Postoperative Complications

– Clavien-Dindo classification: Grade I (any deviation, no treatment), Grade II (pharmacologic), Grade III (surgical/endoscopic/radiologic intervention: IIIa no GA, IIIb GA), Grade IV (ICU: IVa single organ, IVb multi-organ), Grade V (death). Common: ileus (delayed GI motility, NPO, NGT, ambulation, gum chewing, neostigmine for Ogilvie), anastomotic leak (clinical: pain, fever, leukocytosis; CT: extraluminal contrast, fluid; management: antibiotics, percutaneous drainage, diversion, reoperation), wound infection (SSI, superficial/deep/organ space; management: antibiotics, drainage, wound

care, negative pressure wound therapy or vacuum-assisted closure), surgical site infection prevention bundle, pulmonary complications (pneumonia, atelectasis: IS/CPT, O₂, incentive spirometry 10 breaths per hour, early mobilisation), DVT/PE (PESI score, Caprini risk assessment, pharmacologic prophylaxis: enoxaparin 40 mg SC daily or 30 mg BID or unfractionated heparin 5,000 units TID; mechanical prophylaxis: SCD, TED stockings; systemic anticoagulation if PE confirmed). ERAS (Enhanced Recovery After Surgery) pathways: multidisciplinary approach to reduce surgical stress and accelerate recovery; components include pre-operative counseling, avoidance of prolonged fasting (carbohydrate loading 2 hours before surgery), no bowel preparation, epidural analgesia, goal-directed fluid therapy (avoiding excessive crystalloid administration), avoidance of NG tubes and drains, early mobilisation (day of surgery for ambulatory patients, or as soon as the patient can sit in a chair), early oral intake (clear liquids within 4-6 hours, progression to full fluids and then solids as tolerated), and multimodal non-opioid analgesia (paracetamol, NSAIDs, gabapentinoids, lidocaine patches, regional anesthesia blocks); ERAS compliance >70% associated with reduced length of stay (LOS) and complication rates.

Postoperative Ileus

– Temporary impairment of gastrointestinal motility after surgery, most common after abdominal surgery. Pathophysiology: autonomic dysfunction (sympathetic overactivity), inflammatory mediators, opioids, and electrolyte abnormalities. Presents with abdominal distension, nausea/vomiting, inability to tolerate oral intake, and absence of flatus/stool. Normal postoperative GI recovery: small bowel (24h), stomach (48h), colon (72-120h). Distinguish from mechanical obstruction (pain is crampy, bowel sounds high-pitched). Management: NPO, IV fluids, electrolyte correction, early ambulation, minimize opioids (use multimodal analgesia), gum chewing, and alvimopan (mu-opioid receptor antagonist). Neostigmine for Ogilvie syndrome (colonic pseudo-obstruction).

Ranula

– A mucocele (mucus extravasation cyst) of the sublingual salivary gland, presenting as a blue-

translucent, fluctuant swelling in the floor of the mouth, typically lateral to the lingual frenulum. A ranula results from trauma or obstruction of a sublingual gland duct, causing mucus accumulation in the sublingual space. If the ranula extends through the mylohyoid muscle into the submental or submandibular space, it is termed a 'plunging' or 'cervical' ranula (presents as a neck mass). Ranulas are benign and painless unless secondarily infected. Differential diagnosis: dermoid cyst, thyroglossal duct cyst, lymphatic malformation, and submandibular gland swelling. Treatment: excision of the ranula and the ipsilateral sublingual gland (lowest recurrence rate—<5%), marsupialisation (incision and drainage, suturing the cyst wall to the oral mucosa—higher recurrence rate), or laser ablation. Plunging ranulas require transcervical excision of the sublingual gland. Needle aspiration is not curative. Simple oral ranulas can be managed conservatively if small and asymptomatic.

Renal Transplant (Renal Transplantation)

- Best treatment for ESRD with improved survival over dialysis. See [Kidney Transplantation](#).

Skin Graft

- Transfer of skin from a donor site to a recipient site to cover a wound. Split-thickness skin graft (STSG): epidermis + partial dermis (0.008-0.018 inches), harvested with dermatome, donor site heals spontaneously (2-3 weeks). Full-thickness skin graft (FTSG): epidermis + full dermis, donor site requires closure, better cosmetic outcome. Types: autograft (same person), allograft (cadaveric), xenograft (animal), and synthetic (Integra, Biobrane). Uses: burn wounds, traumatic skin loss, chronic ulcers, and post-oncologic reconstruction. Graft take: requires vascularized wound bed, immobilization, and prevention of infection/shear.

Small Bowel Obstruction

- Mechanical blockage of the small intestine most commonly caused by adhesions from prior surgery accounting for sixty to seventy-five percent, followed by hernias and malignancy. See [gastroenterology](#).

Smoke Inhalation Injury

- Pulmonary injury caused by inhalation of toxic products of combustion. Three components: ther-

mal injury (supraglottic: heat causes edema of the upper airway), chemical irritation (lower airway: aldehydes, ammonia, chlorine, hydrogen chloride cause bronchospasm, mucosal edema, and sloughing), and systemic toxicity (carbon monoxide: carboxyhemoglobin >10% causes tissue hypoxia; cyanide: impairs cellular respiration). Presents with facial burns, singed nasal hairs, carbonaceous sputum, hoarseness, stridor, and dyspnea. Diagnosis: bronchoscopy (gold standard), carboxyhemoglobin level. Treatment: 100% oxygen (shortens CO half-life to 60 min); intubation for upper airway edema; mechanical ventilation with lung-protective strategy; bronchodilators; aggressive pulmonary toilet. Hyperbaric oxygen for severe CO poisoning (neuropsychiatric). Hydroxocobalamin for cyanide toxicity.

Spinal Fusion

- Surgical union of two or more vertebrae using bone graft or bone graft substitutes with instrumentation (rods, screws, cages). Approaches: posterior (posterolateral fusion, transforaminal lumbar interbody fusion TLIF), anterior (anterior lumbar interbody fusion ALIF), and lateral (extreme lateral interbody fusion XLIF). Indications: degenerative disc disease, spondylolisthesis, spinal instability, scoliosis, and trauma. Bone graft sources: autograft (iliac crest, gold standard), allograft, BMP (bone morphogenetic protein), and synthetic. Complications: pseudoarthrosis (non-union), hardware failure, adjacent segment disease, infection, and nerve root injury.

Splenectomy

- Indications: trauma (grade IV/V, hemodynamic instability), ITP (refractory), hereditary spherocytosis/elliptocytosis, thalassemia major, sickle cell (sequestration crisis), TTP (refractory), lymphoma staging (historical), hypersplenism, splenic cysts/tumors, Wandering spleen. Laparoscopic preferred. Vaccinations: pneumococcal (PCV20 or PCV15+PPSV23), meningococcal (MenACWY + MenB), Hib - ideally 2 weeks pre-op; post-op if emergency. Antibiotic prophylaxis: penicillin V daily (children <5 or <2 years post-splenectomy or with continued immunosuppression) or amoxicillin daily (adults, alternatively: penicillin V 250 mg BID or amoxicillin 500 mg daily) for at least 2 years

after splenectomy or for life if ongoing immunosuppression; immunocompromised patients require lifelong prophylaxis. Fever: stationary IV ceftriaxone plus azithromycin; seek immediate medical attention (splenectomy alert card/wallet card, medical bracelet, fever algorithm for carers). Overwhelming post-splenectomy infection (OPSI): encapsulated bacteria (*S. pneumoniae* 50-60%, *H. influenzae* type b 10-15%, *N. meningitidis* 10-15%, *E. coli*, Group B *Streptococcus*, *Capnocytophaga canimorsus* from dog bites); rapidly progressive (fulminant) sepsis (mortality 50-70%); presentation: fever, rigors, hypotension, DIC, multi-organ failure within hours; management: IV fluids, broad-spectrum IV antibiotics (ceftriaxone 2 g IV 12-hourly or meropenem 1 g IV 8-hourly) immediately, ICU, vasopressors. Platelet count: rises after splenectomy (thrombocytosis usually transient, peaks at 1-3 weeks, resolves by 2-3 months; platelet count >450,000-1,000,000); aspirin 81 mg daily if platelet count >1,000,000 (to reduce risk of thrombosis). Complications: portal vein thrombosis (3-10%, increased if splenomegaly, myeloproliferative disorder, or hemolytic anemia; duplex ultrasound at day 7 post-operatively in high-risk patients, or CT with portal venous phase imaging if symptomatic; treatment: therapeutic anticoagulation with LMWH or warfarin for 3-6 months or lifelong if there is thrombophilia or persistent splanchnic vein thrombus). Long-term: re-immunise with PPSV23 every 5 years (or per guidelines; Centers for Disease Control and Prevention recommends a single PPSV23 booster 5 years after the initial dose in asplenic adults, and a second booster at age 65 or above if at least 5 years since last). The risk of OPSI is 0.23-4.4% per year, with a lifetime risk of 5-10%.

Sterilization

- A process eliminating all microbial life including spores, achieving a sterility assurance level of at least 10^{-6} . See microbiology.

Stoma Complications

- Complications related to intestinal or urinary stomas. Early (<30 days): ischemia/necrosis (assess with test tube/endoscope, if $\rightarrow$ mucosa or at fascia $\rightarrow$ revision), mucocutaneous separation, retraction, parastomal abscess, high output (>1500 mL/day, may cause dehydration/electrolyte depletion $\rightarrow$ an-

tidiarrheals, loperamide, codeine, octreotide, dietary modification). Late: parastomal hernia (most common late complication, abdominal wall defect $\rightarrow$ support belt, surgical mesh repair), prolapse (full-thickness protrusion $\rightarrow$ reduction, repair), stenosis (fibrous ring at skin level $\rightarrow$ dilation, revision), and skin irritation (leakage $\rightarrow$ proper appliance fit, skin barriers, powder, paste). Patient education and stoma nurse consultation essential.

Surgical Site Infection

- SSI classification (CDC): superficial incisional (skin/subcutaneous, <30 days), deep incisional (fascia/muscle, <30/90 days with implant), organ/space (any part opened/manipulated, <30/90 days with implant). Risk factors: patient (diabetes, obesity, smoking, immunosuppression, malnutrition, age), operative (contamination class, duration, technique, hair removal, hypothermia, hyperglycemia), postoperative (hyperglycemia, hypothermia, hematoma). Prevention: preoperative shower (CHG), appropriate antibiotic (cefazolin or cefoxitin, or ceftriaxone + metronidazole for colorectal surgery; vancomycin or clindamycin for penicillin-allergic patients) within 60 minutes before incision (120 minutes for vancomycin and fluoroquinolones due to longer infusion time), hair removal with clippers (not razors), normothermia (active warming with forced-air warming blankets), oxygenation (FiO₂ 80% during and 6 hours after surgery), maintain euglycaemia (glucose <10 mmol/L, tighter range of 6-10 mmol/L, with insulin sliding scale if needed), wound protector, glove change before closure, and post-operative normothermia, euglycaemia, and oxygen. Antibiotic re-dosing for prolonged surgery (>2 half-lives, approximately 2-4 hours for cefazolin, 4-6 hours for metronidazole, 6-8 hours for ciprofloxacin), appropriate weight-based dosing (e.g., vancomycin 15 mg/kg obese, 30 mg/kg for cefazolin in morbid obesity). Surgical technique: gentle tissue handling, meticulous hemostasis, avoidance of dead space, tension-free closure, use of knotless barbed sutures (e.g., Stratafix, V-Loc) for fascial closure and skin closure techniques: subcuticular absorbable monofilament sutures (skin closure in layers reduces risk of wound infection) or metallic staples (which have the advantage of speed but are not recommended for closure of laparoscopic port sites >5

mm). When closing the fascia, use a continuous slowly absorbable monofilament suture such as PDS (polydioxanone) #1 or #2 for laparotomy incisions, a suture length to wound length ratio of at least 4:1 (the "small bites" technique uses 5 mm bites 5 mm apart, reducing incisional hernia). Prophylactic negative pressure wound therapy (ciNPT, Prevena or PICO system) for high-risk wounds (contaminated, dirty, emergency laparotomy, obese, diabetic, stoma, or immunocompromised patients). Management of established SSI: wound culture, open wound, drainage, debridement, packing with saline-soaked gauze or alginate dressings, VAC or negative pressure wound therapy (NPWT) for large, deep, or chronic wounds. Antibiotics only if cellulitis, systemic signs, or organ/space infection. SSI rates: clean <2%, clean-contaminated <5%, contaminated <15%, dirty >25%.

Suture

– A thread or strand of material used to approximate tissues (bring wound edges together) and hold them in place until healing occurs. Sutures are classified by: (1) Absorbability—absorbable (catgut, polyglactin/Vicryl, poliglecaprone/Monocryl, polydioxanone/PDS—degrade by hydrolysis over weeks to months, used for deep tissues, internal wounds) and non-absorbable (nylon/Ethilon, polypropylene/Prolene, silk, stainless steel—remain permanently, used for skin closure, vascular anastomoses, tendons). (2) Structure—monofilament (single strand—less tissue trauma, lower infection risk, but more difficult to handle, greater knot slippage) and multifilament (braided—easier handling, better knot security, higher infection risk—capillary action harbours bacteria). (3) Needle type—cutting (for skin, tough tissues), reverse cutting, round-bodied (for soft tissues—bowel, vessels, fascia), and taper-cut. Suture size: from 10-0 (ophthalmic microsurgery) to 0-2 (fascia, orthopedics). Suture techniques: simple interrupted (most common, secure, allows individual knot removal), continuous/running (faster, better wound edge eversion, but if one stitch breaks, the entire suture line may fail), horizontal mattress (everts wound edges, tension reduction), vertical mattress (everts edges, good for deep closure), subcuticular (intradermal—best cosmetic result, eliminates suture marks), and purse-

string. Alternatives to sutures: surgical staplers (fast, consistent—bowel anastomoses, skin closure), tissue adhesives (cyanoacrylate/Dermabond—for superficial wounds, topical use), adhesive strips (Steri-Strips—for superficial, low-tension wounds), and knotless barbed sutures (Knotless Tissue Control—used in laparoscopic and robotic surgery).

TACO

– Transfusion-Associated Circulatory Overload, a complication of blood transfusion due to volume overload causing pulmonary edema. Risk factors: pre-existing cardiac or renal disease, extremes of age, large transfusion volume, rapid infusion rate. Presents with dyspnea, orthopnea, hypertension, JVD, pulmonary edema, and BNP elevation within 6-12 hours of transfusion. Distinguish from TRALI: TRALI has hypotension, fever, and no fluid overload signs. Management: diuresis (furosemide), oxygen, and slow or split transfusion units in high-risk patients. Prevention: slow transfusion rate, pre-transfusion furosemide.

Thoracotomy

– A surgical incision into the chest wall to access the thoracic cavity (pleural space, lungs, heart, great vessels, esophagus, diaphragm, mediastinum). Types: (1) Posterolateral thoracotomy (most common)—incision below the tip of the scapula, dividing the latissimus dorsi and serratus anterior, entering the chest through the 4th, 5th, or 6th intercostal space; provides excellent access for pulmonary lobectomy, pneumonectomy, oesophagectomy, and thoracic aortic surgery. (2) Anterolateral thoracotomy—emergency access for trauma, pericardial window, or lung biopsy. (3) Median sternotomy—midline division of the sternum (sternotomy), used for cardiac surgery (CABG, valve surgery, thymectomy, anterior mediastinal mass). (4) Clamshell incision (bilateral anterolateral thoracotomy with transverse sternotomy)—for bilateral lung transplantation, massive trauma. (5) Axillary thoracotomy—for first rib resection, sympathectomy. Complications: post-thoracotomy pain (significant, long-lasting—use of epidural analgesia, paravertebral block, intercostal nerve blocks), wound infection, hemorrhage, persistent air leak, pneumonia, and atelectasis. Minimally invasive alternatives: video-assisted thoracoscopic surgery

(VATS)—reduces pain, hospital stay, and recovery time.

Thyroid Surgery

– lobectomy, subtotal thyroidectomy, and total thyroidectomy. Indications: Bethesda V/VI nodules on cytology, thyroid cancer (papillary >1.5 cm, follicular, medullary, anaplastic), Graves disease (compressive symptoms, failed medical therapy, severe ophthalmopathy), and multinodular goiter with compressive symptoms or substernal extension. Lobectomy is appropriate for Bethesda III/IV nodules and low-risk papillary microcarcinoma (<1.5 cm, solitary, no nodal involvement). Total thyroidectomy is standard for bilateral disease, high-risk features, medullary carcinoma, and anaplastic carcinoma (palliative for airway obstruction). Central compartment dissection (level VI) is performed for clinically involved nodes; prophylactic dissection is controversial due to increased risk of nerve injury and hypoparathyroidism. Lateral neck dissection (levels II-V) is reserved for confirmed cervical metastases. Intraoperative nerve monitoring facilitates identification of the recurrent laryngeal nerve. The external branch of the superior laryngeal nerve is at risk during ligation of the superior thyroid pole. The parathyroid glands are at risk of devascularization or accidental excision. Complications: recurrent laryngeal nerve injury (2-5% transient, <1% permanent) presents with hoarseness and aspiration; bilateral injury causes stridor requiring tracheostomy. Hypoparathyroidism (transient 10-30%, permanent 1-2%) requires calcium and calcitriol supplementation, guided by post-operative PTH monitoring. Haematoma (0.5-2%) requires emergency evacuation to prevent airway compromise. Wound infection and hypertrophic scarring are less common. TSH suppression therapy reduces recurrence risk in thyroid cancer. Radioactive iodine ablation is given for high-risk differentiated cancer after total thyroidectomy.

TIPS (Transjugular Intrahepatic Portosystemic Shunt)

– A radiologically placed shunt connecting the portal vein to a hepatic vein within the liver, creating a portosystemic shunt to reduce portal pressure. Indications: variceal bleeding (refractory or recurrent), refractory ascites, and hepatic hydrothorax. Proce-

dures: transjugular access, hepatic vein cannulation, needle puncture through liver parenchyma into the portal vein, balloon dilation, and covered stent placement. Portal pressure gradient goal: <12 mmHg. Contraindications: severe pulmonary hypertension, right heart failure, severe hepatic encephalopathy, and severe liver failure (MELD >18-20). Complications: encephalopathy (30-40%), shunt stenosis/occlusion, bleeding, infection, and radiation exposure.

Total Hip Arthroplasty (THA)

– Replacement of the hip joint with prosthetic components. Acetabular component: metal shell + polyethylene liner. Femoral component: metal stem + femoral head (cobalt-chrome or ceramic). Fixation: cemented (PMMA, for elderly, osteoporotic bone), cementless (porous-coated, for younger patients, biologic fixation), and hybrid. Approaches: posterior (most common, dislocation risk 2-5%), direct anterior (DAA, muscle-sparing, less pain), anterolateral, and lateral (Hardinge). Indications: end-stage osteoarthritis, avascular necrosis, rheumatoid arthritis, and hip fracture (femoral neck). Complications: dislocation, infection (1-2%), VTE, periprosthetic fracture, leg length discrepancy, and aseptic loosening (long-term).

Total Knee Arthroplasty (TKA)

– Replacement of the knee joint with prosthetic components. Femoral component (cobalt-chrome), tibial component (titanium tray + polyethylene insert), and patellar component (polyethylene, optional). Fixation: cement (PMMA) most common in older adults; cementless in younger. Alignment: mechanical (neutral, most common), kinematic, and anatomic. Indications: end-stage osteoarthritis (most common), inflammatory arthritis, and post-traumatic arthritis. Complications: infection (1-2%), stiffness (manipulation under anesthesia), instability, patellar complications (maltracking, fracture), periprosthetic fracture, VTE, and aseptic loosening.

Tracheostomy

– Surgical creation of an airway opening in the anterior neck into the trachea. See pulmonology.

Tracheotomy

– Surgical creation of an airway opening in the ante-

rior neck into the trachea. See [Tracheostomy](#).

TRALI

- Transfusion-Related Acute Lung Injury, a life-threatening complication of blood transfusion characterized by acute hypoxemia and bilateral pulmonary edema within 6 hours of transfusion, without evidence of volume overload. Pathophysiology: donor antibodies (anti-HLA, anti-HNA) in plasma-rich products (FFP, platelets) activate recipient neutrophils, causing endothelial injury and capillary leak in the lungs. Presents with dyspnea, hypoxemia, fever, and bilateral infiltrates on CXR (mimics ARDS). Management: supportive care (oxygen, mechanical ventilation), similar to ARDS. Prevention: use male-only plasma to reduce antibody risk. Mortality 5-10%.

Transfusion Reaction

- An adverse reaction to transfusion of blood products. Acute hemolytic transfusion reaction: ABO incompatibility, immediate fever/chills, hypotension, back pain, DIC, renal failure; management: STOP transfusion, maintain BP/urine output, supportive care. Febrile non-hemolytic transfusion reaction: most common, fever/chills without hemolysis. Allergic: urticaria; treat with antihistamines. Anaphylactic: severe allergic, IgA deficiency; treat with epinephrine. Transfusion-related acute lung injury (TRALI): acute hypoxemia, bilateral pulmonary edema within 6 hours; supportive care. Transfusion-associated circulatory overload (TACO): pulmonary edema from volume overload; diuretics. Bacterial contamination: sepsis from contaminated unit.

Transplant Rejection

- Immune-mediated destruction of a transplanted organ or tissue, classified by timing and mechanism. Hyperacute: preformed donor-specific antibodies, minutes to hours post-transplant, immediate graft thrombosis, irreversible; prevention by cross-matching. Acute: T-cell mediated (most common, days to weeks/months), responds to immunosuppression; presents with graft dysfunction and biopsy findings. Chronic: antibody-mediated, progressive, irreversible fibrosis and graft dysfunction over months to years. Diagnosis: graft biopsy (Banff classification). Treatment: acute rejection — pulse corticosteroids, thymoglobulin, IVIG, plasmaphere-

sis; chronic — optimize immunosuppression, manage risk factors.

Transplant Surgery

- Transplant surgery involves replacing a failing organ with a healthy donor organ. Kidney transplant: living donors (laparoscopic nephrectomy, left kidney preferred) or deceased donors (standard criteria, expanded criteria, DCD). Induction immunosuppression includes basiliximab (standard risk) or thymoglobulin/alemtuzumab (high immunologic risk). Maintenance typically uses tacrolimus, mycophenolate, and prednisone; belatacept offers CNI-free options for EBV-positive patients. Rejection: hyperacute (preformed antibodies, immediate graft loss), acute cellular (T-cell mediated, responds to steroid pulse or ATG), acute antibody-mediated (C4d+ on biopsy with donor-specific antibodies, treated with IVIG, plasmapheresis, rituximab), and chronic allograft nephropathy (interstitial fibrosis and tubular atrophy). Liver transplant allocation uses the MELD-Na score. Donor hepatectomy may be whole or split/living donor. Recipient hepatectomy uses bicaval or piggyback technique with portal vein, hepatic artery, and biliary reconstruction (duct-to-duct or Roux-en-Y hepaticojejunostomy). Complications: primary non-function, hepatic artery thrombosis (3-5%, requires retransplantation unless collateralized), biliary leak/stricture, portal vein thrombosis, and rejection. PTLN is an EBV-driven lymphoproliferative complication managed by immunosuppression reduction and rituximab. Pancreas transplant (SPK, PAK, PTA) is performed for type 1 diabetes with ESRD; enteric drainage is preferred for exocrine secretion. Long-term management: immunosuppression optimization, infection prophylaxis (CMV, EBV, fungal), and surveillance for graft dysfunction, PTLN, and cardiovascular disease. One-year graft survival exceeds 90% for kidney and 85% for liver; 5-year survival >70% for both.

Trauma Surgery

- Trauma surgery encompasses the acute care of injured patients, guided by ATLS (ABCDE) principles: Airway maintenance with cervical spine protection, Breathing and ventilation, Circulation with hemorrhage control, Disability/neurologic assessment, and Exposure/environmental control. Hemorrhage control is the priority, achieved via di-

rect pressure, tourniquets for extremity injuries, pelvic binders for pelvic fractures, and REBOA for exsanguinating torso hemorrhage. Damage control surgery is indicated for patients with the lethal triad of hypothermia, acidosis, and coagulopathy. Phase 1 involves abbreviated laparotomy with bleeding control (packing, shunting) and contamination control. Phase 2 is ICU resuscitation to correct hypothermia (active rewarming), coagulopathy (massive transfusion at 1:1:1 ratio of pRBCs, FFP, platelets; tranexamic acid 1 g IV within 3 hours of injury), and acidosis. Phase 3 is return to the OR for definitive repair after physiologic normalization. Damage control resuscitation incorporates permissive hypotension (SBP 80-90 mmHg) in penetrating torso trauma without head injury. Definitive surgical management depends on injury pattern and may include splenectomy, liver packing and resection, bowel resection, vascular repair, and fracture fixation. Resuscitative thoracotomy is indicated for penetrating chest trauma with witnessed arrest and short transport time (best survival for cardiac tamponade). Tension pneumothorax requires immediate needle decompression (14G, 2nd ICS midclavicular line) followed by tube thoracostomy. Massive haemothorax (>1500 mL initial output) requires expeditious thoracotomy. Abdominal compartment syndrome (bladder pressure >20 mmHg with organ dysfunction) may necessitate decompressive laparotomy with temporary closure. FAST examination and CT imaging guide surgical decision-making. Enteral nutrition is initiated within 24-48 hours. Outcome depends on injury severity, promptness of intervention, and successful resuscitation.

Traumatic Brain Injury

– Disruption of brain function caused by an external mechanical force. Severity: mild (GCS 13-15, concussion), moderate (GCS 9-12), severe (GCS 3-8). Primary injury: direct damage at moment of impact (contusion, diffuse axonal injury, intracranial hemorrhage). Secondary injury: evolves over hours to days (cerebral edema, increased ICP, hypoxia, hypotension, ischemia, seizures). Intracranial hemorrhage: epidural (arterial, lenticular), subdural (venous, crescentic), intracerebral, subarachnoid. Management: ABCs, prevent secondary injury (maintain SBP >90, SpO₂ >94%, PaCO₂ 35-45), ICP mon-

itoring (goal <22), CPP >60 mmHg, head of bed 30°, hyperosmolar therapy (mannitol, hypertonic saline), seizure prophylaxis, and surgical evacuation of mass lesions.

Trephining (Trepanation)

– A surgical procedure in which a hole is drilled or scraped into the skull (cranium), exposing the dura mater. Historically, trephining dates back to Neolithic times (10,000 BCE) and was performed for ritual, therapeutic (releasing 'evil spirits'), and post-traumatic indications. Modern medical trephination: (1) Burr hole—small craniotomy using a handheld or electric drill (burr) for evacuation of intracranial haematomas (epidural, subdural—including twist-drill craniostomy for chronic subdural haematoma), placement of external ventricular drain (EVD) for intracranial pressure monitoring or CSF drainage, and brain biopsy. (2) Decompressive craniectomy—removal of a large skull flap to treat refractory intracranial hypertension (traumatic brain injury, malignant middle cerebral artery infarction, cerebral venous sinus thrombosis). (3) Craniotomy—larger opening for definitive neurosurgery (tumor resection, aneurysm clipping, epilepsy surgery). (4) Stereotactic trephination—frame-based or frameless stereotactic navigation for biopsy, deep brain stimulation electrode placement, or tumor ablation. Instruments: Hudson brace, perforator and burr, craniotome, and high-speed drills. Complications: bleeding (epidural, subdural, intracerebral), infection (osteomyelitis, meningitis, brain abscess), CSF leak, pneumocephalus, seizures, and brain herniation.

Tubal Ligation

– Surgical sterilization by occluding the fallopian tubes, preventing the ovum from reaching the uterus. Postpartum tubal ligation: after vaginal or cesarean delivery (Pomeroy technique, Parkland). Interval: laparoscopic (bands, clips, bipolar cautery) or mini-laparotomy (Hulka or Filshie clip). Reversal possible with tubal reanastomosis (pregnancy rate 50-80%). Female sterilization: 99% effective, permanent. Complications: ectopic pregnancy if procedure fails (higher after bipolar cautery than clips). Essure (hysteroscopic coils) removed from the market.

Umbilical Hernia

– A hernia through the umbilical ring, common in infants (most umbilical hernias close spontaneously by age 4-5) and adults (risk factors: obesity, pregnancy, ascites, cirrhosis). Presents as a reducible bulge at the umbilicus, worse with increased intra-abdominal pressure. In adults: risk of incarceration and strangulation is higher. Diagnosis: clinical. Treatment: in children: observe, surgically repair if persists >age 4-5 or >2 cm. In adults: surgical repair (primary suture repair, mesh onlay, or laparoscopic IPOM) due to risk of complications.

Vascular Access

– Vascular access for hemodialysis includes arteriovenous fistulas (AVF), arteriovenous grafts (AVG), and central venous catheters (CVC). The fistula first initiative prioritizes AVF as the gold standard due to best long-term patency and lowest complication rates. Common configurations: radiocephalic (wrist), brachiocephalic (elbow), and brachiobasilic transposition (upper arm). Preoperative vein mapping by ultrasound is essential for planning. AVGs (PTFE) mature faster (2-4 weeks vs. 2-4 months for AVF) and are useful when native veins are inadequate, but have higher rates of thrombosis and infection. Tunneled CVCs allow immediate use and serve as a bridge to maturation or for patients with exhausted peripheral options, but carry the highest infection and central venous stenosis risk. Non-tunneled CVCs are for short-term emergent use. Maturation criteria: vein diameter >6 mm, depth <6 mm, flow >600 mL/min. Indications: end-stage renal disease requiring hemodialysis. Complications: stenosis (angioplasty, stenting), thrombosis (thrombectomy, catheter-directed thrombolysis), steal syndrome (hand ischemia managed by DRIL or PAI procedures), aneurysm and pseudoaneurysm (resection, ligation), infection (graft excision, antibiotics), and high-output cardiac failure (revision, banding, or ligation). CVC complications: pneumothorax (reduced by ultrasound guidance), arterial puncture, catheter-related bloodstream infection (removal, tip culture, antibiotics), central venous stenosis, and air embolism. Patency: AVF > AVG > CVC.

Venous Stasis Ulcer

– A chronic wound caused by chronic venous insufficiency, most common type of leg ulcer (70-80%).

Located on the medial gaiter area (medial malleolus). Presents with shallow, irregular ulcer with granulation tissue, surrounded by hemosiderin deposition (brownish discoloration), lipodermatosclerosis, edema, and varicose veins. Often painful and associated with venous insufficiency (CEAP classification). Diagnosis: clinical; venous duplex ultrasound to assess reflux. Treatment: compression therapy (multi-layer bandaging, graded compression stockings 30-40 mmHg) is the mainstay. Adjunctive: leg elevation, wound debridement, moist wound healing, and pentoxifylline. Refractory: venous ablation or surgery.

Venous Ulcer

– A chronic wound caused by chronic venous insufficiency, most common type of leg ulcer (70-80%). See [Venous Stasis Ulcer](#).

Wound Dehiscence

– Separation of the layers of a surgical wound after closure, most commonly occurring within 3-14 days postoperatively. Risk factors: wound infection, poor nutrition (low albumin), immunosuppression, obesity, diabetes, smoking, increased intra-abdominal pressure (coughing, straining, ileus), and poor surgical technique (tight sutures, extensive electrocautery). Presents with sudden serosanguinous drainage from the wound, often with a pop sensation. Superficial dehiscence: skin and subcutaneous layers open. Deep (fascial) dehiscence: separation of the fascia, often with evisceration (viscera protruding through the wound) → surgical emergency. Management: superficial → wound care and NPWT. Deep → emergent return to OR for closure with retention sutures.

Xenograft (Heterograft)

– A surgical graft taken from a donor of a different species (xenos = foreign, Greek). Xenografts are used as temporary biological dressings or as tissue replacements. The most common xenograft source is porcine (pig) skin, used as a temporary wound covering for extensive burns (partial-thickness and deep partial-thickness burns) and large traumatic skin loss. Porcine xenografts adhere to the wound bed, reduce fluid and protein loss, decrease pain, and provide a barrier against bacterial contamination.

tion while the patient's own skin regenerates or until autografting is possible. Other xenograft sources include bovine (cow) pericardium (used in cardiac surgery for valve reconstruction, pericardial patch repair, and as a bioprosthetic heart valve material — Carpentier-Edwards, Hancock valves), and bovine bone grafts (used in orthopaedic and dental surgery for bone void filling, spinal fusion, and maxillofacial reconstruction). Xenografts trigger a strong immune response (hyperacute rejection mediated by pre-existing xenoreactive antibodies against Gal-alpha-1,3-Gal epitopes on porcine cells) and are therefore rejected within 7-14 days if used as viable tissue, limiting their use to temporary coverage. Genetically modified pigs (knockout of Gal epitopes) have been developed to reduce immunogenicity and enable longer-term xenograft survival. The first pig-to-human heart transplant (xenotransplantation) was performed in 2022 (University of Maryland, 10 gene-modified pig heart, recipient survived 2 months). Compared to allografts (human donor grafts) and autografts (patient's own tissue), xenografts have the advantages of unlimited availability and no donor site morbidity, but are inferior in durability and immunocompatibility for permanent replacement.

Preoperative Assessment

- Structured evaluation of a patient's medical conditions, medications, functional status, airway, nutritional state, laboratory results, anesthetic risk, and planned procedure before surgery. It supports optimization, informed consent, risk communication, and perioperative planning.

Surgical Risk Stratification

- Estimation of the likelihood of perioperative complications using patient factors, urgency, procedure risk, functional capacity, and disease-specific assessment. It informs optimization, monitoring level, shared decisions, and postoperative planning but cannot eliminate uncertainty.

Surgical Time-Out

- A deliberate team pause immediately before incision to verify patient identity, procedure, site, consent, allergies, antibiotics, imaging, implants, equipment, and anticipated critical events. It is a core surgical-safety intervention.

Enhanced Recovery After Surgery (ERAS)

- A multimodal, evidence-based perioperative pathway that reduces surgical stress and supports early recovery through preoperative counseling, appropriate fasting, opioid-sparing analgesia, early mobilization, early nutrition, and prevention of complications.

Perioperative Antibiotic Prophylaxis

- Administration of an appropriate antimicrobial within a defined interval before incision to reduce infection risk for selected procedures. Choice, timing, redosing, and discontinuation depend on procedure, organisms, patient factors, and local guidance.

Venous Thromboembolism Prophylaxis

- Measures used to reduce perioperative deep-vein thrombosis and pulmonary embolism, including early mobilization, mechanical compression, and pharmacologic anticoagulation when bleeding risk permits.

Surgical Wound Classification

- Categorization of an operative wound as clean, clean-contaminated, contaminated, or dirty/infected according to the degree of microbial exposure and existing infection. The class helps estimate surgical-site infection risk and guide prophylaxis.

Anastomotic Leak

- Breakdown of a surgically created connection between hollow viscera, allowing luminal contents to escape. It may cause abscess, peritonitis, sepsis, organ failure, and need for drainage, diversion, reoperation, or endoscopic therapy.

Surgical Drain

- A device placed to remove blood, pus, bile, urine, lymph, or other fluid from a surgical site or body cavity. Indications, output characteristics, duration, and removal criteria should be documented because drains can also cause infection, bleeding, or tissue injury.

Damage-Control Surgery

- A staged operative strategy for critically ill or severely injured patients in whom definitive repair

is unsafe because of hypothermia, acidosis, coagulopathy, or physiologic instability. Initial surgery controls hemorrhage and contamination, followed by resuscitation and later definitive reconstruction.

Source Control

- A procedure or intervention that eliminates, drains, debrides, or otherwise controls an anatomic focus of infection or contamination. Examples include drainage of an abscess, removal of infected tissue or device, and repair of a perforation.

Laparoscopy

- Minimally invasive visualization or treatment of the abdominal or pelvic cavity through ports using a camera and instruments. Compared with open surgery, it may reduce incision size and recovery time but requires appropriate expertise and carries risks of access injury and gas-related complications.

Exploratory Laparotomy

- Open surgical entry into the abdominal cavity to diagnose or treat suspected intra-abdominal pathology, such as hemorrhage, perforation, ischemia, or obstruction, when less invasive evaluation is inadequate or inappropriate.

Surgical Hemostasis

- Control of bleeding during an operation using pressure, ligation, sutures, clips, electrosurgery, topical agents, vessel sealing, or other techniques. Effective hemostasis requires identification of the bleeding source and correction of coagulopathy when present.

Postoperative Delirium

- An acute, fluctuating disturbance of attention, awareness, and cognition after surgery, often caused by multifactorial physiologic stress. Prevention emphasizes orientation, sleep, mobility, sensory aids, pain control, hydration, and avoidance of unnecessary deliriogenic medications.

Postoperative Pulmonary Complication

- Respiratory deterioration after surgery, including atelectasis, pneumonia, aspiration, respiratory failure, bronchospasm, and exacerbation of chronic lung disease. Risk reduction includes smoking cessation, lung-protective ventilation, analgesia, mobilization, and appropriate respiratory exercises.

Surgical Site Infection (SSI)

- Infection involving the incision, organ, or operative space within the surveillance period after surgery. It may be superficial incisional, deep incisional, or organ-space and requires appropriate culture, antimicrobial therapy, drainage, debridement, or reoperation when indicated.

Quadrantectomy

- Surgical removal of one quadrant of an organ, most commonly a breast-conserving operation removing a breast tumour with a surrounding margin of tissue. The exact procedure and need for additional treatment depend on pathology and clinical staging.

Chapter 40

Toxicology

Aflatoxin

- A group of toxic metabolites produced mainly by *Aspergillus* fungi that contaminate foods such as maize, peanuts, and tree nuts. Chronic exposure can cause liver injury and substantially increases the risk of hepatocellular carcinoma, particularly in people with chronic hepatitis B infection.

Radiation Sickness

- Acute radiation syndrome caused by high-dose whole-body or substantial partial-body exposure to ionizing radiation. It may produce nausea, vomiting, marrow failure, infection, bleeding, gastrointestinal injury, neurovascular collapse, and death depending on dose.

Acetaminophen (Paracetamol) Toxicity

- Most common cause of acute liver failure in Western countries. Mechanism: toxic metabolite NAPQI depletes glutathione, causing centrilobular hepatic necrosis. Treatment: N-acetylcysteine (NAC) within 8-10 hours of ingestion. Nomogram (Rumack-Matthew) guides treatment based on serum acetaminophen level at 4+ hours. Dosing: loading dose 140 mg/kg, maintenance 70 mg/kg every 4 hours for 17 doses (oral) or continuous IV infusion.

Activated Charcoal

- Fine black powder produced by controlled pyrolysis of organic materials, processed to yield a massive micro-porous surface area (500-1500 m²/g). Mechanism: non-specific adsorption of toxins onto carbon surface via Van der Waals forces and hydrophobic interactions. Dose: 1 g toxin per 10 g charcoal (10:1 ratio), typical adult dose 50-100 g. Indications: recent ingestion (1-2 hours) of adsorbable toxins. Contraindications: corrosives, hydrocarbons, lithium,

iron, ethanol, methanol. Complications: aspiration, constipation, bowel obstruction.

Acute Kidney Injury

- Sudden decline in renal function. Toxic causes: contrast media, aminoglycosides, cisplatin, ethylene glycol, mycotoxins. Mechanisms: direct tubular toxicity, vascular injury, obstruction (crystals). Management: remove toxin, supportive care, dialysis if severe.

Acute Liver Failure

- Rapid loss of liver function with coagulopathy and encephalopathy in non-cirrhotic liver. Causes: acetaminophen toxicity (most common in West), viral hepatitis, toxins (amanitin, halothane), ischemic hepatitis. Management: N-acetylcysteine (early), supportive care, transplantation assessment.

Air Contaminants

- See [occupational medicine](#).

Alcohol

- See ethanol.

Alcohol Intoxication

- Acute effects of ethanol: CNS depression, disinhibition, ataxia, slurred speech, vomiting, respiratory depression (severe). BAC >0.08

Alcoholic Ketoacidosis

- A high-anion-gap metabolic acidosis caused by prolonged heavy alcohol use, poor nutritional intake, and vomiting. It typically presents with abdominal pain, nausea, vomiting, dehydration, and tachypnea, often with a normal or low blood glucose concentration.

Alcohol Withdrawal

- See withdrawal syndromes.

Aluminum Phosphide

- Fumigant poison released as phosphine gas upon contact with moisture. Mechanism: inhibits cytochrome c oxidase, cellular hypoxia. Treatment: supportive, cardiac monitoring, magnesium, calcium. No specific antidote.

Amelogenesis

- See dental.

Anion Gap

- Calculated as $[Na^+] - ([Cl^-] + [HCO_3^-])$. Normal: 8-12 mEq/L. Elevated in: MUDPILES (Methanol, Uremia, DKA, Propylene glycol, Iron/Isoniazid, Lactic acidosis, Ethylene glycol, Salicylates). Used to identify toxic alcohols, metabolic acidosis.

Antidote

- Substance that counteracts poison toxicity. Specific: naloxone (opioids), flumazenil (benzodiazepines), N-acetylcysteine (acetaminophen), digoxin immune Fab (digoxin), chelators (EDTA, deferoxamine, dimercaprol), atropine + pralidoxime (organophosphates), methylene blue (methemoglobinemia), cyanide antidote kit (nitrite + thiosulfate). Non-specific: activated charcoal, supportive care.

Arterial Blood Gas (ABG)

- Measures pH, PaCO₂, PaO₂, HCO₃⁻, base excess. Used to assess acid-base status, oxygenation, ventilation. Normal: pH 7.35-7.45, PaCO₂ 35-45 mmHg, PaO₂ 80-100 mmHg, HCO₃⁻ 22-26 mEq/L. Interpretation: stepwise approach identifies primary disorder and compensation.

Aspirin (Salicylate) Toxicity

- Mixed respiratory alkalosis and metabolic acidosis. Early: tinnitus, hyperventilation, respiratory alkalosis. Late: metabolic acidosis, fever, seizures, coma. Treatment: activated charcoal, urine alkalization (sodium bicarbonate), hemodialysis if severe (renal failure, pulmonary edema, severe acidosis, very high levels).

Barbiturate

- See sedative-hypnotics.

Benzene

- Solvent, industrial chemical. Chronic exposure: aplastic anemia, leukemia (especially AML). Acute: CNS depression, arrhythmias. Prevention: substi-

tution, ventilation, monitoring.

Benzo(a)pyrene

- Polycyclic aromatic hydrocarbon from combustion. Carcinogenic (lung, skin cancer). Found in tobacco smoke, charred meat, air pollution.

Beta-Blocker Overdose

- Bradycardia, hypotension, hypoglycemia, bronchospasm (non-selective). Treatment: atropine, glucagon (1-10 mg IV), high-dose insulin euglycemia therapy, calcium, vasopressors, pacing if refractory.

Bisphenol A (BPA)

- Endocrine disruptor in plastics. Estrogenic effects, associated with reproductive disorders, obesity, diabetes. Avoid BPA-containing products, especially for children.

Blood Alcohol Concentration (BAC)

- Measure of ethanol in blood. Legal limit for driving: 0.08

Bone Marrow Depression

- See myelosuppression.

Calcium Channel Blocker Overdose

- Hypotension, bradycardia, hyperglycemia. Treatment: calcium gluconate/chloride, glucagon, high-dose insulin, vasopressors, lipid emulsion therapy, pacing.

Carbon Monoxide (CO) Poisoning

- Inhibits hemoglobin oxygen binding (affinity 200x oxygen). Causes headache, dizziness, nausea, cherry-red skin, syncope, death. Diagnosis: carboxyhemoglobin level (not routine). Treatment: 100

Carboxyhemoglobin

- Toxicity from inhalation of carbon monoxide (CO), a colorless, odorless gas binding hemoglobin 200-300 times more avidly than oxygen, forming carboxyhemoglobin (COHb) and reducing oxygen delivery. See [carbon monoxide poisoning](#).

Carcinogen

- Substance causing cancer. Types: chemical (benzene, asbestos, aflatoxin), physical (radiation), biological (HPV, HBV, HCV). Mechanisms: DNA damage, mutations, epigenetic changes. IARC classifications: Group 1 (carcinogenic), Group 2A (probably

carcinogenic), Group 2B (possibly carcinogenic), Group 3 (not classifiable).

Carrier State

- Asymptomatic infection with pathogen capable of transmission. Examples: typhoid carrier, hepatitis B carrier, meningococcal carrier. Importance: public health control, screening, treatment.

Cerebellar Ataxia

- A neurological sign characterized by impaired coordination of voluntary movements, resulting from dysfunction of the cerebellum or its connections. See [neurology](#).

Charcoal

- Fine black powder produced by controlled pyrolysis of organic materials, processed to yield a massive micro-porous surface area (500-1500 m²/g). See [activated charcoal](#).

Chelation Therapy

- Use of chelating agents to bind metals for excretion. Agents: EDTA (lead), deferoxamine (iron), dimercaprol (arsenic, mercury, gold), DMSA (lead, mercury), penicillamine (copper, lead). Complications: nephrotoxicity, electrolyte disturbances, redistribution of metals.

Child Poisoning

- Poisoning in children. See [pediatric toxicology](#).

Cholecystokinin

- CCK is a peptide hormone produced by I-cells in the duodenal and jejunal mucosa in response to fatty acids (long-chain fatty acids are the most potent stimuli) and amino acids in the chyme. See [physiology](#).

Chronic Kidney Disease

- Progressive loss of kidney function over months to years, defined by GFR <60 mL/min/1.73 m² or markers of kidney damage for ≥3 months. See [nephrology](#).

Chronic Toxicity

- Adverse effects from repeated or prolonged exposure to low doses. Cumulative damage may be irreversible. Examples: heavy metals (lead, mercury), asbestos, alcohol, solvent exposure. Monitoring: biomarkers, organ function tests.

Circle of Willis

- See [neurology](#).

Clearance

- Volume of plasma cleared of substance per unit time. Renal clearance: urine flow x urine concentration / plasma concentration. Hepatic clearance: blood flow x extraction ratio. Used for dosing adjustments.

CO Poisoning

- Toxicity from inhalation of carbon monoxide (CO), a colorless, odorless gas binding hemoglobin 200-300 times more avidly than oxygen, forming carboxyhemoglobin (COHb) and reducing oxygen delivery. See [carbon monoxide poisoning](#).

Coma

- See [emergency medicine](#).

Coma Scale

- See [Glasgow Coma Scale](#).

Concentration

- Amount of substance per unit volume. Units: mg/dL, mmol/L, mEq/L, ppm. Conversion: molecular weight needed. Critical for toxicity assessment.

Conjunctivitis

- Inflammation of the conjunctiva, the thin, transparent mucous membrane lining the inner surface of the eyelids and the anterior surface of the sclera. See [ophthalmology](#).

Contact Dermatitis

- An inflammatory skin reaction caused by direct contact with an external agent, divided into two main types: allergic contact dermatitis (ACD, type IV delayed hypersensitivity reaction, mediated by sensitized T lymphocytes) and irritant contact dermatitis (ICD, non-immunologic, dose-dependent direct chemical or physical damage to the epidermis, accounting for 80 percent of cases). See [dermatology](#).

Controlled Substance

- A drug or chemical whose manufacture, possession, and use are regulated by government authorities due to its potential for abuse, dependence, or harm. See [pharmacology](#).

Corrosive

- Substance causing tissue destruction by chemical

action. Acids: coagulation necrosis, eschar. Alkalis: liquefaction necrosis, deep penetration. Ingestion: avoid emesis, endoscopy, surgical consultation.

Creatinine

- Waste product from creatine phosphate metabolism. See biochemistry.

Cross-Tolerance

- Tolerance to one substance conferring tolerance to another of similar class. Examples: alcohol-benzodiazepines, opioids-methadone.

CSF Analysis

- See neurology.

Cumulative Dose

- Total amount of substance received over time. Important for carcinogens, teratogens, cumulative toxins.

Cyanide Poisoning

- Inhibits cytochrome c oxidase, blocking cellular respiration. Sources: smoke inhalation, industrial exposure, almonds, apricot kernels. Symptoms: headache, confusion, seizures, coma, cardiac arrest, cherry-red skin. Treatment: hydroxocobalamin (first-line), nitrite + thiosulfate kit.

Delirium

- Acute onset fluctuating disturbance in attention and awareness. See emergency medicine.

Dependence

- A chronic, relapsing brain disorder characterized by compulsive substance use or behavior despite harmful consequences. See [addiction](#).

Detoxification

- Removal of toxic substance from body. Methods: activated charcoal, gastric lavage (rarely used), whole bowel irrigation, hemodialysis, hemoperfusion, chelation, supportive care.

Diabetic Ketoacidosis

- An acute, life-threatening complication of diabetes mellitus, more common in type 1. See [endocrinology](#).

Dialysis

- See nephrology.

Diffusion

- Movement of molecules from high to low concen-

tration. Important for drug absorption, toxin distribution.

Digitalis (Digoxin) Toxicity

- Nausea, vomiting, visual changes (yellow halos), arrhythmias. Risk: narrow therapeutic index, renal impairment, hypokalemia. Treatment: digoxin immune Fab, cardiac monitoring, correct electrolytes.

Dimercaprol (BAL)

- Chelating agent for arsenic, mercury, gold. Given IM. Side effects: hypertension, tachycardia, nausea, pain at injection site.

Dose

- Amount of substance administered. Factors: weight, age, renal/hepatic function, drug interactions. Toxic dose varies by substance and individual.

Drug Interaction

- See [pharmacology](#).

Drug Screening

- Urine, blood, hair testing for substances of abuse. Panels: opiates, cocaine, amphetamines, cannabinoids, PCP, benzodiazepines, barbiturates. False positives possible. Confirmation by GC/MS or LC-MS/MS.

Drug Testing

- Urine, blood, hair testing for substances of abuse. See [drug screening](#).

Drug Therapeutics

- See [pharmacology](#).

Drug Toxicity

- Adverse effects from drugs at normal or elevated doses. Idiosyncratic reactions, cumulative toxicity, organ damage.

Drug Withdrawal

- See withdrawal syndromes.

Dx

- Identification of disease. See [diagnosis](#).

Edema

- Fluid accumulation in tissues. See general.

Effective Dose

- Dose producing desired effect in 50

Elimination Half-Life

- Time for plasma concentration to decrease by 50

Emetics

- Reflex expulsion of gastric contents. See [vomiting](#).

Encephalopathy

- Brain dysfunction from metabolic, toxic, or structural causes. Hepatic, uremic, toxic encephalopathy.

Endocrine Disruptor

- Chemical interfering with hormone systems. Examples: BPA, phthalates, DDT, PCBs. Effects: reproductive disorders, developmental problems, cancer.

Endotoxin

- Lipopolysaccharide from Gram-negative bacteria. Pyrogenic, causes fever, shock, DIC. Contamination concern in pharmaceuticals, medical devices.

Enterohepatic Circulation

- Recycling of toxins between liver and intestine via bile. Prolonged exposure, increased toxicity. Interrupted by activated charcoal, cholestyramine. Examples: morphine, digoxin, estrogen, thyroxine.

Epidemiology

- Study of disease distribution and determinants in populations. See [public health](#).

Ethylene Glycol

- Antifreeze poisoning. See [ethylene glycol poisoning](#).

Ethylene Glycol Poisoning

- Antifreeze poisoning. Metabolized to toxic acids (glycolic, oxalic). Causes high anion gap metabolic acidosis, calcium oxalate crystals in urine, renal failure. Treatment: fomepizole (alcohol dehydrogenase inhibitor), hemodialysis, calcium gluconate if hypocalcemia.

Excretion

- Removal of substance from body. Routes: renal (urine), hepatic (bile), pulmonary (gas), sweat, breast milk. Important for toxicity and drug clearance.

Exposure Route

- Path by which substance enters body. Routes: inhalation, ingestion, dermal, injection, ocular. Determines absorption rate and toxicity.

Eye Irritation

- Chemical injury to eye. Immediate irrigation with water or saline for 15-20 minutes. Alkali burns more dangerous than acid. Ophthalmology consultation.

Fat-Soluble Toxins

- Lipophilic toxins stored in fat, prolonged elimination. Examples: organochlorine pesticides, PCBs, dioxins, tetrachlorodiphenylmethane.

Federal Register

- See regulatory affairs.

Fiber Optic

- See radiology.

Food Poisoning

- Illness caused by consuming food contaminated with bacteria, viruses, parasites, or their toxins. See [infectious disease](#).

Foreign Body

- Any object lodged in body. See medical implants.

Formaldehyde

- Preservative, industrial chemical. Irritant, carcinogen (nasopharyngeal cancer). Sensitizer. Use in fume hood, PPE required.

Gastric Emptying

- See [physiology](#).

Gastroenteritis

- Inflammation of the stomach and intestinal mucosa, most commonly caused by viral infections (norovirus, rotavirus, adenovirus), bacterial pathogens (E. See [gastroenterology](#)).

Gastrointestinal Decontamination

- Methods: activated charcoal, gastric lavage (rare), whole bowel irrigation (sorbitol, PEG). Timing critical for charcoal (1-2 hours post-ingestion).

Genotoxicity

- Ability of substance to damage DNA. Tests: Ames test, chromosomal aberration, micronucleus. Predicts carcinogenicity.

Glucose-6-Phosphatase

- Enzyme converting glucose-6-phosphate to glucose. See biochemistry.

Glutathione

- Antioxidant tripeptide (Glu-Cys-Gly). Detoxifies reactive metabolites (e.g., NAPQI from acetaminophen). Depletion causes toxicity. N-acetylcysteine replenishes glutathione.

Gout

- A crystal deposition disease caused by monosodium

urate (MSU) crystal formation in joints and tissues due to chronic hyperuricemia (serum urate >6.8 mg/dL). See rheumatology.

Half-Life

- See [elimination half-life](#), [biological half-life](#).

Hand, Foot, and Mouth Disease

- See [pediatrics](#).

Heavy Metal Poisoning

- Lead, mercury, arsenic, cadmium, thallium. Chelation therapy, supportive care, prevention. Sources: paint, water pipes, fish, occupational exposure.

Hemodialysis

- Extracorporeal blood purification using semipermeable membrane. See nephrology.

Hemoperfusion

- Blood passed through adsorbent column (charcoal, resin) to remove toxins. Used for drug overdoses with high protein binding, large volume of distribution.

Hemorrhagic

- See [hematology](#).

Hepatic Encephalopathy

- Neuropsychiatric syndrome from liver failure. See [geriatrics](#).

Hepatotoxicity

- Liver damage from toxins, drugs, chemicals. Acetaminophen most common cause of acute liver failure. Monitoring: LFTs, INR, clinical assessment.

Hyaline Membrane

- See [pediatrics](#).

Hyperemesis

- See [gastroenterology](#).

Hypersensitivity

- See [pharmacology](#).

Hypertensive

- See [cardiology](#).

Hypokalemia

- Low potassium. Causes: diuretics, vomiting, diarrhea, hyperaldosteronism. Symptoms: weakness, arrhythmias, ECG changes. Treatment: potassium replacement.

Iatrogenic

- An illness or condition caused by medical examination or treatment. See general.

Idiopathic

- Of unknown cause. See general.

Idiosyncratic Reaction

- Unpredictable adverse reaction not related to dose or pharmacology. Immunological or metabolic origin. Examples: drug-induced liver injury, aplastic anemia. Difficult to predict.

Immunotoxicity

- Immune system damage from chemicals. Effects: immunosuppression, hypersensitivity, autoimmunity. Examples: benzene, chemotherapy, biologics.

Ingestion

- Harmful effect from exposure to toxic substance. See [poisoning](#).

Inhalation Injury

- See [pulmonology](#).

Insulin

- Peptide hormone (51 amino acids) produced by beta cells of pancreatic islets. See [endocrinology](#).

Interference

- See [pharmacology](#).

Intoxication

- Harmful effect from exposure to toxic substance. See [poisoning](#).

Ipecac

- Emetic no longer recommended for routine poisoning management. Risk of aspiration, delays charcoal administration.

Isoniazid Toxicity

- Hepatotoxicity, peripheral neuropathy, seizures. Treatment: pyridoxine (vitamin B6) supplementation, activated charcoal, seizure control.

Kidney Failure

- The inability of the kidneys to maintain fluid, electrolyte, and acid-base homeostasis and to excrete metabolic wastes. See nephrology.

Kinetics

- See [pharmacology](#).

Lactate Dehydrogenase

- Non-specific enzyme. See biochemistry.

LD50

- Lethal dose for 50

Lead Poisoning

- Neurotoxic, hematological, renal effects. Sources: paint, water, gasoline, occupational. Children more vulnerable. Treatment: chelation (succimer, EDTA, dimercaprol), remove exposure. Blood lead level guides treatment.

Liver

- The largest internal organ, located in the right upper quadrant of the abdomen beneath the diaphragm. See [biochemistry](#).

Liver Transplant

- See [gastroenterology](#).

Local Anesthetic Toxicity

- CNS toxicity: tinnitus, perioral numbness, seizures. Cardiovascular toxicity: arrhythmias, hypotension, cardiac arrest. Treatment: lipid emulsion therapy (Intralipid), seizure control, ACLS.

Long-Term Effect

- Adverse effects from repeated or prolonged exposure to low doses. See [chronic toxicity](#).

Loss of Appetite

- See [gastroenterology](#).

Low Molecular Weight Heparin

- See [hematology](#).

Lung Cancer

- Leading cancer death worldwide. See [oncology](#).

Lymphedema

- See [geriatrics](#).

Magnetic Resonance Imaging

- See [radiology](#).

Maltol

- Substance added to food for preservation, flavor, color. See [food additive](#).

Manganese

- Neurotoxic at high exposure. Manganism: Parkinson-like symptoms. Sources: welding, batteries, contaminated water.

Manifestation

- Signs and symptoms of disease. See [clinical presentation](#).

Mechanism of Toxicity

- How substance causes harm. Examples: enzyme inhibition, membrane disruption, receptor binding, oxidative stress, DNA damage.

Melanoma

- A malignant neoplasm arising from melanocytes (pigment-producing cells derived from the neural crest, located in the basal layer of the epidermis, hair follicles, and mucous membranes), representing the most lethal form of skin cancer, with an incidence of approximately 20 to 30 per 100,000 persons per year in fair-skinned populations and a lifetime risk of approximately 2 to 3 percent. See [dermatology](#).

Mercury Poisoning

- Three forms: elemental (inhalation, neurological), inorganic (renal, GI), organic (methylmercury, neurological). Minamata disease from methylmercury. Treatment: chelation (dimercaprol, DMSA), remove exposure.

Micrograms

- See units.

Micromolar

- See units.

Mild Cognitive Impairment

- A transitional cognitive state between normal aging and dementia, characterized by subjective cognitive complaints confirmed by objective cognitive impairment that is not severe enough to significantly interfere with daily activities. See [neurology](#).

Milliequivalent

- See units.

Millimolar

- See units.

Minimum Alveolar Concentration

- See [pharmacology](#).

Minimum Effect Concentration

- See [pharmacology](#).

Minimum Lethal Concentration

- See [pharmacology](#).

Molecular Weight

- Mass of molecule. Important for dosing, toxicity calculations.

Mortality Rate

- Deaths from disease in population. See [public health](#).

Movement Disorder

- See [neurology](#).

Mucosal Irritation

- Chemical injury to mucous membranes. Eyes, nose, throat, GI tract. Treatment: irrigation, supportive care.

Mutagen

- Substance causing genetic mutations. Tests: Ames test, chromosomal aberration. Correlated with carcinogenicity.

N-acetylcysteine

- See [acetaminophen toxicity](#).

NAD+

- See [biochemistry](#).

Nephropathy

- See [nephrology](#).

Nephrotoxicity

- Kidney damage from toxins, drugs, contrast. Aminoglycosides, cisplatin, contrast media, ethylene glycol. Monitoring: creatinine, urine output. Prevention: hydration, dose adjustment.

Neurotoxin

- Substance toxic to nervous system. Examples: lead, mercury, organophosphates, botulinum toxin, tetrodotoxin, snake venoms.

Nicotine

- See [tobacco](#).

Night Blindness

- Impaired vision in dim light (nyctalopia). See [ophthalmology](#).

Nomogram

- Graphical calculation tool. Rumack-Matthew nomogram for acetaminophen toxicity. Guides NAC treatment.

Nuclear Medicine

- A medical specialty that uses small amounts of radioactive substances (radiotracers) to diagnose, stage, and treat various diseases, including cancer and heart disease.

Nursing

- Health of workers. See [occupational health](#).

Occupational Exposure

- Workplace exposure to toxins. Monitoring, PPE, engineering controls, regulations (OSHA, NIOSH).

Occupational Medicine

- Health of workers. See [occupational health](#).

Odor Threshold

- Lowest concentration detectable by smell. Important for warning properties of toxins.

Odynophagia

- Painful swallowing, characterized by a burning, squeezing, or sticking sensation behind the sternum during deglutition. See [gastroenterology](#).

Oliguria

- Decreased urine output (<400 mL/day in adults). See [nephrology](#).

Oncogenic

- Cancer-causing. See [carcinogen](#).

Opioid Antagonist

- See [naloxone](#).

Opportunistic Infection

- Infection in immunocompromised host. Examples: PCP, toxoplasmosis, candidiasis. See [infectious disease](#).

Oral Toxicity

- See [ingestion](#).

Organophosphate

- Acetylcholinesterase inhibitors. See [organophosphate poisoning](#).

Organophosphate Poisoning

- Acetylcholinesterase inhibitors. SLUDGE syndrome: salivation, lacrimation, urination, defecation, GI upset, emesis. Miosis, bradycardia, bronchospasm, muscle fasciculations. Treatment: atropine, pralidoxime, supportive care.

Ovarian Cancer

- See [oncology](#).

Overdose

- Harmful effect from exposure to toxic substance. See [poisoning](#).

Oxidative Stress

- Imbalance between reactive oxygen species and antioxidants. See [biochemistry](#).

Paraquat

- Herbicide, highly toxic if ingested. Pulmonary fibrosis, renal failure. No antidote. Poor prognosis.

Particulate Matter

- See [air pollution](#).

Pathogenesis

- See [pathophysiology](#).

Pathology

- Study of disease.

Pediatric Toxicology

- Poisoning in children. Common: iron, medications, household cleaners, plants. Prevention: child-proof containers, education.

Periodontal Disease

- See [dentistry](#).

Persistent Organic Pollutant

- POCPs: organochlorines, PCBs, dioxins. Bioaccumulate, long-range transport, persistent. Stockholm Convention bans/restricts.

Pharmaceutical

- See [pharmacology](#).

Pharmacodynamics

- The study of the biochemical and physiological effects of drugs on the body and their mechanisms of action, describing what the drug does to the body. See [pharmacology](#).

Pharmacokinetics

- The study of drug movement through the body, describing what the body does to the drug, defined by four processes: Absorption — the process by which a drug enters the systemic circulation from its site of administration (oral, IV, IM, subcutaneous, topical, inhalation); Distribution — the movement of drug from the circulation to body tissues, determined by blood flow, protein binding, tissue affinity, and barriers (blood-brain barrier, placental barrier); Metabolism — the chemical modification of drugs by enzymes (primarily hepatic CYP450) through Phase I (oxidation, reduction, hydrolysis) and Phase II (conjugation) reactions; and Excretion — the elimination of drugs and their metabolites from the

body, primarily through the kidneys (glomerular filtration, tubular secretion, reabsorption) and also through bile, feces, lungs, and sweat. See [pharmacology](#).

Pharmacology

- The scientific study of drugs and their actions, properties, sources, and effects on living systems.

Pharmacovigilance

- Monitoring drug safety after approval. Adverse event reporting, signal detection, risk management.

Phencyclidine (PCP)

- See [hallucinogens](#).

Photoallergy

- See [dermatology](#).

Phototoxicity

- Skin reaction from UV light + chemical. Sunburn-like. Examples: tetracyclines, thiazides, NSAIDs, psoralens.

Plasma Concentration

- The amount of a substance present in a defined volume of plasma at a given time. It is used to interpret exposure, toxicity, therapeutic drug monitoring, and pharmacokinetic relationships.

Poison Control

- See [emergency medicine](#).

Poisoning

- Harmful effect from exposure to toxic substance. Routes: ingestion, inhalation, dermal, injection. Management: ABCs, decontamination, antidote if available, supportive care.

Potency

- See [pharmacology](#).

Prenatal Exposure

- Substance causing birth defects. See [teratogen](#).

Prescription Drug

- A medication that can only be dispensed with a valid prescription from a licensed healthcare provider, requiring professional oversight due to the drug's complexity, toxicity, or potential for harm. See [pharmacology](#).

Prevention

- Measures to prevent disease.

Primary Metabolism

- See hepatic metabolism.

Probable Cause

- Identification of disease. See [diagnosis](#).

Procedure

- See [surgery](#).

Product Liability

- See regulatory affairs.

Prognosis

- Identification of disease. See [diagnosis](#).

Prophylaxis

- Measures to prevent disease. See [prevention](#).

Protein Binding

- Drug bound to plasma proteins (mainly albumin). Only free drug is active. Displacement interactions possible. Low protein binding = easier dialyzable.

Proteinuria

- Excretion of more than 150 mg of protein in urine daily. See nephrology.

Proton Pump Inhibitor

- A class of medications that irreversibly inhibit the gastric H⁺/K⁺ ATPase (proton pump) in parietal cells, the final common pathway of gastric acid secretion, producing profound and sustained suppression of both basal and stimulated acid production. See [gastroenterology](#).

Proximate Cause

- See legal toxicology.

Psychoactive Substance

- See drugs of abuse.

Psychosis

- See psychiatry.

Pulmonary Edema

- Accumulation of fluid in the pulmonary interstitium and alveoli, most commonly due to left-sided heart failure (cardiogenic). See pulmonology.

Pulse Oximetry

- A noninvasive method measuring oxygen saturation by spectrophotometry: light at two wavelengths (red and infrared) passes through a pulsatile vascular bed (finger, ear, toe); absorption difference estimates oxyhemoglobin fraction (SpO₂). See emergency medicine.

Purging

- See eating disorders.

Quality Control

- See regulatory affairs.

Radiation Poisoning

- See radiation injury.

Refeeding Syndrome

- Life-threatening fluid and electrolyte shifts when nutrition restarted in malnourished patient. See clinical nutrition.

Referred Pain

- An unpleasant sensory and emotional experience associated with actual or potential tissue damage, serving as a protective alerting system but becoming maladaptive when chronic (lasting >3 months). See [pain](#).

Relative Risk

- Study of disease distribution and determinants in populations. See [epidemiology](#).

Renal Replacement Therapy

- See nephrology.

Reproductive Toxicity

- Effects on reproduction: infertility, teratogenesis, fetal toxicity, developmental toxicity. Testing required for pharmaceuticals.

Respiratory Depression

- See emergency medicine.

Respiratory Failure

- Inadequate gas exchange resulting in hypoxemia (PaO₂ <60 mmHg), hypercapnia (PaCO₂ >50 mmHg), or both. See pulmonology.

Respiratory Protection

- Health of workers. See [occupational health](#).

Retention Time

- The time required for a compound to pass through a chromatographic system from injection to detection. In analytical toxicology, comparison with validated standards helps identify compounds, but retention time alone is not definitive identification.

Retinopathy

- See ophthalmology.

Reverse Transcription

- See molecular biology.

Risk Assessment

- Process: hazard identification, dose-response, exposure assessment, risk characterization. Used for regulatory decisions.

Risk Factor

- Study of disease distribution and determinants in populations. See [epidemiology](#).

Risk-Benefit Analysis

- Weighing therapeutic benefit against potential harm.

Running Total

- See exposure.

Salicylate

- See aspirin toxicity.

Saturation

- Occupancy of available binding, metabolic, transport, or elimination capacity such that further increases in concentration or dose produce a nonlinear response. Saturable metabolism can cause disproportionate rises in plasma concentration and toxicity.

Schedule I

- See controlled substances.

Schedule II

- See controlled substances.

Schedule III

- See controlled substances.

Schedule IV

- See controlled substances.

Schedule V

- See controlled substances.

Second-Hand Smoke

- See [tobacco](#).

Secretion

- Active movement of a substance from cells into a body fluid, lumen, or external environment. In toxicokinetics, renal tubular or biliary secretion can contribute to elimination of a toxin or metabolite.

Sedative-Hypnotic

- CNS depressants. Benzodiazepines, barbiturates, Z-drugs. Overdose: respiratory depression, coma. Treatment: supportive, flumazenil (benzodiazepines only), airway management.

Seizure

- A transient occurrence of signs and/or symptoms due to abnormal, excessive, or synchronous neuronal activity in the brain. See [neurology](#).

Self-Experimentation

- See [research ethics](#).

Serum Concentration

- The concentration of a substance measured in the liquid component of clotted blood. Interpretation depends on sampling time, exposure history, distribution, metabolism, elimination, and the relationship between concentration and toxicity.

Serum Sickness

- Type III hypersensitivity reaction. Fever, rash, arthritis, proteinuria. Caused by drugs (penicillin, cephalosporins), antivenoms. Treatment: stop offending agent, antihistamines, corticosteroids.

Sexual Dysfunction

- Persistent difficulty in sexual activity causing distress. See [pharmacology](#).

Side Effect

- See adverse effect.

Simethicone

- See [gastroenterology](#).

Single-Dose Toxicity

- See acute toxicity.

Skin Absorption

- See dermal exposure.

Skin Irritation

- See dermatology.

Social Isolation

- See psychiatry.

Sodium Polystyrene Sulfonate

- Potassium-binding resin for hyperkalemia. Risk: colonic necrosis, especially with sorbitol.

Soft Tissue Injury

- See emergency medicine.

Soil Contamination

- Environmental toxicology. Heavy metals, pesticides, industrial waste. Remediation: excavation, bioremediation, containment.

Solvent Exposure

- See [occupational medicine](#).

Source Control

- See [infection](#).

Specificity

- Proportion of true negatives correctly identified. See [pharmacology](#).

Spinal Cord Injury

- Spinal cord injury: ASIA impairment scale (A-E). See [neurology](#).

St. John's Wort

- Herbal supplement. CYP3A4 inducer, reduces efficacy of many drugs (oral contraceptives, warfarin, antiretrovirals).

Steady State

- A condition in which the average rate of drug input equals the average rate of elimination, producing relatively stable mean concentration during repeated dosing or infusion. Time to steady state is determined mainly by the drug's effective half-life.

Substance Abuse

- A chronic, relapsing brain disorder characterized by compulsive substance use or behavior despite harmful consequences. See [addiction](#).

Substance Dependence

- A chronic, relapsing brain disorder characterized by compulsive substance use or behavior despite harmful consequences. See [addiction](#).

Substance Use Disorder

- A chronic, relapsing brain disorder characterized by compulsive substance use or behavior despite harmful consequences. See [addiction](#).

Sulfa Drugs

- A class of bacteriostatic antibiotics that competitively inhibit dihydropteroate synthase, an enzyme essential for folic acid synthesis in bacteria. See [sulfonamides](#).

Sulfonamide

- A class of antibiotics (sulfamethoxazole, sulfadiazine, sulfasalazine) that inhibit bacterial dihydropteroate synthase, blocking folate synthesis—bacteriostatic. See [pharmacology](#).

Supportive Care

- Mainstay of poison management. Airway, breathing, circulation, IV access, monitoring, treat complications.

Suspected Cause

- Identification of disease. See [diagnosis](#).

Syncope

- Transient loss of consciousness due to cerebral hypoperfusion. See [cardiology](#).

Systemic Effects

- Whole-body effects of toxins. Cardiac, neurological, renal, hepatic, hematological.

Teratogen

- Substance causing birth defects. Examples: thalidomide, isotretinoin, alcohol, warfarin, valproate, ACE inhibitors. Prenatal exposure critical.

Testicular Cancer

- Most common solid malignancy in young men 15-35 years. See [oncology](#).

Therapeutic Index

- Ratio of toxic dose to therapeutic dose. $TI = TD_{50}/ED_{50}$. Wide TI = safer drug. Narrow TI drugs require monitoring (digoxin, lithium, warfarin, phenytoin).

Therapeutic Window

- Ratio of toxic dose to therapeutic dose. See [therapeutic index](#).

Therapy

- Medical intervention for disease. See [treatment](#).

Thiamine

- See [biochemistry](#).

Thrombocytopenia

- A reduced platelet count ($<150,000/\mu\text{L}$), causing bleeding risk when severe ($<10-20,000$). See [hematology](#).

Tidal Volume

- The volume of air inspired or expired during each normal breath, approximately 500 mL (6-8 mL/kg) in a resting adult. See [physiology](#).

Tissue Distribution

- Reversible movement of a chemical from blood into tissues and organs. Distribution is influenced by perfusion, lipid solubility, protein binding, tissue

affinity, barriers, body composition, and time after exposure.

Tobacco

- See [nicotine](#).

Tolerance

- A decreased response to a drug after repeated administration, requiring dose escalation to achieve the same effect. See [pharmacology](#).

Toxic Dose

- Dose causing toxicity. Varies by substance, individual, route, duration.

Toxicology

- Study of poisons and their effects. Branches: clinical, forensic, environmental, occupational, regulatory.

Toxin

- Poison produced by living organism. Bacterial (botulinum, tetanus, diphtheria), animal (snake venom, spider venom, scorpion venom), plant (ricin, amanitin), fungal (aflatoxin).

Trace Elements

- Minerals needed in small amounts. Zinc, copper, manganese, selenium, chromium, molybdenum, iodine. Deficiency or toxicity possible.

Treatment

- See management.

Tricyclic Antidepressant Overdose

- Anticholinergic effects, cardiac toxicity (QRS prolongation, arrhythmias), seizures, hypotension. Treatment: sodium bicarbonate (QRS >100 ms), seizure control, supportive care.

Tylenol

- See acetaminophen.

Typhoid

- See [infectious disease](#).

Tyramine

- See [pharmacology](#).

Uremia

- The clinical syndrome of advanced renal failure resulting from the accumulation of nitrogenous waste products and toxins (urea, creatinine, others), usually with GFR <15-20 mL/min (CKD stage 5). See nephrology.

Urine Analysis

- See nephrology.

Urine Toxicology

- Urine, blood, hair testing for substances of abuse. See [drug screening](#).

UV Light

- Skin reaction from UV light + chemical. See [phototoxicity](#).

Vaccine

- A biological preparation that induces protective immunity against a specific pathogen, administered before exposure (prophylactic) or therapeutically (e.g., rabies, some cancer vaccines). See [pharmacology](#).

Vascular Access

- Vascular access for hemodialysis includes arteriovenous fistulas (AVF), arteriovenous grafts (AVG), and central venous catheters (CVC). See emergency medicine.

Venom

- A biological poison produced by a microorganism, plant, or animal that damages host tissues at low concentrations. See [toxin](#).

Venomous Bite

- See emergency medicine.

Volume of Distribution

- $V_d = \text{dose} / \text{plasma concentration}$. Indicates tissue distribution. High V_d = extensive tissue binding, harder to remove by dialysis.

Vomiting

- Reflex expulsion of gastric contents. Causes: GI, neurological, metabolic, toxic, psychological. Treatment: antiemetics, identify cause, prevent aspiration.

Water Soluble Toxins

- Excreted by kidneys. Dialysis effective for small molecules with low protein binding (ethanol, methanol, ethylene glycol, lithium, salicylates).

Withdrawal Syndrome

- See withdrawal syndromes.

Xanax

- A class of drugs that enhance the effect of the inhibitory neurotransmitter gamma-aminobutyric

acid at the GABA-A receptor, increasing the frequency of chloride channel opening and producing anxiolytic, sedative, anticonvulsant, and muscle relaxant effects. See [benzodiazepines](#).

Xenobiotic

- Foreign chemical substance in body. Drugs, pollutants, pesticides, industrial chemicals. Metabolized by liver enzymes.

Zinc

- Trace element. Deficiency: growth retardation, delayed wound healing, hypogonadism, dysgeusia. Sources: meat, shellfish, legumes, nuts.

Toxidrome

- A recognizable constellation of clinical findings caused by a class of toxic exposure. Common toxidromes include opioid, sympathomimetic, anticholinergic, cholinergic, sedative-hypnotic, and serotonin syndromes; they guide initial stabilization and empiric treatment.

Toxicokinetics

- The study of absorption, distribution, metabolism, and excretion of a toxic substance and its relationship to concentration over time. Toxicokinetics helps estimate exposure, timing, accumulation, and expected duration of toxicity.

Decontamination

- Measures that reduce continued absorption of a toxic substance from the skin, eyes, gastrointestinal tract, or clothing. Interventions are exposure-specific and may include removal from the source, irrigation, washing, activated charcoal, or specialist procedures.

Naloxone

- A competitive opioid-receptor antagonist used to reverse opioid-induced respiratory depression and central nervous-system depression. Repeated dosing or continuous infusion may be required because naloxone can have a shorter duration than the opioid involved.

Fomepizole

- An alcohol dehydrogenase inhibitor used as an antidote for toxic alcohol exposure, particularly methanol and ethylene glycol. It prevents formation of toxic metabolites and is used with supportive care and hemodialysis when indicated.

Hydroxocobalamin

- A cobalt-containing form of vitamin B12 used as an antidote for cyanide poisoning. It binds cyanide to form cyanocobalamin, which is excreted in urine; it can cause red discoloration of skin and body fluids and interfere with some laboratory tests.

Atropine in Organophosphate Poisoning

- A muscarinic antagonist used to reverse bronchorrhea, bronchospasm, bradycardia, and other muscarinic effects of organophosphate toxicity. Treatment is titrated to drying of respiratory secretions and improvement in ventilation, not to pupil size alone.

Pralidoxime

- An oxime that can reactivate inhibited acetylcholinesterase when administered early after organophosphate poisoning, particularly for nicotinic weakness and respiratory-muscle dysfunction. It is used with atropine and supportive care according to exposure and local guidance.

Digoxin Immune Fab

- Antibody fragments that bind free digoxin and related cardiac glycosides, reducing their tissue activity. Indications include life-threatening dysrhythmia, severe hyperkalemia from acute toxicity, or a potentially massive ingestion.

Intravenous Lipid Emulsion Therapy

- Administration of a lipid emulsion as a rescue treatment for selected severe lipophilic drug toxicities, especially local-anesthetic systemic toxicity. It may act as a lipid sink and through metabolic and cardiovascular effects and requires critical-care monitoring.

Methylene Blue

- An oxidizing-reducing agent used primarily to treat clinically significant methemoglobinemia by facilitating conversion of methemoglobin to functional hemoglobin. It may be ineffective or hazardous in glucose-6-phosphate dehydrogenase deficiency and can interact with serotonergic drugs.

Methemoglobinemia

- A condition in which hemoglobin iron is oxidized to the ferric state, reducing oxygen delivery and caus-

ing functional anemia. Cyanosis, chocolate-brown blood, headache, dyspnea, neurologic symptoms, and cardiovascular compromise may occur depending on level and comorbidity.

Carbon Monoxide Poisoning

- Toxic exposure to carbon monoxide, which binds hemoglobin with high affinity and disrupts cellular oxygen utilization. Symptoms include headache, dizziness, confusion, syncope, ischemia, and metabolic acidosis; treatment begins with immediate removal from exposure and high-concentration oxygen.

Serum Osmolal Gap

- The difference between measured serum osmolality and calculated osmolality. An increased gap suggests unmeasured osmoles, including toxic alcohols, but interpretation must consider timing, renal function, lactate, ketones, and laboratory variation.

Acid-Base Analysis in Poisoning

- Integration of pH, bicarbonate, carbon dioxide, anion gap, delta gap, lactate, ketones, and osmolal gap to identify toxic metabolic disturbances. Mixed disorders are common and a normal pH does not exclude severe poisoning.

Occupational Exposure Limit

- A regulatory or advisory concentration or dose limit intended to reduce worker exposure to a hazardous substance over a defined averaging period. Limits vary by substance, jurisdiction, route, and whether the value is a ceiling, short-term limit, or time-weighted average.

Poison-Center Consultation

- Specialist toxicology advice used to identify hazards, interpret exposure and laboratory data, select antidotes, guide observation or disposition, and coordinate public-health response. Consultation is appropriate for significant, uncertain, mixed, pediatric, or unusual exposures.

Alcohol dependency

- A chronic relapsing disorder characterized by compulsive ethanol use, loss of control over intake, and negative emotional state during withdrawal, leading to tolerance, dependence, and organ damage over time.

Amiodarone-induced

vortex keratopathy

- Whorl-like corneal epithelial deposits caused by amiodarone accumulation, appearing as golden-brown verticillata on slit-lamp examination, usually asymptomatic but reversible upon drug discontinuation.

Arsenic toxicity

- Systemic poisoning from arsenic exposure causing gastrointestinal distress, cardiac arrhythmias, peripheral neuropathy, and characteristic Mees lines on nails, requiring chelation therapy with dimercaprol or succimer.

Bismuth Salicylate

- A compound combining bismuth subsalicylate with salicylic acid that provides antimicrobial and antisecretory effects, used for diarrhea and gastric upset but capable of causing salicylate toxicity in overdose.

Chronic lead poisoning

- Prolonged low-level lead exposure causing abdominal pain, anemia with basophilic stippling, peripheral neuropathy, and nephropathy, requiring chelation therapy and removal of the exposure source.

Cocaine

- A potent central nervous system stimulant and sympathomimetic causing vasoconstriction, tachycardia, hypertension, and euphoria, with acute toxicity manifesting as myocardial ischemia, seizures, and hyperthermia.

Decompression sickness

- A systemic illness caused by nitrogen bubble formation in tissues during rapid decompression, presenting with joint pain, skin mottling, and neurological deficits, treated with hyperbaric oxygen therapy.

Drug reaction with eosinophilia and systemic symptoms

- A severe hypersensitivity syndrome characterized by fever, rash, lymphadenopathy, and multiorgan involvement triggered by medications, requiring prompt drug cessation and systemic corticosteroids.

Fluorouracil side effect

- Toxicity from the antimetabolite 5-fluorouracil causing mucositis, diarrhea, hand-foot syndrome, myelosuppression, and potential cardiotoxicity, requiring dose adjustment or discontinuation.

Iododerma

- A papulopustular or acneiform skin eruption

caused by iodine excess, presenting on the face and extensor surfaces, resolving with iodine restriction and symptomatic treatment.

Neonatal thyrotoxicosis

- Transient hyperthyroidism in newborns caused by transplacental transfer of maternal thyroid-stimulating immunoglobulins, presenting with tachycardia, irritability, and poor weight gain in the first weeks of life.

Paracetamol overdose

- Toxic ingestion of paracetamol that can cause dose-dependent hepatic necrosis; risk assessment uses the timing and serum concentration of the ingestion.

Chapter 41

Urology

Androgen Deficiency

- Low testosterone levels. Symptoms: decreased libido, erectile dysfunction, fatigue, decreased muscle mass, depression. Diagnosis: morning testosterone measurement. Treatment: testosterone replacement therapy.

Anejaculation

- Absence of ejaculation. Causes: neurological, surgical, pharmacological, psychological.

Benign Prostatic Hyperplasia (BPH)

- Non-cancerous enlargement of the prostate gland, common in aging men. Symptoms: lower urinary tract symptoms (LUTS) including hesitancy, weak stream, frequency, urgency, nocturia, incomplete emptying. Diagnosis: DRE, PSA, uroflowmetry, post-void residual. Treatment: watchful waiting, alpha-blockers (tamsulosin), 5-alpha-reductase inhibitors (finasteride), combination therapy, surgical options (TURP, laser).

Bladder Carcinoma

- Malignant neoplasm originating from the urothelium lining the urinary bladder, with transition cell carcinoma (urothelial carcinoma) accounting for over 90 percent of cases. Predominant risk factor: cigarette smoking (responsible for 50

Bladder Diverticulum

- Outpouching of bladder wall. Congenital or acquired (obstruction). Asymptomatic or causes urinary stasis, stones, infection. Treatment: address obstruction, diverticulectomy if symptomatic.

Bladder Health and Disorders

- Bladder health involves the proper storage and voluntary release of urine through coordinated function of the detrusor muscle and sphincters. Common

disorders include urinary tract infections, overactive bladder, stress incontinence, and interstitial cystitis. Maintaining bladder health includes adequate hydration, pelvic floor exercises, and prompt treatment of infections.

Bladder Problems

- A range of conditions affecting urine storage and voiding, including incontinence, overactive bladder, urinary retention, and recurrent infections. Causes may include neurological damage, pelvic floor weakness, prostate enlargement, or bladder outlet obstruction. Evaluation includes urinalysis, urodynamics, and imaging; treatment varies from behavioral modifications and medications to surgery.

Bladder Stone

- Calculus forming in bladder. Causes: obstruction, infection, foreign body, stasis. Symptoms: dysuria, hematuria, interrupted stream. Treatment: removal, address underlying cause.

Catheterization (Urinary)

- Insertion of a flexible tube (catheter) through the urethra or suprapubically into the urinary bladder to drain urine. Types: Foley catheter (indwelling balloon catheter), intermittent (in-out) catheter, and suprapubic catheter. Indications: acute urinary retention, monitoring hourly urine output in critically ill patients, intraoperative management, neurogenic bladder, or intractable incontinence when conservative measures fail. Complications: catheter-associated urinary tract infection (CAUTI), urethral trauma, stricture formation, bladder spasms, and balloon malfunction. Prevention of CAUTI requires strict aseptic insertion technique, maintaining a closed drainage system, and prompt removal when no longer clinically indicated.

Circumcision

- Surgical removal of the foreskin (prepuce) covering the glans penis. Indications: medical reasons such as severe phimosis, recurrent balanoposthitis, paraphimosis, or lichen sclerosus (balanitis xerotica obliterans); elective infant circumcision for religious, cultural, or preventive health reasons. Preventive benefits: reduced risk of urinary tract infections in male infants, reduced risk of heterosexually acquired HIV transmission (demonstrated in sub-Saharan African clinical trials), decreased incidence of penile cancer, and lower risk of human papillomavirus (HPV) and herpes simplex virus type 2 transmission to partners. Surgical methods: Gomco clamp, Plastibell device, Mogen clamp, or dorsal slit and sleeve resection in older males.

Cystitis

- Inflammation of the urinary bladder, most commonly caused by bacterial infection (*Escherichia coli*). Symptoms: dysuria, frequency, urgency, suprapubic pain, hematuria. Diagnosis: urinalysis, urine culture. Treatment: antibiotics (nitrofurantoin, trimethoprim-sulfamethoxazole, fluoroquinolones). Complicated cystitis requires longer treatment and investigation for underlying causes.

Cystometrogram

- Suite of diagnostic procedures designed to evaluate the physiological function of the lower urinary tract (bladder and urethral sphincter) during filling, storage, and emptying phases. See [urodynamic testing](#).

Cystometry

- See [cystometrogram](#).

Cystoscopy

- Endoscopic examination of the urethra and bladder using a cystoscope. Diagnostic: evaluates hematuria, recurrent UTIs, suspected bladder tumors. Therapeutic: resection of bladder tumors, stone removal, stricture dilation, stent placement. Types: flexible and rigid cystoscopes.

Delayed Ejaculation

- Delayed or absent ejaculation despite adequate stimulation. Causes: medications (SSRIs), neurological, hormonal, psychological.

Dysuria

- Painful, burning, or uncomfortable sensation experienced during urination. Most commonly indicates inflammation or infection of the lower urinary tract. Causes in females: acute cystitis, urethritis (*Chlamydia trachomatis*, *Neisseria gonorrhoeae*), vaginitis (*Candida*, *Trichomonas*), and vulvar atrophy. Causes in males: urethritis, prostatitis, benign prostatic hyperplasia, or epididymitis. Non-infectious causes: bladder calculi, urethral trauma, chemical irritation (soaps, spermicides), interstitial cystitis, and urothelial neoplasms. Initial diagnostic evaluation involves urinalysis, urine culture, and testing for sexually transmitted infections when indicated.

Ejaculation

- The expulsion of seminal fluid from the male urethra during sexual climax, a reflex coordinated by the sympathetic nervous system (T10-L2) and involving contraction of the epididymis, vas deferens, seminal vesicles, prostate, and bulbospongiosus muscle. The process has two phases: emission (deposition of sperm and seminal fluid into the posterior urethra) and expulsion (rhythmic contraction of the pelvic floor muscles propelling semen through the urethra). Ejaculatory disorders include premature ejaculation (most common), delayed ejaculation, retrograde ejaculation (semen flows backward into the bladder), anejaculation (no ejaculation), and painful ejaculation. Causes: neurologic, pharmacologic (SSRIs, alpha-blockers), psychologic, and structural.

Electromyography

- Suite of diagnostic procedures designed to evaluate the physiological function of the lower urinary tract (bladder and urethral sphincter) during filling, storage, and emptying phases. See [urodynamic testing](#).

Emission

- The discharge or release of a substance, usually a fluid. In male reproduction, emission refers to the movement of semen into the posterior urethra in preparation for ejaculation.

Emphysematous Pyelonephritis

- Severe necrotizing infection of renal parenchyma with gas formation. Almost exclusively in diabetic

patients. Presents with high fever, flank pain, and sepsis. CT shows gas within renal parenchyma. A urological emergency requiring aggressive antibiotics and usually nephrectomy. Mortality is high even with treatment.

Epididymal Cyst

- Simple fluid-filled cyst in epididymis. Transilluminates. Asymptomatic, requires no treatment unless large or symptomatic.

Epididymitis

- Inflammation of the epididymis, a common cause of acute scrotal pain in adults, typically resulting from infection. In sexually active men under 35 years, the most common pathogens are sexually transmitted: *Chlamydia trachomatis* (most common) and *Neisseria gonorrhoeae*, with epididymitis often accompanied by urethritis. In men over 35 years and in children, the causative organisms are enteric gram-negative bacilli (*Escherichia coli*, *Pseudomonas*, *Klebsiella*) from urinary tract infection, prostatitis, or following urological instrumentation. Presents with gradual onset of scrotal pain and swelling, often with fever and dysuria. Diagnosis is clinical, supported by urine analysis and NAAT testing for sexually transmitted infections. Treatment includes appropriate antibiotics targeting the causative organism, scrotal elevation, and NSAIDs for symptom control.

Erectile Dysfunction

- The persistent inability to achieve or maintain an erection sufficient for satisfactory sexual performance. Affects up to 50

Erectile Dysfunction (ED)

- Inability to attain or maintain a penile erection sufficient for satisfactory sexual performance. Etiologies: vasculogenic (atherosclerosis, hypertension, diabetes mellitus), neurogenic (radical prostatectomy, spinal cord injury, multiple sclerosis, diabetic neuropathy), hormonal (hypogonadism, hyperprolactinemia), psychogenic (performance anxiety, depression, relationship conflict), and drug-induced (antihypertensives, antidepressants, antiandrogens). Vascular ED serves as an early marker for systemic coronary artery disease due to endothelial dysfunction in smaller cavernosal arteries. First-line therapy: oral phosphodiesterase type 5 (PDE5) inhibitors

(sildenafil, tadalafil, vardenafil). Second-line therapy: intracavernosal alprostadil injection or vacuum erection devices. Third-line therapy: surgical implantation of an inflatable penile prosthesis.

Extracorporeal Shock Wave Lithotripsy (ESWL)

- Non-invasive treatment method for urinary calculi that uses focused acoustic shock waves generated outside the body to fragment kidney or ureteral stones into smaller gravel-like pieces (dust/sand) that pass spontaneously in urine. Shock wave sources: electrohydraulic, electromagnetic, or piezoelectric generators, focused using fluoroscopic or ultrasound guidance. Most effective for renal stones <2 cm and proximal ureteral stones with density <1000 Hounsfield Units on non-contrast CT. Contraindications: pregnancy, uncorrected bleeding diatheses, uncontrolled urinary tract infection, severe body habitus, and abdominal aortic aneurysm. Complications: renal hematoma, steinstrasse (ureteral obstruction by stone fragments), and transient hematuria.

Extravasation

- Leakage of urine outside urinary tract. Causes: trauma, surgery, obstruction. Pseudovesical extravasation (rectus sheath), extraperitoneal, intraperitoneal. Treatment: catheter drainage, surgical repair.

Female Infertility

- See [obstetrics_gynecology](#).

Fistula

- Abnormal connection involving the urinary tract. See [Fistula \(Pathology\)](#).

Functional Urinary Incontinence

- Urinary incontinence due to physical or cognitive impairment preventing toilet access.

Gland

- Prostate gland, seminal vesicles, bulbourethral glands. See [prostate](#).

Hematuria

- Presence of red blood cells in the urine, categorized as microscopic (>3 RBCs per high-power field on urine microscopy) or gross (macroscopic, visible color change from pink to dark red). Microscopic hematuria is often asymptomatic and detected on

routine urinalysis. Gross hematuria requires urgent urological investigation to exclude malignancy. Etiologies: urological sources (bladder carcinoma, renal cell carcinoma, prostate cancer, nephrolithiasis, UTI, BPH, trauma) versus nephrological sources (IgA nephropathy, post-infectious glomerulonephritis, Alport syndrome). Glomerular origin is suggested by dysmorphic RBCs, red cell casts, and significant proteinuria. Workup for non-glomerular hematuria: multiphase CT urography and flexible cystoscopy.

Hydrocele

- Accumulation of serous fluid within the tunica vaginalis surrounding the testis. Congenital hydrocele results from patent processus vaginalis; acquired hydrocele may follow infection, trauma, or tumor. Transilluminates on examination. Ultrasound confirms fluid collection. Treatment: observation in infants (spontaneous resolution), surgical hydrocelectomy if persistent or symptomatic.

Hypergonadotropic Hypogonadism

- Primary testicular failure with elevated LH/FSH. Causes: Klinefelter syndrome, cryptorchidism, orchitis, chemotherapy, radiation.

Hypogonadotropic Hypogonadism

- Secondary testicular failure with low/normal LH/FSH. Causes: Kallmann syndrome, pituitary tumors, obesity, medications, systemic illness.

Hypospadias

- Congenital anomaly of male urogenital development characterized by an abnormally proximal urethral meatus located on the ventral surface of the penis, scrotum, or perineum, rather than at the tip of the glans. Classified by meatal location: anterior (glandular, subcoronal—60-70

Iatrogenic Injury

- Urological injury from medical procedures. Ureteral injury most common. Recognition and repair essential.

Interstitial Cystitis

- Chronic bladder pain syndrome. Symptoms: suprapubic pain, frequency, urgency. Diagnosis: exclusion, cystoscopy with hydrodistension. Treatment: lifestyle modification, medications, bladder instillations, surgery.

Juxtavesical

- Near bladder. Juxtavesical ureterocele, juxtavesical mass.

Kegel Exercise

- Pelvic floor muscle strengthening exercises. Treatment for stress urinary incontinence, post-prostatectomy incontinence.

Kidney Stone

- Stone formation in the urinary tract. See [nephrolithiasis](#).

Kidney Stones (Nephrolithiasis / Urolithiasis)

- Crystalline mineral deposits formed within the renal pelvis and calyces due to supersaturation of urine. Types: calcium oxalate/phosphate (75-80

Libido and Sexual Performance

- Libido (sexual desire) is modulated by a complex interplay of hormonal (testosterone, estrogen, prolactin), neurologic, psychologic, and relational factors. Low libido in men is commonly associated with hypogonadism, depression, medication side effects (SSRIs, antihypertensives), and chronic illness; in women, contributing factors include hormonal changes (menopause, postpartum), relationship distress, stress, and body image concerns. Sexual performance encompasses erectile function, ejaculatory control, and orgasmic capacity. Evaluation includes validated questionnaires, laboratory testing (testosterone, prolactin, thyroid function, glucose, lipids), and psychologic assessment. Treatment targets the underlying cause: testosterone replacement for hypogonadism, PDE5 inhibitors for ED, SSRIs or topical anesthetics for premature ejaculation, and psychosexual therapy or couples counseling for relationship or psychogenic contributors.

Lithiasis

- Stone formation. Nephrolithiasis, ureterolithiasis, cystolithiasis, urethrolithiasis.

Lithotripsy

- A medical procedure that uses shock waves to fragment kidney stones (renal calculi) into smaller pieces that can pass through the urinary tract. See [Shock Wave Lithotripsy](#).

Male Infertility

- Failure to conceive after 12 months of unprotected

intercourse. Causes: spermatogenic (varicocele, genetic, environmental), obstructive, hormonal, sexual, immunological. Evaluation: semen analysis, hormonal profile, genetic testing, imaging.

Masturbation

- Self-stimulation of the genitalia for sexual pleasure, a normal and common human behavior across all ages and genders. Prevalence: >90

Micturition

- Voiding, urination. Process of bladder emptying. Coordination of detrusor contraction and sphincter relaxation.

Mixed Urinary Incontinence

- Involuntary leakage of urine, significantly affecting psychological, social, and physical well-being. See [urinary incontinence](#).

Nephrectomy

- Surgical removal of kidney. Radical: for cancer. Simple: for benign disease. Partial: for select tumors. Laparoscopic/robotic approach common.

Nephrolithiasis

- Stone formation in the urinary tract. Calcium oxalate most common at 80

Nerve Conduction Study

- A diagnostic test that measures the speed and strength of electrical signals traveling through a nerve to detect nerve damage or dysfunction.

Neurogenic Bladder

- Bladder dysfunction due to neurological disease. Types: overactive (spastic), underactive (flaccid). Causes: spinal cord injury, multiple sclerosis, diabetic neuropathy, stroke. Management: catheterization, medications, surgery.

Nocturia

- Complaint of waking one or more times during the night to void, with each void preceded and followed by sleep. Highly prevalent in older adults and significantly impairs sleep quality and quality of life. Etiologies: nocturnal polyuria (nocturnal urine volume >33

Obstruction

- Blockage of urinary flow. Ureteral, urethral, bladder outlet. Causes: stones, stricture, tumor, BPH. Complications: hydronephrosis, infection, renal fail-

ure.

Orchitis

- Inflammation of the testicle, most commonly viral (mumps orchitis) or bacterial (secondary to epididymitis or UTI). Mumps orchitis occurs in 30

Overactive Bladder

- Urinary urgency with frequency and nocturia, with or without urge incontinence. Causes: detrusor overactivity. Treatment: behavioral therapy, anticholinergics, beta-3 agonists, botulinum toxin, neuromodulation.

Overflow Urinary Incontinence

- Involuntary leakage of urine, significantly affecting psychological, social, and physical well-being. See [urinary incontinence](#).

Paraphimosis

- Urological emergency in uncircumcised males occurring when a retracted, tight foreskin becomes trapped behind the coronal sulcus of the glans penis, forming a constricting ring. Venous and lymphatic congestion causes progressive edema of the glans and prepuce, eventually impairing arterial perfusion and risking glans ischemia, necrosis, and gangrene. Causes: failure to return the foreskin to its anatomical position following urinary catheterization, hygiene, or physical examination. Management: immediate manual reduction using digital compression to reduce edema followed by traction on the prepuce; if manual reduction fails, ice packs, osmotic agents (granulated sugar), hyaluronidase injections, dorsal slit procedure, or emergency circumcision are indicated.

Penile Cancer

- Rare malignancy, mostly squamous cell carcinoma. Risk factors: HPV, phimosis, poor hygiene, smoking. Presentation: penile lesion, ulcer, mass. Treatment: surgery (partial/total penectomy), radiation, chemotherapy.

Penile Fracture

- Rupture of tunica albuginea during erection. "Pop" sound, immediate detumescence, swelling, ecchymosis. Surgical emergency.

Percutaneous Nephrolithotomy (PCNL)

- Minimally invasive surgical procedure for removing

large, complex, or staghorn renal calculi. Access: a needle track is established under fluoroscopic or ultrasound guidance from the flank through the renal parenchyma into the target renal calyx, dilated to allow passage of a nephroscope and working sheath. Stones are fragmented using ultrasonic, pneumatic, or laser energy sources and extracted under direct vision. Indications: kidney stones >2 cm, staghorn calculi, lower pole stones >1.5 cm, or cases where ESWL and ureteroscopy have failed. Complications: hemorrhage requiring transfusion, retroperitoneal hematoma, pleural entry (hydro/pneumothorax), sepsis, and adjacent organ injury.

Peyronie Disease

- Fibrous plaque in penis causing curvature, pain, erectile dysfunction. Treatment: observation, medications, injection therapy, surgery.

Phimosis

- Inability to retract the foreskin (prepuce) proximally over the glans penis. Physiologic phimosis is normal in infants and uncircumcised young boys due to natural adhesions between glans and prepuce, resolving spontaneously in over 90

Post-Void Residual

- Urine remaining in bladder after voiding. Normal: <50 mL. Elevated: >100-150 mL. Measured by ultrasound or catheterization. Indicates incomplete emptying.

Premature Ejaculation

- Ejaculation occurring sooner than desired. Most common sexual dysfunction in men. Treatment: behavioral techniques, topical anesthetics, SSRIs, counseling.

Pressure-Flow Study

- Suite of diagnostic procedures designed to evaluate the physiological function of the lower urinary tract (bladder and urethral sphincter) during filling, storage, and emptying phases. See [urodynamic testing](#).

Priapism

- Prolonged, painful erection lasting longer than 4 hours, occurring independently of sexual desire or stimulation. Medical emergency categorized into two types: ischemic (low-flow, veno-occlusive) and non-ischemic (high-flow, arterial). Ischemic pri-

apism accounts for >95

Prostate Cancer

- Most common non-cutaneous cancer in men. Risk factors: age, family history, African American race, high red meat intake. Screening: PSA testing, DRE. Diagnosis: transrectal ultrasound-guided biopsy. Staging: TNM system, Gleason score. Treatment: active surveillance (low-risk), surgery (radical prostatectomy), radiation (EBRT, brachytherapy), hormone therapy (androgen deprivation), chemotherapy (metastatic).

Prostate-Specific Antigen (PSA)

- Glycoprotein enzyme (serine protease) produced almost exclusively by the luminal epithelial cells of the prostate gland, secreted into seminal fluid to liquefy the semen coagulum. Small amounts enter the bloodstream, where total PSA can be measured. Reference range: generally <4 ng/mL, though age-adjusted thresholds are used. Elevated PSA occurs in prostate cancer, but is non-specific and also elevated in benign prostatic hyperplasia, acute/chronic prostatitis, urinary retention, prostate biopsy, and recent ejaculation. Clinical utility: screening (discussed with informed decision-making), monitoring response to prostate cancer treatment, and surveillance for disease recurrence. Diagnostic specificity is improved using free-to-total PSA ratio, PSA velocity, and PSA density.

Prostatectomy

- Surgical procedure involving the partial or total removal of the prostate gland. Simple prostatectomy: removal of the inner adenoma while leaving the peripheral capsule intact, performed open, laparoscopically, or robotically for very large BPH (>80-100 grams). Radical prostatectomy: complete excision of the entire prostate gland, seminal vesicles, and ampullae of the vas deferens, along with pelvic lymph node dissection for localized prostate cancer. Radical prostatectomy approaches: open retropubic, perineal, or robot-assisted laparoscopic radical prostatectomy (RALP). Key surgical complications: urinary stress incontinence (due to external urethral sphincter trauma) and erectile dysfunction (due to cavernous nerve injury; nerve-sparing techniques preserve potency when oncologically feasible).

Prostatitis

– Inflammation of the prostate gland, categorized by the NIH into four types: Acute bacterial prostatitis (Category I—fever, chills, dysuria, perineal pain, tender prostate; treatment: antibiotics, possible hospitalization), Chronic bacterial prostatitis (Category II—recurrent UTIs, pelvic pain; treatment: prolonged antibiotics), Chronic prostatitis/chronic pelvic pain syndrome (Category III—most common, pelvic pain >3 months without infection; treatment: alpha-blockers, anti-inflammatories, physical therapy), Asymptomatic inflammatory prostatitis (Category IV—incidental finding, no symptoms; no treatment required). Diagnosis involves urine culture, expressed prostatic secretion analysis, and sometimes transrectal ultrasound.

Pyelonephritis

– Bacterial infection of the renal parenchyma and renal pelvis, usually ascending from the lower urinary tract. Most common pathogen: *Escherichia coli*. Risk factors: female sex, urinary tract obstruction, pregnancy, diabetes, indwelling catheters. Acute pyelonephritis presents with fever, chills, flank pain, nausea, vomiting, and dysuria. Diagnosis: urinalysis (pyuria, bacteriuria, leukocyte esterase, nitrites), urine culture. Treatment: antibiotics (fluoroquinolones, cephalosporins), hydration, analgesics. Complicated pyelonephritis requires longer treatment and investigation for underlying causes. Chronic pyelonephritis may lead to renal scarring and chronic kidney disease.

Pyonephrosis

– Pus in renal collecting system. Urological emergency. Requires drainage (stent or nephrostomy) and antibiotics.

Renal Cell Carcinoma (RCC)

– Primary malignant adenocarcinoma of the renal cortex, originating from proximal renal tubular epithelial cells. Represents 85

Renal Colic

– Severe flank pain from ureteral stone. Colicky, radiates to groin. Nausea, vomiting, hematuria. Diagnosis: CT, ultrasound. Treatment: analgesics, hydration, medical expulsive therapy, stone removal.

Retrograde Ejaculation

– Semen enters bladder instead of exiting urethra. Causes: diabetes, surgery, medications. Dry orgasm. Treatment: medications, sperm retrieval for fertility.

Semen

– Fluid composed of spermatozoa and secretions from the seminal vesicles, prostate, and bulbourethral glands. Normal semen volume: 1.5-5 mL. Sperm concentration: >15 million/mL. Total sperm count: >39 million per ejaculate. Motility: >40

Sexual Dysfunction

– Problems occurring during sexual activity. Male: ED, premature ejaculation, delayed ejaculation, anejaculation, retrograde ejaculation. Female: decreased libido, dyspareunia, anorgasmia, vaginismus.

Shock Wave Lithotripsy

– Non-invasive procedure using extracorporeal shock waves to fragment renal and ureteral stones. The patient is positioned over a water cushion coupling the shock wave generator to the body. Shock waves are focused on the stone under fluoroscopic or ultrasound guidance. Most effective for stones less than two centimeters in the renal pelvis or upper ureter. Success rates decrease with larger stones and lower pole location. Complications include renal hematoma, stone street from multiple fragments, residual stones, and need for multiple sessions, though the non-invasive nature makes it the preferred first-line treatment for suitable stones.

Sperm

– Male gamete cell produced in the testes. Structure: head (contains nucleus with 23 chromosomes and acrosome with enzymes), midpiece (contains mitochondria for energy), tail (flagellum for motility). Production: spermatogenesis in seminiferous tubules takes 74 days. Maturation: epididymal maturation takes 12 days. Ejaculation releases 200-500 million sperm per mL. Semen analysis evaluates sperm count, motility, morphology.

Spermatocele

– Benign, painless, fluid-filled cystic retention cavity arising from the epididymis (usually the head/caput), containing avascular fluid and non-viable spermatozoa. Etiology: obstruction of an

efferent ductule of the epididymis. Clinical presentation: smooth, spherical, non-tender mass located superior and posterior to the testis, distinct from the testicular parenchyma. Transilluminates clearly on physical examination. Scrotal ultrasound confirms a well-demarcated anechoic lesion separate from the testicle. Management: reassurance and conservative observation; surgical spermatocelectomy is reserved for large, painful, or bothersome cysts.

Stress Urinary Incontinence

- Involuntary leakage of urine, significantly affecting psychological, social, and physical well-being. See [urinary incontinence](#).

Surgical Repair

- See repair.

Testicular Cancer

- Most common solid malignancy in young men 15-35 years. Types: germ cell tumors (seminoma, non-seminoma), sex cord-stromal tumors. Presentation: painless testicular mass, heaviness, ache. Diagnosis: scrotal ultrasound, tumor markers (AFP, beta-hCG, LDH). Treatment: radical inguinal orchiectomy, surveillance, chemotherapy, radiation (seminoma), retroperitoneal lymph node dissection.

Testicular Disorders

- Conditions affecting the testes, including testicular torsion (spermatic cord twisting causing ischemic pain and swelling, a surgical emergency requiring detorsion within 6 hours for testicular salvage), epididymitis (inflammation of the epididymis, often from bacterial infection—STI in young men, urinary pathogens in older men—treated with antibiotics and supportive care), orchitis (testicular inflammation, often viral from mumps), hydrocele (fluid collection in the tunica vaginalis, benign), varicocele (dilated pampiniform plexus veins, the most common correctable cause of male infertility), and testicular cancer (most common solid malignancy in young men 15-35, typically presenting as a painless testicular mass, diagnosed with scrotal ultrasound and tumor markers—AFP, hCG, LDH—and treated with radical inguinal orchiectomy with possible chemotherapy or radiation). Evaluation includes scrotal ultrasound, urinalysis, STI screening, and tumor markers.

Testicular Microlithiasis

- Multiple tiny calcifications in testes. Associated with testicular cancer risk. Surveillance recommended.

Testicular Torsion

- Surgical emergency caused by twisting of the spermatic cord around its longitudinal axis, cutting off venous return and leading to arterial occlusion, ischemia, and infarction of the testicle. Predisposing anatomy: "bell-clapper" deformity, where the tunica vaginalis completely encircles the epididymis and distal cord, allowing the testis to rotate freely within the scrotum. Most common in neonates and post-pubertal males (ages 12-18). Symptoms: sudden onset of severe, unilateral scrotal pain, nausea, vomiting, high-riding testis with horizontal lie, and absent cremasteric reflex. Negative Prehn sign (pain is not relieved by scrotal elevation). Color Doppler ultrasound shows absent or decreased intratesticular blood flow. Management: urgent surgical exploration with manual detorsion and bilateral orchidopexy; testicular salvage rate is >90

Transurethral Resection of the Prostate (TURP)

- Gold standard surgical procedure for benign prostatic hyperplasia (BPH) refractory to medical management or complicated by urinary retention, renal insufficiency, or recurrent hematuria. Performed using a rigid resectoscope inserted through the urethra; a high-frequency electrosurgical wire loop (monopolar or bipolar) is used to systematically resect obstructive hyperplastic prostatic tissue from the transition zone under direct vision. Resected tissue chips are irrigated out and sent for histopathology. Complications: bleeding, retrograde ejaculation (>75

Tumor

- Abnormal growth of tissue, may be benign or malignant. See [neoplasm](#).

Undescended Testis (Cryptorchidism)

- Congenital failure of one or both testes to descend along the normal path from the retroperitoneum into the scrotum during fetal development. Most common congenital anomaly of the male genitalia, affecting 3

Ureteral Obstruction

- Blockage of urine flow causing proximal dilation and increased pressure. Acute causes renal colic with flank pain. Chronic leads to hydronephrosis and CKD. Emergent decompression with stent or nephrostomy for infected obstructed kidney. Diagnosis by CT or ultrasound showing hydronephrosis.

Ureteral Stent (Double-J Stent)

- A tube placed in the ureter from the renal pelvis to the bladder to maintain patency, with pigtail coils at both ends (hence double-J). Indications: ureteral obstruction (stones, stricture, malignancy), after ureteroscopy (prevent post-op obstruction), and as a pre-treatment for complex ureteral stones. Placed cystoscopically or antegrade through a nephrostomy. Sizes: 6-8 Fr, lengths 22-30 cm. Left in for weeks to months (though should not exceed 3 months due to encrustation). Complications: stent-related discomfort (urgency, frequency, hematuria, flank pain — very common), infection, migration, encrustation (forgotten stent), and stone formation.

Ureteroscopy

- Endoscopic procedure utilizing a thin, flexible or semirigid ureteroscope passed through the urethra, bladder, and into the ureter or renal collecting system. Used primarily for the diagnostic evaluation and therapeutic management of ureteral and renal calculi, ureteral strictures, and upper tract urothelial carcinoma (UTUC). Therapeutic ureteroscopy incorporates laser fiber lithotripsy (holmium:YAG or thulium fiber laser) to pulverize stones into dust, followed by stone basket retrieval. A temporary ureteral stent (Double-J stent) is frequently placed postoperatively to ensure urine drainage and prevent ureteral spasm or stricture formation.

Urethral Meatus

- External opening of urethra. Position abnormal in hypospadias, epispadias.

Urethral Pressure Profile

- Measurement of urethral closure pressure along urethra. Used in incontinence evaluation.

Urethral Pressures

- Measurement of urethral closure pressure along urethra. See [urethral pressure profile](#).

Urethral Stricture

- Narrowing of the urethra due to fibrosis of the corpus spongiosum, most commonly caused by trauma (pelvic fracture, straddle injury, iatrogenic from catheterisation or urethral instrumentation), infection (gonococcal urethritis leading to stricture years later, now less common in the antibiotic era), and lichen sclerosus (Balanitis Xerotica Obliterans, BXO). Presents with progressive urinary obstruction: weak stream, hesitancy, straining, incomplete bladder emptying, frequency, and recurrent UTIs. Complete obstruction causes acute urinary retention. Diagnosis: retrograde urethrogram demonstrates the location and length of the stricture. Urethroscopy confirms and may allow simultaneous treatment. Treatment depends on location, length, and severity: urethral dilation (temporary, high recurrence rate), internal urethrotomy (optical incision of the stricture, 50

Urethritis

- Inflammation of the urethra, most commonly infectious. Causes: sexually transmitted infections (Chlamydia trachomatis, Neisseria gonorrhoeae most common), urinary tract pathogens (Escherichia coli), trauma, chemical irritation. Symptoms: dysuria, urethral discharge, frequency, urgency. Diagnosis: urine NAAT for STIs, urinalysis, urethral swab. Treatment: antibiotics targeting causative organism, partner treatment, abstinence until cured.

Urge Urinary Incontinence

- Involuntary leakage of urine, significantly affecting psychological, social, and physical well-being. See [urinary incontinence](#).

Urinary Bladder

- Muscular hollow organ in the pelvis storing urine until micturition. Capacity: 400-600 mL. Wall composed of mucosa (urothelium), submucosa, muscularis (detrusor muscle), and adventitia. Innervation: parasympathetic (S2-S4, contraction), sympathetic (T11-L2, relaxation), somatic (pudendal nerve, external sphincter). Disorders: infection, malignancy, stones, dysfunction, incontinence.

Urinary Incontinence

- Involuntary leakage of urine, significantly affecting psychological, social, and physical well-being. Main

types: Stress Urinary Incontinence (SUI—leakage with increased intra-abdominal pressure such as coughing, sneezing, laughing; caused by urethral hypermobility or intrinsic sphincter deficiency), Urge Urinary Incontinence (UUI—involuntary leakage accompanied by a sudden, intense desire to void; caused by detrusor overactivity), Mixed Urinary Incontinence (combination of SUI and UUI), and Overflow Urinary Incontinence (involuntary dribbling due to urinary retention and bladder overdistension; caused by BPH, urethral stricture, or neurogenic detrusor underactivity). Management: pelvic floor muscle training (Kegel exercises), lifestyle modifications, anticholinergics/beta-3 agonists (mirabegron) for UUI, and surgical slings (mid-urethral sling) or artificial urinary sphincter for SUI.

Urinary Retention

– Inability to completely empty the bladder, which can be acute (sudden, painful, inability to void) or chronic (gradual, often painless, with overflow incontinence). Causes: benign prostatic hyperplasia, urethral stricture, neurogenic bladder, medications (anticholinergics), and pelvic organ prolapse. Diagnosis: post-void residual >100 mL, ultrasound, cystoscopy. Acute treatment: urethral catheterization. Chronic: alpha-blockers, 5-alpha-reductase inhibitors, and surgery.

Urinary Tract Infection

– Infection of the urinary tract, classified as lower (cystitis, urethritis) or upper (pyelonephritis).

Urinary Tract Infection (UTI)

– Inflammatory response of the urothelium to microbial invasion, ranging from lower tract infection (cystitis, urethritis) to upper tract infection (pyelonephritis, renal abscess). Classification: uncomplicated (infection in a healthy, non-pregnant, immunocompetent adult female with normal urinary anatomy) versus complicated (infection associated with factors increasing treatment failure or tissue damage, such as male gender, pregnancy, urinary obstruction, neurogenic bladder, indwelling catheter, immunosuppression, or renal insufficiency). *Escherichia coli* causes >80

Urodynamic Testing

– Suite of diagnostic procedures designed to evaluate the physiological function of the lower urinary

tract (bladder and urethral sphincter) during filling, storage, and emptying phases. Components: Uroflowmetry (measures urine flow rate and volume), Cystometrogram (CMG—evaluates bladder compliance, sensation, capacity, and involuntary detrusor contractions during saline filling), Pressure-Flow Studies (differentiates bladder outlet obstruction from detrusor muscle underactivity during voiding), Urethral Pressure Profiling, and Electromyography (EMG—assesses sphincter muscle activity and detrusor-sphincter dyssynergia). Indications: neurogenic bladder, refractory urinary incontinence, failed BPH surgery, and complex voiding dysfunction.

Urodynamics

– Suite of diagnostic procedures designed to evaluate the physiological function of the lower urinary tract (bladder and urethral sphincter) during filling, storage, and emptying phases. See [urodynamic testing](#).

Uroflow

– Measurement of urine flow rate. See [uroflowmetry](#).

Uroflowmetry

– Measurement of urine flow rate. Parameters: max flow rate (Qmax), mean flow rate, flow time, pattern. Normal Qmax: >15 mL/s. Reduced in obstruction, weak detrusor.

Urolithiasis

– Stone formation in the urinary tract (kidneys, ureters, bladder, urethra). Types: calcium oxalate (most common, 60-70

Urology

– Surgical and medical specialty concerned with the study, diagnosis, and management of diseases affecting the male and female urinary tract (kidneys, ureters, urinary bladder, urethra) and the male reproductive system (prostate, testes, epididymis, seminal vesicles, penis). Subspecialties: urologic oncology, endourology and stone disease, female pelvic medicine and reconstructive surgery (FPMRS), neurourology and urodynamics, andrology and male infertility, pediatric urology, and renal transplantation. Common diagnostic modalities include urinalysis, cystoscopy, ultrasound, CT urography, and urodynamics.

Varicocele

- Abnormal dilation and tortuosity of the pampiniform venous plexus within the spermatic cord, resulting from incompetent or absent venous valves. Occurs in 15

Vasectomy

- Minor surgical procedure for permanent male contraception involving surgical interruption, occlusion, or excision of a segment of both vasa deferentia, preventing spermatozoa from entering the ejaculate. Performed under local anesthesia using traditional incisional or no-scalpel vasectomy (NSV) techniques. Vas occlusion methods: cauterization, ligation with clips/sutures, or fascial interposition. Contraceptive reliance is not immediate; patients must use alternative contraception until a post-vasectomy semen analysis (PVSA) confirms azoospermia or $<100,000$ non-motile sperm/mL, typically evaluated 8-12 weeks and 20 ejaculations post-procedure. Reversal (vasovasostomy) is possible but technically challenging and not guaranteed to restore fertility.

Vesical

- Relating to bladder. Vesical carcinoma, vesical diverticulum, vesical neck.

Vesicoureteral Reflux

- Retrograde flow of urine from the bladder into the ureters and potentially the kidneys, most commonly due to incompetent ureterovesical valve. Predisposes to pyelonephritis and renal scarring. More common in children, presenting with recurrent febrile UTIs. Diagnosis: voiding cystourethrogram (VCUG). Grading I-V. Management: observation with prophylactic antibiotics for low-grade, ureteral reimplantation or endoscopic injection for high-grade.

Xanthogranulomatous

- Chronic destructive renal infection with replacement of parenchyma by lipid-laden macrophages. See [xanthogranulomatous pyelonephritis](#).

Xanthogranulomatous Pyelonephritis

- Chronic destructive renal infection with replacement of parenchyma by lipid-laden macrophages. Associated with obstructing stones and *Proteus* infection. Enlarged kidney with scattered low-

attenuation areas on CT resembling a bear paw. Treated with nephrectomy as the kidney is non-functional and harbors chronic infection.

Urologic Diagnostic Yield

- The proportion of urologic diagnostic procedures or tests that provide a definitive and clinically useful result.

Zoon Balanitis

- A chronic benign inflammatory disorder of the glans penis, usually presenting as a sharply demarcated shiny orange-red or rust-colored patch in uncircumcised men. Diagnosis is clinical but biopsy may be needed to exclude premalignant or malignant disease; treatment includes hygiene, topical corticosteroids or calcineurin inhibitors, and circumcision for recurrent disease.

Lower Urinary Tract Symptoms (LUTS)

- Urinary symptoms arising from the bladder, bladder outlet, or urethra, classified as storage symptoms, voiding symptoms, and post-micturition symptoms. Causes include benign prostatic obstruction, overactive bladder, infection, neurologic disease, stricture, and malignancy.

Benign Prostatic Obstruction (BPO)

- Bladder-outlet obstruction caused by benign prostatic enlargement or increased prostatic smooth-muscle tone. It can produce weak stream, hesitancy, intermittency, straining, incomplete emptying, retention, infection, and upper-tract deterioration.

Prostate Biopsy

- Sampling of prostate tissue, commonly by transperineal or transrectal needle technique, for histologic diagnosis of prostate cancer. Targeted and systematic cores may be combined, with attention to infection prevention, bleeding, urinary retention, and sepsis risk.

Multiparametric MRI of the Prostate

- MRI protocol combining T2-weighted, diffusion-weighted, and dynamic contrast-enhanced sequences to detect and characterize clinically significant prostate cancer. Findings are commonly reported using the PI-RADS system.

Complicated Urinary Tract Infection

- A urinary infection associated with functional or structural abnormality, obstruction, catheterization, renal impairment, male anatomy, pregnancy, or another factor increasing treatment failure or complication risk. Management requires culture-directed therapy and correction of the underlying problem when possible.

Obstructed Infected Urinary System

- Urinary tract obstruction accompanied by infection, pyonephrosis, or sepsis. It is a urologic emergency requiring immediate resuscitation, antimicrobial therapy, and urgent decompression by nephrostomy or ureteral stent.

Ureteropelvic Junction Obstruction (UPJO)

- Impaired drainage from the renal pelvis into the proximal ureter, caused by intrinsic narrowing, aberrant vessels, scarring, or functional peristaltic abnormality. It may cause hydronephrosis, flank pain, infection, stones, or loss of renal function.

Ureteral Stricture

- Narrowing of the ureter caused by fibrosis, surgery, instrumentation, radiation, infection, malignancy, or congenital disease. It can produce upstream hydronephrosis, pain, infection, and declining renal function.

Post-Void Residual Volume

- The amount of urine remaining in the bladder immediately after urination, measured by ultrasound or catheterization. An elevated residual suggests incomplete emptying but must be interpreted with timing, bladder volume, symptoms, and repeated measurements.

Semen Analysis

- Laboratory assessment of ejaculate volume, sperm concentration, total count, motility, morphology, vitality, and other characteristics. It is a key initial test in male-factor infertility and should usually be repeated because results vary biologically.

Azoospermia

- Absence of spermatozoa in the ejaculate after appropriate centrifugation and microscopic examina-

tion. It may be obstructive, with sperm production preserved but outflow blocked, or nonobstructive, with impaired spermatogenesis.

Testicular Torsion Emergency

- Rotation of the spermatic cord that compromises testicular blood flow, causing sudden unilateral scrotal pain, nausea, a high-riding testis, and an abnormal cremasteric reflex. Immediate surgical exploration and detorsion are required; imaging must not delay treatment when suspicion is high.

Bladder Pain Syndrome

- Chronic bladder-related pain, pressure, or discomfort associated with urinary symptoms in the absence of infection or another identifiable cause. It is a diagnosis of exclusion and is managed with multimodal, patient-centered treatment.

Urothelial Carcinoma

- Malignancy arising from the urothelial lining of the renal pelvis, ureter, bladder, or urethra. Painless visible hematuria is a common presentation; evaluation may include cystoscopy, upper-tract imaging, urine cytology, and tissue diagnosis.

Flank Pain

- Pain arising from the lateral back between the ribs and iliac crest, often reflecting disease of the kidney, ureter, musculoskeletal structures, or adjacent abdominal organs. Associated fever, haematuria, vomiting, urinary symptoms, trauma, or hypotension helps distinguish infection, obstruction, stones, injury, and other causes.

Retroperitoneal Fibrosis

- Chronic fibroinflammatory tissue formation in the retroperitoneum, often encasing the ureters and great vessels. It can cause hydronephrosis, flank pain, reduced kidney function, hypertension, or lower-limb edema and may be idiopathic, immune-mediated, drug-related, or secondary to malignancy.

Urachal Cyst

- A cystic remnant of the embryonic urachus between the bladder and umbilicus. It may be asymptomatic or become infected, causing lower-abdominal pain, fever, umbilical discharge, or urinary symptoms.

Ureter Duplex

- A congenital duplication of the ureter, complete or partial, draining one kidney. It may be asymp-

tomatic or associated with vesicoureteral reflux, ureterocele, obstruction, recurrent urinary infection, or impaired renal drainage.

Ureteritis

- Inflammation of the ureter, usually related to infection, obstruction, stone passage, instrumentation, or adjacent inflammatory disease. It may cause flank or abdominal pain, urinary symptoms, hematuria, and fever.

Ureterocele

- A cystic dilatation of the distal ureter within the bladder wall or bladder lumen. It can obstruct urine flow and cause urinary infection, hydronephrosis, reflux, stone formation, or impaired renal function.

Urethral Diverticulum

- A periurethral outpouching that communicates with the urethral lumen, usually arising from infected or obstructed periurethral glands. It may cause dysuria, post-void dribbling, recurrent urinary infection, dyspareunia, or a palpable anterior-vaginal-wall mass.

Bladder Outlet Obstruction

- Blockage of urine flow at the bladder neck or urethra, commonly caused by benign prostatic enlargement, urethral stricture, stones, tumors, or pelvic-organ prolapse. It may cause weak stream, hesitancy, retention, hydronephrosis, infection, and renal impairment.

Bladder Stones

- Calculi that form in or migrate into the urinary bladder. They may cause lower abdominal pain, dysuria, urinary frequency, hematuria, recurrent infection, or intermittent urinary obstruction.

Chapter 42

Vascular Surgery & Angiology

Peripheral Artery Disease

- Narrowing of arteries supplying the limbs, usually caused by atherosclerosis. It may cause exertional leg pain relieved by rest, reduced pulses, nonhealing wounds, or critical limb ischemia. Also called peripheral arterial disease.

Mesenteric Artery Ischemia

- Inadequate blood flow through the mesenteric arteries, usually caused by embolism, thrombosis, or severe low-flow states. Acute disease presents with severe abdominal pain out of proportion to examination and can progress to bowel infarction.

AAA Repair

- See [abdominal aortic aneurysm](#).

Abdominal Aortic Aneurysm

- Abnormal focal dilation of blood vessel. See [aneurysm](#).

ABI

- Ankle-brachial index. Ratio of ankle to arm systolic pressure. Normal: 1.0-1.4. <0.9 indicates PAD.

Acute Aortic Syndrome

- A spectrum of life-threatening conditions involving the thoracic aorta, including aortic dissection, intramural hematoma (IMH), and penetrating aortic ulcer (PAU). See [acute aortic syndromes](#).

Acute Limb Ischemia (ALI)

- Sudden, rapid decrease in lower extremity arterial perfusion threatening limb viability, typically caused by acute arterial thrombosis or embolism. Presentation: the 6 Ps—pain, pallor, pulselessness, paresthesia, paralysis, poikilothermia. Diagnosis: clinical, Doppler ultrasound, CT angiography. Treatment: emergency revascularization (thrombolysis, thrombectomy, bypass) within 6 hours for salvage-

able limb.

Amputation

- Last resort for unsalvageable limb. Below-knee, above-knee, transmetatarsal.

Aneurysm

- Abnormal focal dilation of blood vessel. Types: arterial (aortic, peripheral), venous (rare). Risk factors: atherosclerosis, hypertension, smoking, genetic disorders (Marfan, Ehlers-Danlos), infection. Abdominal aortic aneurysm (AAA): screening by ultrasound in men 65-75 who smoked. Repair indicated if >5.5 cm, symptomatic, or expanding.

Aneurysm Repair

- Surgical or endovascular treatment of aneurysm. Indications: size, symptoms, expansion rate.

Angioplasty

- Balloon dilation of stenotic vessel. Often combined with stenting.

Anticoagulation

- Blood thinning medication. Used for DVT, PE, arterial thrombosis, after stenting.

Antiplatelet Therapy

- Medication preventing platelet aggregation. Aspirin, clopidogrel. Used after stenting, bypass.

Aorta

- Main arterial trunk carrying blood from heart to body. Thoracic and abdominal segments. AAA most common aneurysm.

Aortic Aneurysm

- Abnormal focal dilation of blood vessel. See [aneurysm](#).

Aortic Aneurysm Screening

- Abnormal focal dilation of blood vessel. See

aneurysm.

Aortic Dissection

- A spectrum of life-threatening conditions involving the thoracic aorta, including aortic dissection, intramural hematoma (IMH), and penetrating aortic ulcer (PAU). See [acute aortic syndromes](#).

Arterial Duplex

- Ultrasound technique combining B-mode imaging and Doppler flow assessment. Used for evaluating arterial stenosis, aneurysm, graft patency. Non-invasive, widely available.

Arterial Ulcer

- Wound caused by inadequate arterial blood supply. Location: toes, heels, pressure points. Appearance: painful, punched-out, pale base, minimal granulation. Assessment: ABI, doppler pressures, angiography. Treatment: revascularization, wound care, offloading.

Arteriole

- Small artery leading to capillaries. Regulates blood flow and blood pressure.

Arteriovenous Fistula

- Vascular access for hemodialysis. See [dialysis access](#).

Arteriovenous Malformation

- Abnormal connection between artery and vein without capillary bed. Can bleed or cause symptoms.

Artery

- Blood vessel carrying blood away from heart. Thick muscular walls. Pulse palpable.

Atherectomy

- Mechanical removal of atherosclerotic plaque. Types: directional, laser, rotational, orbital. Used for peripheral arterial disease.

Atherosclerosis

- Plaque buildup in arteries. Major cause of PAD, CAD, stroke. Risk factors: smoking, diabetes, hypertension, hyperlipidemia.

Barthel Index

- Standardized measure of functional independence in activities of daily living (ADL). See [geriatrics](#).

Bruits

- Turbulent blood flow sounds heard with stetho-

scope. Indicates stenosis.

Buerger Disease

- See thromboangiitis obliterans.

Bypass

- Surgical creation of alternative route around blocked vessel. Uses vein or prosthetic graft.

Bypass Graft

- Surgical procedure creating detour around blocked vessel using autologous vein (saphenous) or prosthetic graft (PTFE, Dacron). Indications: peripheral arterial disease, coronary artery disease, aortic aneurysm. Long-term patency depends on graft type, inflow/outflow, patient factors.

Bypass Surgery

- Surgical procedure creating detour around blocked vessel using autologous vein (saphenous) or prosthetic graft (PTFE, Dacron). See [bypass graft](#).

Calcific Uremic Arteriopathy

- Calcification of small blood vessels in kidney disease. Painful skin necrosis. Treatment: sodium thiosulfate, wound care.

Calciphylaxis

- Calcification of small blood vessels in kidney disease. See [calcific uremic arteriopathy](#).

Capillary

- Smallest blood vessel. Site of exchange between blood and tissues.

Carotid Endarterectomy

- Narrowing of carotid artery, usually from atherosclerosis. See [carotid stenosis](#).

Carotid Stenosis

- Narrowing of carotid artery, usually from atherosclerosis. Risk: ischemic stroke. Asymptomatic: screening by auscultation (bruit), ultrasound if risk factors. Symptomatic: TIA or stroke. Treatment: carotid endarterectomy (CEA) or carotid artery stenting (CAS) if >70

Chronic Venous Insufficiency (CVI)

- Inadequate venous return causing venous hypertension. Symptoms: edema, skin changes (hyperpigmentation, lipodermatosclerosis), venous ulcer. Diagnosis: venous duplex ultrasound. Treatment: compression therapy, wound care, surgical interven-

tion if indicated.

Claudication

- Atherosclerotic occlusive disease of arteries supplying the lower limbs, causing reduced blood flow. See [peripheral arterial disease](#).

Claudication Distance

- Distance walked before pain onset. Improves with exercise, medication, revascularization.

Collateral Circulation

- Alternative blood flow pathways. Develop with chronic obstruction. Important for limb salvage.

Color Doppler

- Ultrasound technique combining B-mode imaging and Doppler flow assessment. See [arterial duplex](#).

Compartment Syndrome

- Increased pressure within fascial compartment compromising circulation. See emergency medicine.

Complications (Vascular)

- Post-procedural issues: bleeding, infection, thrombosis, embolism, limb ischemia.

Compression Therapy

- External pressure on veins. Used for DVT prevention, venous insufficiency, varicose veins.

Critical Limb Ischemia

- See acute limb ischemia.

Deep Vein Thrombosis (DVT)

- Blood clot in deep veins, usually lower extremity. Risk factors: Virchow triad (stasis, hypercoagulability, endothelial injury). Symptoms: leg swelling, pain, warmth, redness. Diagnosis: D-dimer, compression ultrasound. Treatment: anticoagulation (heparin, DOACs), compression stockings, IVC filter if contraindication to anticoagulation.

Diabetes Management

- Tight glucose control reduces complications. Foot examination essential.

Diabetic Foot

- See [endocrinology](#).

Dialysis Access

- Vascular access for hemodialysis. Types: arteriovenous fistula (AVF, gold standard), arteriovenous graft (AVG), central venous catheter. AVF: autogenous, durable, lower complication rate. AVG: pros-

thetic, used when veins unsuitable. Complications: stenosis, thrombosis, infection, steal syndrome.

Dissection

- A tear in the intima of the aorta allowing blood to dissect through the media, creating a false lumen. See [aortic dissection](#).

Duplex Ultrasound

- Ultrasound technique combining B-mode imaging and Doppler flow assessment. See [arterial duplex](#).

DVT Prevention

- Formation of a blood clot in a deep vein, most commonly in the lower extremities. See [deep vein thrombosis](#).

Embolectomy

- Surgical removal of embolus from blood vessel. Indications: acute arterial occlusion, pulmonary embolism. Techniques: Fogarty catheter, open surgical extraction. Often combined with thrombolysis.

Embolism

- Traveling clot or debris blocking vessel. Source: DVT (PE), heart (stroke), artery (limb ischemia).

Embolization

- Intentional blocking of blood vessel. Used for hemorrhage control, tumor devascularization, aneurysm treatment.

Endovascular

- Minimally invasive vascular procedure via catheter. Examples: angioplasty, stenting, aneurysm repair.

Endovascular Aneurysm Repair (EVAR)

- Minimally invasive technique for abdominal aortic aneurysm repair using stent graft. Accessed via femoral arteries. Advantages: lower perioperative mortality, faster recovery. Disadvantages: need for surveillance, endoleak risk, may require reintervention.

Endovascular Repair

- See EVAR.

Supervised Exercise Therapy

- A structured walking program for peripheral artery disease that improves claudication distance and functional capacity, commonly prescribed for 30–45 minutes three times weekly.

Fasciotomy

- Surgical incision through the fascia to relieve compartment syndrome. See emergency medicine.

Femoral Artery

- Major artery supplying lower extremity. Common site for peripheral arterial disease, catheterization access, aneurysm. Pulse palpable in femoral triangle. Bruit indicates stenosis.

Fluoroscopy

- Real-time X-ray imaging used to visualize dynamic processes. See radiology.

Follow-up

- Regular surveillance after vascular procedures. Monitor for restenosis, graft patency.

Graft

- Surgical procedure creating detour around blocked vessel using autologous vein (saphenous) or prosthetic graft (PTFE, Dacron). See [bypass graft](#).

Hemangioma

- Benign vascular tumor. Common in infants. Most resolve spontaneously.

Hemodialysis

- Vascular access for hemodialysis. See [dialysis access](#).

Hypercoagulable State

- Condition increasing thrombosis risk. Inherited: Factor V Leiden, prothrombin mutation, protein C/S deficiency, antithrombin deficiency. Acquired: cancer, pregnancy, oral contraceptives, antiphospholipid syndrome, myeloproliferative disorders.

Hyperlipidemia

- See lipid disorders. Statin therapy reduces cardiovascular events in PAD.

Hypertension

- See cardiology. Target BP <130/80 in PAD patients.

Infarction

- Tissue death from prolonged ischemia. Examples: myocardial infarction, cerebral infarction.

Inguinal Hernia

- See [Inguinal Hernia](#).

Interventional Radiology

- Image-guided minimally invasive procedures. See

radiology.

Ischemia

- Reduced blood flow causing oxygen deprivation. Can lead to tissue damage or death.

IVC Filter

- Formation of a blood clot in a deep vein, most commonly in the lower extremities. See [deep vein thrombosis](#).

Kinetics

- See [pharmacology](#).

Laser Ablation

- Laser energy for vessel closure. Endovenous laser ablation for varicose veins.

Ligation

- The surgical process of tying off a blood vessel or duct using a suture or clip to prevent bleeding or block fluid flow.

Lymphedema

- See [geriatrics](#).

Lymphedema Management

- See [geriatrics](#).

Magnetic Resonance Angiography

- See MR angiography.

Marfan Syndrome

- An autosomal dominant connective tissue disorder caused by mutations in the FBN1 gene (fibrillin-1). See genetics.

May-Thurner Syndrome

- Compression of left common iliac vein by right common iliac artery. Causes left lower extremity DVT. Diagnosis: CT/MR venography, phlebography. Treatment: angioplasty and stenting.

Nephrostomy

- An artificial opening created between the kidney and the skin to drain urine directly when the normal pathway is blocked. See [urology](#).

Neuropathic Ulcer

- A chronic wound of the foot in a patient with diabetes, resulting from peripheral neuropathy, peripheral artery disease, and impaired wound healing. See [diabetic foot ulcer](#).

Occlusion

- Complete blockage of vessel. May be natural

(thrombosis) or iatrogenic (embolization).

Open Surgery

- Traditional surgical approach with incision. Used for bypass, aneurysm repair, thrombectomy.

PAD Management

- Atherosclerotic occlusive disease of arteries supplying the lower limbs, causing reduced blood flow. See [peripheral arterial disease](#).

Pain (Vascular)

- Claudication pain with walking. Rest pain indicates critical ischemia.

Patient Education

- Teach about disease, medications, lifestyle modification, warning signs. **Percutaneous Transluminal Angioplasty**

- Balloon dilation of arterial stenosis. Often combined with stenting.

Perfusion

- Blood flow through tissue. Adequate perfusion essential for organ function.

Peripheral Arterial Disease (PAD)

- Atherosclerotic narrowing of arteries supplying limbs. Symptoms: intermittent claudication (pain with walking, relieved by rest), critical limb ischemia (rest pain, ulcers, gangrene). Diagnosis: ABI <0.9, Doppler, angiography. Treatment: risk factor modification, exercise, cilostazol, revascularization for severe disease.

Phlebitis

- The formation of a blood clot (thrombus) within a vein, most commonly in the deep veins of the lower extremities (deep vein thrombosis, DVT). See [venous thrombosis](#).

Phlebography

- Venography using contrast dye. Used for diagnosing venous thrombosis, malformations. Largely replaced by duplex ultrasound.

Plaque

- Atherosclerotic buildup of lipid, cholesterol, calcium, cells. Can rupture causing thrombosis.

Popliteal Aneurysm

- Aneurysm of popliteal artery behind knee. Associated with AAA. Risk: thrombosis, embolism, compression. Treatment: surgical repair or endovas-

cular stenting.

Postoperative Care

- Monitoring after vascular surgery. Watch for bleeding, graft patency, compartment syndrome.

Prognosis

- PAD prognosis depends on disease severity, comorbidities. Cardiovascular risk elevated.

Pulse Examination

- Assessment of arterial pulses. Absent or weak pulses indicate disease.

Radial Artery

- Common access site for coronary angiography. Alternative to femoral artery.

Radiocontrast

- Substance enhancing image visibility. See [contrast agent](#).

Raynaud Phenomenon

- Vasospastic disorder causing digital ischemia. Primary: benign, symmetric. Secondary: associated with connective tissue disease. Triggered by cold, stress. Treatment: warmth, calcium channel blockers, smoking cessation.

Rehabilitation

- See rehabilitation medicine. Post-amputation or post-revascularization.

Risk Factor Modification

- Smoking cessation, blood pressure control, lipid management, diabetes control, exercise.

Saphenous Vein

- Surgical procedure creating detour around blocked vessel using autologous vein (saphenous) or prosthetic graft (PTFE, Dacron). See [bypass graft](#).

Segmental Pressures

- Blood pressure measurements at different leg levels. Localizes level of obstruction.

Smoking Cessation

- Critical for PAD patients. Increases amputation risk if continued.

Steal Syndrome

- Ischemia of distal extremity due to blood flow diversion to bypass graft or AV fistula. Most common: upper extremity after AV fistula creation. Symptoms: hand pain, pallor, numbness, weakness.

Treatment: banding, ligation, revision.

Stenosis

- Narrowing of vessel lumen. Causes: atherosclerosis, thrombosis, dissection, external compression. Symptoms depend on location and severity. Treatment: medical, angioplasty, stenting, bypass.

Stent

- Tubular scaffold maintaining vessel/duct patency. See medical implants.

Stenting

- Placement of mesh tube to keep vessel open. Drug-eluting stents reduce restenosis.

Takayasu Arteritis

- Large-vessel vasculitis affecting aorta and major branches. Predominantly young Asian women. Symptoms: pulselessness, blood pressure discrepancy, claudication, visual symptoms. Treatment: corticosteroids, immunosuppressants, surgical/endovascular intervention for stenosis.

Thoracic Aortic Aneurysm

- Aneurysm of thoracic aorta. Associated with hypertension, Marfan syndrome, bicuspid aortic valve.

Thrombectomy

- Surgical removal of thrombus. Techniques: open thrombectomy, catheter-directed thrombolysis, mechanical thrombectomy. Indications: acute arterial occlusion, DVT with phlegmasia.

Thromboangiitis Obliterans (Buerger Disease)

- Segmental inflammatory disease of small/medium arteries and veins, strongly associated with smoking. Affects upper and lower extremities. Symptoms: ischemic rest pain, Raynaud, superficial thrombophlebitis, ulceration, gangrene. Treatment: complete smoking cessation (only effective intervention), sympathectomy, amputation for gangrene.

Thrombolysis

- Pharmacological dissolution of thrombus. tPA, streptokinase, alteplase. Used for acute arterial occlusion, PE, stroke.

Thrombosis

- Formation of blood clot within vessel. Can obstruct flow. Arterial or venous.

Toe Pressure

- Pressure in toe digits. Useful when ankle pressures non-compressible (diabetes, renal disease).

Trauma (Vascular)

- See vascular trauma.

Ulcer (Vascular)

- See arterial ulcer, venous ulcer, diabetic foot ulcer.

Ultrasound

- Imaging using high-frequency sound waves (2-18 MHz). See radiology.

Varicose Ulcer

- Impaired venous return from the lower extremities due to venous valve incompetence or obstruction. See [chronic venous insufficiency](#).

Varicose Veins

- Dilated, tortuous superficial veins, usually lower extremity. Caused by venous valve incompetence. Symptoms: aching, heaviness, swelling, cosmetic concern. Complications: thrombophlebitis, bleeding, ulceration. Treatment: compression stockings, sclerotherapy, endovenous ablation, surgical stripping.

Vascular Imaging

- Techniques for visualizing blood vessels: duplex ultrasound, CT angiography, MR angiography, conventional angiography.

Vascular Malformation

- Abnormal blood vessel development. Arteriovenous malformation, venous malformation, lymphatic malformation.

Vasculitis

- Inflammation of blood vessels causing tissue ischemia and necrosis. See rheumatology.

Vein

- Blood vessel carrying blood to heart. Thinner walls, valves prevent backflow. Varicose veins common.

Venous Insufficiency

- Impaired venous return from the lower extremities due to venous valve incompetence or obstruction. See [chronic venous insufficiency](#).

Venule

- Small vein draining capillaries. Collects blood from tissues.

Wound Care

- Management of traumatic wounds: irrigation, debridement, closure (sutures, staples, glue), dressing. See emergency medicine.

X-ray

- See radiology.

Chronic Limb-Threatening Ischemia (CLTI)

- The most severe clinical form of peripheral arterial disease, characterized by chronic ischemic rest pain, nonhealing ulceration, or gangrene attributable to arterial insufficiency. It carries high risks of limb loss and cardiovascular mortality and requires vascular evaluation for revascularization and wound management.

Acute Limb Ischemia Six Ps

- The classic findings of acute arterial perfusion loss: pain, pallor, pulselessness, paresthesia, paralysis, and poikilothermia. Motor or sensory deficit indicates threatened limb and requires urgent vascular assessment and revascularization planning.

Toe-Brachial Index (TBI)

- The ratio of systolic toe pressure to brachial systolic pressure. It can support diagnosis of peripheral arterial disease when ankle arteries are noncompressible because of medial arterial calcification.

Pseudoaneurysm

- A contained arterial wall disruption in which blood communicates with the arterial lumen but is held by surrounding tissue rather than all layers of the arterial wall. It may follow catheterization, trauma, surgery, infection, or grafting and can rupture or embolize.

Aortic Aneurysm Rupture

- Full-thickness failure of an aortic aneurysm with bleeding into a body cavity or surrounding tissue. Ruptured aneurysm commonly causes sudden pain, shock, and collapse and requires immediate resuscitation and operative or endovascular repair.

Endoleak

- Persistent blood flow into an aneurysm sac after endovascular aneurysm repair. Type I and III endoleaks reflect inadequate sealing or device failure and generally require urgent correction; other types are managed according to sac expansion and risk.

Aortic Graft Infection

- Infection involving a prosthetic or endovascular aortic graft, potentially causing sepsis, pseudoaneurysm, hemorrhage, or aortoenteric fistula. Management usually requires prolonged antimicrobial treatment and individualized surgical or endovascular source control.

Carotid Artery Stenting

- Endovascular placement of a stent across a carotid stenosis, usually with embolic-protection strategies, to improve cerebral blood flow and reduce stroke risk in selected patients. Antiplatelet therapy and peri-procedural neurologic monitoring are required.

Intermittent Claudication

- Reproducible muscle discomfort, usually in the calf, thigh, or buttock, induced by walking and relieved by rest, caused by exertional arterial insufficiency. It is distinguished from rest pain and nonvascular musculoskeletal pain by history and vascular testing.

Chronic Venous Disease

- A spectrum of venous outflow disorders caused by reflux, obstruction, or calf-muscle-pump dysfunction. Findings range from edema and varicose veins to skin changes, lipodermatosclerosis, and venous ulceration.

Deep Venous Reflux

- Retrograde flow through incompetent venous valves in the deep venous system. It contributes to chronic venous hypertension, edema, skin changes, and venous ulcer formation.

Post-Thrombotic Syndrome

- Chronic pain, heaviness, edema, skin change, and sometimes ulceration developing after deep-vein thrombosis because of persistent venous obstruction and valvular damage. Compression, exercise, skin care, and selected interventions may reduce disability.

Vascular Graft Patency

- Continued openness and functional blood flow through a vascular graft or bypass. Patency is monitored clinically and with duplex or other imaging because thrombosis, stenosis, infection, intimal hyperplasia, and anastomotic problems can cause failure.

Intimal Hyperplasia

- Proliferation and migration of vascular smooth-muscle cells with extracellular-matrix deposition within the intima after vascular injury or graft placement. It can produce restenosis at anastomoses, stents, dialysis access, or bypass grafts.

Vascular Trauma

- Injury to an artery or vein from blunt, penetrating, iatrogenic, or crush mechanisms. Assessment prioritizes hemorrhage control, distal perfusion, ischemia, expanding hematoma, bruit, thrill, and associated nerve or bone injury.

Duplex Surveillance

- Scheduled clinical and ultrasound monitoring of an artery, vein, graft, stent, aneurysm, or dialysis access to detect restenosis, thrombosis, endoleak, or other failure before symptoms or limb threat develop.

Vascular Diagnostic Yield

- The proportion of vascular diagnostic procedures or tests that provide a clinically useful result.

Leriche Syndrome

- Aortoiliac occlusive disease causing reduced blood flow to the pelvis and lower limbs. The classic presentation includes buttock or thigh claudication, diminished femoral pulses, and erectile dysfunction, although symptoms vary with the extent of collateral circulation.

Milroy Disease

- An inherited primary lymphedema caused most often by pathogenic variants affecting VEGFR3 signaling. It typically presents with chronic swelling of the lower limbs from birth or early infancy and may be associated with papillomatosis, hydrocele, or recurrent skin infection.

Vascular Ring

- A congenital abnormality of the aortic arch or its branches that encircles and may compress the trachea, esophagus, or both. Symptoms include stridor, wheezing, recurrent respiratory infection, dysphagia, feeding difficulty, or respiratory distress.

Blood Clot

- A mass of coagulated blood within a blood vessel or body cavity. A clot may be protective when it stops bleeding, but an abnormal thrombus can obstruct

blood flow or embolize to the lungs, brain, heart, or other organs.

Carotid Artery Disease

- Narrowing or blockage of the carotid arteries, most often caused by atherosclerotic plaque. It can reduce cerebral blood flow or release emboli and is an important cause of transient ischemic attack and ischemic stroke.

Chapter 43

General Medical Terms

Armpit Lump

- A lump or swelling in the axilla, commonly caused by an enlarged lymph node, skin infection, cyst, or benign growth. Persistent, hard, fixed, enlarging, or unexplained lumps require medical assessment.

Abdomen

- The body region between the thorax and pelvis, containing the digestive organs, liver, gallbladder, pancreas, spleen, kidneys, and major blood vessels. Divided into nine regions (right/left hypochondriac, epigastric, umbilical, right/left lumbar, right/left inguinal) or four quadrants (RUQ, LUQ, RLQ, LLQ) for clinical description.

Abdominal Rigidity

- Involuntary tensing of the abdominal wall, usually caused by irritation or inflammation of the parietal peritoneum. It is a characteristic sign of peritonitis and may accompany perforation, severe infection, or intra-abdominal hemorrhage.

Abscess

- See emergency__medicine.

Acute

- Sudden onset, short duration. Examples: appendicitis, pneumonia.

Adherence

- Extent to which patient follows treatment recommendations. Affected by factors: regimen complexity, side effects, beliefs, socioeconomic.

Adverse Event

- Unintended harm from medical care. Includes medical errors and complications.

Patient Advocacy

- Acting on behalf of a patient to ensure that the patient's needs, rights, and preferences are addressed

in healthcare.

Airborne Disease

- Disease transmitted by airborne particles. Examples: tuberculosis, measles, COVID-19.

Anatomy

- Study of body structure. Regions: head, neck, thorax, abdomen, pelvis, extremities. Systems: skeletal, muscular, nervous, circulatory, respiratory, digestive, urinary, reproductive, endocrine, immune.

Antibiotic Stewardship

- Program to optimize antibiotic use. Improves outcomes, reduces resistance.

Antimicrobial Resistance

- Microorganisms becoming resistant to antibiotics. Major global health threat. Prevention: appropriate antibiotic use, infection control.

Auscultation

- The act of listening to sounds produced within the body, typically using a stethoscope. Essential for assessing heart sounds, lung sounds, bowel sounds, and vascular bruits. Normal findings: S1 and S2 heart sounds, vesicular breath sounds, normal bowel sounds. Abnormal: murmurs, crackles, wheezes, rubs, bruits.

Auscultatory Gap

- A transient silence between the first and second sounds of blood pressure measurement, sometimes heard in hypertensive patients. Can lead to underestimation of systolic pressure if not recognized.

Barium Swallow

- Radiographic examination of the esophagus using barium sulfate contrast. Evaluates swallowing function, motility, strictures, masses. Modified barium swallow assesses aspiration risk.

Health Behavior Change

- Modification of behaviors that affect health, such as tobacco use, diet, physical activity, and adherence to treatment.

Clinical Research Bias

- Systematic error in clinical study design or analysis, including selection bias, information bias, and confounding.

Biomarker

- Measurable indicator of disease.

Biomonitoring

- Measurement of substances in body. Examples: blood glucose, drug levels, toxicants.

Biopsy

- Removal of tissue for histological examination to diagnose disease. Types: needle biopsy (fine needle aspiration, core needle), excisional, incisional, punch, endoscopic. Sites: breast, lung, liver, lymph node, bone marrow. Complications: bleeding, infection, seeding (rare).

Blinding

- Concealing treatment assignment in trials. Single-blind (patient), double-blind (patient and investigator).

Blood Pressure

- Force of blood against vessel wall. Measured in mmHg. Systolic/diastolic. Normal: <120/80.

Blood-Borne Disease

- Disease transmitted via blood. Examples: HIV, hepatitis B, hepatitis C.

Capillary Refill Time

- Time for color to return to blanched nail bed or skin after pressure. Normal: <2 seconds. Prolonged in shock, dehydration, peripheral vasoconstriction.

Case Fatality Rate

- Proportion of cases dying from disease. Measures severity.

Case-Control Study

- Observational study comparing cases with disease to controls without. Looks back at exposures.

Chronic

- Long-lasting, persistent. Examples: diabetes, hypertension.

Clinical Presentation

- Signs and symptoms of disease. Varies by disease, severity, patient factors.

Clinical Trial

- Research study testing new cancer treatments. See oncology.

Cohort Study

- Observational study following group over time. Can be prospective or retrospective.

Communicable Disease

- Disease transmissible between persons. Examples: influenza, TB, HIV.

Clinical Communication

- Exchange of information between healthcare professionals, patients, and caregivers to support diagnosis, treatment, safety, and informed decisions.

Community-Acquired

- Obtained outside hospital. Examples: community-acquired pneumonia.

Comorbidity

- Presence of one or more additional conditions co-occurring with a primary disease. Common in chronic illnesses (diabetes with hypertension, COPD with heart failure). Affects treatment decisions, prognosis, and healthcare utilization.

Compliance

- Following medical advice. Preferred term: adherence.

Complication

- Unexpected problem during disease or treatment. Examples: surgical complication, drug complication.

Concomitant

- Occurring simultaneously. Concomitant medication: additional drug taken with primary treatment.

Medical Condition

- A state affecting health or bodily function, whether acute, chronic, symptomatic, or asymptomatic.

Confirmatory Test

- Test following positive screening to confirm diagnosis.

Confounding

- Distortion of association by third variable. Con-

trolled by randomization, matching, statistical adjustment.

Contact Tracing

- Identifying and monitoring contacts of infected person. Important for outbreak control.

Contraindication

- A condition or factor that renders a particular procedure, treatment, or medication inadvisable. Absolute contraindication: condition where intervention should never be performed. Relative contraindication: risks outweigh benefits but may be acceptable in specific circumstances. Examples: pregnancy (absolute for isotretinoin), severe renal impairment (relative for contrast CT).

Control Group

- Group not receiving experimental intervention. Used for comparison.

Cost-Effectiveness

- Comparison of costs and outcomes of interventions. Used for resource allocation.

Costochondritis

- Inflammation of the costochondral or costosternal junctions, the most common cause of chest wall pain. Presents with sharp, reproducible tenderness on palpation of the anterior chest, usually unilateral involving the 2nd to 5th ribs. May follow respiratory infection, trauma, or vigorous coughing, but often idiopathic. Affects 13-16 percent of chest pain presentations to emergency departments. Important differential diagnosis for cardiac chest pain. Diagnosis: clinical (reproducible tenderness, normal cardiac workup). Self-limited (weeks to months). Treatment: NSAIDs, local heat, reassurance, and activity modification. Recurrent cases may require intercostal nerve block or topical lidocaine.

Clinical Counseling

- Guidance provided in healthcare to help patients make informed decisions about health, prevention, treatment, and self-management.

Cross-Sectional Study

- Observational study measuring prevalence at single time point.

DALY

- Disability-adjusted life year. Measure of disease burden.

Diagnosis

- Identification of disease. Based on history, examination, tests. Differential diagnosis considers multiple possibilities.

Diagnostic Test

- Procedure to identify disease. Examples: laboratory tests, imaging, biopsies.

Differential Diagnosis

- The process of distinguishing a particular disease or condition from others that present with similar symptoms. Systematic approach: consider life-threatening conditions first, use pretest probability, apply diagnostic criteria, and order targeted tests.

Disease

- Abnormal condition affecting body. Can be infectious, degenerative, neoplastic, etc.

Disorder

- Functional abnormality. Less severe than disease. Examples: sleep disorder, eating disorder.

Diuresis

- Increased urine production. Can be physiological (fluid overload) or pharmacological (diuretics). Osmotic diuresis (hyperglycemia), water diuresis (DI), saline diuresis (hypertonic saline).

Clinical Documentation

- Recording of patient history, examination, assessment, treatment, and follow-up in the medical record.

Echo

- Ultrasound imaging of the heart, the primary modality for assessing cardiac structure and function. See [echocardiography](#).

Edema

- Swelling caused by excess fluid trapped in body tissues. Types: pitting (press leaves indentation), non-pitting (myxedema, lymphedema). Causes: heart failure, kidney disease, liver cirrhosis, venous insufficiency, lymphatic obstruction, medications (calcium channel blockers, NSAIDs). Assessment: degree, distribution, symmetry, associated symptoms.

Endoscopy

- Visual examination of internal organs using scope. Examples: colonoscopy, gastroscopy, bronchoscopy.

Epidemiology

- Study of disease distribution and determinants in populations. Measures: incidence, prevalence, mortality, morbidity.

Medical Ethics

- Moral principles guiding healthcare practice, including autonomy, beneficence, non-maleficence, and justice.

Etiology

- Cause or origin of disease. Examples: genetic, infectious, environmental, idiopathic.

Evidence-Based Medicine

- Practice informed by best available evidence. Combines clinical expertise, patient values, research evidence.

Examination

- Systematic assessment of a patient's health status. Components: inspection, palpation, percussion, auscultation (IPPA). General survey: appearance, posture, gait, vital signs. Focused examination based on chief complaint.

Fever

- Elevated body temperature ($>38^{\circ}\text{C}$ or 100.4°F). Workup depends on duration, height, and patient factors. Common causes: infections (bacterial, viral), autoimmune disorders, malignancies, drug reactions. Management: antipyretics (acetaminophen, ibuprofen), treat underlying cause. Febrile seizures: generally benign, prevent recurrence with fever control.

Fistula

- See [Fistula \(Pathology\)](#).

Food-Borne Disease

- Disease from contaminated food. Examples: salmonella, E. coli, listeria. **Gait**
- Pattern of walking. Normal gait involves coordinated movement of legs, arms, trunk. Abnormal gait patterns: antalgic (pain), hemiplegic (stroke), parkinsonian (shuffling), ataxic (cerebellar), step-page (foot drop).

Genetic Testing

- Analysis of DNA for disease risk or diagnosis. Examples: BRCA testing, carrier screening.

Clinical Guideline

- An evidence-based recommendation intended to guide clinical practice, diagnosis, prevention, or treatment.

Hand Hygiene

- Cleaning hands to prevent infection transmission. Most important precaution.

Health Disparity

- Difference in health outcomes between populations. Due to social, economic, environmental factors.

Health Literacy

- Ability to obtain, process, understand health information. Affects health outcomes.

Healthy Years Lost

- Years of life lost due to premature death or disability. DALYs combine YLL and YLD.

Hemostasis

- The process of stopping bleeding. Primary: platelet plug formation. Secondary: coagulation cascade. Tertiary: vasoconstriction and fibrinolysis regulation.

Herd Immunity

- Population-level protection when sufficient individuals immune. Reduces disease spread.

Homeostasis

- The maintenance of stable internal conditions despite external changes. Key regulated variables: temperature, pH, glucose, electrolytes, blood pressure, fluid balance. Mechanisms: negative feedback loops (most common), positive feedback (rare, e.g., labor, blood clotting). Organs involved: hypothalamus, kidneys, lungs, liver, endocrine glands.

Hospital-Acquired Infection

- Infection acquired during hospitalization. Also: healthcare-associated infection (HAI). Examples: CLABSI, CAUTI, surgical site infection.

Iatrogenic

- An illness or condition caused by medical examination or treatment. Examples: hospital-acquired infections, drug side effects, surgical complications, radiation-induced damage. Prevention: proper technique, informed consent, monitoring, reporting systems.

Idiopathic

- Of unknown cause. Examples: idiopathic pulmonary fibrosis, idiopathic thrombocytopenia.

Medical Illness

- The subjective experience of being unwell, which may or may not correspond to an identifiable disease.

Imaging

- See radiology.

Immunization

- Administration of a vaccine to stimulate immune response and provide protection against infectious disease. See [vaccination](#).

Incidence

- Number of new cases of a disease in a population during a specified time period. Measures risk of developing disease. Incidence rate = new cases / population at risk x time unit.

Infection

- See [infectious_disease](#).

Infection Control

- Measures to prevent healthcare-associated infections: hand hygiene, personal protective equipment (PPE), isolation precautions (contact, droplet, airborne), sterilization, disinfection.

Infectious Disease

- Disease caused by pathogen. Examples: bacterial, viral, fungal, parasitic.

Inflammation

- The body's protective response to injury or infection. Cardinal signs: redness (rubor), heat (calor), swelling (tumor), pain (dolor), loss of function (functio laesa). Mediators: histamine, prostaglandins, cytokines, complement. Acute: neutrophil-predominant. Chronic: lymphocyte/macrophage-predominant.

Informed Consent

- The process by which a patient voluntarily confirms understanding of a proposed treatment or procedure, including risks, benefits, alternatives, and consequences of non-treatment. Elements: disclosure, comprehension, voluntariness, competence, consent. Documented on consent form. Exceptions: emergencies, waived consent (minimal risk research),

therapeutic privilege.

Inspection

- Visual examination of the patient. Part of physical assessment. Observes symmetry, color, lesions, movement, posture.

Isolation

- Separation of sick individuals with contagious disease.

Isolation Precautions

- Measures to prevent spread of infection. Contact, droplet, airborne precautions.

Medical Jargon

- Specialized terminology used by healthcare professionals. Unexplained medical jargon can hinder communication with patients.

Joint Effusion

- Excess fluid within a joint space. Common sites: knee (most accessible), ankle, wrist, shoulder. Causes: trauma, infection, inflammatory arthritis, crystal arthropathy. Detected by ballottement or bulge sign.

Kernig Sign

- Sign of meningeal irritation. Patient supine, hip and knee flexed 90 degrees; inability to extend knee indicates positive sign. Seen in meningitis, subarachnoid hemorrhage.

Kussmaul Respirations

- Deep, labored breathing pattern associated with diabetic ketoacidosis. Compensatory hyperventilation to blow off CO₂ and correct metabolic acidosis. Name: Adolf Kussmaul, German physician.

Laboratory Test

- Analysis of body fluids or tissues. Includes hematology, chemistry, microbiology, immunology.

Lateral

- Positioned away from the midline of the body. Opposite of medial. Example: the thumb is lateral to the little finger in anatomical position.

Leukocytosis

- Elevated white blood cell count (>11,000/ μ L). Causes: infection, inflammation, stress, medications (corticosteroids), malignancy (leukemia). Neutrophilia, lymphocytosis, eosinophilia, monocytosis have different implications.

Life Expectancy

- Average years remaining for person at given age. Varies by country, sex, socioeconomic status.

Likelihood Ratio

- Probability of test result in disease vs. non-disease. LR+ >1 increases probability; LR- <1 decreases.

Malpractice

- Professional negligence by healthcare provider. Requires duty, breach, causation, damages.

Medication Error

- See [toxicology](#).

Meta-Analysis

- Statistical combination of multiple studies. Increases power.

Monitoring Test

- Test to track disease progression or treatment response.

Morbidity

- Disease or illness in population. Morbidity rate: new cases per population per time.

Mortality

- Death from disease. Mortality rate: deaths per population per time.

Murmur

- Heart sound caused by turbulent blood flow. Grades I-VI. Systolic murmurs more common; diastolic murmurs always pathological. Evaluation: timing, location, radiation, intensity, quality, position changes.

Nadir

- The lowest point, particularly referring to the lowest white blood cell count after chemotherapy. Bone marrow suppression typically reaches nadir 7-14 days post-treatment. Important for infection risk assessment.

Negative Predictive Value

- Probability disease absent given negative test. Affected by prevalence.

Nocebo

- Negative placebo effect. Adverse events from negative expectations.

Nodule

- Small, palpable mass <2 cm. Can be solid or cystic.

Examples: thyroid nodule, rheumatoid nodule, pulmonary nodule. Evaluation depends on location.

Non-Adherence

- Failure to follow treatment. Major cause of treatment failure.

Non-Communicable Disease

- Disease not transmitted between persons. Examples: cancer, heart disease, diabetes.

Nosocomial

- Hospital-acquired. Nosocomial infection: infection acquired in hospital.

Oliguria

- Decreased urine output (<400 mL/day in adults). Causes: prerenal (dehydration, heart failure), renal (acute kidney injury), postrenal (obstruction). Medical emergency if anuric.

Opportunistic Infection

- Infection in immunocompromised host. Examples: PCP, toxoplasmosis, candidiasis.

Oropharynx

- The posterior portion of the mouth leading to the esophagus, containing the tonsils and base of tongue. Area for swallowing and speech. Examination with tongue depressor and light source. Pathology: pharyngitis, tonsillitis, malignancy.

Outbreak

- Sudden increase in disease cases. Requires investigation and control measures.

Oxygen Saturation

- Percentage of hemoglobin bound with oxygen. Normal: 95-100

Pain

- Unpleasant sensory and emotional experience. Fifth vital sign. Assessment: location, intensity, character, timing.

Palpation

- Examination by touch to detect abnormalities in size, shape, consistency, and tenderness of organs or tissues. Uses fingers, palm, or heel of hand. Light vs. deep palpation. Bimanual palpation uses two hands.

Pandemic

- Worldwide epidemic. Examples: COVID-19, in-

fluenza pandemics.

Pathogenesis

- Mechanism of disease development. Steps: initiation, promotion, progression.

Pathology

- Study of disease. Includes general pathology (cell injury, inflammation, neoplasia) and systemic pathology (organ-specific diseases).

Patient

- Person receiving medical care. Also: patient zero (initial case), patient safety.

Patient Education

- Teaching patients about health conditions and self-management. Improves adherence, outcomes.

Patient Safety

- Prevention of harm during care. Goals: reduce errors, improve systems, promote culture of safety.

Percussion

- Tapping body surface to assess underlying structures. Sounds: dull (solid organ, fluid), resonant (lung), tympanic (gas-filled). Used to assess organ size, presence of fluid, air.

Personal Protective Equipment

- PPE: gloves, gowns, masks, eye protection. Used based on transmission-based precautions.

Pharmacogenomics

- Study of genetic variation affecting drug response. Personalizes medication selection.

Physiology

- Study of body function. Systems physiology: cardiovascular, respiratory, renal, gastrointestinal, endocrine, nervous, muscular, reproductive.

Placebo

- Inactive substance used as control in trials. Placebo effect: improvement from expectation.

Positive Predictive Value

- Probability disease present given positive test. Affected by prevalence.

Predictive Test

- Test predicting response to treatment.

Prevalence

- Proportion of population with disease at specific time. Measures disease burden.

Prevention

- Measures to prevent disease. Primary (before disease), secondary (early detection), tertiary (complication prevention).

Medical Privacy

- Protection of identifiable patient information and control of its disclosure in healthcare.

Prognosis

- Predicted disease outcome. Depends on disease, treatment, patient factors.

Prognostic Test

- Test predicting disease outcome.

Protective Factor

- Attribute decreasing disease probability. Examples: vaccination, exercise, healthy diet.

Healthcare Provider

- A healthcare professional or organization that provides medical care, such as a physician, nurse, therapist, or clinic.

Paneth Cell

- Specialized secretory epithelial cell at the base of a small-intestinal crypt that produces antimicrobial substances.

Parathyroid

- One of the small endocrine glands behind the thyroid that secretes parathyroid hormone and regulates calcium and phosphate balance.

Photocoagulation

- Coagulation of tissue by intense light, often laser light, to treat lesions such as abnormal retinal vessels.

Photopheresis

- Extracorporeal treatment in which white blood cells are exposed to a photosensitizer and ultraviolet A light before being returned to the patient.

Physiological Dead Space

- Volume of ventilated respiratory tract that does not participate in gas exchange, including anatomic and alveolar dead space.

Pleurodynia

- Acute, severe chest pain caused by inflammation or spasm of the intercostal muscles, often associated with viral infection.

Polydactylysm

- Congenital presence of extra fingers or toes.

Powassan Encephalitis

- Encephalitis caused by Powassan virus, a tick-borne flavivirus.

Pseudobulbar Affect

- Involuntary episodes of laughing or crying disproportionate to mood, usually due to neurologic disease.

Puberty

- Developmental period during which sexual maturation and reproductive capability are attained.

Pulposus

- Relating to the nucleus pulposus, the gelatinous central portion of an intervertebral disk.

Pyelotomy

- An incision into the renal pelvis, usually made to remove an obstruction or kidney stone.

Public Health

- The science and practice of protecting and improving the health of communities through education, policy-making, and research for disease and injury prevention.

Pulse

- Rhythmic expansion of artery with each heartbeat. Normal: 60-100 bpm. Rate, rhythm, amplitude assessed.

QALY

- Quality-adjusted life year. Measure of health outcome incorporating quality of life.

Quadrant

- One of four sections of the abdomen (RUQ, LUQ, RLQ, LLQ) used for clinical description. RUQ: liver, gallbladder, duodenum, right kidney. LUQ: stomach, spleen, left kidney, pancreas tail. RLQ: appendix, cecum, right ovary. LLQ: sigmoid colon, left ovary.

Quality Improvement

- Systematic efforts to enhance care. Methods: PDSA cycles, root cause analysis, peer review.

Quarantine

- Separation of exposed individuals to prevent disease spread. For symptomatic incubation period.

Q Wave

- The negative deflection that follows the P wave in some electrocardiographic leads, representing initial ventricular depolarization.

Rhinencephalon

- The part of the brain concerned chiefly with the sense of smell and related limbic functions.

Rouleau

- A stack or column of red blood cells, commonly seen in blood with increased plasma proteins.

Radiosensitization

- Increased susceptibility of cells or tissues to injury from ionizing radiation.

Sensorium

- The state or level of consciousness and awareness of one's surroundings.

Serodiagnostic

- Relating to diagnosis by detecting antibodies or other markers in blood serum.

Sinus Rhomboidalis

- A diamond-shaped depression in the floor of the fourth ventricle of the brain.

Spermatogonium

- A germ cell in the testis that divides and develops into primary spermatocytes.

Spermatorrhea

- Involuntary discharge of semen, especially without orgasm.

Spirochaete

- A slender, spiral-shaped bacterium of the group Spirochaetes.

Subarachnoid

- Situated beneath the arachnoid membrane surrounding the brain and spinal cord.

Subscapular Artery

- An artery arising from the axillary artery that supplies the scapular region and adjacent muscles.

Sulfatide

- A sulfated glycolipid found particularly in myelin and nervous tissue.

Suprascapular Nerve

- A branch of the brachial plexus that supplies the supraspinatus and infraspinatus muscles.

Torticollis

- A condition in which the head is held tilted to one side because of neck-muscle spasm or contracture.

Tractotomy

- Surgical interruption of a nerve tract in the brain or spinal cord.

Transferase

- An enzyme that transfers a functional group from one molecule to another.

Transplacental

- Passing through or occurring across the placenta.

Trophoderm

- The outer cellular layer of a blastocyst that contributes to formation of the placenta.

Quiescent

- Inactive or dormant state of disease. Example: quiescent ulcerative colitis (no symptoms but histologic inflammation may persist).

Umbilication

- Formation of a central depression or navel-like indentation in a lesion or structure.

Urothelium

- The specialized transitional epithelium lining the renal pelvis, ureters, bladder, and part of the urethra.

Vasoconstriction

- Narrowing of a blood vessel caused by contraction of its muscular wall.

Ventriculoatrial

- Relating to or connecting a ventricle of the brain or heart with an atrium; often describing a cerebrospinal-fluid shunt to the right atrium.

Wrisberg Ganglion

- A sensory ganglion associated with the intermediate nerve of the facial nerve.

Myalgic**Encephalomyelitis/Chronic Fatigue Syndrome**

- A chronic, disabling illness characterized by substantial reduction in function, post-exertional malaise, and unrefreshing sleep, often with cognitive impairment or orthostatic intolerance.

Zooglea

- A gelatinous mass of bacteria embedded in a polysaccharide matrix.

Zymogen

- An inactive enzyme precursor that is converted into an active enzyme, often by cleavage.

Randomization

- Random assignment to treatment groups. Reduces bias.

Randomized Controlled Trial

- RCT: experimental study randomly assigning intervention. Gold standard for evidence.

Receiver Operating Characteristic

- ROC curve: plot of sensitivity vs. 1-specificity. Area under curve measures test accuracy.

Recurrent

- Disease returning after remission. Examples: recurrent UTI, herpes.

Referred Pain

- Pain perceived at location other than site of pathology. Examples: myocardial infarction (left arm/jaw), gallbladder (right shoulder), diaphragmatic irritation (shoulder).

Relapse

- Return of cancer after treatment. See [recurrence](#).

Reliability

- Consistency of measurement. Test-retest, inter-rater reliability.

Remission

- Decrease or disappearance of cancer signs. See oncology.

Disease Reporting

- Mandatory notification of specified diseases or health events to public-health authorities.

Resolution

- Complete healing or disappearance of disease.

Respiratory Rate

- Number of breaths per minute. Normal: 12-20. Assessment of rate, rhythm, depth.

Risk Assessment

- Evaluation of likelihood and impact of health risks. Used for screening, prevention planning.

Risk Factor

- Attribute increasing disease probability. Examples: smoking, hypertension, obesity.

Rx

- Prescription or treatment. Symbol derives from Latin "requirere" (to take). Also used as abbreviation for remedy. Rx symbol: Rx or &x;

Screening

- Testing asymptomatic individuals for disease. Criteria: disease should be important, detectable, treatable. Examples: mammography, colonoscopy, blood pressure measurement.

Screening Test

- Test for asymptomatic disease. Should be safe, acceptable, accurate.

Sensitivity

- Proportion of true positives correctly identified by a test. High sensitivity: few false negatives. Useful for screening. Formula: true positives / (true positives + false negatives).

Sentinel Event

- Unexpected occurrence involving death or serious physical/psychological injury. Requires root cause analysis.

Sequelae

- Conditions resulting from previous disease. Examples: post-polio syndrome, stroke sequelae.

Sexually Transmitted Infection

- STI: infection transmitted via sexual contact. Examples: syphilis, gonorrhea, chlamydia, HIV.

Sign

- Objective evidence of disease. Examples: rash, murmur, edema. Observed by examiner.

Specificity

- Proportion of true negatives correctly identified. High specificity: few false positives. Useful for confirmation.

Standard of Care

- Accepted medical practice for particular circumstances. Legal and professional benchmark.

Subacute

- Between acute and chronic. Examples: subacute thyroiditis.

Surveillance

- Ongoing collection, analysis, interpretation of health data. Used for public health action.

Survival Rate

- Percentage of patients surviving for specified time after diagnosis. See oncology.

Symptom

- Subjective experience of disease. Examples: pain, fatigue, nausea. Reported by patient.

Syndrome

- Group of symptoms and signs occurring together. Examples: metabolic syndrome, irritable bowel syndrome.

Systematic Review

- Comprehensive literature review following protocol. GRADE system for evidence quality.

Tachypnea

- Rapid breathing (>20 breaths/min in adults). Causes: fever, pain, anxiety, pulmonary disease, metabolic acidosis. Assessment of rate, depth, pattern essential.

Temperature

- Measure of body heat. Normal: 36.5-37.5°C. Sites: oral, rectal, axillary, temporal.

Tincture

- Alcohol extract of plant or chemical substance. Common concentration: 10-40

Treatment

- Medical intervention for disease. Includes pharmacological, surgical, lifestyle, supportive.

Ulnar

- Relating to the ulna bone of the forearm or the ulnar side (medial side) of the hand. Ulnar nerve compression causes paresthesia in medial one and a half fingers.

Urination

- The biological process of releasing urine from the bladder through the urethra out of the body; also known as micturition.

Vaccination

- Administration of a vaccine to stimulate immune response and provide protection against infectious disease. Types: live attenuated, inactivated, subunit,

mRNA, viral vector. Schedule varies by country. Herd immunity achieved when sufficient proportion immune.

Validity

- Accuracy of measurement. Internal validity: study correctness. External validity: generalizability.

Vector-Borne Disease

- Disease transmitted by vector (insect, tick). Examples: malaria, dengue, Lyme disease.

Vital Signs

- Key physiological measurements: temperature, pulse, respiration rate, blood pressure, oxygen saturation, pain. Normal ranges: T 36.5-37.5°C, HR 60-100, RR 12-20, BP <120/80, SpO2 >95

Water-Borne Disease

- Disease transmitted via contaminated water. Examples: cholera, typhoid, hepatitis A.

Wedge resection

- Surgical removal of a wedge-shaped piece of tissue, typically lung or breast. Used for diagnosis or treatment of localized lesions. Less extensive than lobectomy.

Wheal

- Raised, itchy swelling of skin (urticaria/hives). Caused by mast cell degranulation and histamine release. Examples: insect bite, allergic reaction, dermatographism.

X-ray

- See radiography.

Xerosis

- Abnormal dryness of skin or mucous membranes. Causes: aging, environmental factors, medications, systemic disease (hypothyroidism, diabetes), nutritional deficiencies. Treatment: emollients, humidification, treat underlying cause.

Zollinger-Ellison Syndrome

- Gastrin-secreting tumor called gastrinoma causing gastric acid hypersecretion, severe peptic ulcers, and diarrhea. See [gastroenterology](#).

Zoonosis

- Disease transmitted from animals to humans. Examples: rabies, Lyme disease, avian influenza.

Red Flag

- A symptom, sign, or test result suggesting a potentially serious condition that requires urgent assessment or escalation of care. Red flags are context-specific and should not be used as a substitute for clinical judgment.

Clinical Reasoning

- The cognitive process of collecting, weighting, and integrating clinical information to formulate diagnostic and management decisions. It includes problem representation, differential diagnosis, probability assessment, and recognition of cognitive bias.

Triage

- The rapid sorting of patients according to urgency, clinical risk, and expected resource needs so that those requiring immediate intervention are prioritized. Triage is dynamic and must be repeated when a patient's condition changes.

Multimorbidity

- The coexistence of two or more chronic health conditions in the same person, without requiring one to be considered the primary disease. It complicates treatment, increases polypharmacy risk, and requires coordinated patient-centered care.

Frailty

- A state of increased vulnerability to physiologic stress caused by reduced multisystem reserve. It is associated with weakness, slowed mobility, fatigue, weight loss, falls, disability, hospitalization, and mortality but is distinct from chronological age alone.

Shared Decision-Making

- A collaborative process in which clinicians and patients combine best available evidence with patient values, preferences, goals, and circumstances to choose among reasonable options.

Care Coordination

- Deliberate organization and communication of healthcare activities among professionals, services, patients, and caregivers to support safe, continuous, and appropriate care across settings.

Medication Reconciliation

- A structured comparison of the patient's complete medication history with current orders at transitions of care to identify omissions, duplications, interac-

tions, incorrect doses, and unintended changes.

Polypharmacy

- Use of multiple medications by one patient, particularly when the regimen is unnecessary, inappropriate, or difficult to manage. It increases risks of adverse effects, interactions, nonadherence, and prescribing cascades.

Clinical Deterioration

- Worsening of physiologic function or symptoms that increases risk of organ failure, disability, or death. Changes in mental status, respiratory effort, perfusion, urine output, and vital signs may precede overt collapse.

Discharge Planning

- A multidisciplinary process that prepares a patient for safe transition from hospital or facility care to the next setting. It includes medication review, follow-up, education, equipment, self-management support, and communication of pending results.

Continuity of Care

- Consistent and coordinated care over time and across clinicians or settings, integrating the patient's history, current needs, treatment plan, and preferences. It supports safety, adherence, prevention, and chronic-disease outcomes.

Clinical Handover

- Transfer of responsibility and relevant patient information from one healthcare professional or team to another. Effective handover communicates diagnosis, current status, risks, pending tasks, contingency plans, and accountability.

Patient-Centered Outcome

- An outcome that reflects what matters to the patient, including symptoms, function, quality of life, treatment burden, and ability to achieve personal goals, rather than relying only on laboratory or imaging measures.

Diagnostic Uncertainty

- The state in which available information does not establish a single diagnosis with sufficient confidence. It should be communicated transparently and managed with safety-netting, planned reassessment, and targeted additional evaluation.

Zoster

- A painful, vesicular rash caused by reactivation

of latent varicella-zoster virus (VZV, human herpesvirus 3) in the dorsal root ganglia. See [herpes zoster \(shingles\)](#).

A1c

- A glycated form of hemoglobin that reflects average blood glucose over approximately the preceding two to three months. It is used to diagnose and monitor diabetes, although anemia, hemoglobin variants, altered red-cell survival, and assay limitations can affect interpretation.

Abducens Nerve

- The sixth cranial nerve, a motor nerve that supplies the lateral rectus muscle and abducts the eye. Lesion of the nerve causes failure of lateral gaze and horizontal diplopia.

Accessory Nerve

- The eleventh cranial nerve, formed by cranial and spinal roots. Its spinal component supplies the sternocleidomastoid and trapezius muscles; injury can cause shoulder droop and weak head rotation.

Abdominal Reflex

- A superficial cutaneous reflex elicited by stroking the abdominal skin toward the umbilicus, producing contraction of the underlying abdominal muscles. Asymmetry may indicate corticospinal tract dysfunction.

Abasia

- Inability to walk despite preserved strength or the ability to move the legs in other circumstances, usually reflecting a disorder of gait coordination or another neurologic condition rather than paralysis alone.

Acalculia

- An acquired inability to perform previously learned numerical operations or understand numerical relationships, commonly associated with dominant parietal or other cortical dysfunction.

Acapnia

- An abnormally low partial pressure of carbon dioxide in arterial blood, usually caused by excessive alveolar ventilation. It may accompany respiratory alkalosis, light-headedness, or paresthesias.

Acariasis

- Infestation or disease caused by mites or ticks. Clinical manifestations vary with the organism and

may include dermatitis, pruritus, tissue invasion, or transmission of an associated pathogen.

Acathisia

- A syndrome of inner restlessness accompanied by a compelling need to move, often with pacing or shifting of the legs. It is a clinically recognized movement disorder characterized by observable motor activity and subjective distress.

Abetalipoproteinemia

- A rare inherited disorder of lipoprotein assembly that causes very low circulating apoB-containing lipoproteins, fat malabsorption, deficiency of fat-soluble vitamins, acanthocytosis, and progressive neurologic or retinal disease.

ABO Blood Group

- The classification of blood according to the presence or absence of A and B antigens on red blood cells and the corresponding antibodies in plasma. The major groups are A, B, AB, and O.

Acardia

- Absence or severe malformation of the fetal heart, usually occurring in the setting of a rare twin perfusion sequence. The affected fetus cannot sustain independent circulation.

Acetabular Labrum

- A fibrocartilaginous rim attached to the margin of the acetabulum that deepens the hip socket, helps maintain a fluid seal, and contributes to hip-joint stability.

Acetabular Notch

- The indentation in the inferior margin of the acetabulum, bridged by the transverse ligament of the acetabulum and forming a passage for structures entering the hip joint.

Acetabuloplasty

- A surgical procedure that reshapes or augments the acetabular rim or socket to improve coverage of the femoral head in selected structural hip disorders.

Bainbridge Reflex

- An increase in heart rate produced by stretch of the atrial walls, especially during increased venous return. The reflex helps limit venous congestion by adjusting cardiac output.

Ballism

- A hyperkinetic movement disorder characterized by sudden, involuntary, large-amplitude, flinging movements of a limb or limbs. It is often related to dysfunction of the subthalamic region or connected basal-ganglia circuits.

Ballistocardiography

- The graphic recording of repetitive body movements produced by the ejection of blood with each heartbeat. It has been used to study cardiac mechanical activity and circulation.

Band Keratopathy

- A horizontal band of calcium deposition in the superficial cornea, typically across the interpalpebral area. It may occur with chronic ocular inflammation, hypercalcemia, renal disease, or longstanding eye disease and can impair vision.

Banti Disease

- A historical term for congestive splenomegaly associated with portal hypertension and hypersplenism. Modern evaluation usually identifies the underlying hepatic, portal-venous, or hematologic cause.

Barognosis

- The ability to recognize and distinguish the weight of objects by handling them, with intact primary sensation. Impaired barognosis indicates a cortical sensory deficit.

Balanoposthitis

- Inflammation of both the glans penis and the prepuce. It may cause pain, erythema, swelling, discharge, or difficulty retracting the foreskin and can result from infection, irritation, or inflammatory skin disease.

Bacilluria

- The presence of bacilli in the urine, usually referring to rod-shaped bacteria detected by microscopy or culture. Its clinical significance depends on symptoms, quantitative culture, and the organism identified.

Bauhin Valve

- The ileocecal valve, a mucosal sphincter at the junction of the terminal ileum and cecum that helps regulate passage of intestinal contents and limits reflux from the colon.

B Chromosome

- A supernumerary chromosome that is not part of the standard chromosome complement and is not required for normal development. It may occur in certain plants, animals, or tumors and varies in number between cells.

Beals Syndrome

- A congenital connective-tissue disorder characterized by congenital contractures, arachnodactyly, kyphoscoliosis, and crumpled ears. It is usually associated with pathogenic variants affecting fibrillin-2.

Beau's Lines

- Transverse grooves or depressions across a nail caused by temporary interruption of nail-matrix growth. They may follow severe illness, trauma, nutritional stress, or systemic disease and grow distally with the nail.

Bence-Jones Protein

- A monoclonal immunoglobulin light chain found in urine or blood, classically associated with plasma-cell disorders such as multiple myeloma. Detection contributes to evaluation of monoclonal gammopathy and kidney injury.

Bends

- A manifestation of decompression sickness caused by gas bubbles forming in tissues or blood after a rapid reduction in ambient pressure. It commonly produces deep joint or muscle pain but may also involve the nervous system or lungs.

Benign Intracranial Hypertension

- An older term for idiopathic intracranial hypertension, a disorder of raised intracranial pressure without an intracranial mass or hydrocephalus. Headache and papilledema are typical, and untreated disease may threaten vision.

Bent Spine Syndrome

- A marked, usually reducible forward flexion of the trunk caused by weakness or abnormal contraction of axial extensor muscles. It is also called camp-tocormia and may accompany neuromuscular or movement disorders.

Berry Aneurysm

- A small, rounded saccular aneurysm arising at an arterial branch point in the circle of Willis. Rupture is a major cause of nontraumatic subarachnoid

hemorrhage.

Biceps Reflex

- A tendon reflex produced by tapping the biceps tendon, causing elbow flexion through the musculocutaneous nerve and predominantly C5–C6 spinal segments. It helps assess the corresponding peripheral and central pathways.

Bicipital Groove

- The intertubercular groove of the humerus that transmits the tendon of the long head of the biceps brachii, with the transverse humeral ligament and adjacent rotator-cuff structures contributing to tendon stability.

Bicipital Tuberosity

- The radial tuberosity, a roughened prominence on the proximal radius where the biceps brachii tendon inserts and produces flexion and supination of the forearm.

Bicuspid Valve

- A heart valve with two leaflets rather than the usual three. The term most often refers to congenital bicuspid aortic valve, which can cause aortic stenosis, regurgitation, infective endocarditis, or ascending-aortic disease.

Biliary Fever

- Fever associated with infection or inflammation of the biliary tract, classically acute ascending cholangitis. It may occur with right-upper-quadrant pain and jaundice and can progress rapidly to sepsis.

Bilirubinuria

- The presence of conjugated bilirubin in urine. It indicates that water-soluble bilirubin has entered the circulation, often because of hepatocellular disease or biliary obstruction.

Binet-Simon Scale

- An early developmental assessment used to estimate intellectual functioning in children by comparing performance with age-based tasks. Modern evaluation uses standardized, validated developmental and cognitive instruments.

Biosensor

- A device that combines a biological recognition element with a physical or chemical transducer to detect and measure an analyte. Medical examples include sensors for glucose, pathogens, hormones,

and cardiac biomarkers.

Bird Flu

- Influenza caused by avian-adapted influenza A viruses. Human infection is uncommon but may cause severe respiratory disease, and public-health assessment depends on exposure history, testing, and infection-control measures.

Biotelemetry

- The remote measurement and transmission of physiologic data from a person or animal. Clinical applications include ambulatory cardiac rhythm monitoring, temperature monitoring, and intensive-care observation.

Bacterial Toxin

- A poisonous molecule produced by bacteria that damages host cells or disrupts normal physiology. Exotoxins are secreted or released from viable bacteria, whereas endotoxin refers principally to lipopolysaccharide from the outer membrane of gram-negative bacteria.

Bitot's Spots

- Foamy, whitish, triangular patches on the conjunctiva, usually near the temporal limbus, associated classically with vitamin A deficiency. They may accompany night blindness and xerosis of the conjunctiva or cornea.

Bitewing

- A dental radiograph that records the crowns of the upper and lower teeth and the adjacent alveolar bone in one image. It is particularly useful for detecting interproximal caries and assessing crestal bone levels.

Black Hairy Tongue

- A benign elongation and dark discoloration of the filiform papillae on the dorsal tongue caused by impaired desquamation and trapping of debris or pigment. Predisposing factors include smoking, poor oral hygiene, dry mouth, and some exposures.

Black Lung

- Coal workers' pneumoconiosis caused by prolonged inhalation of coal-mine dust. It ranges from simple anthracosis to progressive massive fibrosis and may cause cough, breathlessness, and permanent lung impairment.

Blalock-Taussig Operation

- A surgical systemic-to-pulmonary shunt that increases pulmonary blood flow in selected cyanotic congenital heart disease. The modern modified procedure commonly uses a prosthetic conduit rather than direct sacrifice of a subclavian artery.

Blennorrhea

- A mucopurulent discharge from a mucous membrane, especially the urethra or conjunctiva. The finding requires clinical assessment for infectious and noninfectious causes rather than treatment based on the symptom alone.

Blepharoconjunctivitis

- Inflammation involving the eyelid margins and conjunctiva. It may cause crusting, itching, redness, tearing, irritation, and recurrent symptoms associated with infection, allergy, or eyelid-gland dysfunction.

Blepharoplasty

- Surgical reconstruction or reshaping of the eyelids, often involving removal or repositioning of excess skin, muscle, or orbital fat. It may be functional, cosmetic, or reconstructive.

Body Ringworm

- Dermatophyte infection of the glabrous skin, also called tinea corporis. It typically produces an expanding annular scaly lesion with a more active border and central clearing.

Boeck's Sarcoid

- An older eponym for sarcoidosis, a multisystem granulomatous disease characterized by noncaseating granulomas and commonly involving the lungs, intrathoracic lymph nodes, skin, or eyes.

Bornholm Disease

- An acute epidemic pleurodynia caused most often by coxsackieviruses. It produces sudden attacks of severe chest or upper-abdominal muscle pain, fever, and sometimes headache or vomiting.

Borreliosis

- Infection caused by bacteria of the genus *Borrelia*. Human disease includes Lyme borreliosis and relapsing fever, with manifestations varying according to species, stage, and organ involvement.

Botryomycosis

- A chronic bacterial infection characterized by granule-forming lesions that can resemble a fungal infection. It most often affects skin and subcutaneous tissue but may involve viscera in susceptible patients.

Bouchard's Node

- A hard, palpable enlargement of the proximal interphalangeal joint caused by osteoarthritis. It reflects osteophyte formation and may be associated with pain, stiffness, and reduced finger motion.

Bougienage

- The use of a bougie to dilate or explore a narrowed tubular structure, such as the esophagus or urethra. It is a procedure that requires assessment of the cause and risks of the stricture.

Boutonneuse Fever

- A tick-borne rickettsial infection, usually caused by *Rickettsia conorii*, characterized by fever, headache, rash, and often a dark inoculation eschar called a *tache noire*.

Bovine Spongiform Encephalopathy

- A fatal transmissible prion disease of cattle causing progressive neurologic degeneration. It is related to variant Creutzfeldt–Jakob disease in humans through exposure to contaminated tissue.

Bowman's Gland

- A serous gland in the olfactory mucosa whose secretion helps dissolve odorant molecules and cleanse the olfactory surface. It is located in the lamina propria beneath the olfactory epithelium.

Branchial Arch

- One of the paired embryonic arches that contribute to development of facial, pharyngeal, laryngeal, muscular, skeletal, vascular, and neural structures of the head and neck.

Branchial Cleft

- An embryonic groove between adjacent branchial arches. Persistence of cleft remnants can produce congenital branchial cysts, sinuses, or fistulas, most commonly along the lateral neck.

Breakbone Fever

- A traditional name for dengue fever, reflecting the

severe myalgia and arthralgia that may accompany the acute viral illness.

Broca's Aphasia

- A nonfluent language disorder caused by dysfunction of the dominant inferior frontal language region. Speech is effortful and reduced, while comprehension is relatively preserved compared with repetition and fluent language production.

Broca's Area

- A language-related region of the dominant inferior frontal gyrus involved in speech production, language formulation, and aspects of syntax. Lesions may cause expressive aphasia.

Bright's Disease

- A historical term encompassing several forms of kidney disease, particularly glomerular disorders associated with proteinuria, edema, and altered urinary findings. Modern diagnosis specifies the underlying renal lesion.

Brill's Disease

- A recrudescent form of epidemic typhus caused by reactivation of latent *Rickettsia prowazekii* infection years after the original illness. It is usually milder than the initial infection but can transmit to body lice.

Bromhidrosis

- Excessive or unpleasant body odor produced when microbial metabolism acts on sweat or skin secretions. It is often prominent in the axillae or feet and may be associated with hyperhidrosis or local skin disease.

Bromoderma

- A skin eruption or dermatitis attributed to exposure to bromine or bromide compounds. It may present with acneiform, pustular, or other inflammatory lesions.

Bronchial Artery

- An artery arising from the systemic circulation that supplies the walls of the bronchi, connective tissue of the lungs, and visceral pleura. It differs from the pulmonary arteries, which carry blood for gas exchange.

Bronchial Tree

- The branching airway system formed by the trachea, main bronchi, lobar and segmental bronchi,

bronchioles, and terminal airways leading toward the alveoli.

Bronchial Vein

- A vein draining portions of the bronchial walls and larger airways. It empties partly into the azygos system and partly into pulmonary veins, creating a small physiologic venous admixture.

Bronchiolectasis

- Permanent abnormal dilation of bronchioles, usually caused by chronic inflammation, infection, or obstruction. It may accompany bronchiectasis and contribute to impaired mucus clearance and recurrent infection.

Bronchostenosis

- Narrowing of a bronchus that restricts airflow. Causes include scarring, tumors, foreign bodies, inflammation, external compression, or postinfectious and postprocedural changes.

Brown Lung Disease

- An occupational airway disease associated with inhalation of cotton, flax, or hemp dust, classically causing byssinosis. Symptoms may include chest tightness, cough, wheezing, and work-related airflow limitation.

Brudzinski Sign

- Flexion of the hips and knees that occurs involuntarily when the neck is passively flexed. It is a meningeal irritation sign that may occur in meningitis but lacks sufficient sensitivity or specificity to establish the diagnosis alone.

Brunner's Gland

- A mucus-secreting gland in the submucosa of the duodenum. Its alkaline secretion helps protect the mucosa from gastric acid and provides conditions favorable for intestinal enzymes.

Buccal Gland

- A minor salivary gland located in the cheek. It secretes mucus into the oral cavity to lubricate the buccal mucosa and assist formation and handling of the food bolus.

Bulbar Paralysis

- Weakness or paralysis of muscles supplied by the lower cranial nerves, causing dysarthria, dysphagia, impaired gag or cough, and sometimes respiratory compromise. Causes include brainstem disease,

motor-neuron disease, and neuromuscular disorders.

Buerger's Disease

- Thromboangiitis obliterans, a nonatherosclerotic inflammatory disease of small and medium arteries and veins, strongly associated with tobacco exposure. It causes distal ischemia, pain, ulcers, and sometimes gangrene.

Buphthalmos

- Enlargement of the eye caused by elevated intraocular pressure during early childhood, when the ocular coats are still distensible. It is classically associated with congenital or infantile glaucoma.

Byssinosis

- An occupational obstructive airway disease caused by inhalation of textile fibers, especially cotton, flax, or hemp dust. It may cause chest tightness and cough that worsen during or after work exposure.

Bursectomy

- Surgical excision of a bursa, usually performed for persistent painful bursitis, recurrent infection, or another structural problem that has not responded to appropriate conservative management.

Cabot Ring

- A threadlike or ring-shaped inclusion in a red blood cell, sometimes seen in severe anemia or disorders of erythropoiesis. It represents residual nuclear material or mitotic spindle remnants.

Cacosmia

- A distorted or unpleasant perception of smell, in which odors may seem foul or disagreeable. It can occur with sinonasal disease, infection, seizures, trauma, or other neurologic disorders.

Caecitis

- Inflammation of the cecum. Causes include infection, inflammatory bowel disease, ischemia, neutropenic enterocolitis, and extension of adjacent inflammatory disease.

Caecopexy

- Surgical fixation of the cecum to the abdominal wall or retroperitoneum, performed to prevent or treat abnormal cecal mobility or recurrent cecal volvulus.

Caecostomy

- Surgical creation of an opening from the cecum to

the abdominal wall for decompression or diversion of intestinal contents. It may be temporary or part of treatment for selected distal obstruction.

Caecotomy

- Surgical incision into the cecum, usually to remove a foreign body, access the bowel, or facilitate another abdominal procedure.

Caisson Disease

- Decompression sickness caused by formation of inert-gas bubbles after a rapid reduction in ambient pressure. It can cause joint pain, neurologic injury, respiratory symptoms, or circulatory collapse.

Café au Lait Spot

- A flat, sharply demarcated, light-brown skin macule caused by increased melanin. Multiple lesions may be a feature of neurofibromatosis type 1 or other genetic disorders.

Caldwell-Luc Operation

- A surgical approach to the maxillary sinus through the canine fossa of the anterior maxilla. It is used selectively for access to maxillary sinus disease, lesions, or foreign bodies.

Campimetry

- Measurement and mapping of the visual field, usually by presenting stimuli at different locations while the patient maintains fixation. It helps detect and characterize defects from retinal, optic-nerve, or retinohypothalamic disease.

Camptodactyly

- A congenital or acquired flexion deformity of one or more fingers, usually caused by shortening or abnormality of tendons, muscles, fascia, or joints. It often affects the proximal interphalangeal joints.

Campylobacteriosis

- Infection caused by *Campylobacter* species, commonly producing fever, abdominal pain, and inflammatory diarrhea that may be bloody. Complications can include dehydration, bacteremia, reactive arthritis, or Guillain-Barré syndrome.

Canal of Schlemm

- A circular endothelial-lined channel at the corneoscleral junction that drains aqueous humor from the anterior chamber into the episcleral venous circulation. Impaired outflow contributes to glaucoma.

Canavan Disease

- An autosomal-recessive leukodystrophy caused by aspartoacylase deficiency, leading to accumulation of N-acetylaspartate and progressive spongy degeneration of cerebral white matter. It typically presents in infancy with hypotonia followed by developmental impairment and macrocephaly.

Cancrum Oris

- Noma, a rapidly destructive gangrenous infection of the mouth and face that occurs mainly in severely malnourished or immunocompromised children. It begins with gingival or mucosal necrosis and can extend through facial tissues.

Candidemia

- The presence of *Candida* species in the bloodstream. It is an invasive fungal infection associated with intravascular devices, surgery, intensive care, immunosuppression, and substantial risk of organ dissemination.

Canicola Fever

- A form of leptospirosis associated particularly with *Leptospira interrogans* serovar canicola. It may cause fever, headache, myalgia, conjunctival suffusion, and renal or hepatic involvement.

Canker Sore

- A common aphthous ulcer of the oral mucosa, appearing as a painful, shallow, round or oval ulcer with an erythematous border. Most heal spontaneously, but recurrent, severe, or atypical ulcers require assessment.

Cannulation

- The insertion of a cannula into a blood vessel, body cavity, duct, or other anatomical passage to permit drainage, infusion, monitoring, sampling, or access for a procedure.

Capgras Syndrome

- A delusional misidentification syndrome in which a person believes that someone familiar has been replaced by an identical impostor. It can occur in neurodegenerative disease, psychosis, brain injury, or other neurologic conditions.

Capillaroscopy

- Examination of the small vessels in the nail-fold or another accessible surface using magnification. It can reveal capillary dilation, hemorrhage, avascu-

lar areas, and abnormal architecture in connective-tissue and microvascular disease.

Capsular Contracture

- Abnormal tightening and hardening of the fibrous capsule around an implanted device, especially a breast implant. It may cause pain, distortion, firmness, or displacement.

Capsulectomy

- Surgical removal of part or all of a fibrous capsule surrounding an organ, implant, or other structure. The indication depends on contracture, infection, pathology, or the need to revise a reconstruction.

Capsule of Glisson

- The connective-tissue capsule surrounding the liver, which sends fibrous septa inward along portal tracts and supports the organ's vessels, ducts, and nerves.

Capsule of Tenon

- A fascial sheath surrounding the globe of the eye and separating it from orbital fat. It contributes to eye movement and forms a potential space used in some ophthalmic procedures.

Cardioplegia

- Deliberate temporary arrest and protection of the heart during cardiac surgery, usually achieved with a cold or blood-based solution that alters myocardial electrical and metabolic activity.

Cardiospasm

- Spasm or impaired relaxation of the lower esophageal sphincter, historically used as a term for achalasia. It causes dysphagia, regurgitation, and sometimes chest discomfort.

Cardiotoxicity

- Injury or functional impairment of the heart caused by a toxic exposure, systemic disease, or treatment. Manifestations include arrhythmia, myocardial dysfunction, ischemia, or heart failure.

Cardioversion

- Restoration of a normal cardiac rhythm from an arrhythmia by synchronized electrical shock or, in some contexts, a planned pharmacologic intervention. Synchronized shock avoids delivery during vulnerable ventricular repolarization.

Carditis

- Inflammation of the heart or one of its layers,

including the myocardium, endocardium, or pericardium. It may result from infection, immune-mediated disease, or systemic inflammation.

Caries

- Progressive destruction of calcified tooth tissue caused by acid-producing microbial biofilm acting on fermentable carbohydrates. Untreated disease can extend from enamel into dentin and pulp.

Cariogenic

- Capable of promoting dental caries, especially by producing acid from fermentable carbohydrates or supporting a plaque environment that demineralizes tooth structure.

Camptocormia

- A marked forward flexion of the trunk that increases while standing or walking and improves when lying down. It can occur with axial myopathy, Parkinsonian disorders, dystonia, or other neuromuscular disease.

Central Auditory Processing Disorder

- Impaired processing of auditory information by the central nervous system despite adequate peripheral hearing. It may cause difficulty understanding speech, especially in noise, and can affect learning and communication.

Central Diabetes Insipidus

- Excessive urination and thirst caused by deficient secretion of antidiuretic hormone from the hypothalamus or posterior pituitary. The kidneys cannot appropriately concentrate urine, producing hypernatremia if water intake is insufficient.

Central Deafness

- Loss or severe impairment of hearing caused by disease of the auditory pathways or auditory cortex in the brain, rather than by a disorder of the external, middle, or inner ear.

Cerebellitis

- Inflammation of the cerebellum, often after infection and sometimes associated with an autoimmune response. It may produce ataxia, dysarthria, nystagmus, headache, and altered consciousness.

Cerebellopontine Angle

- The angle-shaped region at the junction of the cerebellum, pons, and petrous temporal bone. Le-

sions in this space may affect cranial nerves and commonly include vestibular schwannoma.

Cephalalgia

- Headache or pain in the head, including pain arising from cranial or related structures. It is a symptom with many possible primary and secondary causes.

Cephalohematoma

- A collection of blood beneath the periosteum of a newborn's skull, usually caused by birth trauma. It is confined by suture lines and generally resolves gradually.

Cephalopelvic Disproportion

- A mismatch between the size or shape of the maternal pelvis and the fetal head that prevents or impedes vaginal delivery. It may be suspected from clinical assessment but cannot always be diagnosed reliably before labor.

Ceramide

- A sphingolipid composed of a sphingoid base linked to a fatty acid. Ceramides are structural components of cell membranes and the epidermal permeability barrier and also participate in cell signaling.

Ceruloplasmin

- The principal copper-carrying protein in blood, synthesized mainly by the liver. Its concentration and copper-binding function are clinically relevant in disorders such as Wilson disease.

Cervical Dystonia

- A focal movement disorder causing involuntary contractions of neck muscles and abnormal positioning of the head. It may produce pain, tremor, and sustained or intermittent twisting of the neck.

Cervical Rib

- An extra rib arising from a cervical vertebra, usually the seventh. It may be asymptomatic or contribute to thoracic outlet syndrome by compressing the brachial plexus or subclavian vessels.

Cestodiasis

- Infection or infestation caused by cestodes, commonly called tapeworms. Disease may involve the intestine or tissues, depending on the species and life-cycle stage.

Chagoma

- A localized inflammatory lesion at the site where

Trypanosoma cruzi enters the body. It is an early manifestation of Chagas disease and may be accompanied by regional lymphadenopathy.

Channelopathy

- A disorder caused by abnormal structure or function of an ion channel or its regulatory proteins. Channelopathies can affect excitable tissues and cause neurologic, muscular, or cardiac disease.

Chancere

- A usually painless ulcer at the site of inoculation of an infection, especially the primary lesion of syphilis. It may be accompanied by regional lymph-node enlargement and heals without treatment, although infection persists.

Charcot Arthropathy

- Progressive destruction and deformity of a joint caused by loss of protective pain or proprioceptive sensation. It is most often associated with peripheral neuropathy, particularly diabetic neuropathy.

Cheilectropion

- An eversion deformity of the lip, usually involving the lower lip. It may result from scarring, congenital malformation, or loss of tissue support.

Cheiloplasty

- Plastic or reconstructive surgery of the lip, performed to repair congenital clefting, trauma, tumors, scars, or other deformity.

Cheiloschisis

- Cleft lip, a congenital fissure of the upper lip caused by incomplete fusion of facial processes during embryonic development. It may occur alone or with cleft palate.

Cheilosis

- A disorder of the lips characterized by dryness, scaling, fissuring, or inflammation. Causes include irritation, nutritional deficiency, infection, and systemic disease.

Cheiopompholyx

- A form of dyshidrotic eczema affecting the hands, with intensely itchy small vesicles on the palms or sides of the fingers.

Chelation

- The formation of a stable complex between a metal ion and a molecule with multiple binding sites. In

medicine, chelation can be used under supervision to bind and promote elimination of selected toxic metals.

Chemodectomy

- A tumor arising from paraganglionic tissue, especially a carotid-body tumor. It is usually slow-growing and may compress nearby cranial nerves or vessels.

Chemoembolization

- A procedure that combines delivery of an antineoplastic agent with embolization of the blood supply to a tumor, most commonly for selected liver cancers.

Chemokinesis

- Nonspecific stimulation of cell movement by a chemical substance, without directional movement toward or away from a concentration gradient.

Chemophobia

- An excessive or irrational fear of chemicals, sometimes associated with anxiety or obsessive concerns about contamination or toxicity.

Chemoreceptor Trigger Zone

- A region near the floor of the fourth ventricle that detects emetic stimuli in blood and cerebrospinal fluid and helps initiate vomiting.

Chemoresistance

- Reduced or absent responsiveness of cells, especially tumor cells, to a chemical treatment that would ordinarily inhibit or destroy them.

Chemosensitivity

- The degree to which cells or a tumor respond to a chemical treatment. Testing may be used experimentally or clinically to help characterize treatment response.

Chemosis

- Edema of the conjunctiva, producing a swollen, often translucent or blister-like appearance. It may occur with allergy, infection, inflammation, trauma, or orbital disease.

Chemotaxis

- Directed movement of a cell or organism toward or away from a chemical stimulus. It is important in immune-cell recruitment and inflammatory responses.

Cherry Eye

- Prolapse of the gland of the third eyelid, producing a rounded red mass at the inner corner of the eye. The term is used especially in veterinary ophthalmology.

Cherubism

- A rare inherited disorder characterized by bilateral enlargement of the jaws from expansile giant-cell lesions, usually beginning in childhood and often regressing after puberty.

Chiari-Frommel Syndrome

- Persistent postpartum secretion of milk with absence of menstruation, associated with hyperprolactinemia after pregnancy. It is a form of galactorrhea-amenorrhea syndrome.

Chionablepsia

- Temporary visual impairment caused by exposure to intense reflected light from snow or ice, commonly called snow blindness. It is usually related to ultraviolet injury of the cornea.

Chikungunya

- An acute mosquito-borne viral infection characterized by fever and often severe joint pain, with rash and other systemic symptoms in some patients.

Chilblain

- An inflammatory skin lesion caused by an abnormal response to cold and damp conditions. It produces itchy, red or violaceous swollen areas, usually on fingers, toes, ears, or nose.

Childhood Absence Epilepsy

- An epilepsy syndrome beginning in childhood with frequent brief absence seizures, characterized by sudden impairment of awareness and a typical generalized spike-and-wave EEG pattern.

Chimerism

- The presence in one individual of cell populations derived from genetically different zygotes or sources. It may occur naturally, after transplantation, or through exchange of cells between a pregnant person and fetus.

Chlamydiosis

- Infection caused by bacteria of the genus *Chlamydia*. Depending on the species and site, it may cause sexually transmitted infection, conjunctivitis,

pneumonia, or other disease.

Chloasma

- Patchy brown hyperpigmentation, especially of the face, associated with pregnancy, hormones, sun exposure, or other causes. It is commonly called melasma.

Chloracne

- An acne-like eruption caused by exposure to certain halogenated aromatic compounds, such as dioxins and related industrial chemicals.

Chloranemia

- Anemia in which the red blood cells are abnormally pale, usually because of reduced hemoglobin content, as in iron deficiency.

Chloroleukemia

- A rare form of myeloid leukemia associated with greenish tumor masses composed of myeloid cells, also called granulocytic sarcoma or chloroma.

Chloroma

- A greenish extramedullary mass of immature myeloid cells, usually associated with acute myeloid leukemia. It is also called granulocytic sarcoma or myeloid sarcoma.

Chloropsia

- A visual disturbance in which objects appear green or have a greenish tint. It can occur with retinal disease, medication or toxin exposure, or other visual-pathway disorders.

Churg-Strauss Syndrome

- Eosinophilic granulomatosis with polyangiitis, a necrotizing inflammation of small and medium blood vessels associated with asthma, eosinophilia, and possible injury to the lungs, nerves, skin, heart, or kidneys.

Chylangioma

- A benign malformation or tumor-like lesion of lymphatic vessels containing chyle or lymph. It may occur in the neck, mediastinum, or other tissues.

Chyluria

- Passage of lymphatic fluid into the urine, giving it a milky appearance. It usually results from an abnormal communication between lymphatic vessels and the urinary tract.

Ciliopathy

- A disorder caused by abnormal structure or function of cellular cilia. Ciliopathies may affect development, vision, kidney function, respiration, or multiple organ systems.

Cineangiocardiology

- Radiographic recording of the heart and blood vessels during passage of contrast material, used to visualize cardiac chambers, valves, and coronary or great vessels.

Cinefluorography

- Motion-picture recording of fluoroscopic images, used to document movement of organs or contrast material during a diagnostic examination.

Cineplasty

- Surgical creation of a muscle-controlled stump or related reconstruction, historically used to improve control of a prosthetic limb.

Cingulotomy

- Surgical interruption of selected fibers of the cingulum, sometimes performed as a psychosurgical treatment for severe, treatment-resistant psychiatric illness or chronic pain.

Ciguatera

- Food poisoning caused by eating reef fish containing ciguatoxins. It may cause gastrointestinal illness followed by neurologic symptoms such as paresthesias and temperature-sensation disturbance.

Cholangiitis

- Inflammation of the bile ducts. It may be caused by infection, obstruction, autoimmune disease, or other biliary disorders.

Cholecystography

- Radiographic examination of the gallbladder, usually after administration of a contrast substance, to assess its filling, concentration, and emptying.

Cholesterolemia

- The presence and concentration of cholesterol in the blood. Abnormal elevation is a risk factor for atherosclerotic cardiovascular disease.

Chondritis

- Inflammation of cartilage, such as the cartilage of the ear, nose, ribs, or larynx. It may result from infection, trauma, or immune-mediated disease.

Chondrodysplasia

- A disorder of cartilage and bone development that causes abnormal skeletal growth and, in some forms, disproportionate short stature.

Chondromalacia

- Softening and degeneration of cartilage, especially articular cartilage. The term is often used for changes affecting the patella and causing anterior knee pain.

Chopart's Joint

- The transverse tarsal joint, consisting of the talonavicular and calcaneocuboid joints, between the hindfoot and the midfoot.

Chorioretinitis

- Inflammation involving the choroid and retina, often caused by infection, autoimmune disease, or systemic inflammatory illness. It can produce floaters and impaired vision.

Christmas Disease

- Hemophilia B, an inherited bleeding disorder caused by deficiency or dysfunction of coagulation factor IX.

Chromaffinoma

- A tumor of chromaffin cells, usually a pheochromocytoma of the adrenal medulla or a related extra-adrenal paraganglioma. It may secrete catecholamines and cause episodic hypertension.

Chromatopsia

- A visual disturbance in which objects appear abnormally colored. It may result from retinal disease, toxic exposure, medication effects, or other disorders of the visual system.

Chromhidrosis

- A rare condition in which sweat is abnormally colored, often yellow, green, blue, or black, because of pigment in the sweat glands or on the skin surface.

Claw Foot

- A deformity in which the toes are hyperextended at the metatarsophalangeal joints and flexed at the interphalangeal joints. It may result from muscle imbalance or neurologic disease.

Claw Hand

- A hand deformity with hyperextension at the metacarpophalangeal joints and flexion at the inter-

phalangeal joints, classically caused by ulnar-nerve palsy or lower brachial-plexus injury.

Claw Toe

- A toe deformity characterized by extension at the metatarsophalangeal joint and flexion at the proximal and distal interphalangeal joints.

Cleidocranial Dysplasia

- An inherited skeletal disorder characterized by defective development or ossification of the clavicles and skull, delayed closure of cranial sutures, dental abnormalities, and short stature.

Climacteric

- The period of physiologic change around the end of reproductive capacity, including the menopausal transition. It may involve changes in menstruation, vasomotor symptoms, and other endocrine effects.

Clinical Depression

- A depressive disorder marked by persistent depressed mood or loss of interest with associated cognitive, emotional, or physical symptoms that cause clinically significant distress or impairment.

Clinodactyly

- A congenital or developmental lateral curvature of a finger or toe, most often affecting the fifth finger and resulting from abnormal shape of a phalanx.

Clinoid Process

- One of several bony projections of the sphenoid bone that form part of the cranial base and support structures around the optic canal and cavernous sinus.

Clitoridectomy

- Surgical removal of part or all of the clitoris. In medicine it may be performed for selected tumors or severe disease; nonmedical removal is a harmful practice with no health benefit.

Cloacitis

- Inflammation of a cloaca or cloacal region, particularly in disorders affecting the common terminal outlet of the urinary, genital, and intestinal tracts.

Clonorchiasis

- Infection with the Chinese liver fluke, *Clonorchis sinensis*. It affects the biliary tract and may cause inflammation, obstruction, and long-term hepatobiliary complications.

Closed-Angle Glaucoma

- Glaucoma caused by obstruction of the drainage angle of the anterior chamber, preventing aqueous humor outflow and producing potentially rapid elevation of intraocular pressure.

Closed Comedo

- A small skin lesion formed when a follicular opening is blocked by sebum and keratin but remains covered by the epidermis. It is commonly called a whitehead.

Closed Fracture

- A fracture in which the broken bone does not communicate through a wound with the external environment.

Closed Reduction

- Nonoperative realignment of a fractured or dislocated bone or joint by manipulation without surgically opening the site.

Clostridium

- A genus of anaerobic, usually spore-forming bacteria that includes species capable of causing diseases such as tetanus, botulism, gas gangrene, and antibiotic-associated colitis.

Coarctation

- A localized narrowing of a tubular anatomical structure, especially coarctation of the aorta, which obstructs blood flow and produces characteristic pressure differences.

Coats Disease

- An uncommon retinal disorder characterized by abnormal retinal blood vessels, leakage, exudation, and sometimes retinal detachment, usually affecting one eye in childhood.

Clubhand

- A congenital deformity of the hand in which the wrist and hand deviate toward the radial or ulnar side, often associated with deficiency or abnormal development of forearm bones.

Clutton's Joints

- Painless bilateral swelling of the knees or other large joints associated with congenital syphilis, caused by chronic synovitis.

Coccidiosis

- Infection by coccidian protozoa. In humans it may cause intestinal disease or, in immunocompromised

patients, infection of other organs.

Coccydynia

- Pain in the region of the coccyx, often worsened by sitting. Causes include trauma, childbirth, degenerative change, and less commonly infection or tumor.

Coccygectomy

- Surgical removal of the coccyx, reserved for selected cases of severe persistent coccygeal pain or a lesion that has not responded to conservative treatment.

Cockayne Syndrome

- A rare inherited disorder of DNA repair characterized by progressive neurologic dysfunction, growth failure, developmental impairment, photosensitivity, and a prematurely aged appearance.

Code Blue

- A hospital emergency signal indicating that a person may be in cardiopulmonary arrest and requires immediate resuscitation response.

Cold Abscess

- An abscess that develops slowly with little heat, redness, or acute inflammation, classically in tuberculosis or other chronic infections.

Cold Agglutinin

- An antibody that causes red blood cells to agglutinate at relatively low temperatures. Pathologic cold agglutinins can cause autoimmune hemolytic anemia.

Colibacillosis

- Disease caused by pathogenic strains of *Escherichia coli*, which may produce intestinal infection, urinary-tract infection, sepsis, or other illness.

Collagen Disease

- A systemic disorder involving connective tissue and often immune-mediated injury to collagen-rich structures. The term has historically included diseases such as systemic lupus erythematosus and systemic sclerosis.

Colles Fracture

- A fracture of the distal radius with dorsal displacement and angulation of the distal fragment, usually caused by falling on an outstretched hand.

Colorado Tick Fever

- An acute viral infection transmitted by ticks and

characterized by fever, headache, myalgia, and sometimes leukopenia or rash.

Colpitis

- Inflammation of the vagina, often due to infection, altered vaginal flora, irritation, or hormonal change.

Comedocarcinoma

- A form of ductal carcinoma in situ of the breast characterized by central necrosis within malignant ducts, which may produce a comedo-like appearance.

Comminuted

- Describing a fracture in which a bone is broken into multiple fragments.

Commissurotomy

- Surgical incision or separation of a commissure, especially a fused cardiac valve commissure, to relieve obstruction.

Commotio Cordis

- Sudden cardiac arrest caused by a blunt, nonpenetrating impact to the chest at a vulnerable moment in the cardiac cycle, without structural heart injury.

Complete Blood Count

- A laboratory test measuring blood-cell numbers and indices, commonly including erythrocytes, hemoglobin, hematocrit, leukocytes, and platelets.

Concato's Disease

- A historical term for primary polycythemia, now generally called polycythemia vera, a myeloproliferative neoplasm causing increased red-cell mass and often elevated blood viscosity.

Concretio Cordis

- Abnormal adhesion or fusion of structures within or around the heart, including adhesion of the pericardial surfaces or fusion of cardiac components.

Conduction Deafness

- Hearing loss caused by impaired transmission of sound through the external or middle ear, with the inner ear and neural auditory pathways relatively preserved.

Conductive Deafness

- Hearing loss resulting from a problem in the external auditory canal, tympanic membrane, or middle ear that reduces conduction of sound to the inner ear.

Condylar Process

- The rounded articular projection of a bone, especially the mandibular process that articulates with the temporal bone to form the temporomandibular joint.

Confabulation

- Production of false or inaccurate statements or memories without conscious intent to deceive, often associated with memory impairment or frontal-lobe dysfunction.

Congenital Contractural Arachnodactyly

- An inherited connective-tissue disorder characterized by long slender fingers and toes, congenital flexion contractures, muscular hypoplasia, and sometimes kyphoscoliosis.

Congenital Megacolon

- Hirschsprung disease, a congenital absence of enteric ganglion cells in a segment of the bowel that causes functional obstruction and enlargement of the proximal colon.

Conjunctivoplasty

- Plastic or reconstructive surgery of the conjunctiva, performed to repair defects, scarring, adhesions, or other abnormalities of the ocular surface.

Conn's Syndrome

- Primary hyperaldosteronism caused by autonomous secretion of aldosterone, leading to hypertension and often low serum potassium.

Conization

- Surgical removal of a cone-shaped portion of the cervix for diagnosis or treatment of cervical dysplasia or selected early cervical cancers.

Contagious Disease

- An infectious disease that can be transmitted directly or indirectly from one person, animal, or source to another.

Continuous Positive Airway Pressure

- Noninvasive respiratory support that delivers a constant positive pressure throughout the breathing cycle to keep the upper airway or alveoli open.

Contracted Pelvis

- A pelvis whose size or shape is reduced or abnormal

enough to interfere with passage of the fetus during labor.

Contrecoup

- An injury occurring on the side of an organ opposite the site of impact, especially a brain injury produced when the brain moves within the skull after trauma.

Coombs Test

- A laboratory test that detects antibodies or complement attached to red blood cells, or antibodies in serum that can react with red cells. It is used in evaluating immune hemolysis and blood compatibility.

Cooper's Ligament

- Fibrous connective-tissue septa extending from the deep surface of the breast toward the skin and pectoral fascia. Tumor invasion or fibrosis may cause skin retraction.

Ciclopia

- A rare severe congenital malformation in which the eyes are fused or a single median eye develops, usually as part of holoprosencephaly.

Corneitis

- Inflammation of the cornea, often producing pain, photophobia, tearing, and impaired vision. It may be infectious, immune-mediated, traumatic, or related to exposure.

Cordocentesis

- A prenatal diagnostic procedure in which fetal blood is sampled from the umbilical cord, usually under ultrasound guidance.

Cordotomy

- Surgical division of selected nerve fibers, especially a spinal cord tract, to interrupt transmission of severe chronic pain.

Core Biopsy

- Removal of a cylindrical sample of tissue with a hollow cutting needle for microscopic examination, commonly used for breast, liver, prostate, and other lesions.

Corneal Implant

- An implanted device or tissue substitute placed in or on the cornea to restore vision, replace diseased tissue, or alter corneal shape.

Coronary Artery Bypass

- A surgical procedure that creates a new route for blood flow around a narrowed or blocked coronary artery using a vascular graft.

Coronary Insufficiency

- Inadequate blood flow through the coronary circulation to meet myocardial oxygen demand, usually because of coronary artery disease.

Coronary Occlusion

- Obstruction of a coronary artery, commonly by atherosclerotic plaque and thrombus, that can cause myocardial ischemia or infarction.

Coronavirus Disease 2019

- A respiratory and systemic infectious disease caused by SARS-CoV-2. Illness ranges from asymptomatic infection to pneumonia, respiratory failure, and multisystem complications.

Corrigan Pulse

- A forceful, rapidly rising and collapsing arterial pulse, classically associated with aortic regurgitation.

Corti's Ganglion

- The spiral ganglion of the cochlea, containing the cell bodies of sensory neurons that transmit auditory information from the organ of Corti.

Coryza

- Acute inflammation of the nasal mucous membranes with nasal discharge and obstruction, commonly occurring in the common cold or other upper-respiratory infection.

Cot Death

- Sudden infant death syndrome, the sudden unexplained death of an apparently healthy infant, usually during sleep, that remains unexplained after investigation.

COVID Toe

- A chilblain-like skin lesion reported in association with COVID-19, usually affecting the toes or fingers and appearing red, purple, or swollen.

Cowper's Gland

- One of a pair of small male accessory sex glands below the prostate. Its secretion contributes mucus and fluid to the urethra before ejaculation.

Cowpox

- A zoonotic viral infection caused by cowpox virus or related orthopoxviruses, producing localized pustular or ulcerative skin lesions and sometimes systemic illness.

Coxalgia

- Pain in the hip or hip joint.

Coxa Vara

- A deformity in which the angle between the femoral neck and shaft is abnormally reduced, potentially causing a limp, shortened limb, or altered hip mechanics.

Cranial Arteritis

- Giant-cell arteritis, an inflammatory disease of medium and large arteries, especially branches of the external carotid artery, that can cause headache, visual loss, and systemic symptoms.

Craniectomy

- Surgical removal of part of the skull without immediate replacement, performed to relieve intracranial pressure or provide access to the brain.

Craniofacial Dysostosis

- A congenital disorder involving premature fusion of cranial sutures and characteristic abnormalities of the face and skull, such as those seen in Crouzon syndrome.

Cranioplasty

- Surgical repair or reconstruction of a skull defect using bone, an implant, or another suitable material.

C-Reactive Protein

- An acute-phase protein produced mainly by the liver whose blood concentration rises with inflammation, infection, tissue injury, and some malignancies.

Creatine Kinase

- An enzyme found largely in skeletal muscle, heart muscle, and brain. Blood levels may rise after muscle injury, myocardial injury, or strenuous exertion.

Cretenism

- An outdated term for severe congenital or early-childhood hypothyroidism causing impaired physical and intellectual development; modern clinical language uses congenital hypothyroidism.

Creutzfeldt-Jakob Disease

- A rapidly progressive fatal neurodegenerative dis-

ease caused by abnormal prion protein, characterized by dementia, myoclonus, ataxia, and other neurologic signs.

Cri du Chat Syndrome

- A congenital genetic disorder caused by deletion of part of the short arm of chromosome 5, characterized in infancy by a high-pitched cry, developmental delay, and characteristic facial features.

Cryopexy

- A procedure that uses controlled freezing to destroy or seal abnormal tissue, especially retinal breaks or small retinal detachments.

Cryoprecipitate

- A plasma fraction rich in fibrinogen, factor VIII, von Willebrand factor, and factor XIII, used selectively to treat certain bleeding disorders.

Cryopreservation

- Preservation of cells, tissues, or embryos by cooling them to very low temperatures, usually with protective substances that limit ice-related injury.

Cryosurgery

- Surgery that destroys abnormal tissue by controlled freezing, used in selected skin lesions, tumors, and other conditions.

Cryptitis

- Inflammation of a crypt or small anatomical recess, especially inflammation of the anal glands and crypts.

Crystalluria

- The presence of crystals in urine, which may reflect precipitation of salts, medication effects, metabolic disease, or a tendency to form urinary stones.

C-Section

- Cesarean section, surgical delivery of a fetus through incisions in the abdominal wall and uterus.

Cubitus Valgus

- An abnormal outward angulation of the forearm relative to the upper arm when the elbow is extended.

Cubitus Varus

- An abnormal inward angulation of the forearm relative to the upper arm when the elbow is extended, often developing after a childhood elbow fracture.

Culdocentesis

- Surgical puncture of the posterior vaginal fornix to sample or drain fluid from the rectouterine pouch.

Cumulative Trauma Disorder

- A disorder caused by repeated forceful or awkward movements that progressively injure muscles, tendons, nerves, or other soft tissues.

Curettage

- Removal of tissue from a body cavity or surface with a curette, used for diagnosis, treatment, or removal of abnormal tissue.

Curling's Ulcer

- An acute peptic ulcer associated with severe burns, often occurring in the duodenum or stomach during physiologic stress.

Cushing's Disease

- Hypercortisolism caused specifically by an adrenocorticotrophic-hormone-secreting pituitary adenoma.

Cushing's Syndrome

- The clinical state caused by prolonged excessive exposure to cortisol, from endogenous overproduction or exogenous corticosteroid use.

Cystadenoma

- A usually benign glandular epithelial tumor that forms cystic spaces or cyst-like structures.

Cystostomy

- Surgical creation of an opening from the urinary bladder to the skin or another structure to permit drainage of urine.

Cystourethrography

- Radiographic imaging of the urinary bladder and urethra, usually during filling and voiding after contrast has been introduced.

Cytokine Storm

- A severe, dysregulated systemic inflammatory response involving excessive cytokine release that can cause tissue injury, organ dysfunction, and shock.

Dacryocystorhinostomy

- A surgical procedure creating a passage between the lacrimal sac and the nasal cavity to bypass an obstructed nasolacrimal duct.

Dacryostenosis

- Narrowing or obstruction of the lacrimal drainage passages, which can cause excessive tearing and recurrent infection of the lacrimal sac.

Dactylosymphysis

- Abnormal fusion or webbing of adjacent digits, usually present from birth.

Daltonism

- Color-vision deficiency, especially difficulty distinguishing certain colors because of abnormal or absent retinal cone function.

D and C

- Dilation and curettage, a procedure in which the cervix is dilated and tissue is removed from the uterine cavity for diagnosis, treatment, or management of pregnancy-related conditions.

Dandruff

- Scaling and shedding of the scalp skin, commonly associated with seborrheic dermatitis or dry skin.

Dandy Fever

- Dengue fever, an acute mosquito-borne viral illness causing fever, headache, severe muscle or joint pain, and sometimes hemorrhage or shock.

Dane Particle

- The complete infectious particle of hepatitis B virus, consisting of the viral core and envelope.

Darier's Disease

- An inherited skin disorder characterized by abnormal keratinization, greasy crusted papules, and nail changes, often worsened by heat and sweating.

Dark Adaptation

- The process by which the eyes become increasingly sensitive to dim light after moving from bright illumination into darkness.

Dartos

- A layer of smooth muscle and connective tissue beneath the skin of the scrotum that wrinkles the scrotal skin in response to temperature and other stimuli.

Darwin's Tubercle

- A variable small thickening or projection on the rim of the external ear, regarded as a remnant of an ancestral mammalian ear form.

Daubenton's Plane

- An anatomical reference plane extending from the lower margin of the orbit to the upper margin of the external auditory opening, used in describing skull orientation.

D and E

- Dilation and evacuation, a surgical procedure in which the cervix is dilated and uterine contents are removed by suction and instruments.

Deafferentation

- Loss or interruption of sensory nerve input from a body region to the central nervous system, which may produce abnormal sensation or deafferentation pain.

Decerebration

- Severe loss of cerebral function, often with extension and rigid posturing of the limbs from brainstem dysfunction; it may result from major injury or increased intracranial pressure.

Deciduitis

- Inflammation of the decidua, the specialized uterine lining of pregnancy.

Deciduosis

- The presence of extensive or ectopic decidual tissue, usually associated with pregnancy and sometimes involving the cervix, peritoneum, or other sites.
- ### Decompensation

Decompensation is deterioration of a previously compensated physiologic state, especially when an organ or body system can no longer maintain adequate function.

Decompression Illness

Decompression illness is an umbrella term for illness caused by a reduction in ambient pressure, including decompression sickness and arterial gas embolism.

Decortication

Decortication is surgical removal of a fibrous or restrictive outer layer, especially a pleural peel, to permit re-expansion of the lung.

Deep Brain Stimulation

Deep brain stimulation is treatment that delivers electrical stimulation through implanted electrodes to selected brain regions for movement disorders and other selected conditions.

Deficiency Anemia

Deficiency anemia is anemia caused by insufficient iron, vitamin B12, folate, or another essential nutrient needed for red-cell production.

Dehiscence

Dehiscence is reopening or separation of a wound, surgical incision, or anatomical structure that had been closed or fused.

Dehydrogenase

Dehydrogenase is an enzyme that catalyzes removal of hydrogen from a substrate, usually transferring the hydrogen or electrons to a coenzyme such as NAD or FAD.

Deiters' Cell

A Deiters' cell is a supporting cell in the organ of Corti that helps support an inner or outer hair cell and contributes to the structural organization of the cochlea.

Deiters' Nucleus

Deiters' nucleus is the lateral vestibular nucleus in the brainstem, which receives vestibular input and contributes to balance, posture, and vestibulospinal reflexes.

Delayed Hypersensitivity

Delayed hypersensitivity is a cell-mediated immune reaction that typically develops hours to days after exposure to an antigen, as in tuberculin reactions and contact dermatitis.

Delta Hepatitis

Delta hepatitis is hepatitis caused by hepatitis D virus, which requires hepatitis B virus for replication and may produce severe acute or chronic liver disease.

Delta Variant

The delta variant is a variant of SARS-CoV-2 associated with increased transmissibility and a distinct epidemiologic phase of the COVID-19 pandemic.

Delta Virus

Delta virus is another name for hepatitis D virus, a defective RNA virus that causes infection only in the presence of hepatitis B virus.

Delta Wave

A delta wave is a high-amplitude, low-frequency brain wave, generally between about 0.5 and 4 hertz, prominent during deep non-REM sleep and sometimes associated with brain dysfunction when present during wakefulness.

Deltoid

The deltoid is the large triangular muscle covering the shoulder, arising from the clavicle and scapula and inserting on the humerus to help abduct, flex, and extend the arm.

Deltoid Ligament

The deltoid ligament is the strong medial ligament complex of the ankle that connects the tibia with the talus, calcaneus, and navicular bones.

Deltoid Tuberosity

The deltoid tuberosity is the roughened area on the lateral shaft of the humerus where the deltoid muscle attaches.

Dementia

Dementia is a syndrome of acquired, persistent decline in cognitive abilities severe enough to interfere with daily functioning, commonly involving memory, language, executive function, or visuospatial skills.

Dementia Paralytica

Dementia paralytica is a historical term for the progressive neuropsychiatric disease caused by

late-stage neurosyphilis, characterized by cognitive decline, psychiatric symptoms, and neurologic impairment.

Dementia Praecox

Dementia praecox is an obsolete historical term formerly used for schizophrenia and related psychotic disorders beginning in adolescence or early adulthood.

Dementia Pugilistica

Dementia pugilistica is a chronic neurodegenerative syndrome associated with repeated head trauma, especially in boxing, with cognitive, behavioral, and motor impairment.

Demilune

A demilune is a crescent-shaped anatomical structure, especially a crescent of serous cells surrounding a mucous acinus in a mixed gland.

Demineralization

Demineralization is loss of mineral, especially calcium phosphate, from bone or tooth enamel, reducing structural strength and potentially causing osteoporosis or dental caries.

Demodicosis

Demodicosis is infestation or inflammatory skin disease caused by excessive proliferation of *Demodex* mites, commonly producing facial follicular or sebaceous lesions.

Demonomania

Demonomania is an obsolete psychiatric term for a delusion that one is possessed or controlled by demons.

Demyelination

Demyelination is destruction or loss of the myelin sheath surrounding nerve fibers, which impairs conduction and occurs in disorders such as multiple sclerosis and some peripheral neuropathies.

Denervation

Denervation is loss or interruption of the nerve supply to a muscle, organ, or tissue, often causing weakness, atrophy, or impaired function.

Dengue Hemorrhagic Fever

Dengue hemorrhagic fever is a severe form of dengue characterized by increased vascular permeability, thrombocytopenia, bleeding, and possible shock.

Densitometry

Densitometry is measurement of the density of a substance or tissue, especially bone mineral density for assessment of osteoporosis and fracture risk.

Dental Arch

A dental arch is the curved arrangement of the teeth and their supporting alveolar bone in the upper or lower jaw.

Dental Artery

A dental artery is an artery supplying a tooth and its supporting structures, including branches that enter the tooth through the apical foramen.

Dental Formula

A dental formula is a notation that records the number and arrangement of each type of tooth in one half of the upper and lower jaws.

Dental Lamina

The dental lamina is a band of epithelial tissue in the developing jaw from which the tooth buds arise.

Dental Nerve

A dental nerve is a nerve branch supplying a tooth, its periodontal tissues, and associated gingiva, usually arising from the trigeminal nerve.

Dental Papilla

The dental papilla is embryonic connective tissue within a developing tooth germ that forms the dentin and dental pulp.

Dental Pulp

Dental pulp is the vascular, lymphatic, and nervous connective tissue occupying the central pulp cavity of a tooth.

Dental Sac

The dental sac is the connective-tissue layer surrounding a developing tooth germ that contributes to the periodontal ligament, cementum, and alveolar bone.

Dentate Gyrus

The dentate gyrus is a narrow, folded region of the hippocampal formation involved in learning, memory, and regulation of neural circuits.

Dentate Ligament

A dentate ligament is one of the toothlike lateral extensions of the pia mater that anchors the spinal cord to the dura mater.

Dentate Nucleus

The dentate nucleus is the largest deep nucleus of the cerebellum and participates in coordination and planning of voluntary movement.

Dentigerous Cyst

A dentigerous cyst is an odontogenic cyst that surrounds the crown of an unerupted tooth and is attached near the tooth's cervical region.

Denudation

Denudation is removal or loss of a covering, such as the epidermis, mucosa, or vascular endothelium, exposing the underlying tissue.

Depressive Disorder

Depressive disorder is a mental disorder characterized by persistent depressed mood or loss of interest with associated cognitive, physical, and functional symptoms.

Dependent Lividity

Dependent lividity is postmortem pooling of blood

in body parts lowest in position, producing purplish discoloration of the skin.

Depersonalization

Depersonalization is a persistent or recurrent feeling of detachment from one's body or mental processes, as though observing oneself from outside.

De Quervain's Disease

De Quervain's disease is painful stenosing tenosynovitis of the first dorsal wrist compartment involving the abductor pollicis longus and extensor pollicis brevis tendons.

Dermabrasion

Dermabrasion is controlled mechanical removal of superficial skin layers to treat scars, irregularities, or selected skin lesions.

Dermatology

Dermatology is the medical specialty concerned with the skin, hair, nails, and associated diseases and disorders.

Dermatome

A dermatome is a strip of skin supplied by sensory fibers from a single spinal nerve root.

Dermatoplasty

Dermatoplasty is plastic or reconstructive surgery of the skin, including repair or replacement of damaged or missing skin.

Deuteranopia

Deuteranopia is red-green color blindness caused by absence or severe dysfunction of the green-sensitive cone photopigment.

Devascularization

Devascularization is loss or surgical interruption of the blood supply to a tissue or organ, potentially causing ischemia or necrosis.

Developmental Disability

Developmental disability is a significant lifelong impairment in intellectual, physical, or adaptive functioning that begins during the developmental period.

Developmental Disorder

Developmental disorder is a condition beginning in childhood that affects physical, cognitive, language, behavioral, or social development.

Devitalization

Devitalization is loss of vitality or viability in a tissue, commonly because of ischemia, infection, trauma, or other injury.

Diabetic

Diabetic describes a person with diabetes or a condition caused by or associated with diabetes mellitus.

Diadochokinesia

Diadochokinesia is the ability to perform rapidly alternating movements, which is impaired in some cerebellar disorders.

Dialysis Dementia

Dialysis dementia is a rare neurologic syndrome formerly associated with long-term dialysis, characterized by progressive cognitive, speech, and motor abnormalities.

Diapedesis

Diapedesis is passage of blood cells, especially leukocytes, through intact vessel walls into surrounding tissue.

Diaphoresis

Diaphoresis is profuse sweating, often associated with fever, exertion, pain, hypoglycemia, shock, or autonomic activation.

Diaphragma Sellae

The diaphragma sellae is a fold of dura mater

forming the roof of the sella turcica and surrounding the stalk of the pituitary gland.

Diarrheal Shellfish Poisoning

Diarrheal shellfish poisoning is an acute gastrointestinal illness caused by eating shellfish contaminated with certain marine toxins, producing diarrhea, nausea, and abdominal pain.

Diarthrosis

A diarthrosis is a freely movable joint, usually a synovial joint, permitting substantial movement between its articulating bones.

Diaschisis

Diaschisis is reduced function in a brain region connected to, but distant from, an area of acute injury such as an infarct.

Diastasis

Diastasis is separation of normally joined anatomical structures, such as separation of the rectus abdominis muscles or widening of a cranial suture.

Diastema

A diastema is an abnormal space or gap between two adjacent teeth or other normally apposed structures.

Diastematomyelia

Diastematomyelia is a congenital spinal cord malformation in which the cord is split longitudinally, often by a bony or fibrous septum.

Diastolic Blood Pressure

Diastolic blood pressure is the arterial pressure during ventricular relaxation and filling, represented by the lower number in a blood-pressure reading.

Diastrophic Dwarfism

Diastrophic dwarfism is an inherited skeletal dysplasia characterized by short stature, shortened limbs, joint contractures, deformities of the hands and feet, and abnormal spine development.

Diathesis

Diathesis is an inherent or acquired predisposition to develop a particular disease, symptom, or abnormal response.

Dietl's Crisis

Dietl's crisis is intermittent acute abdominal or flank pain, often with nausea and vomiting, caused by episodic obstruction associated with a mobile or abnormally positioned kidney.

Dietotherapy

Dietotherapy is treatment or management of disease through a planned diet, including modification of nutrients, calories, consistency, or food composition.

Differential Blood Count

A differential blood count is a laboratory determination of the relative and absolute numbers of the different types of white blood cells in a blood sample.

Differential Cell Count

A differential cell count is a laboratory count that identifies and quantifies the different cell types in a specimen, such as blood, bone marrow, or a body fluid.

DiGeorge's Syndrome

DiGeorge's syndrome is a congenital disorder usually caused by deletion of part of chromosome 22, with variable thymic hypoplasia, parathyroid deficiency, heart defects, and characteristic facial features.

Digestive System

The digestive system consists of the gastrointestinal tract and associated organs that ingest, digest, absorb, and process nutrients and eliminate waste.

Digestive Tract

The digestive tract is the continuous muscular tube from the mouth through the pharynx, esophagus, stomach, intestines, and anus.

Digastric Muscle

The digastric muscle is a two-bellied muscle beneath the mandible that helps depress the mandible and elevate the hyoid during swallowing.

Digital Nerve

A digital nerve is a nerve supplying a finger or toe, carrying sensory fibers and, in some locations, motor fibers to associated muscles.

Dipsomania

Dipsomania is an obsolete term for an irresistible periodic craving for and uncontrolled consumption of alcohol.

Dipstick

A dipstick is a reagent-impregnated strip used for rapid testing of a specimen, especially urine, for substances such as blood, glucose, protein, or ketones.

Diprosopus

Diprosopus is a rare congenital anomaly in which parts or all of the face are duplicated, usually in association with severe abnormalities of forebrain development.

Dismutase

Dismutase is an enzyme that catalyzes a reaction in which identical molecules are simultaneously oxidized and reduced, as in superoxide dismutase.

Disorientation

Disorientation is loss of awareness of, or inability to identify, one's place, time, identity, or circumstances.

Distal Convoluted Tubule

The distal convoluted tubule is the nephron segment after the loop of Henle that modifies the filtrate through selective reabsorption and secretion before it enters the collecting system.

Distal Radioulnar Joint

The distal radioulnar joint is the synovial joint between the lower radius and ulna that permits rotation of the forearm.

Distension

Distension is stretching or enlargement of an organ, vessel, or other structure caused by increased pressure, volume, or weakening of its wall.

Diver's Palsy

Diver's palsy is neurologic dysfunction caused by decompression, often involving spinal cord or peripheral nerve injury after rapid ascent from depth.

Drepanocytosis

Drepanocytosis is the presence of sickle-shaped red blood cells, especially the inherited disorder associated with hemoglobin S.

Duodenal Gland

A duodenal gland is a submucosal gland of the duodenum that secretes alkaline mucus to protect the intestinal lining and help neutralize gastric acid.

Duodenectomy

Duodenectomy is surgical removal of all or part of the duodenum.

Dysfunction

Dysfunction is abnormal or impaired operation of an organ, tissue, body system, or mental process.

Dysphoria

Dysphoria is a state of marked unease, dissatisfaction, or distress, sometimes occurring as a symptom of a psychiatric or medical condition.

Dysreflexia

Dysreflexia is abnormal or excessive reflex activity, especially autonomic dysreflexia, a potentially dangerous response to stimuli below a spinal-cord

injury.

Dysrhythmia

Dysrhythmia is an abnormal rhythm, especially an abnormal cardiac rhythm.

Dysthymia

Dysthymia is a persistent depressive mood state; the term is now generally associated with persistent depressive disorder.

Dystocia

Dystocia is difficult or abnormal labor caused by factors involving the uterus, birth canal, fetus, or maternal and fetal conditions.

Echogenicity

Echogenicity is the capacity of a tissue or structure to reflect ultrasound waves and produce an echo on an ultrasound image.

Eggshell Nail

An eggshell nail is a thin, fragile, excessively curved nail that may be associated with nutritional deficiency, chronic illness, or other systemic disease.

Electrodiagnosis

Electrodiagnosis is diagnosis of neuromuscular or other disorders using electrical tests such as nerve-conduction studies and electromyography.

Electrooculography

Electrooculography is recording of the electrical potential between the front and back of the eye to measure eye movements and related function.

Elizabethan Collar

An Elizabethan collar is a cone-shaped protective device placed around an animal's or patient's neck to prevent touching or traumatizing an injured area.

Endogenous

Endogenous describes a substance, process, or condition originating within the body or arising

from an internal source.

Entameba

Entameba is a genus of amoeboid protozoa that includes species capable of infecting humans, especially *Entamoeba histolytica*, which causes amebiasis.

Entoptic

Entoptic describes a visual phenomenon arising from structures within the eye, such as visible shadows from retinal vessels or vitreous opacities.

Epicanthal Fold

An epicanthal fold is a fold of skin extending from the upper eyelid over the inner canthus, occurring normally in some populations and in several congenital syndromes.

Epithelioma

An epithelioma is a tumor arising from epithelial tissue; the term has been used for both benign and malignant epithelial growths.

Erythroleukemia

Erythroleukemia is an acute leukemia involving abnormal proliferation of erythroid and myeloid precursor cells in the bone marrow.

Excitotoxicity

Excitotoxicity is neuronal injury or death caused by excessive stimulation of excitatory neurotransmitter receptors, with calcium overload and cellular damage.

Exogastrulation

Exogastrulation is an experimental developmental abnormality in which gastrulation occurs outside the normal embryonic configuration.

Fab Fragment

A Fab fragment is the antigen-binding portion of an immunoglobulin molecule produced by enzymatic cleavage and containing a light chain paired with part of a heavy chain.

Facetectomy

Facetectomy is surgical removal of part or all of a vertebral facet joint, usually to decompress a nerve root or enlarge the spinal canal.

Facial Artery

The facial artery is a branch of the external carotid artery that supplies much of the face and terminates near the medial angle of the eye.

Facial Canal

The facial canal is the passage through the temporal bone containing the facial nerve as it travels from the internal auditory canal to the stylomastoid foramen.

Facial Colliculus

The facial colliculus is an elevation in the floor of the fourth ventricle formed by fibers of the facial nerve looping around the abducens nucleus.

Facial Nerve

The facial nerve is the seventh cranial nerve, carrying motor fibers to muscles of facial expression and parasympathetic and taste fibers from selected regions.

Facial Vein

The facial vein drains blood from the face and communicates with deeper venous channels, including routes that can transmit infection toward the cavernous sinus.

Faecalith

A faecalith is a hard mass of fecal material, especially one obstructing the appendix or another part of the intestine.

Facies Hippocratica

Facies Hippocratica is the characteristic sunken facial appearance historically associated with severe illness or impending death, including hollow eyes and pinched features.

Fetal Hemoglobin

Fetal hemoglobin is the predominant hemoglobin of the fetus, composed of two alpha and two gamma chains and having high affinity for oxygen.

Fetal Hydrops

Fetal hydrops is abnormal accumulation of fluid in at least two fetal compartments, such as the skin, pleural or pericardial spaces, or abdomen.

Fibrocystic Disease of the Pancreas

Fibrocystic disease of the pancreas is cystic fibrosis, an inherited disorder in which abnormal secretions obstruct exocrine ducts and cause pancreatic and multisystem disease.

Fibrodysplasia Ossificans Progressiva

Fibrodysplasia ossificans progressiva is a rare inherited disorder in which soft tissues progressively ossify, causing disabling extra-skeletal bone formation and joint restriction.

Fibular Collateral Ligament

The fibular collateral ligament is a strong lateral ligament of the knee extending from the lateral femoral epicondyle to the head of the fibula.

Filaria

Filaria is a threadlike parasitic nematode, especially one that causes filariasis in humans or other animals.

Gartner's Duct

Gartner's duct is a remnant of the mesonephric duct that may persist in the female genital tract and form a vaginal or cervical cyst.

Gasserian Ganglion

The Gasserian ganglion is the sensory ganglion of the trigeminal nerve, located in a dural recess near the apex of the petrous temporal bone.

Gastric Artery

A gastric artery is an artery supplying the stomach, including the left and right gastric arteries and branches from the gastroepiploic vessels.

Gastric Banding

Gastric banding is a bariatric procedure in which an adjustable band creates a small upper stomach pouch to restrict food intake.

Gastric Gland

A gastric gland is a gland in the stomach lining that secretes substances such as acid, pepsinogen, mucus, or hormones involved in digestion.

Gastrocolic Reflex

The gastrocolic reflex is increased motility of the colon after food enters the stomach, often contributing to the urge to defecate after a meal.

Gastroduodenal Artery

The gastroduodenal artery is a branch of the common hepatic artery that supplies parts of the stomach and duodenum and gives rise to the right gastroepiploic artery.

Gastroduodenitis

Gastroduodenitis is inflammation of the lining of the stomach and duodenum.

Gastroesophageal Reflux Disease

Gastroesophageal reflux disease is recurrent reflux of stomach contents into the esophagus causing troublesome symptoms or complications such as esophagitis.

Gastrointestinal Tract

The gastrointestinal tract is the continuous digestive tube from the mouth through the pharynx, esophagus, stomach, small and large intestines, and anus.

Gastrojejunostomy

Gastrojejunostomy is surgical creation of an

opening between the stomach and jejunum to provide passage for food or bypass an obstruction.

Gastropathy

Gastropathy is a disease or abnormal condition of the stomach, often characterized by mucosal injury without the inflammatory findings of gastritis.

Gastropexy

Gastropexy is surgical fixation of the stomach to the abdominal wall or another supporting structure.

Gastroplasty

Gastroplasty is reconstructive surgery of the stomach, including procedures that reduce stomach capacity for treatment of severe obesity.

Gastroptosis

Gastroptosis is downward displacement or prolapse of the stomach.

Gastroscopy

Gastroscopy is visual examination of the stomach with a gastroscope, usually performed as part of upper gastrointestinal endoscopy.

Geniculate Body

A geniculate body is one of two sensory relay nuclei of the thalamus: the lateral geniculate body for vision and medial geniculate body for hearing.

Geniculate Ganglion

The geniculate ganglion is the sensory ganglion of the facial nerve located in the facial canal.

Genioglossus

The genioglossus is a fan-shaped muscle of the tongue that protrudes and depresses the tongue and helps maintain the upper airway.

Geniohyoid

The geniohyoid is a muscle extending from the mandible to the hyoid bone that helps elevate the hyoid and floor of the mouth.

Genitourinary System

The genitourinary system comprises the urinary organs and reproductive organs, which share developmental and anatomical relationships.

Genodermatosis

Genodermatosis is an inherited disorder primarily affecting the skin and often associated with abnormalities in other organs.

GERD

GERD is the abbreviation for gastroesophageal reflux disease, recurrent reflux of gastric contents into the esophagus causing symptoms or complications.

German Measles

German measles is rubella, an infectious viral disease that commonly causes fever and rash and can produce severe congenital abnormalities when acquired during pregnancy.

Germ Cell

A germ cell is a reproductive cell, such as an ovum or sperm, that carries genetic material to the next generation.

Germ Center

A germ center is a specialized region of a lymphoid follicle where activated B lymphocytes proliferate, mutate, and undergo selection during an immune response.

Giantism

Giantism is excessive growth and unusually large stature caused by excess growth hormone before closure of the epiphyseal growth plates.

Heat Shock Protein

A heat shock protein is a protein produced or increased in response to cellular stress that helps other proteins fold, stabilize, or recover from damage.

Hemangiomas

Hemangiomas is a condition characterized by multiple hemangiomas involving the skin, soft tissues, or internal organs.

Hemiglossectomy

Hemiglossectomy is surgical removal of one side or a substantial half of the tongue, usually for treatment of a tumor or severe lesion.

Herpetophobia

Herpetophobia is an excessive or irrational fear of reptiles or crawling animals, classified as a specific phobia when it causes significant distress or impairment.

Heterophile

Heterophile describes an antibody that reacts with antigens from unrelated species or cells; heterophile antibodies are used in some diagnostic tests.

High-Pressure Liquid Chromatography

High-pressure liquid chromatography is a laboratory technique that separates, identifies, and quantifies substances in a liquid sample under high pressure.

Hodgkin's Lymphoma

Hodgkin's lymphoma is a malignant lymphoma characterized by Hodgkin and Reed–Sternberg cells in an appropriate inflammatory background.

Hughes Syndrome

Hughes syndrome is antiphospholipid syndrome, an autoimmune disorder characterized by thrombosis or pregnancy morbidity associated with antiphospholipid antibodies.

Hydrocelectomy

Hydrocelectomy is surgical removal or repair of a hydrocele, a fluid collection around a testis or along the spermatic cord.

Hypergammaglobulinemia

Hypergammaglobulinemia is an abnormally increased concentration of gamma globulins, usually reflecting increased immunoglobulins from immune stimulation or a plasma-cell disorder.

Hypermagnesemia

Hypermagnesemia is an abnormally high concentration of magnesium in the blood, which can cause weakness, hypotension, depressed reflexes, and cardiac or respiratory impairment.

Hypouricemia

Hypouricemia is an abnormally low concentration of uric acid in the blood.

Beta-2 Microglobulin

Beta-2 microglobulin is a small protein associated with class I major histocompatibility complex molecules and used clinically as a marker of immune activity and some hematologic or renal disorders.

Immunodeficient

Immunodeficient describes a person or organism whose immune response is reduced or defective, increasing susceptibility to infection or certain malignancies.

Immunoprecipitate

An immunoprecipitate is a complex of antigen and antibody that is precipitated from solution, or the material obtained by that immunologic separation.

Infant

An infant is a child in the first period after birth, especially during the first year of life.

Inferior Rectal Artery

The inferior rectal artery is a branch of the internal pudendal artery that supplies the lower rectum, anal canal, and surrounding tissues.

Infraspinatus

The infraspinatus is a rotator-cuff muscle occupying

the infraspinous fossa of the scapula and producing lateral rotation of the arm.

Intraventricular

Intraventricular describes a location or process within a ventricle, especially a ventricle of the brain or the heart.

Iron-Deficiency Anemia

Iron-deficiency anemia is anemia caused by insufficient iron for hemoglobin synthesis, commonly resulting from blood loss, inadequate intake, or impaired absorption.

Isoagglutination

Isoagglutination is agglutination of red blood cells by antibodies from another individual of the same species, as in an incompatible blood transfusion.

Isoagglutinin

An isoagglutinin is an antibody that agglutinates cells from another individual of the same species, especially naturally occurring blood-group antibodies.

Isomerism

Isomerism is the condition in which compounds or structures have the same composition but different arrangement of their atoms or parts.

Isthmus of the Fauces

The isthmus of the fauces is the opening between the oral cavity and the pharynx, bounded by the soft palate, tongue, and palatoglossal arches.

Jacksonian Epilepsy

Jacksonian epilepsy is focal epilepsy in which a seizure begins in a localized motor or sensory area and spreads progressively along the corresponding cortical representation.

Jacobson's Cartilage

Jacobson's cartilage is a small cartilage associated with the nasal septum and vomeronasal region.

Jacobson's Nerve

Jacobson's nerve is the tympanic branch of the glossopharyngeal nerve, which supplies sensation to the middle ear and contributes to the lesser petrosal nerve.

Jacobson's Organ

Jacobson's organ is the vomeronasal organ, a chemosensory structure in the nasal septum that is well developed in many animals and vestigial or variable in humans.

Jaffé Reaction

The Jaffé reaction is a colorimetric laboratory reaction used to measure creatinine, historically involving reaction with alkaline picrate.

Jail Fever

Jail fever is an older name for epidemic typhus, an infection caused by *Rickettsia prowazekii* and transmitted primarily by body lice.

Jake Leg

Jake leg is a historical neurologic syndrome of weakness or paralysis caused by poisoning with adulterated alcohol containing organophosphorus compounds.

Jakob-Creutzfeldt Disease

Jakob-Creutzfeldt disease is a historical name for Creutzfeldt–Jakob disease, a rapidly progressive prion-related neurodegenerative disorder.

Jarisch-Herxheimer Reaction

The Jarisch–Herxheimer reaction is a transient systemic reaction with fever, chills, and worsening symptoms after antimicrobial treatment of certain spirochetal infections.

Jejunitis

Jejunitis is inflammation of the jejunum.

Jock Itch

Jock itch is *tinea cruris*, a superficial dermatophyte

infection of the groin and adjacent skin.

Johne's Disease

Johne's disease is chronic intestinal infection caused by *Mycobacterium avium* subspecies *paratuberculosis*, primarily affecting ruminants and occasionally relevant to veterinary or zoonotic medicine.

Joint Capsule

A joint capsule is the connective-tissue envelope surrounding a synovial joint, enclosing the joint cavity and helping stabilize the articulating bones.

Joint Fluid

Joint fluid is synovial fluid within a synovial joint that lubricates articular surfaces and helps nourish cartilage.

Jumper's Knee

Jumper's knee is patellar tendinopathy, an overuse disorder causing pain and degeneration at the patellar tendon, commonly near its attachment to the patella.

Junctional Tachycardia

Junctional tachycardia is a rapid cardiac rhythm arising from the atrioventricular junction rather than the sinoatrial node.

Junctional Epidermolysis Bullosa

Junctional epidermolysis bullosa is an inherited blistering disorder caused by defective adhesion within the basement membrane zone of the skin and mucous membranes.

Juvenile Myoclonic Epilepsy

Juvenile myoclonic epilepsy is a generalized epilepsy syndrome beginning in adolescence, characterized especially by myoclonic jerks and often generalized tonic–clonic seizures.

Juxtaglomerular Cell

A juxtaglomerular cell is a modified smooth-muscle cell in the wall of an afferent arteriole that secretes renin and helps regulate blood pressure and renal

perfusion.

Juxtarestiform Body

The juxtarestiform body is a part of the inferior cerebellar peduncle connecting vestibular and spinal pathways with the cerebellum.

Kala-Azar

Kala-azar is visceral leishmaniasis, a systemic infection caused by *Leishmania* parasites and characterized by prolonged fever, splenomegaly, anemia, and other reticuloendothelial involvement.

Kallmann's Syndrome

Kallmann's syndrome is congenital hypogonadotropic hypogonadism associated with deficient or absent sense of smell due to abnormal development of gonadotropin-releasing hormone neurons and olfactory structures.

Kaposi's Sarcoma

Kaposi's sarcoma is a vascular neoplasm associated with human herpesvirus 8, producing lesions of the skin, mucosa, lymph nodes, or internal organs.

Kartagener's Syndrome

Kartagener's syndrome is a form of primary ciliary dyskinesia characterized by bronchiectasis, chronic sinusitis, and situs inversus.

Kayser-Fleischer Ring

A Kayser-Fleischer ring is a brown or greenish ring of copper deposition at the periphery of the cornea, classically associated with Wilson disease.

Kegel Exercises

Kegel exercises are repeated contractions of the pelvic-floor muscles used to improve pelvic support and help treat urinary or fecal incontinence.

Kennedy Disease

Kennedy disease is an X-linked degenerative motor-neuron disorder caused by androgen-receptor mutation, producing progressive weakness, muscle atrophy, fasciculations, and endocrine abnormali-

ties.

Keratectomy

Keratectomy is surgical removal of part of the cornea.

Ketoacidosis

Ketoacidosis is metabolic acidosis caused by accumulation of ketone bodies, most commonly in diabetic ketoacidosis or severe starvation.

Ketonuria

Ketonuria is the presence of ketone bodies in the urine.

Kienböck's Disease

Kienböck's disease is avascular necrosis of the lunate bone of the wrist, causing pain, stiffness, and progressive carpal collapse.

Kinaesthesia

Kinaesthesia is the sensory awareness of movement and position of the body or its parts.

Kinase

A kinase is an enzyme that transfers a phosphate group, usually from ATP, to a substrate such as a protein, lipid, or carbohydrate.

Kindling

Kindling is progressive intensification of a seizure or other neural response after repeated initially subthreshold stimulation.

Lagophthalmos

Lagophthalmos is inability to close the eyelids completely, potentially causing exposure, drying, and injury of the cornea.

LAK Cell

A LAK cell is a lymphokine-activated killer cell, a cytotoxic lymphocyte generated in vitro that can destroy some tumor cells without the specificity of conventional antigen-directed immunity.

Lallation

Lallation is speech characterized by repeated or excessive use of the syllable “la,” historically described in some language disorders.

Lambert-Eaton Syndrome

Lambert-Eaton syndrome is an autoimmune disorder of the neuromuscular junction causing proximal muscle weakness, reduced reflexes, and autonomic symptoms, often associated with small-cell lung cancer.

Lamellar Ichthyosis

Lamellar ichthyosis is an inherited disorder of cornification characterized by generalized scaling and thickened plates of skin.

Lamina Cribrosa

The lamina cribrosa is a sieve-like portion of the sclera through which the optic-nerve fibers and central retinal vessels pass.

Lamina Dura

The lamina dura is the radiopaque compact bone lining the tooth socket and forming the inner wall of the alveolar process.

Laminitis

Laminitis is inflammation and structural failure of the laminae supporting the hoof or claw, especially in horses and other large animals.

Lancefield Group

A Lancefield group is a serologic classification of certain streptococci based on specific carbohydrate antigens in their cell walls.

Landolt Ring

A Landolt ring is a standardized visual-acuity test figure consisting of a ring with a gap whose position the examinee identifies.

Landry’s Paralysis

Landry’s paralysis is an older name for rapidly progressive ascending paralysis, classically associated with Guillain–Barré syndrome.

Langerhans Cell

A Langerhans cell is an antigen-presenting dendritic cell of the epidermis and other stratified epithelia.

Large-Cell Carcinoma

Large-cell carcinoma is a poorly differentiated malignant epithelial tumor of the lung composed of large atypical cells lacking the features of small-cell or glandular and squamous differentiation.

Larsen’s Syndrome

Larsen’s syndrome is a congenital connective-tissue disorder characterized by multiple joint dislocations, distinctive facial features, and skeletal abnormalities.

Larva Migrans

Larva migrans is a condition caused by migration of immature nematode larvae through human tissues, producing cutaneous or visceral disease.

Laryngopharyngitis

Laryngopharyngitis is inflammation involving the larynx and pharynx.

Laryngoplasty

Laryngoplasty is reconstructive or corrective surgery of the larynx.

Laryngotracheitis

Laryngotracheitis is inflammation of the larynx and trachea, commonly producing hoarseness, cough, and sometimes airway obstruction.

Lassitude

Lassitude is a state of weariness, weakness, or lack of energy.

Lateral Epicondylitis

Lateral epicondylitis is pain and degenerative tendinopathy at the lateral epicondyle of the elbow, commonly called tennis elbow.

Lateral Femoral Cutaneous Nerve

The lateral femoral cutaneous nerve supplies sensation to the skin of the anterolateral thigh and may be compressed in meralgia paresthetica.

Lateral Geniculate Nucleus

The lateral geniculate nucleus is a thalamic relay nucleus that receives visual information from the retina and projects to the visual cortex.

Lateral Meniscus

The lateral meniscus is the crescent-shaped fibrocartilage on the lateral side of the knee that distributes load and contributes to joint stability.

Malunion

Malunion is healing of a fractured bone in an abnormal position, potentially causing deformity, pain, or impaired function.

Pituitary Gland

The pituitary gland is an endocrine organ at the base of the brain that secretes hormones regulating growth, reproduction, thyroid function, adrenal function, and water balance.

Maturation Factor

A maturation factor is a substance that promotes or regulates maturation of a cell, tissue, or organism; in cell biology the term may refer to factors controlling meiotic or cellular maturation.

Medial Pterygoid Nerve

The medial pterygoid nerve is a branch of the mandibular division of the trigeminal nerve that supplies the medial pterygoid muscle and related small muscles.

Meningococcus

Meningococcus is *Neisseria meningitidis*, a bacterium that can cause meningitis, meningococemia, pneumonia, and other invasive disease.

Meningocele

A meningocele is a protrusion of the meninges through a defect in the skull or vertebral column, containing cerebrospinal fluid and meninges but not usually neural tissue.

Mesenchymoma

A mesenchymoma is a tumor containing more than one type of mesenchymal tissue, such as combinations of cartilage, bone, fat, or fibrous tissue.

Mesolimbic

Mesolimbic describes the neural pathway connecting the midbrain ventral tegmental area with limbic structures and involved in motivation, reward, and psychosis.

Metarteriole

A metarteriole is a small vessel connecting an arteriole with a capillary bed and contributing to regulation of blood flow into the capillaries.

Microangiopathy

Microangiopathy is disease of small blood vessels, often involving endothelial injury, thickening, thrombosis, or impaired tissue perfusion.

Microelectrode

A microelectrode is a very small electrode used to record electrical activity from or deliver current to individual cells, tissues, or small regions.

Miner's Asthma

Miner's asthma is an occupational asthma caused or aggravated by inhalation of dusts or other airborne substances encountered in mining.

Miner's Consumption

Miner's consumption is an older term for pulmonary tuberculosis associated historically with miners and other workers exposed to dust and crowded conditions.

Monochorionic

Monochorionic describes twins or a twin pregnancy sharing a single chorion and usually a single placenta.

Morbillivirus

Morbillivirus is a genus of viruses in the family Paramyxoviridae that includes measles virus and related pathogens causing serious disease in humans or animals.

Musculospiral Nerve

The musculospiral nerve is the radial nerve, the major nerve of the posterior arm and forearm that supplies extensor muscles and sensation to parts of the upper limb.

Mycobacterium Avium-Intracellulare Complex

Mycobacterium avium-intracellulare complex is a group of nontuberculous mycobacteria that can cause pulmonary or disseminated infection, especially in immunocompromised persons.

Myofibroblast

A myofibroblast is a contractile fibroblast-like cell that contributes to wound contraction, tissue repair, and fibrosis.

Musculoskeletal

Musculoskeletal describes the bones, joints, muscles, tendons, ligaments, and related connective tissues, or conditions affecting those structures.

Necropermia

Necropermia is the presence of predominantly or completely nonviable spermatozoa in semen.

Necrotizing Ulcerative Gingivitis

Necrotizing ulcerative gingivitis is an acute painful infection of the gingiva characterized by necrosis, ulceration, bleeding, and foul odor.

Necrotizing Vasculitis

Necrotizing vasculitis is inflammation of blood-vessel walls causing tissue necrosis and potentially ischemia, hemorrhage, or organ injury.

Necrotomy

Necrotomy is an incision into dead tissue or a dead body, especially an incision made during a postmortem examination.

Neisseria

Neisseria is a genus of gram-negative bacteria that includes *Neisseria meningitidis* and *Neisseria gonorrhoeae*, important human pathogens.

Neisseriaceae

Neisseriaceae is the bacterial family containing *Neisseria* and related gram-negative genera.

Neocortex

The neocortex is the multilayered outer portion of the cerebral hemispheres involved in perception, language, cognition, and voluntary movement.

Nephroptosis

Nephroptosis is abnormal downward displacement of a kidney, especially when the person changes from lying to standing.

Nephrosclerosis

Nephrosclerosis is hardening and scarring of the small renal arteries and arterioles, commonly associated with chronic hypertension.

Nerve Block

A nerve block is injection or application of an anesthetic or other agent near a nerve or nerve plexus to interrupt sensation or nerve conduction.

Nerve Deafness

Nerve deafness is hearing loss caused by damage to the cochlea, auditory nerve, or central auditory pathways, rather than by obstruction of sound transmission in the outer or middle ear.

Nerve Growth Factor

Nerve growth factor is a neurotrophin that supports the growth, survival, and maintenance of selected sensory and sympathetic neurons.

Nervous System

The nervous system consists of the brain, spinal cord, peripheral nerves, and associated structures that coordinate sensation, movement, regulation, and cognition.

Neural Crest

The neural crest is a transient embryonic cell population that migrates from the developing neural tube and forms diverse tissues, including peripheral nerves, pigment cells, and craniofacial structures.

Neural Tube

The neural tube is the embryonic structure that develops into the brain and spinal cord.

Neural Tube Defect

A neural tube defect is a congenital malformation caused by incomplete closure or abnormal development of the embryonic neural tube, as in spina bifida or anencephaly.

Neurapraxia

Neurapraxia is a temporary conduction block in a peripheral nerve without axonal disruption, usually recovering spontaneously.

Neurasthenia

Neurasthenia is a historical diagnostic term for persistent fatigue, weakness, headache, and irritability, sometimes associated with exertion or emotional stress.

Neurectomy

Neurectomy is surgical excision or division of part of a nerve.

Neurilemmoma

A neurilemmoma is a usually benign tumor arising from Schwann cells of a peripheral nerve, also called a schwannoma.

Neuritis

Neuritis is inflammation of a nerve, often causing pain, sensory disturbance, weakness, or impaired nerve conduction.

Neurocardiogenic Syncope

Neurocardiogenic syncope is transient loss of consciousness caused by an abnormal reflex leading to reduced heart rate, vasodilation, and cerebral hypoperfusion.

Oat Cell Carcinoma

Oat cell carcinoma is small-cell carcinoma, a highly malignant neuroendocrine carcinoma composed of small cells with scant cytoplasm, most commonly arising in the lung.

Obex

The obex is the lower apex of the fourth ventricle where it narrows into the central canal of the spinal cord.

Objective Vertigo

Objective vertigo is the sensation that the surroundings are moving or rotating around the person, rather than that the person is moving.

Obliterating Endarteritis

Obliterating endarteritis is inflammation and progressive occlusion of the inner lining of an artery, impairing blood flow to the supplied tissue.

Obnubilation

Obnubilation is clouding or dulling of consciousness with reduced alertness and impaired clarity of

thought.

Obstipation

Obstipation is severe constipation with inability to pass stool or flatus, often indicating intestinal obstruction.

Obtundation

Obtundation is a state of reduced alertness and slowed responses, in which the person can be aroused but quickly becomes drowsy again.

Obturator Nerve

The obturator nerve is a branch of the lumbar plexus that supplies the adductor muscles of the thigh and sensation to part of the medial thigh.

Occipital Artery

The occipital artery is a branch of the external carotid artery that supplies the posterior scalp and parts of the upper neck.

Occupational Disease

An occupational disease is an illness caused or materially contributed to by conditions or exposures associated with a person's work.

Oculogyric Crisis

An oculogyric crisis is a sustained involuntary upward deviation of the eyes, usually caused by a neurologic disorder or a medication-related dystonic reaction.

Oculomotor Nerve

The oculomotor nerve is the third cranial nerve, supplying most muscles that move the eye, the levator of the upper eyelid, and parasympathetic fibers to the pupil and lens.

Oddi's Sphincter

Oddi's sphincter is the muscular sphincter controlling the flow of bile and pancreatic juice into the duodenum.

Odontalgia

Odontalgia is toothache or pain arising from a tooth or its supporting tissues.

Odontoblast

An odontoblast is a cell lining the dental pulp that produces dentin.

Oesophagectomy

Oesophagectomy is surgical removal of part or all of the esophagus, usually for cancer or severe structural disease.

Oesophagoscopy

Oesophagoscopy is visual examination of the esophagus with an endoscope.

Oesophagus

The oesophagus, or esophagus, is the muscular tube carrying swallowed material from the pharynx to the stomach.

Fatigue

– A persistent feeling of tiredness, exhaustion, or lack of energy that is not fully relieved by rest. It may result from sleep disturbance, anemia, infection, endocrine disease, chronic organ disease, medication exposure, or psychological and neurological conditions.

Appendix A

Abbreviations

This appendix lists commonly used medical abbreviations appearing in clinical practice and in this dictionary. Abbreviations can have different meanings in different specialties; the expansions below are the meanings intended in this work. Medicine and drug names are excluded from this appendix.

ACE	Angiotensin-converting enzyme	CNS	Central nervous system
ACTH	Adrenocorticotrophic hormone	COPD	Chronic obstructive pulmonary disease
ADH	Antidiuretic hormone	COX	Cyclo-oxygenase
AFB	Acid-fast bacillus	CRP	C-reactive protein
AHR	Airway hyper-reactivity	CSF	Cerebrospinal fluid
AIDS	Acquired immunodeficiency syndrome	CT	Computed tomography
ALT	Alanine aminotransferase	CTPA	Computed tomography pulmonary angiography
ANA	Antinuclear antibody	CURB-65	Confusion, urea, respiratory rate, blood pressure, and age 65 years or older
APACHE-II	Acute Physiology and Chronic Health Evaluation II	DHEAS	Dehydroepiandrosterone sulphate
APC	Adenomatous polyposis coli	DIP	Distal interphalangeal joint
AST	Aspartate aminotransferase	DKA	Diabetic ketoacidosis
ATP	Adenosine triphosphate	DMARDs	Disease-modifying antirheumatic drugs
AV node	Atrioventricular node	DNA	Deoxyribonucleic acid
BCR-ABL	Fusion gene formed from the BCR and ABL genes	DVT	Deep venous thrombosis
BG	Blood glucose	DXA	Dual-energy X-ray absorptiometry
BMD	Bone mineral density	EBV	Epstein–Barr virus
BMI	Body mass index	ECG	Electrocardiogram
BNP	B-type natriuretic peptide	ECL	Enterochromaffin-like cells
BPPV	Benign paroxysmal positional vertigo	ELISA	Enzyme-linked immunosorbent assay
CAP	Community-acquired pneumonia	ELISpot	Enzyme-linked immunospot
CEA	Carcinoembryonic antigen	EMG	Electromyogram
CFU	Colony-forming unit	eNOS	Endothelial nitric oxide synthase
CK-MB	Creatine kinase myocardial band	ERCP	Endoscopic retrograde cholangiopancreatography
CML	Chronic myeloid leukaemia	ESR	Erythrocyte sedimentation rate
CMV	Cytomegalovirus	ESRD	End-stage renal disease
		FEV1	Forced expiratory volume in one second
		FRAX	Fracture Risk Assessment Tool
		FVC	Forced vital capacity
		G6PD	Glucose-6-phosphate dehydrogenase
		GABA	Gamma-aminobutyric acid

GGT Gamma-glutamyl transferase	MRI Magnetic resonance imaging
GH Growth hormone	MuSK Muscle-specific tyrosine kinase
GnRH Gonadotrophin-releasing hormone	NADPH Reduced nicotinamide adenine dinucleotide phosphate
GP Globus pallidus	NICE National Institute for Health and Care Excellence
GTP Guanosine triphosphate	NLRP3 NLRP3 inflammasome component
Hb Haemoglobin	OPG Osteoprotegerin
HbA1c Glycated haemoglobin	OS Opening snap
HBsAg Hepatitis B surface antigen	PAS Periodic acid–Schiff
HBV Hepatitis B virus	PCR Polymerase chain reaction
HCV Hepatitis C virus	PCV Packed cell volume
HDL High-density lipoprotein	PDGFR Platelet-derived growth factor receptor
HIV Human immunodeficiency virus	PE Pulmonary embolism
HLA Human leukocyte antigen	PEF Peak expiratory flow
hs-cTnT High-sensitivity cardiac troponin T	PET Positron emission tomography
IBD Inflammatory bowel disease	PIP Proximal interphalangeal joint
IBS Irritable bowel syndrome	PLA2R Phospholipase A2 receptor
IBS-C Constipation-predominant irritable bowel syndrome	PTH Parathyroid hormone
IBS-D Diarrhoea-predominant irritable bowel syndrome	RA Right atrium
IBS-M Mixed bowel-pattern irritable bowel syndrome	RANKL Receptor activator of nuclear factor kappa-B ligand
IBS-U Unclassified irritable bowel syndrome	RBC Red blood cell
Ig Immunoglobulin	RF Rheumatoid factor
IL Interleukin	RNA Ribonucleic acid
INR International normalised ratio	RV Right ventricle
ITP Immune thrombocytopenic purpura	SAH Subarachnoid haemorrhage
JVP Jugular venous pressure	SaO2 Arterial oxygen saturation
LA Left atrium	SARS-CoV-2 Severe acute respiratory syndrome coronavirus 2
LAP Leukocyte alkaline phosphatase	SIADH Syndrome of inappropriate antidiuretic hormone secretion
LDH Lactate dehydrogenase	SLE Systemic lupus erythematosus
LDL Low-density lipoprotein	SPEP Serum protein electrophoresis
LV Left ventricle	SSTR2 Somatostatin receptor type 2
MALT Mucosa-associated lymphoid tissue	TIA Transient ischaemic attack
MCHC Mean corpuscular haemoglobin concentration	TIBC Total iron-binding capacity
MCTD Mixed connective tissue disease	TNF Tumour necrosis factor
MCV Mean corpuscular volume	TNM Tumour, nodes, and metastasis staging
MEN Multiple endocrine neoplasia	TPMT Thiopurine methyltransferase
MGUS Monoclonal gammopathy of undetermined significance	TRAb Thyrotrophin receptor antibody
MHC Major histocompatibility complex	TSH Thyroid-stimulating hormone

tTG Tissue transglutaminase
TTP Thrombotic thrombocytopenic purpura
UGI Upper gastrointestinal
UPEP Urine protein electrophoresis
UTI Urinary tract infection
V/Q Ventilation/perfusion
VAP Ventilator-associated pneumonia
WBC White blood cell
WPW Wolff–Parkinson–White

Appendix B

Medical Specialties

This appendix provides a comprehensive reference of medical specialties, their primary focus, and the organ systems or patient populations they serve. Specialties are organized by their primary classification: medical (internal medicine), surgical, diagnostic, and multidisciplinary.

Medical (Internal Medicine) Specialties

Specialty	Primary Focus
Allergy/Immunology	Allergic reactions, asthma
Cardiology	Heart and cardiovascular
Critical Care Medicine	Life support, critically ill
Dermatology	Skin, hair, nails, sweat glands
Emergency Medicine	Acute, emergent medical
Endocrinology	Endocrine glands, hormones
Family Medicine	Comprehensive primary
Gastroenterology	Alimentary tract, liver, gallbladder
Geriatrics	Elderly patients
Hematology	Blood disorders, coagulation
Hepatology	Liver and biliary tract
Hospital Medicine	Inpatient medical care
Infectious Disease	Diseases caused by biological agents
Internal Medicine	Adult internal diseases
Nephrology	Kidney diseases
Neurology	Central, peripheral, autonomic
Obstetrics & Gynecology	Female reproductive health
Oncology	Cancer diagnosis and treatment
Pediatrics	Children's diseases
Physical Medicine & Rehabilitation	Disability, rehabilitation
Psychiatry	Mental health disorders
Public Health	Population health, disease prevention
Pulmonology	Respiratory system diseases
Rheumatology	Autoimmune, musculoskeletal
Toxicology	Poisoning, drug toxicity
Urology	Urinary tract, male reproductive

Surgical Specialties

Specialty	Primary Focus
Anesthesiology	Pain management, sedation
Cardiothoracic Surgery	Heart, lungs, major chest
Colorectal Surgery	Colon, rectum, anus
General Surgery	Abdominal, breast, soft tissue
Hand Surgery	Hand, wrist, forearm conditions
Neurosurgery	Brain, spine, peripheral nerves
Oral/Maxillofacial Surgery	Face, jaw, mouth
Orthopedic Surgery	Musculoskeletal system
Ophthalmology	Eye diseases and surgery
Otolaryngology (ENT)	Ear, nose, throat
Pediatric Surgery	Surgical conditions in children
Plastic Surgery	Reconstructive, aesthetic
Thoracic Surgery	Chest, esophagus, lungs
Vascular Surgery	Blood vessels, circulatory

Multidisciplinary & Subspecialties

Specialty	Primary Focus
Adolescent Medicine	Health issues of teenagers
Basics	Causes, prevention, treatment
Cardiac Electrophysiology	Heart rhythm disorders
Developmental Pediatrics	Child developmental disorders
Gynecologic Oncology	Female reproductive cancers
Hyperbaric Medicine	Oxygen therapy in pressurized
Maternal-Fetal Medicine	High-risk pregnancy
Neonatology	Newborn intensive care
Occupational Medicine	Work-related health
Pain Management	Chronic and acute pain treatment
Perinatology	High-risk pregnancy management
Preventive Medicine	Disease prevention, public health
Reproductive Endocrinology	Infertility, reproductive hormones
Sleep Medicine	Sleep disorders
Sports Medicine	Athletic injuries, exercise

Diagnostic Specialties

Specialty	Primary Focus
Clinical Neurophysiology	Nervous system electrical activity
Forensic Medicine	Medicolegal investigation
Medical Genetics	Genetic disorders, inherited
Pathology	Tissue examination, disease
Radiology	Diagnostic imaging, X-rays, CT, MRI
Nuclear Medicine	Radioactive tracers for diagnosis

Specialties by Organ System

Organ System	Specialty
Brain/Neurological	Neurology, Neurosurgery
Cardiovascular	Cardiology, Cardiothoracic Surgery
Dermatological	Dermatology
Endocrine	Endocrinology
Gastrointestinal	Gastroenterology
Genitourinary	Urology
Hematological	Hematology
Hepatobiliary	Hepatology
Immunological	Allergy/Immunology
Musculoskeletal	Orthopedics, Rheumatology
Nephrological	Nephrology
Ophthalmological	Ophthalmology
Otorhinolaryngological	Otolaryngology
Pulmonary	Pulmonology
Reproductive	Obstetrics & Gynecology

Age-Based Specialties

Age Group	Specialty
All ages	Family Medicine, Emergency Medicine
Children (Pediatric)	Pediatrics, Pediatric Surgery
Adolescents	Adolescent Medicine
Adults	Internal Medicine, Cardiology, etc.
Elderly (Geriatric)	Geriatrics
