ulation territories —non-fluent speech, severely impaired comprehension, and poor repetition. Additional types include conduction aphasia (arcuate fasciculus lesion—fluent speech with impaired repetition but relatively intact comprehension), transcortical motor aphasia (disconnection of supplementary motor area—non-fluent speech with intact repetition), transcortical sensory aphasia (temporoparietal lesion—fluent speech with impaired comprehension but intact repetition), and anomic aphasia (angular gyrus lesion—word-finding difficulty with fluent speech). Diagnosis is through formal language assessment using the Boston Diagnostic Aphasia Examination or the Western Aphasia Battery. Treatment involves speech and language therapy, with compensatory strategies and communication aids for severe cases. Prognosis depends on the size and location of the lesion; Broca aphasia generally has a better recovery than Wernicke or global aphasia.

Apraxia

– Inability to perform learned, skilled motor movements despite intact motor function, sensation, coordination, and comprehension. Types: ideomotor apraxia (inability to perform movements on command, e.g., waving goodbye or using a hammer, due to parietal lobe lesions, typically left hemisphere), ideational apraxia (inability to sequence multi-step tasks, e.g., making a cup of tea, due to frontal or temporal lobe dysfunction), limb-kinetic apraxia (loss of fine motor dexterity, e.g., difficulty with finger tapping, due to premotor cortex lesions), buccofacial/oral apraxia (difficulty performing facial movements on command, e.g., blowing out a candle), and gait apraxia (difficulty initiating walking, common in normal pressure hydrocephalus). Apraxia is most commonly caused by stroke affecting the dominant (left) hemisphere, but can also result from Alzheimer disease, corticobasal degeneration, brain tumors, and traumatic brain injury. Diagnosis is clinical; there is no specific pharmacological treatment. Management: occupational therapy, task-specific training, and compensatory strategies.

Ataxia

– Lack of voluntary coordination of muscle movements, resulting from dysfunction of the cerebellum, posterior columns, or peripheral nerves. Types:

cerebellar (gait and limb ataxia, dysarthria, nystagmus), sensory (impaired proprioception causing sensory ataxia, positive Romberg sign), and vestibular (vertigo, nystagmus, nausea). Cerebellar causes include stroke, tumors, alcohol, medications (phenytoin), degenerative diseases (spinocerebellar ataxias), and multiple sclerosis. Sensory causes include peripheral neuropathy, tabes dorsalis (neurosyphilis), and vitamin B12 deficiency causing posterior column dysfunction. Diagnosis is clinical, supported by neuroimaging (MRI brain for cerebellar causes, MRI spine for spinal causes), nerve conduction studies, and blood tests. Treatment is directed at the underlying cause, with symptomatic management including physical therapy, occupational therapy, and adaptive devices.

Autism Spectrum Disorder

– Neurodevelopmental disorder characterized by persistent deficits in social communication and social interaction across multiple contexts, restricted and repetitive patterns of behavior, interests, or activities. Symptoms present in early developmental period and cause clinically significant impairment. Severity levels: Level 1 (requiring support), Level 2 (requiring substantial support), Level 3 (requiring very substantial support). Associated features include intellectual disability (30-40 percent of cases), seizures, sleep disturbances, and gastrointestinal symptoms. Diagnosis is clinical using DSM-5 criteria, supported by multidisciplinary assessment including developmental history, cognitive testing, and speech and language evaluation. Management involves early intensive behavioural intervention (applied behaviour analysis), speech and language therapy, occupational therapy, social skills training, pharmacological treatment of associated conditions (SSRIs for anxiety, stimulants for inattention, antipsychotics for irritability and aggression), and educational support. Prognosis is highly variable, with early intervention being the most important predictor of functional outcome.

Babinski Sign

– The Babinski sign is a pathological reflex elicited by stroking the lateral aspect of the sole of the foot from the heel to the metatarsal heads with a blunt object. A normal response (flexor plantar response) is plantar flexion (curling downward) of all toes. An

abnormal Babinski sign (extensor plantar response) is dorsiflexion (upgoing) of the great toe with fanning (abduction) of the other toes, indicating an upper motor neuron lesion affecting the corticospinal tract. The Babinski sign is a sign of corticospinal tract dysfunction rather than a specific disease. In infants, an extensor plantar response (upgoing toes) is normal until approximately 12-24 months of age due to incomplete myelination of the corticospinal tract, after which a flexor plantar response becomes established. A persistent Babinski sign beyond this age indicates upper motor neuron pathology and can be caused by stroke, multiple sclerosis, spinal cord injury, traumatic brain injury, cerebral palsy, amyotrophic lateral sclerosis, and other neurodegenerative conditions affecting the corticospinal tract.

Balance

- The ability to maintain the body's center of mass over its base of support, relying on input from the vestibular system, vision, and proprioception. It is essential for walking, standing, and performing daily activities without falling. Age-related decline, medications, and neurological disorders can impair balance, increasing fall risk.

Bell Palsy

- Acute, idiopathic, unilateral facial nerve (CN VII) paralysis of lower motor neuron type, with an incidence of approximately 20-30 per 100,000 person-years. The cause is thought to be herpes simplex virus type 1 reactivation in the geniculate ganglion, leading to inflammation, demyelination, and edema of the facial nerve within the narrow confines of the facial canal (fallopian canal) of the temporal bone. Onset is acute and progressive over hours to days, with maximal weakness reached within 48 hours. Clinical features include acute-onset unilateral facial weakness that involves both the upper and lower face (forehead, eye closure, and mouth), inability to close the eye (lagophthalmos), which can lead to corneal exposure and ulceration, hyperacusis (due to stapedius muscle paralysis), loss of taste in the anterior two-thirds of the tongue (due to chorda tympani nerve involvement), and decreased tearing and salivation. Pain behind the ear is common and may precede the weakness. Diagnosis is clinical, requiring exclusion of other causes of facial paralysis such as stroke (upper motor neuron pat-

tern sparing the forehead), Ramsay Hunt syndrome (herpes zoster oticus), Lyme disease, Guillain-Barre syndrome, otitis media, and parotid tumors. Treatment includes oral corticosteroids (prednisolone 60 mg daily for 7 days with rapid taper) started within 72 hours of symptom onset to improve outcomes, and eye protection with artificial tears, lubricating ointment, and taping the eye closed at night to prevent corneal damage. Antiviral agents (acyclovir or valacyclovir) are added if Ramsay Hunt syndrome is suspected. Prognosis is excellent, with approximately 70 percent of patients achieving near-complete recovery within 3-6 months, 15 percent developing some residual weakness, and 15 percent having moderate-to-severe permanent weakness.

Brain Death

- The irreversible cessation of all brain and brainstem function, including consciousness and brainstem reflexes, with absent respiratory drive—a legal definition of death. Diagnosis requires: (1) known catastrophic cause (structural or anoxic), (2) exclusion of reversible factors (drugs, sedatives, hypothermia, metabolic, neuromuscular blockade), and (3) demonstration of absent brainstem reflexes (pupillary, corneal, oculocephalic, oculovestibular, gag/cough) and absent respiratory drive (apnea test) on two examinations by qualified physicians. Ancillary tests: EEG (no electrocerebral activity), cerebral blood flow studies (no flow), SSEP. Organ donation considerations follow.

Brain Health

- Brain health encompasses the ability to perform cognitive functions such as memory, learning, decision-making, and emotional regulation across the lifespan. Key factors include cardiovascular health, nutrition, sleep, social engagement, cognitive stimulation, and management of chronic conditions like hypertension and diabetes. Protecting brain health reduces the risk of dementia, stroke, and other neurological disorders.

Brain Ventricles

- The four interconnected fluid-filled cavities within the brain that produce and contain cerebrospinal fluid (CSF). The lateral ventricles (first and second, paired, C-shaped, within each cerebral hemisphere, each with anterior/frontal horn, body, atrium, posterior/occipital horn, and temporal/inferior horn)

communicate with the third ventricle via the interventricular foramina (foramina of Monro). The third ventricle (midline, within the diencephalon, between the thalami) communicates with the fourth ventricle via the cerebral aqueduct (aqueduct of Sylvius, within the midbrain). The fourth ventricle (between the brainstem and cerebellum) is continuous with the central canal of the spinal cord and drains CSF into the subarachnoid space via the midline foramen of Magendie and paired lateral foramina of Luschka. Hydrocephalus: accumulation of CSF causing ventricular enlargement, classified as communicating (impaired CSF absorption) or non-communicating/obstructive (blockage within the ventricular system). CSF is produced by the choroid plexus (modified ependymal cells) within the ventricles at a rate of 500 mL/day., which encodes a copper-transporting ATPase in hepatocytes. The defective ATP7B protein impairs incorporation of copper into apoceruloplasmin and biliary excretion of copper, leading to progressive copper accumulation in the liver, brain, cornea, and other organs. Clinical manifestations typically present between ages five and thirty-five and include hepatic disease (ranging from asymptomatic elevation of liver enzymes to acute hepatitis, cirrhosis, and fulminant hepatic failure), neurological disease (dysarthria, ataxia, dystonia, parkinsonism, tremor—particularly a wing-beating tremor of the arms, chorea, and cognitive impairment with executive dysfunction), psychiatric symptoms (depression, personality changes, psychosis), and Kayser-Fleischer rings (golden-brown discolouration at the limbus of the cornea due to copper deposition in Descemet membrane, visible on slit-lamp examination and pathognomonic for Wilson disease when present). Diagnosis is based on a combination of clinical features, Kayser-Fleischer rings on slit-lamp examination, low serum caeruloplasmin (less than 0.2 g/L), elevated 24-hour urinary copper excretion (greater than 100 micrograms), elevated hepatic copper content on liver biopsy, and genetic testing for ATP7B mutations. Serum free copper (non-caeruloplasmin-bound copper) is elevated. Treatment involves lifelong copper chelation therapy with D-penicillamine (first-line, acts by chelating copper and promoting urinary excretion) or trientine, zinc acetate (which blocks intestinal absorption of copper

and induces hepatic metallothionein, used as maintenance therapy or first-line for presymptomatic patients), and dietary restriction of copper-rich foods (shellfish, nuts, chocolate, mushrooms, organ meats). Liver transplantation is curative for severe hepatic failure or refractory neurological disease. Prognosis is excellent with early diagnosis and lifelong treatment; without treatment, Wilson disease is progressive and fatal. Patients who stop chelation therapy are at risk of irreversible neurological deterioration and hepatic decompensation.

Brown Sequard Syndrome

– Brown-Sequard syndrome (hemisection of the spinal cord) results from a lesion affecting one half of the spinal cord, producing a characteristic pattern of ipsilateral and contralateral neurological deficits. The ipsilateral side below the lesion demonstrates upper motor neuron paralysis (corticospinal tract), loss of vibration and proprioception (dorsal column), and loss of tactile sense. The contralateral side below the lesion demonstrates loss of pain and temperature sensation (spinothalamic tract). The syndrome is most commonly caused by penetrating trauma (knife or gunshot wounds), but may also result from spinal cord tumors, haematomas, disc herniation, demyelinating disease (multiple sclerosis), or infarction of the spinal cord (anterior spinal artery syndrome affecting the spinothalamic tract on the contralateral side). Diagnosis is clinical, confirmed by MRI of the spinal cord showing the lateralised lesion. Treatment is directed at the underlying cause and includes high-dose corticosteroids for inflammatory or demyelinating causes, surgical decompression for compressive lesions, and supportive care including pain management and rehabilitation. Prognosis depends on the etiology and severity of the cord injury, with some recovery possible over months.

Cerebellar Ataxia

– A neurological sign characterized by impaired coordination of voluntary movements, resulting from dysfunction of the cerebellum or its connections. The cerebellum coordinates the timing, force, and accuracy of movements, and cerebellar dysfunction produces a characteristic constellation of findings. Gait ataxia presents with a wide-based, unsteady, staggering gait with difficulty performing tandem (heel-to-

toe) walking. Limb ataxia includes dysmetria (overshooting or undershooting targets), dysdiadochokinesia (impaired rapid alternating movements), intention tremor (tremor that worsens as the target is approached), and rebound phenomenon. Speech is affected with scanning dysarthria (slow, irregular, slurred speech with variable volume and tempo). Ocular findings include nystagmus and impaired smooth pursuit. Cerebellar ataxia can be caused by stroke (ischemic or hemorrhagic), tumors, alcohol toxicity and nutritional deficiencies (thiamine), medications (phenytoin, carbamazepine, lithium, benzodiazepines), autoimmune conditions (anti-GAD, anti-glutamate receptor antibodies), paraneoplastic syndromes, neurodegenerative diseases (spinocerebellar ataxias, multiple system atrophy), multiple sclerosis, infectious and post-infectious causes, and hypothyroidism. Diagnosis is clinical with MRI brain to identify structural, inflammatory, or degenerative causes. Management focuses on treating the underlying cause and providing symptomatic relief with physical and occupational therapy, and assistive devices for gait instability.

Cerebral Aneurysm

– An abnormal focal dilation of a cerebral artery, most commonly at bifurcations of the Circle of Willis. Saccular (berry) aneurysms account for 90% of intracranial aneurysms. Risk factors: smoking, hypertension, female sex, polycystic kidney disease, Ehlers-Danlos, family history. Most are asymptomatic (incidental finding). Rupture causes subarachnoid hemorrhage: thunderclap headache, nuchal rigidity, photophobia, and altered mental status. Diagnosis: CTA or MRA for detection; DSA is gold standard. Treatment: microsurgical clipping or endovascular coiling for ruptured and high-risk unruptured aneurysms.

Cerebral Cortex

– The outermost layer of the cerebrum, composed of gray matter (neuronal cell bodies) folded into gyri (ridges) and sulci (grooves), greatly increasing surface area. Divided into four lobes: frontal (motor cortex, prefrontal cortex—executive function, personality, Broca area—speech production), parietal (somatosensory cortex, spatial orientation, integration of sensory modalities), temporal (auditory cortex, Wernicke area—language comprehension, memory

formation via hippocampus), and occipital (primary visual cortex, visual processing). The cortex is organized into six horizontal layers (molecular, external granular, external pyramidal, internal granular, internal pyramidal, multiform) with distinct cell types and connectivity. Cortical functions are topographically organized (homunculus in motor and sensory cortices). Damage causes focal deficits corresponding to the affected region.

Cerebral Hemorrhage

– Bleeding within the brain parenchyma, a type of hemorrhagic stroke causing mass effect, edema, and neurological deficits. Causes: hypertension (most common—basal ganglia, thalamus), cerebral amyloid angiopathy (lobar, elderly), arteriovenous malformation, aneurysm, anticoagulants, trauma, tumors. Features: sudden focal deficit, headache, vomiting, decreased consciousness, seizures; hypertension common. Diagnosis: CT (immediate, high sensitivity), MRI for chronic. Management: blood pressure control, reverse anticoagulation, neurosurgical evacuation for cerebellar/large supratentorial hemorrhage, mannitol/ICP control; prognosis depends on size/location. Contrast with SAH (subarachnoid).

Cerebrospinal Fluid (CSF)

– A clear, colorless fluid that fills the ventricles of the brain, the central canal of the spinal cord, and the subarachnoid space around the brain and spinal cord. Produced primarily by the choroid plexus of the lateral, third, and fourth ventricles (500 mL/day, total volume 150 mL in adults). Functions: mechanical cushioning of the brain (buoyancy reduces effective brain weight by 97%), removal of metabolic waste, transport of hormones and nutrients, and maintenance of stable intracranial pressure. Normal composition: protein 15–45 mg/dL, glucose 50–80 mg/dL (two-thirds of serum glucose), WBC 0–5/mL (mononuclear). CSF analysis by lumbar puncture is essential for diagnosing meningitis, subarachnoid hemorrhage, multiple sclerosis, and other neurologic conditions.

Cerebrovascular Accident

– Stroke: an acute neurological deficit resulting from cerebral ischemia (80–85 percent) or hemorrhage (15–20 percent). Ischemic: thrombotic (large/small vessel), embolic (cardioembolic—AF), and others;

hemorrhagic: intracerebral hemorrhage (hypertension) and subarachnoid hemorrhage (aneurysm). Risk factors: hypertension, diabetes, smoking, hyperlipidemia, AF. Diagnosis: non-contrast CT (exclude hemorrhage), then MRI; acute management: thrombolysis (alteplase) within 4.5 h, mechanical thrombectomy (large vessel occlusion), BP management, aspirin after ICH excluded; secondary prevention with antiplatelets, statins, risk factor control; rehabilitation. 'Brain attack'—time critical.

Cerebrovascular Accident (Stroke)

– Stroke is a neurological deficit caused by focal cerebral ischemia (ischemic stroke, 87%) or hemorrhage (hemorrhagic stroke, 13%). Ischemic stroke results from thrombotic or embolic occlusion of a cerebral artery. Risk factors: hypertension, atrial fibrillation, diabetes, smoking. Management: acute thrombolysis (tPA within 4.5 hours), mechanical thrombectomy for large vessel occlusion, secondary prevention with antiplatelets and risk factor control.

Cervical Radiculopathy

– A condition caused by compression, irritation, or inflammation of a spinal nerve root in the cervical spine, resulting in pain, numbness, tingling, and weakness in the distribution of the affected nerve root. The most commonly affected nerve roots are C6 and C7, accounting for approximately seventy to eighty percent of cervical radiculopathies. C5 radiculopathy causes shoulder pain, weakness of deltoid and biceps, and decreased biceps reflex. C6 radiculopathy causes pain radiating from the neck into the lateral arm, thumb, and index finger, weakness of biceps and brachioradialis, and decreased biceps reflex. C7 radiculopathy causes pain radiating into the middle finger, weakness of triceps and wrist and finger extensors, and decreased triceps reflex. C8 radiculopathy causes pain radiating into the medial arm, ring and little fingers, weakness of hand intrinsic, and decreased finger jerk. Diagnosis is by MRI of the cervical spine, with EMG/NCS confirming the level of nerve root involvement and excluding peripheral nerve entrapment. Management is initially conservative with analgesics, NSAIDs, physical therapy, and cervical epidural steroid injections. Surgical options include anterior cervical discectomy and fusion (ACDF) or cervical disc replacement for persistent or progres-

sive symptoms despite conservative therapy, or for cases with myelopathy.

Cervical Spondylosis

– Age-related degenerative changes of the cervical spine—disc degeneration, osteophyte formation, facet joint arthritis, and ligament hypertrophy—affecting the intervertebral discs, vertebrae, and joints. May cause neck pain, stiffness, and, with cord/nerve root involvement, cervical radiculopathy (pain radiating down arm, paresthesias, weakness, diminished reflexes) or cervical myelopathy (spasticity, gait disturbance, hyperreflexia, hand dysfunction, Lhermitte sign). Diagnosis: X-ray, CT, MRI (best for cord/root). Management: physiotherapy, analgesics/NSAIDs, neck exercises, and surgery (discectomy, decompression/fusion) for progressive myelopathy or refractory radiculopathy.

Chorea

– Involuntary, irregular, brief, non-repetitive jerky movements flowing randomly from one body part to another ('dance-like'), due to basal ganglia (striatal) dysfunction. Causes: Huntington disease (autosomal dominant, CAG repeat, with dementia and psychiatric features), Sydenham chorea (post-streptococcal), drug-induced (levodopa, antipsychotics—tardive), Wilson disease, SLE/antiphospholipid, pregnancy (chorea gravidarum), stroke. Features vary from subtle fidgeting to disabling movements. Diagnosis: history, exam, genetic testing (HTT), labs (ceruloplasmin, ASO, ANA). Management: treat cause; dopamine-blocking agents or VMAT2 inhibitors (tetrabenazine, deutetabenazine) for Huntington chorea.

Clonus

– A rhythmic, involuntary oscillation of a muscle (usually ankle or patellar) produced by sustained stretch, indicating upper motor neuron (UMN) disease—hyperreflexia. Elicited by rapid dorsiflexion of the foot (sustained clonus—5 or more beats) or tapping. Associated with spasticity, hyperreflexia, and UMN signs (Babinski). Causes: stroke, spinal cord injury, multiple sclerosis, cerebral palsy, ALS (UMN form), and severe hepatic encephalopathy (asterixis-like). Contrast with tremor (not stretch-induced). Management targets spasticity (stretching, baclofen, botulinum toxin).

Cognitive Fitness

– The active maintenance of mental sharpness and brain health through stimulating activities, physical exercise, social engagement, and proper nutrition. Regular challenges such as learning new skills, puzzles, reading, and social interaction support neuroplasticity and cognitive reserve. Maintaining cognitive fitness throughout life may delay age-related cognitive decline and reduce dementia risk.

Cognitive Health and Memory

– Cognitive health encompasses the ability to think clearly, learn, remember, and make decisions, with memory being a core component that involves encoding, storing, and retrieving information. Age-related changes in processing speed and recall are normal, but persistent decline may signal mild cognitive impairment or dementia. Protective factors include cardiovascular health, mental stimulation, physical activity, and social engagement.

Coma

– A state of profound unconsciousness in which the patient cannot be aroused and shows no awareness of self or environment, with eyes closed and no sleep-wake cycles. Results from widespread bilateral cerebral hemisphere dysfunction or brainstem reticular formation damage. Causes: structural (traumatic brain injury, stroke, intracranial hemorrhage, brain tumor), metabolic (hypoglycemia, hepatic encephalopathy, uremia, hyperhyponatremia, hypothyroidism), toxic (drug overdose—opioids, benzodiazepines, alcohol, barbiturates), infectious (meningitis, encephalitis), and hypoxic-ischemic (cardiac arrest). Assessment: Glasgow Coma Scale (eye, motor, verbal responses; range 3–15). Management: stabilize ABCs, treat reversible causes (naloxone, flumazenil, glucose, thiamine), neuroimaging, EEG to rule out nonconvulsive status epilepticus. Prognosis depends on cause, duration, and neurologic examination findings.

Communicating Hydrocephalus

– A type of hydrocephalus in which there is free flow of cerebrospinal fluid (CSF) between the ventricles, but impaired absorption of CSF at the arachnoid granulations or increased CSF production. The ventricles are uniformly dilated, including the fourth ventricle. The most common cause is impaired CSF absorption due to prior subarachnoid hemorrhage,

meningitis, or intracranial surgery, which causes scarring and fibrosis of the arachnoid granulations. Other causes include idiopathic intracranial hypertension, cerebral venous sinus thrombosis, and overproduction of CSF by a choroid plexus papilloma. Clinical presentation includes headache, nausea and vomiting, gait disturbance, cognitive slowing, and papilloedema from increased intracranial pressure. In contrast to obstructive (non-communicating) hydrocephalus, the ventricles are uniformly dilated and there is no obstruction to CSF flow within the ventricular system. Diagnosis is by neuroimaging (CT or MRI) showing ventricular dilation with no obstructive lesion, supported by CSF drainage or infusion studies. Management includes CSF diversion procedures such as ventriculoperitoneal (VP) shunting or endoscopic third ventriculostomy (ETV) in selected cases where an obstructive component is present. The underlying cause must also be addressed (e.g., treatment of meningitis, management of subarachnoid hemorrhage complications).

Concussion

– A form of mild traumatic brain injury caused by a biomechanical force (direct blow to the head, face, neck, or elsewhere on the body with impulsive force transmitted to the head), resulting in a transient disturbance of brain function without structural damage visible on conventional neuroimaging. Concussion is a functional rather than structural injury, involving neurometabolic dysfunction: neuronal membrane disruption, ionic shifts (potassium efflux, calcium influx), and increased glucose metabolism (initially hyperglycolysis followed by metabolic depression), lactate accumulation, and impaired mitochondrial function. The result is a state of metabolic vulnerability in which the brain is less able to tolerate a second impact, which is the basis for the principle of avoiding repeat head injury during the recovery period. Clinical features include headache, dizziness, nausea, balance problems, blurred vision, sensitivity to light and noise, fatigue, sleep disturbance, difficulty concentrating, memory impairment, and emotional lability (irritability, anxiety, depression). Loss of consciousness occurs in fewer than 10 percent of concussions; post-traumatic amnesia is common. Diagnosis is clinical, based on history of head trauma and symp-

tom assessment using standardised tools such as the Sport Concussion Assessment Tool (SCAT-5) or the Standardised Assessment of Concussion (SAC). Neuroimaging (CT or MRI) is normal. Management includes physical and cognitive rest during the acute phase (24-48 hours), followed by gradual stepwise return to activity guided by symptom tolerance. Most patients recover fully within 7-14 days in adults and within 2-4 weeks in children and adolescents. Persistent symptoms beyond 4 weeks are termed post-concussion syndrome and require multidisciplinary management.

Conus Medullaris Syndrome

– A clinical condition resulting from damage to the conus medullaris, the tapered, terminal end of the spinal cord located at approximately the L1-L2 vertebral level. The conus medullaris contains the sacral spinal cord segments (S2-S5) and the lowest lumbar segments, which innervate the bladder, bowel, sexual function, and the lower extremities. Clinical features include acute or subacute bilateral lower extremity weakness (usually symmetric), saddle anesthesia (loss of sensation in the perineal, perianal, and inner thigh regions), and early bladder and bowel dysfunction (urinary retention, overflow incontinence, and fecal incontinence). The presence of a bulbocavernosus reflex and anal wink reflex helps distinguish conus medullaris syndrome from cauda equina syndrome, and the early onset of bladder and bowel dysfunction (often before significant lower extremity weakness) is a distinguishing feature. Causes include compression from tumors (metastases, ependymomas), trauma, lumbar disc herniation, spinal cord infarction from anterior spinal artery occlusion, and inflammatory conditions such as transverse myelitis. Diagnosis is by urgent MRI of the thoracolumbar spine. Management requires prompt treatment of the underlying cause, including surgical decompression for compressive lesions. Prognosis is often poor for neurological recovery, particularly for bladder and bowel function.

Cranial Nerve Palsy

– Weakness or paralysis of one or more cranial nerves (CN III-XII) causing specific deficits: CN III (ptosis, mydriasis, 'down and out' eye—aneurysm, diabetes, herniation), CN IV (vertical diplopia—trauma), CN VI (lateral rectus weak-

ness, horizontal diplopia—increased ICP, diabetes, microvascular), CN VII (facial palsy—Bell palsy, Ramsey Hunt, stroke [upper face spared]), and others. Causes: vascular (diabetes, hypertension), trauma, tumor, aneurysm, infection, inflammatory (sarcoid, MS), and congenital. Diagnosis: detailed neuro exam, imaging (MRI/MRA), labs; distinguish nuclear/fascicular from peripheral. Management: treat cause; eye protection, physiotherapy, prism.

Creutzfeldt Jakob Disease

– Creutzfeldt-Jakob disease (CJD) is a rare, fatal, transmissible spongiform encephalopathy caused by the accumulation of misfolded prion protein (PrPSc) in the brain, leading to rapid, progressive dementia and myoclonus. Sporadic CJD is the most common form, accounting for approximately eighty-five percent of cases, with an incidence of approximately one to two per million per year, typically affecting patients in their sixties. The clinical presentation includes rapidly progressive cognitive decline, myoclonus (brief, involuntary muscle jerks that are pathognomonic when elicited by startle), ataxia, visual disturbances (cortical blindness, visual hallucinations), and pyramidal and extrapyramidal signs. In the late stages, patients become akinetic and mute. The classic EEG finding is generalised periodic sharp-wave complexes (PSWCs) at 1-2 Hz, which are present in approximately two-thirds of cases. MRI brain may show hyperintensity in the basal ganglia (particularly the caudate and putamen) and cortical ribboning on diffusion-weighted imaging. CSF analysis may detect 14-3-3 protein and elevated tau protein, and real-time quaking-induced conversion (RT-QuIC) testing of CSF has high sensitivity and specificity for detecting PrPSc. The disease is uniformly fatal, usually within 6-12 months of symptom onset. Variant CJD (vCJD), linked to bovine spongiform encephalopathy, affects younger patients and has a longer disease course. Management is supportive, with no effective disease-modifying treatment available.

CVA

– See Cerebrovascular Accident (Stroke).

Deep Tendon Reflex

– The monosynaptic stretch reflex elicited by tapping a tendon with a reflex hammer, testing the integrity of the reflex arc (sensory afferent, spinal cord,

motor efferent). Common reflexes: biceps (C5-6), triceps (C7), brachioradialis (C5-6), knee/patellar (L3-4), ankle/Achilles (S1). Graded 0 (absent) to 4+ (hyperactive, clonus). Hyperreflexia indicates upper motor neuron lesions (stroke, cord); hyporeflexia/areflexia indicates lower motor neuron/peripheral nerve disease (radiculopathy, neuropathy, GBS). Asymmetric reflexes localize pathology. Plantar response (Babinski sign) assesses UMN integrity.

Dizziness

– A common symptom encompassing multiple distinct sensations requiring careful differentiation: vertigo (false sense of motion—vestibular: BPPV, vestibular neuritis, Ménière, CNS—brainstem/cerebellar), presyncope (feeling about to faint—cardiac/orthostatic), disequilibrium (unsteadiness with walking—neuro, vestibular, sensory), and lightheadedness (anxiety, hyperventilation, anemia, drugs). Evaluation: history (timing, triggers, associated hearing/neuro/cardiac symptoms), HINTS exam for acute vestibular syndrome, orthostatics, ECG. Red flags: new headache, focal deficit, head/neck trauma, hearing loss. Management: treat underlying cause; vestibular rehabilitation, repositioning (Epley) for BPPV.

Duchenne Muscular Dystrophy

– An X-linked recessive neuromuscular disorder caused by mutations in the dystrophin gene (DMD gene) on chromosome Xp21.2, resulting in absent or severely reduced dystrophin protein, which is essential for maintaining the structural integrity of the sarcolemma during muscle contraction. Most mutations are frameshift mutations (deletions, duplications, or point mutations) that introduce premature stop codons, leading to truncated, non-functional dystrophin. The incidence is approximately one in 3,500 male births, making it the most common muscular dystrophy in children. Onset of symptoms typically occurs before age five, with delayed motor milestones (late walking), difficulty running and climbing stairs, toe walking, and a waddling gait. Gowers manoeuvre (using the hands to push against the thighs to stand from a sitting position) is a classic finding. Calf pseudohypertrophy (enlargement due to fatty infiltration) is characteristic.

Progression is rapid: most boys lose ambulation by age 12, develop respiratory insufficiency requiring non-invasive ventilation in adolescence, and die from respiratory or cardiac failure in their twenties or thirties. Cardiac involvement (dilated cardiomyopathy) is universal and requires regular surveillance with echocardiography and ECG. Diagnosis is confirmed by genetic testing showing out-of-frame dystrophin gene deletions, duplications, or point mutations, or by muscle biopsy showing absent dystrophin staining. Management includes corticosteroids (prednisolone or deflazacort) to prolong ambulation and reduce the need for scoliosis surgery, angiotensin-converting enzyme inhibitors for cardiomyopathy management, respiratory support, physiotherapy, and orthopaedic management for contractures and scoliosis. Gene therapy (delandistrogene moxeparvovec) has recently been approved for ambulatory patients with specific DMD mutations, and exon skipping agents (eteplirsen, golodirsen, viltolarsen) are available for specific mutation subtypes.

DWI FLAIR Mismatch

– Diffusion-weighted imaging (DWI) and fluid-attenuated inversion recovery (FLAIR) MRI sequences are used together to estimate the age of an ischemic stroke lesion and guide treatment decisions. DWI demonstrates restricted diffusion in acute ischemic tissue within minutes of stroke onset, appearing as a hyperintense (bright) lesion with corresponding hypointensity on the apparent diffusion coefficient (ADC) map. FLAIR demonstrates increased signal from vasogenic edema, which takes approximately four to six hours to become visible on FLAIR after stroke onset. A DWI-positive, FLAIR-negative lesion, indicating that the stroke is within the window where the patient may benefit from thrombolysis even if the onset time is unknown (e.g., wake-up stroke). If both DWI and FLAIR are positive, the lesion is estimated to be greater than approximately 4.5 hours old and thrombolysis is relatively contraindicated. This mismatch paradigm has been validated in the WAKE-UP trial, which demonstrated that patients with DWI-FLAIR mismatch who received alteplase had better functional outcomes at 90 days compared to placebo, without increased mortality.

Dysarthria

– A motor speech disorder resulting from neurological impairment of the muscular components of speech production, including the lips, tongue, palate, vocal cords, and respiratory muscles. It is caused by lesions affecting the central or peripheral nervous system at various levels: upper motor neuron (stroke, traumatic brain injury, multiple sclerosis), lower motor neuron (bulbar palsy, myasthenia gravis, Guillain-Barre syndrome), extrapyramidal (Parkinson disease, Huntington disease), cerebellar (ataxic dysarthria from cerebellar lesions), and neuromuscular (myasthenia gravis, muscular dystrophies, motor neuron disease). The type of dysarthria can help localise the neurological lesion and guide diagnosis. Flaccid dysarthria (lower motor neuron) presents with hypernasal, breathy, imprecise speech with audible inspiration. Spastic dysarthria (upper motor neuron) presents with strained, strangled, slow speech with reduced range of movement. Ataxic dysarthria (cerebellar) presents with scanning, irregular, and explosive speech. Hypokinetic dysarthria (extrapyramidal, e.g., Parkinson disease) presents with quiet, rapid, monotonous, mumbling speech with festination. Hyperkinetic dysarthria (e.g., Huntington disease) presents with variable speech rate, involuntary vocalisations, and variable volume. Diagnosis is by speech-language pathology assessment and identification of the underlying neurological cause. Management includes speech and language therapy, treatment of the underlying neurological condition, and augmentative and alternative communication devices for severe cases.

Dysphasia

– A language disorder caused by damage to the language-dominant hemisphere of the brain (typically left), involving difficulty with expression, comprehension, reading, or writing. Dysphasia (often used interchangeably with aphasia): partial loss of language function. Types: expressive dysphasia (Broca area–non-fluent, effortful speech with preserved comprehension, agrammatism), receptive dysphasia (Wernicke area–fluent but meaningless speech, poor comprehension, word substitutions (paraphasias)), global dysphasia (both hemispheres extensively affected, all language modalities impaired), conduction dysphasia (arcuate fasciculus lesion–good comprehension and fluency but poor

repetition), and anomia (word-finding difficulty with otherwise fluent speech). Most common cause: ischemic stroke. Management: speech and language therapy.

Dystonia

– A movement disorder characterized by sustained or intermittent muscle contractions causing abnormal, often repetitive, movements and postures. It can be classified by the body region affected (focal, segmental, multifocal, or generalized), by age of onset (childhood, adolescent, or adult), and by etiology (primary/genetic or secondary/symptomatic). Focal dystonia includes cervical dystonia (torticollis, the most common adult-onset focal dystonia), blepharospasm (involuntary closure of the eyelids (blepharospasm)), oromandibular dystonia (jaw opening, closing, or deviation), laryngeal dystonia (spasmodic dysphonia), and task-specific dystonias such as writer's cramp and musician's dystonia. Secondary dystonia can be caused by drugs (tardive dystonia from antipsychotics), stroke, traumatic brain injury, cerebral palsy, Wilson disease, and neurodegenerative disorders. Diagnosis is clinical, supported by genetic testing for primary dystonia (DYT genes including TOR1A, THAP1, GCH1, GNAL) and neuroimaging to exclude structural causes. Management includes botulinum toxin injections for focal dystonia (the treatment of choice), oral medications (anticholinergics, benzodiazepines, baclofen, tetrabenazine), and deep brain stimulation of the globus pallidus internus for severe, medically refractory generalised or segmental dystonia.

Echolalia

– The involuntary, automatic repetition of words or phrases spoken by another person, a speech phenomenon observed in various neurologic and psychiatric conditions. Immediate echolalia involves repeating sounds immediately after hearing them; delayed echolalia involves repeating phrases heard hours, days, or weeks earlier. Most commonly associated with autism spectrum disorder (where it may serve communicative or self-regulatory functions), Tourette syndrome, and transcortical sensory aphasia. Also occurs in Alzheimer disease, frontotemporal dementia, catatonia, and schizophrenia. Echolalia can be distinguished from palilalia (repetition of one's own words) and coprolalia (involuntary

utterance of obscenities).

Electroencephalogram

– EEG: a recording of electrical activity of the brain via scalp electrodes, reflecting cortical neuronal activity. Uses: diagnosis and classification of seizures/epilepsy (interictal epileptiform discharges, spikes/waves), status epilepticus monitoring, assessment of encephalopathy, sleep disorders, and determination of brain death. Normal: alpha (posterior, awake, eyes closed), beta (frontal, active), theta, delta (sleep/deep). Abnormal: slowing (focal—lesion; diffuse—metabolic/encephalopathy), epileptiform discharges, burst suppression, absence of activity. Video-EEG monitors seizures; ambulatory EEG captures intermittent events.

Electroencephalography

– A non-invasive neurophysiological test that records the electrical activity of the brain using electrodes placed on the scalp according to the international 10-20 system. The EEG measures the summated postsynaptic potentials of cortical pyramidal neurons and displays them as waveforms characterized by frequency (delta 0.5-4 Hz, theta 4-8 Hz, alpha 8-13 Hz, beta 13-30 Hz, gamma greater than 30 Hz), amplitude, and morphology. The normal waking EEG shows a posterior dominant alpha rhythm (8-13 Hz) that attenuates with eye opening. EEG is essential for the diagnosis of epilepsy, classification of seizure types and syndromes, and monitoring of status epilepticus. Abnormal findings include epileptiform discharges (spikes, sharp waves, spike-wave complexes) indicating an epileptic focus or generalised epilepsy. EEG is also used in the evaluation of encephalopathy (generalised slowing), brain death (electrocerebral silence), and sleep disorders. Prolonged video-EEG monitoring is used for presurgical evaluation of drug-resistant epilepsy, capturing ictal and interictal EEG patterns to localise the seizure onset zone. Standard EEG records from 21 scalp electrodes at the standard 10-20 positions, with additional electrodes (T1/T2, zygomatic, sphenoidal) used for better localisation of temporal lobe foci. Limitations include low spatial resolution, sensitivity to movement artifact, and inability to detect deep or mesial structures.

Encephalopathy

– Any diffuse disease of the brain that alters its

structure or function, presenting with a global change in mental status (confusion, lethargy, personality change, coma) rather than focal neurologic deficits. Causes are numerous and often reversible: metabolic (hepatic encephalopathy—ammonia accumulation, uremic encephalopathy—uremic toxins, hypoglycemia, hyper/hyponatremia, hypercapnia, Wernicke encephalopathy—thiamine deficiency), toxic (drug overdose, alcohol intoxication/withdrawal, heavy metals), infectious (sepsis-associated encephalopathy, meningitis, encephalitis), hypoxic-ischemic (cardiac arrest), hypertensive (posterior reversible encephalopathy syndrome—PRES), and neurodegenerative (chronic traumatic encephalopathy, prion disease). Diagnosis: clinical assessment, metabolic panel, toxicology screen, neuroimaging (CT/MRI), EEG. Treatment: address underlying cause.

Epidural Hematoma

– Accumulation of blood between the skull and the dura mater, typically from arterial bleeding (middle meningeal artery) following temporal bone fracture. Presents with loss of consciousness, then a lucid interval (hours), followed by rapid neurological deterioration due to mass effect. Head CT: biconvex (lenticular), hyperdense collection that does not cross suture lines. Midline shift is common. Treatment: emergency burr hole or craniotomy for evacuation within 2-4 hours. Delay increases mortality. Outcome is excellent with prompt surgical intervention.

Essential Tremor

– The most common movement disorder, characterized by a bilateral, symmetrical, postural and kinetic tremor predominantly affecting the upper extremities, with a frequency of four to twelve hertz. It typically begins insidiously in the second or third decade of life and slowly progresses over years. The tremor is most apparent when the arms are held in a sustained posture (such as arms outstretched) and during intentional movement (such as reaching for an object), and it usually improves temporarily with alcohol consumption (a characteristic feature). The tremor can also affect the head (titubation), voice (vocal tremor, producing a quavering quality), legs, and trunk. Advanced cases may cause significant disability in writing, drinking from a cup,

eating, and fine motor tasks. Essential tremor is often misdiagnosed as Parkinson disease, but key distinguishing features include the bilateral symmetrical presentation, predominant postural and kinetic tremor (rather than the resting tremor of Parkinson disease), lack of other parkinsonian signs such as bradykinesia and rigidity, and positive family history (autosomal dominant inheritance in up to 50 percent of cases, with incomplete penetrance). The pathophysiology is not fully understood but likely involves abnormal oscillatory activity in the cerebello-thalamo-cortical circuit, with the cerebellum playing a central role. Diagnosis is clinical, based on the Movement Disorder Society consensus criteria. Treatment includes beta-blockers (propranolol is first-line) and primidone as first-line medications, with topiramate, gabapentin, and benzodiazepines as second-line options. For medically refractory cases, botulinum toxin injections can reduce tremor amplitude, and deep brain stimulation of the ventral intermediate nucleus of the thalamus is highly effective. Focused ultrasound thalamotomy is a newer, incisionless ablative option.

Facial paralysis

– Loss of voluntary motor function of the facial muscles, most commonly from peripheral facial nerve (CN VII) dysfunction. The most frequent cause is Bell palsy (idiopathic peripheral facial paralysis), accounting for 60-70 percent of cases, with an incidence of 20-30 per 100,000 annually. Bell palsy presents as acute onset (over hours to 2-3 days) of unilateral lower motor neuron facial weakness involving both the upper and lower face (forehead, eye closure, mouth), often preceded by pain behind the ear (mastoid pain). Other causes of facial paralysis include Ramsay Hunt syndrome (herpes zoster oticus presenting with vesicles in the external auditory canal and severe pain), Lyme disease (erythema migrans and systemic symptoms), Guillain-Barre syndrome (bilateral facial weakness), otitis media, parotid tumors (slowly progressive), and stroke (upper motor neuron pattern sparing the forehead). Diagnosis involves careful history and physical examination to localise the lesion and identify the cause, with additional testing (MRI, nerve conduction studies, serology) as indicated. Management is directed at the underlying cause: Bell

palsy is treated with corticosteroids, Ramsay Hunt syndrome with antivirals plus corticosteroids, Lyme disease with antibiotics, and tumors with surgical resection. Eye protection is critical in all cases of incomplete eye closure to prevent corneal abrasion and ulceration. Prognosis depends on the cause: Bell palsy has 70 percent complete recovery, while facial nerve tumors and trauma have variable outcomes.

Friedreich Ataxia

– The most common inherited ataxia, an autosomal recessive neurodegenerative disorder caused by a GAA trinucleotide repeat expansion in intron one of the frataxin gene (FXN) on chromosome 9q21.1. Normal individuals have five to thirty-three GAA repeats, while patients with Friedreich ataxia have typically sixty-six to one thousand seven hundred repeats on both alleles. The expanded repeat causes transcriptional silencing of the frataxin gene, leading to reduced frataxin protein, a mitochondrial protein involved in iron-sulphur cluster biogenesis and iron homeostasis. Reduced frataxin leads to mitochondrial iron accumulation, oxidative stress, and impaired mitochondrial function, particularly in neurons and cardiac myocytes. Clinical onset is typically between ages 10 and 15, with progressive gait and limb ataxia, dysarthria, loss of deep tendon reflexes (areflexia), loss of vibration and proprioception, extensor plantar responses (upper motor neuron signs due to corticospinal tract involvement), and scoliosis. Non-neurological features include hypertrophic cardiomyopathy (the most common cause of death), diabetes mellitus, and pes cavus. Diagnosis is clinical, supported by nerve conduction studies showing absent sensory nerve action potentials with preserved motor conduction velocities, and confirmed by genetic testing demonstrating biallelic GAA repeat expansions in the FXN gene. Management is supportive and multidisciplinary, including physical and occupational therapy, speech therapy, management of cardiomyopathy, treatment of diabetes, and orthopaedic management of scoliosis. The antioxidant idebenone has not shown consistent benefit in clinical trials. Prognosis is variable, with most patients becoming wheelchair-bound within 10-15 years of onset; mean survival is approximately 40-50 years, with cardiac failure as the leading cause of death.

Gait

– The pattern or style of walking. Gait is a complex motor function involving coordination of the central and peripheral nervous systems, muscles, and joints. Gait assessment evaluates stance, stride length, cadence, arm swing, truncal stability, and turning. Abnormal gait patterns include: hemiplegic gait (circumduction, stroke), Parkinsonian gait (festinating, shuffling, reduced arm swing), ataxic gait (wide-based, unsteady, cerebellar or sensory; Romberg test positive in sensory ataxia), steppage gait (foot drop, e.g., common peroneal nerve palsy or Charcot-Marie-Tooth disease), waddling gait (hip girdle weakness, myopathy), antalgic gait (pain avoidance, shortened stance phase on affected side), and Trendelenburg gait (pelvic drop on the swing side, gluteus medius weakness).

Gait Assessment

– A crucial component of the neurological examination that provides significant diagnostic information about the underlying neurological condition. Normal gait requires intact motor, sensory, cerebellar, and vestibular systems, as well as intact cognition. Several characteristic gait patterns are associated with specific neurological disorders. The hemiplegic gait is seen in stroke and other upper motor neuron lesions, with the affected leg stiffly circumducted and the arm flexed and adducted at the side. The parkinsonian gait (festinating gait) is characterized by small, shuffling steps with reduced arm swing, flexed posture, and difficulty initiating or stopping movement, sometimes with freezing of gait. The sensory ataxic gait is broad-based with high-stepping (foot slap) and a positive Romberg sign, caused by impaired proprioception from peripheral neuropathy, tabes dorsalis, or posterior column disease. The cerebellar ataxic gait is broad-based, staggering, and lurching, with difficulty performing tandem gait, and is caused by cerebellar vermis pathology. The myopathic gait (waddling gait) features a broad-based stance, exaggerated lateral trunk sway, and Trendelenburg lurch due to weak hip girdle muscles, seen in muscular dystrophies. The apraxic gait (magnetic gait) is characterized by difficulty lifting the feet from the floor, as if glued to the ground, with initiation difficulty, seen in normal pressure hydrocephalus and frontal lobe lesions. Diagnosis

of the gait pattern and the underlying neurological cause directs further investigation and management.

Gait Disturbance

– An abnormality of walking—a common presenting symptom with diverse causes. Patterns: hemiparetic (circumduction—stroke), spastic (scissoring—spastic paraparesis), ataxic (wide-based, staggering—cerebellar), parkinsonian (small shuffling steps, reduced arm swing), festinating (Parkinson), sensory ataxic (worse with eyes closed—B12, proprioceptive loss), apraxic (frontal lobe, normal legs but cannot initiate—normal pressure hydrocephalus), waddling (proximal myopathy), steppage (foot drop—peroneal/lumbar radiculopathy). Diagnosis: focused history and neurologic exam, targeted imaging/labs. Management: treat cause and rehabilitate (physiotherapy, mobility aids).

Generalized Tonic-Clonic Seizure

– A generalized tonic-clonic seizure (formerly grand mal seizure) is a seizure involving bilateral tonic stiffening followed by rhythmic clonic jerking of the extremities, with loss of consciousness. The tonic phase consists of sustained muscle contraction causing initial extension or flexion of the limbs, opisthotonus, and jaw clenching, lasting ten to twenty seconds. The clonic phase follows with rhythmic jerking of the limbs at a frequency of approximately two to four hertz, gradually slowing over time. The postictal phase follows with confusion, drowsiness, headache, and muscle soreness, lasting minutes to hours. During the generalised seizure, there is loss of consciousness, autonomic changes (tachycardia, hypertension, diaphoresis, pupillary dilation), and sometimes tongue biting, urinary incontinence, and cyanosis during the tonic phase. Generalised tonic-clonic seizures can be primary generalised (arising from both hemispheres simultaneously, often with a genetic basis) or secondary generalised (focal seizure spreading to become bilateral). Diagnosis is clinical, supported by EEG which may show generalised spike-wave discharges interictally. First-line treatment includes sodium valproate (for primary generalised) or levetiracetam, lamotrigine, and topiramate. Status epilepticus is a medical emergency defined as a generalised tonic-clonic seizure lasting longer than 5 minutes or recurrent seizures without return to baseline, requiring urgent management

with benzodiazepines, followed by second-line anti-convulsants and anesthetic agents.

Glioblastoma

– Grade IV astrocytoma (WHO), the most common and aggressive primary malignant brain tumor in adults. Arises *de novo* (primary GBM, IDH-wildtype) or from low-grade astrocytoma (secondary, IDH-mutant—better prognosis). Features: progressive headache, seizures, focal deficits, personality change; imaging: enhancing ring lesion with central necrosis ('butterfly' across corpus callosum possible). Management: maximal safe surgical resection, radiotherapy with concurrent and adjuvant temozolomide (Stupp protocol), tumor-treating fields in some; prognostic markers: MGMT promoter methylation (predicts temozolomide response), IDH1/2, 1p/19q. Median survival 14-16 months despite treatment.

Grand Mal

– A type of generalised seizure characterized by bilateral synchronous epileptic activity involving the entire brain. Formerly called grand mal, now classified as bilateral tonic-clonic seizure according to the ILAE 2017 classification. Phases: (1) tonic phase (10-30 s): sudden loss of consciousness, sustained muscle contraction causing arching of the back (opisthotonos), extension of limbs, respiratory arrest with cyanosis; (2) clonic phase (30-60 s): rhythmic alternating contraction and relaxation of all muscle groups, initially rapid then slowing; (3) postictal phase (variable): confusion, headache, drowsiness, muscle soreness, sometimes Todd paralysis (transient focal neurological deficit). Complications: tongue biting, urinary incontinence, aspiration, injury from falls. Status epilepticus: continuous seizure activity >5 minutes or >2 seizures without full recovery. Emergency management: airway, benzodiazepines (lorazepam IV or midazolam IM), then levetiracetam/phenytoin/valproate if needed.

Hemifacial Spasm

– Involuntary, unilateral, intermittent twitching of the facial muscles innervated by the facial nerve (CN VII). Typically begins around the eye (orbicularis oculi) and spreads to the lower face. Most commonly caused by vascular compression of the facial nerve at the root exit zone (anterior inferior cerebellar artery or posterior inferior cerebellar artery). Other

causes: facial nerve injury, tumors, MS. Diagnosis: clinical; MRI/MRA to rule out structural cause. Treatment: botulinum toxin injections (first-line), microvascular decompression for refractory cases.

Hemiplegia

– Paralysis of one side of the body (the face, arm, and leg on the same side), caused by damage to the corticospinal tract (pyramidal tract) at any level from the cerebral cortex to the spinal cord. The most common cause of acute hemiplegia in adults is ischemic stroke affecting the contralateral cerebral hemisphere, particularly lesions of the internal capsule or motor cortex. Other causes include hemorrhagic stroke, brain tumors, traumatic brain injury, cerebral palsy (in children), and brain tumors. The clinical presentation includes contralateral facial weakness (lower face only, with forehead sparing due to bilateral cortical innervation of the upper face), contralateral arm and leg weakness (typically more severe in the arm and face than the leg in cortical strokes, or equal involvement in internal capsule or brainstem lesions), and associated neurological deficits depending on the location of the lesion (aphasia, neglect, visual field defects, sensory loss, dysarthria). The weakness is initially flaccid in the acute phase, with spasticity and hyperreflexia developing over days to weeks. Diagnosis is by neuroimaging (CT for acute hemorrhage, MRI for ischemic stroke) to identify the cause. Management is directed at the underlying cause: acute stroke management, rehabilitation, and prevention of secondary complications including contractures, pressure ulcers, DVT, and shoulder pain. Functional recovery depends on the extent of damage and the patient's age and pre-morbid status.

Hemorrhagic Stroke

– A neurological deficit caused by rupture of a cerebral blood vessel, accounting for 13% of all strokes but 40% of stroke mortality. Intracerebral hemorrhage: hypertensive (basal ganglia, thalamus, pons, cerebellum), amyloid angiopathy (lobar, elderly), vascular malformations, anticoagulation. Subarachnoid hemorrhage: aneurysm rupture. Presents with sudden severe headache, neurological deficits, decreased consciousness, and hypertension. Diagnosis: non-contrast CT is first-line. Management: ABCs, reversal of anticoagulation (vitamin K, FFP, PCC,

idarucizumab for dabigatran, andexanet alfa for factor Xa inhibitors), blood pressure control (SBP <140-160), neurosurgical evacuation for cerebellar >3cm or lobar >30cc, external ventricular drain for hydrocephalus.

Herpes Simplex Encephalitis

– The most common cause of sporadic fatal encephalitis, caused by herpes simplex virus type 1 (HSV-1) in over ninety percent of cases. The virus typically infects the temporal lobes, orbitofrontal cortex, and insular cortex, causing hemorrhagic necrosis. Clinical presentation includes fever, headache, altered mental status, behavioral changes, seizures, focal neurological deficits (aphasia, hemiparesis), and personality changes. The temporal lobe predilection explains the common presenting features of personality changes, aphasia, and temporal lobe seizures. MRI brain is the imaging modality of choice, showing characteristic T2 hyperintensity and swelling of the temporal lobes (especially the medial temporal lobe including the hippocampus and amygdala), insular cortex, and orbitofrontal region, sometimes with areas of hemorrhage. The diagnosis is confirmed by detection of HSV-1 DNA in CSF by polymerase chain reaction (PCR), which has high sensitivity and specificity. CSF analysis typically shows a lymphocytic pleocytosis, elevated protein, and normal or slightly low glucose. EEG may show periodic lateralising epileptiform discharges (PLEDs) originating from the temporal region. Treatment with high-dose intravenous acyclovir (10 mg/kg every 8 hours for 14-21 days) should be started immediately when the diagnosis is suspected, even before confirmation by PCR, as early treatment significantly reduces mortality and improves neurological outcomes. Mortality is approximately 10-20 percent with treatment, and survivors often have long-term neurological deficits including memory impairment, personality changes, and epilepsy.

Holoprosencephaly

– A structural brain malformation resulting from incomplete or failed division of the forebrain (prosencephalon) into the cerebral hemispheres during the fifth week of gestation. Classified by severity: alobar (single ventricle, fused thalami, no interhemispheric fissure, most severe), semilobar (partial division), and lobar (nearly complete di-

vision, mildest). Presents with developmental delay, seizures, spasticity, and hypothalamic/pituitary dysfunction. Craniofacial anomalies correlate with severity: cyclopia, ethmocephaly, cebocephaly, or cleft lip/palate. Causes include trisomy 13 and mutations in SHH, ZIC2, SIX3, or TGIF genes. Treatment is supportive.

Horner Syndrome

– A clinical triad caused by disruption of the sympathetic pathway to the eye and face, resulting in ipsilateral miosis (constricted pupil), ptosis (drooping of the upper eyelid due to paralysis of the superior tarsal muscle), and anhidrosis (loss of sweating on the affected side of the face). The sympathetic pathway to the eye is a three-neuron chain: the first-order neuron descends from the hypothalamus through the brainstem to the ciliospinal center of Budge at C8-T2; the second-order neuron exits the spinal cord at C8-T2, ascends in the sympathetic chain, and synapses in the superior cervical ganglion; the third-order neuron travels along the internal carotid artery to innervate the pupillary dilator muscle, Muller muscle of the upper eyelid, and sweat glands of the face. Causes of Horner syndrome are classified by the site of the lesion along this three-neuron chain. Central (first-order) causes include brainstem stroke (Wallenberg syndrome), multiple sclerosis, syringobulbia, and spinal cord lesions above T1. Preganglionic (second-order) causes include Pancoast tumor (apical lung cancer), cervical rib, thoracic aortic aneurysm, thyroid carcinoma, neck trauma or surgery, and mediastinal masses. Postganglionic (third-order) causes include carotid artery dissection (a critical cause to identify), carotid aneurysm or thrombosis, cavernous sinus lesions, cluster headache, and otitis media. Diagnosis involves pharmacological testing with topical apraclonidine or cocaine drops, which confirm Horner syndrome, and topical hydroxyamphetamine to differentiate preganglionic from postganglionic lesions. Urgent imaging of the brain, neck, and chest (CT, MRI, CTA, or MRA) is required to identify the underlying cause, with carotid dissection being a medical emergency requiring antithrombotic therapy.

Huntington Disease

– An autosomal dominant neurodegenerative disorder

caused by a CAG trinucleotide repeat expansion in the huntingtin (HTT) gene on chromosome 4p16.3. The normal number of CAG repeats is ten to thirty-five, while forty or more repeats are fully penetrant, causing the disease. There is an inverse correlation between the number of CAG repeats and the age of onset: larger repeat expansions cause earlier onset. The disease is characterized by a classic triad of motor, cognitive, and psychiatric abnormalities. The motor features include chorea (rapid, involuntary, dance-like movements) as the most characteristic feature, which initially may be subtle—mild fidgetiness, clumsiness, or involuntary facial movements—and progresses to involve the trunk and limbs, affecting gait, speech, and swallowing. Dystonia and parkinsonism can also occur, particularly in juvenile-onset cases. Cognitive decline begins with executive dysfunction (reduced flexibility, poor planning, and impulsivity), progressing to global dementia. Psychiatric manifestations are common and include depression (the most common), apathy, irritability, obsessive-compulsive symptoms, and psychosis. Diagnosis is clinical, confirmed by genetic testing demonstrating 40 or more CAG repeats in the HTT gene. Presymptomatic testing is available for individuals at risk, requiring careful genetic counseling. MRI brain shows atrophy of the caudate nucleus and putamen (striatal atrophy) with corresponding enlargement of the frontal horns of the lateral ventricles. There is no disease-modifying treatment; management is symptomatic with antipsychotics (particularly tetrabenazine and deutetrabenazine for chorea), antidepressants, and anxiolytics. Mean survival is 15-20 years from symptom onset.

Huntington's Disease (Chorea)

– An autosomal dominant neurodegenerative disorder caused by a CAG trinucleotide repeat expansion (>36 repeats, normally <26) in the HTT gene on chromosome 4 (4p16.3), which encodes the huntingtin protein. The expanded repeat produces an elongated polyglutamine tract causing toxic protein aggregation and neuronal death, especially in the caudate nucleus, putamen, and cerebral cortex. Anticipation: repeat length tends to increase in successive generations, especially with paternal transmission (daughters of affected fathers are more likely to develop earlier onset). Prevalence: 5-10 per 100,000.

Age of onset: typically 35-50 years; juvenile onset (<20 years, large repeats >60 CAG) presents with rigidity and seizures. Clinical triad: (1) Movement disorder: chorea (irregular, rapid, jerky, purposeless movements of face, trunk, limbs; initially subtle may be masked by voluntary movement), dystonia, parkinsonism (rigidity, bradykinesia, especially in later stages), impaired voluntary movement (incoordination, dysarthria, dysphagia). (2) Cognitive decline: executive dysfunction (impaired planning, organising, multitasking, cognitive flexibility), memory deficits, psychomotor slowing, progressing to subcortical dementia. (3) Psychiatric symptoms: depression (most common, 30-50%, may precede motor onset), irritability, apathy, anxiety, obsessive-compulsive symptoms, psychosis (hallucinations, delusions, 5-15%). Diagnosis: clinical (positive family history in 90%, diagnostic criteria: motor symptoms in at-risk individual), genetic testing (CAG repeat length, confirmatory). Presymptomatic testing offered with genetic counseling. Imaging: MRI/CT shows caudate atrophy (bicaudate ratio increased) and ex vacuo ventricular enlargement. Management: no disease-modifying treatment. Chorea: tetrabenazine (VMAT2 inhibitor, depletes dopamine), deutetrabenazine, valbenazine; antipsychotics (olanzapine, risperidone) for chorea and psychiatric symptoms. Depression: SSRIs. Multidisciplinary care: physiotherapy, speech therapy, occupational therapy, nutritional support (high-calorie diet). Disease progression: inexorable, median survival 15-20 years from onset, death typically from pneumonia or complications of immobility. Research: antisense oligonucleotides (ASO) targeting HTT mRNA are in clinical trials.

Hydranencephaly

– A rare congenital condition where the cerebral hemispheres are nearly completely absent, replaced by thin-walled, fluid-filled sacs, while the brainstem, basal ganglia, and cerebellum are relatively preserved. Caused by bilateral internal carotid artery occlusion in utero (vascular insult, infection, or twin-twin transfusion). Presents with normal head size at birth, rapid head growth (mimicking hydrocephalus), preserved brainstem reflexes (sucking, swallowing, eye movements), but no cognitive development, visual tracking, or voluntary movement.

Diagnosis by transillumination (glows brightly) and MRI/CT showing absent cerebral tissue with preserved posterior fossa structures. Differentiated from severe hydrocephalus (which has a thin cortical rim). No treatment; supportive care. Most die in infancy or childhood.

Hydrocephalus

– Abnormal accumulation of cerebrospinal fluid (CSF) within the ventricles of the brain, leading to increased intracranial pressure. Communicating hydrocephalus: impaired CSF absorption (subarachnoid hemorrhage, meningitis, leptomeningeal carcinomatosis). Non-communicating (obstructive) hydrocephalus: blockage within the ventricular system (aqueductal stenosis, mass lesions, colloid cyst). Normal pressure hydrocephalus (NPH): classic triad of gait apraxia, urinary incontinence, and cognitive decline (dementia); enlarged ventricles on imaging with normal opening pressure. In infants: rapidly enlarging head circumference, bulging fontanelles, sunset eyes. Treatment: ventriculoperitoneal shunt (mainstay), endoscopic third ventriculostomy for selected obstructive cases.

Hyperesthesia

– Increased sensitivity to sensory stimulation—touch (tactile), pain (hyperalgesia), or other stimuli—so that normally non-painful or mildly painful stimuli produce exaggerated discomfort. Caused by nerve injury or sensitization: peripheral neuropathy, radiculopathy, postherpetic neuralgia, complex regional pain syndrome, spinal cord lesions, and central sensitization. Presents as burning, tingling, or unpleasant sensation on light touch (allodynia). Diagnosis: history and neurologic exam; EMG for neuropathy. Management: neuropathic pain agents (gabapentin, pregabalin, tricyclics, duloxetine), treat underlying cause, and protective skin care.

Internuclear Ophthalmoplegia

– A conjugate horizontal gaze disorder caused by a lesion of the medial longitudinal fasciculus (MLF), a heavily myelinated fiber tract that connects the abducens nucleus (CN VI) on one side to the oculomotor nucleus (CN III) on the contralateral side, coordinating horizontal gaze. In a left INO (the most common type), a lesion of the left MLF impairs adduction of the left eye (the eye cannot move

past the midline) and causes abducting nystagmus of the right eye (the abducting eye develops jerky nystagmus as it tries to overcome the impaired adduction signal). Convergence is preserved because the medial rectus subnucleus in CN III is also innervated via the vergence pathway, which bypasses the MLF. INO is most commonly bilateral in multiple sclerosis and unilateral in ischemic stroke affecting the brainstem (particularly the pons). The lesion is in the ipsilateral MLF relative to the eye that fails to adduct. Diagnosis is clinical by examination of horizontal gaze in both directions, with the characteristic pattern of impaired adduction on the ipsilateral side and abducting nystagmus on the contralateral side. MRI brain demonstrates the MLF lesion and any associated demyelinating or ischemic pathology. Treatment is directed at the underlying cause, with symptomatic management of oscillopsia from the nystagmus (gabapentin, memantine, clonazepam).

Intracerebral Hemorrhage

– Bleeding directly into the brain parenchyma, accounting for approximately ten to fifteen percent of all strokes and carrying a high mortality rate of approximately forty percent at thirty days. The most common cause is chronic hypertension, which causes lipohyalinosis and Charcot-Buchard microaneurysm formation in the penetrating arterioles of the basal ganglia (most commonly the putamen), thalamus, pons, and cerebellum. Other causes include cerebral amyloid angiopathy (common cause of lobar ICH in elderly patients), vascular malformations (arteriovenous malformations, cavernous malformations), intracranial aneurysms, coagulopathy (warfarin, DOACs, thrombocytopenia), brain tumors (tumoural hemorrhage), vasculitis, cerebral venous sinus thrombosis with venous infarction, and drug abuse (cocaine, amphetamines). Clinical presentation includes sudden onset of severe headache, vomiting, focal neurological deficit (hemiparesis, aphasia, sensory loss, visual field defects), altered level of consciousness, and seizures. The deficit progresses over minutes to hours as the haematoma expands. Diagnosis is by non-contrast CT head, which shows a hyperdense (white) lesion within the brain parenchyma. MRI is more sensitive for detecting the underlying cause (amyloid angiopathy,

cavernous malformations, tumors). CT angiography may detect a spot sign indicating active extravasation and risk of haematoma expansion. Management includes blood pressure control (systolic <140 mmHg to reduce haematoma expansion), reversal of anticoagulation (vitamin K, prothrombin complex concentrate, protamine), intracranial pressure monitoring and management, and surgical haematoma evacuation for cerebellar hemorrhage greater than 3 cm, lobar hemorrhage with significant mass effect, or superficial hemorrhage in a deteriorating patient. The STICH trial showed no overall benefit for early surgery in spontaneous supratentorial ICH.

Intracranial Hemorrhage

– Bleeding within the cranial cavity. Epidural hematoma: arterial bleeding (middle meningeal artery), typically from temporal bone fracture; lucid interval then rapid deterioration. Subdural hematoma: venous bleeding from bridging veins; acute (<72h), subacute, or chronic (elderly, alcoholics). Subarachnoid hemorrhage: arterial bleeding (aneurysm rupture 85%); thunderclap headache, nuchal rigidity. Intracerebral hemorrhage: hypertensive (basal ganglia, thalamus, pons, cerebellum), amyloid angiopathy, vascular malformations. Intraventricular hemorrhage: extension from ICH or primary. Diagnosis: non-contrast CT is first-line. Treatment: ABCs, reversal of anticoagulation, blood pressure control (SBP <140 for ICH), surgical evacuation (cerebellar >3cm, lobar >30cc), external ventricular drain for hydrocephalus, aneurysm clipping/coiling for SAH.

Ischemic Stroke

– A neurological deficit caused by focal cerebral ischemia due to thrombotic or embolic occlusion of a cerebral artery (87% of all strokes). Thrombotic: in situ occlusion of atherosclerotic vessel. Embolic: embolus from cardiac source (atrial fibrillation, valvular disease, patent foramen ovale) or large artery (carotid/vertebral). Lacunar: small vessel occlusion due to lipohyalinosis. Presents with sudden focal deficits (hemiparesis, aphasia, neglect, ataxia) corresponding to vascular territory. Diagnosis: non-contrast CT (rule out hemorrhage), CT perfusion, MRI DWI (gold standard). Acute management: IV tPA within 4.5 hours, mechanical thrombectomy for large vessel occlusion within 24 hours. Secondary

prevention: antiplatelets, statins, blood pressure control, anticoagulation for cardioembolic.

Jacksonian Epilepsy (Focal Seizures)

– A type of focal (partial) seizure originating in the primary motor cortex, characterized by clonic (rhythmic jerking) or tonic (sustained contraction) movements that spread sequentially to adjacent body parts along the motor homunculus (Jacksonian march). Named after John Hughlings Jackson (1835-1911), who first described the phenomenon. The march typically begins in the hand or face (largest cortical representation) and spreads proximally up the arm, then to the leg on the same side. Can also present as sensory seizures (somatosensory cortex, paraesthesiae) or versive seizures (frontal eye field). Consciousness is usually preserved during the seizure (focal aware seizure, ILAE 2017 classification). May evolve into a bilateral tonic-clonic seizure (secondary generalisation). Aetiologies: any focal brain lesion—cortical dysplasia, tumor (gliomas, meningiomas), stroke, arteriovenous malformation, traumatic brain injury, infection (abscess, encephalitis), and mesial temporal sclerosis. Diagnosis: EEG (may show focal spikes or sharp waves over the contralateral central region), MRI brain with epilepsy protocol. Treatment: antiseizure medications (carbamazepine, lamotrigine, levetiracetam, oxcarbazepine). Surgical resection of the epileptogenic focus may be curative in 60-80% of drug-resistant cases.

Limbic System

– A set of interconnected brain structures located in the medial temporal lobe and around the corpus callosum, involved in emotion, memory, motivation, behaviour, and autonomic regulation. The term was coined by Paul Broca (1878, le grand lobe limbique) and expanded by Papez (1937, Papez circuit) and MacLean (1952, 'visceral brain'). Key structures: (1) Hippocampus: memory formation (spatial, episodic), encoding and consolidation from short-term to long-term memory. (2) Amygdala: emotional processing (fear, anger, anxiety, pleasure), emotional memory, social behaviour, and threat detection. (3) Cingulate gyrus: emotional processing, conflict monitoring, pain processing, decision-making. (4) Hypothalamus: autonomic

(sympathetic and parasympathetic), neuroendocrine (CRH, TRH, GHRH, GnRH, ADH), hunger/satiety, thirst, thermoregulation, circadian rhythms. (5) Fornix: major output tract from hippocampus to mammillary bodies. (6) Mammillary bodies: memory (reciprocal connections with hippocampus via fornix, and with thalamus). (7) Anterior thalamic nucleus: part of the Papez circuit, spatial memory. (8) Septal nuclei: reward, pleasure, reinforcement. (9) Parahippocampal gyrus: input to hippocampus. (10) Olfactory tubercle: smell. Limbic system dysfunction causes: memory disorders (Alzheimer disease–hippocampal atrophy, Korsakoff syndrome–mammillary body and thalamic damage), emotional dysregulation (anxiety, depression, PTSD, phobias), seizure disorders (temporal lobe epilepsy), schizophrenia (disrupted limbic connectivity), and autonomic dysfunction.

Locked-in Syndrome

– A neurological condition in which the patient is fully conscious and aware but cannot move or speak due to complete paralysis of all voluntary muscles except for vertical eye movements and blinking (total locked-in syndrome: loss of all eye movements). The patient is 'locked in' a body that cannot respond but has intact cognition, sensation, and consciousness. Most common cause: bilateral ventral pontine stroke (basilar artery occlusion/ thrombosis, infarction of the ventral pons, damaging the corticospinal tracts and corticobulbar tracts, sparing the reticular activating system (consciousness) and the midbrain tectum (vertical eye movements). Other causes: central pontine myelinolysis (rapid correction of hyponatremia), pontine hemorrhage, brainstem tumor, encephalitis (enterovirus 71), trauma (basilar skull fracture), amyotrophic lateral sclerosis (advanced), and severe Guillain-Barré syndrome. Diagnosis: clinical (consciousness confirmed by eye movement communication). MRI brain shows ventral pontine lesion. EEG is normal (distinguishes from vegetative state/minimally conscious state). Communication: often established through eye movements (blinking code, eye-tracker technology, EEG-based brain-computer interfaces). Prognosis: poor for functional recovery; mortality 60-90% in the first year. Some patients survive many years with intensive support and communication devices. The

condition is distinguished from: coma (no eye opening, no awareness), vegetative state (wakefulness without awareness, no purposeful responses), and minimally conscious state (inconsistent but reproducible evidence of awareness).

Locomotor Ataxia (Tabes Dorsalis)

– A late manifestation of untreated tertiary syphilis (neurosyphilis) caused by infection with *Treponema pallidum*, involving progressive degeneration of the dorsal columns (fasciculus gracilis and cuneatus) and dorsal roots of the spinal cord. The demyelination and neuronal loss affect the sensory pathways mediating proprioception (joint position sense) and vibration sense. Clinical features: sensory ataxia (wide-based, stamping gait, worse with eyes closed, positive Romberg sign), paraesthesiae (lightning pains–sudden, severe, stabbing pain in the legs, back, trunk), loss of deep tendon reflexes (especially knee and ankle jerks, areflexia due to dorsal root involvement), impaired proprioception and vibration sense, Charcot joints (neuropathic arthropathy, painless joint destruction, most commonly knee, ankle), Argyll Robertson pupils (bilateral small irregular pupils that accommodate but do not react to light, light-near dissociation), and optic atrophy. Onset is typically 15-30 years after primary infection. Diagnosis: clinical, serum treponemal tests (TPPA, FTA-ABS) positive, CSF analysis (lymphocytic pleocytosis, elevated protein, positive CSF VDRL), and spinal cord MRI (dorsal column T2 hyperintensity and atrophy). Treatment: aqueous crystalline penicillin G 18-24 million units IV daily for 10-14 days. Prognosis: some improvement in symptoms, but neurological deficits are often permanent.

Lumbar puncture

– Also known as spinal tap, a procedure to obtain cerebrospinal fluid from the subarachnoid space in the lumbar spine, typically at the L3-L4 or L4-L5 interspace (below the termination of the spinal cord at L1-L2 in adults). Indications include diagnosis of meningitis and encephalitis (CSF Gram stain, culture, cell count, glucose, protein, PCR for viruses and bacteria), subarachnoid hemorrhage (xanthochromia from bilirubin breakdown products, RBC count not clearing from tube 1 to tube 4), neuroinflammatory and demyelinating diseases (mul-

tiple sclerosis, Guillain-Barre syndrome, chronic inflammatory demyelinating polyneuropathy), and neoplastic conditions (leptomeningeal carcinomatosis, lymphoma). The procedure involves inserting a hollow needle (typically 22G or 20G) into the subarachnoid space at the L3-L4 or L4-L5 interspace, after sterile preparation and local anesthesia. The patient is positioned in the lateral decubitus (fetal) position or sitting and leaning forward to widen the interlaminar space. Opening pressure is measured using a manometer before CSF is collected, with normal opening pressure ranging from 10-20 cm H₂O. CSF is collected in sequential tubes for cell count and differential, glucose and protein, Gram stain and culture, and additional studies (PCR, cytology, oligoclonal bands, flow cytometry) as indicated. Contraindications include increased intracranial pressure with mass effect or intracranial mass (risk of brain herniation—the most feared complication), coagulopathy or thrombocytopenia, infection at the puncture site, and spinal cord compression. Complications include post-dural puncture headache (the most common complication, caused by CSF leak through the dural puncture, managed with bed rest, caffeine, hydration, and epidural blood patch for severe cases), bleeding (spinal epidural haematoma, rare but serious), infection (meningitis, epidural abscess), and radicular pain from nerve root irritation.

Lumbar Radiculopathy

– A condition caused by compression, irritation, or inflammation of a spinal nerve root in the lumbar spine, resulting in pain radiating into the lower extremity along the distribution of the affected nerve root (sciatica). The most commonly affected nerve roots are L4, L5, and S1. L4 radiculopathy causes pain radiating into the medial leg and medial foot, weakness of knee extension (quadriceps), and decreased knee reflex. L5 radiculopathy causes pain radiating into the lateral leg and dorsum of the foot, weakness of ankle dorsiflexion (foot drop) and great toe extension (extensor hallucis longus), with no reflex changes. S1 radiculopathy causes pain radiating into the posterior leg and lateral foot, weakness of plantar flexion (gastrocnemius, soleus), and decreased ankle jerk reflex. Diagnosis is clinical, confirmed by MRI of the lumbar spine demonstrat-

ing nerve root compression from disc herniation, spinal stenosis, or foraminal narrowing. EMG/NCS may confirm the affected nerve root and exclude peripheral neuropathy or plexopathy. Management is initially conservative with NSAIDs, activity modification, and physiotherapy. Epidural corticosteroid injections provide temporary relief. Surgical intervention (microdiscectomy or decompressive laminectomy) is indicated for cauda equina syndrome, progressive motor deficit, or persistent radicular pain despite 6-12 weeks of conservative management.

Memory

– The cognitive process of encoding, storing, and retrieving information, mediated by distributed neural networks involving the hippocampus, medial temporal lobe, prefrontal cortex, and limbic system. Types: sensory memory (brief, millisecond–second), short-term/working memory (seconds–minutes, limited capacity 7 items), and long-term memory (subdivided into explicit/episodic and semantic and implicit/procedural). Memory impairment (amnesia) can be acute (transient global amnesia, concussion, seizure, medication side effects) or progressive (Alzheimer disease, vascular dementia, frontotemporal dementia, Lewy body dementia). Evaluation includes mental status examination (MMSE, MoCA), collateral history, laboratory workup (B12, TSH, syphilis, HIV), and brain imaging (MRI for atrophy pattern, vascular disease). Management: treat reversible causes, cognitive stimulation, safety planning, and pharmacotherapy (cholinesterase inhibitors for Alzheimer disease; memantine for moderate–severe stages).

Migraine With Aura

– A primary headache disorder characterized by recurrent attacks of fully reversible visual, sensory, or speech symptoms that develop gradually over at least five minutes and last no more than sixty minutes, followed by headache with the characteristics of migraine. Visual aura is the most common type, affecting approximately ninety percent of patients with migraine with aura, and typically consists of a fortification spectrum (scintillating scotoma) that expands over the visual field over 20-60 minutes, leaving a scotoma (blind spot) in its wake. Sensory aura is the second most common type, presenting with unilateral tingling and numbness that spreads

slowly from the hand up the arm to the face, typically lasting 5-30 minutes. Speech and language aura is less common and presents with dysphasic speech. The migraine aura is thought to be caused by cortical spreading depression (CSD)—a wave of neuronal and glial depolarisation followed by prolonged suppression of neural activity that propagates across the cerebral cortex at a rate of 2-6 mm per minute. The visual aura localises to the occipital cortex, sensory aura to the somatosensory cortex, and speech aura to the language areas. If the aura occurs without headache (migraine aura without headache, formerly called acephalgic migraine), other causes such as transient ischemic attack and seizure must be excluded, particularly in older patients. Triptans and NSAIDs are effective for acute treatment, and they are safe to take during the aura phase. Preventive treatment is indicated for frequent or disabling attacks (typically more than 4 per month) and includes the same options as for migraine without aura. The risk of ischemic stroke is slightly elevated in migraine with aura, particularly in women who smoke and use oral contraceptives, and this should be considered in management.

Mild Cognitive Impairment

– A transitional cognitive state between normal aging and dementia, characterized by subjective cognitive complaints confirmed by objective cognitive impairment that is not severe enough to significantly interfere with daily activities. MCI is classified as amnesic MCI (aMCI), where memory is the primary domain affected, and non-amnesic MCI (naMCI), where other cognitive domains (attention, executive function, visuospatial ability, language) are primarily affected. The amnesic subtype is the most common and is considered a prodromal stage of Alzheimer disease in most cases. The prevalence of MCI in adults over 60 is approximately 15-20 percent, and the annual conversion rate from MCI to dementia is approximately 10-15 percent, although some patients remain stable or revert to normal cognition. Diagnosis requires objective cognitive testing confirming impairment one to two standard deviations below age- and education-matched norms, with intact functional abilities. Biomarkers such as CSF A-beta and tau levels, amyloid PET imaging, and FDG-PET can help determine the likelihood

of progression to Alzheimer disease. Management includes addressing modifiable vascular risk factors (hypertension, diabetes, smoking), cognitive stimulation, physical exercise, and monitoring for cognitive decline. There is no pharmacological treatment approved for MCI; acetylcholinesterase inhibitors are not recommended as they do not prevent progression to dementia. Prognosis is variable, with some patients remaining stable indefinitely while others progress to dementia within a few years.

Multiple System Atrophy

– A progressive, fatal neurodegenerative disorder characterized by varying combinations of autonomic failure, cerebellar ataxia, parkinsonism, and pyramidal signs. It is classified into two subtypes: MSA-P (Parkinsonian variant, previously striatonigral degeneration), characterized by prominent parkinsonism with poor levodopa response, and MSA-C (cerebellar variant, previously sporadic olivopontocerebellar atrophy), characterized by prominent cerebellar ataxia. Pathologically, MSA is characterized by the accumulation of alpha-synuclein in oligodendrocytes, forming glial cytoplasmic inclusions (GCIs), which is the pathological hallmark and distinguishes MSA from other synucleinopathies such as Parkinson disease and Lewy body dementia where alpha-synuclein accumulates in neurons. Onset is typically in the 50s or 60s, with rapidly progressive course leading to severe disability within 5-10 years. Clinical features of autonomic failure (present in both subtypes) include orthostatic hypotension (symptomatic drop in blood pressure on standing, often the earliest symptom), urinary incontinence, erectile dysfunction, and impaired sweating. Other features include stridor (nocturnal and diurnal, indicating vocal cord abductor paralysis, a potentially life-threatening complication requiring CPAP or tracheostomy), REM sleep behaviour disorder, and respiratory dysfunction. The parkinsonism in MSA-P is typically symmetrical, with poor or absent response to levodopa, early postural instability, and craniocervical dystonia. The cerebellar features in MSA-C include gait and limb ataxia, dysarthria, and oculomotor abnormalities. Diagnosis is clinical (second consensus criteria for MSA) with supportive features including MRI findings: putaminal atrophy, putaminal rim sign (hy-

perintense rim on T2-weighted MRI in MSA-P), hot cross bun sign (cruciform hyperintensity in the pons on T2-weighted MRI in MSA-C), and middle cerebellar peduncle atrophy. The putaminal rim sign on susceptibility-weighted imaging is characteristic. There is no disease-modifying treatment; management is symptomatic and supportive, including treatment of orthostatic hypotension (fludrocortisone, midodrine, droxidopa), physical therapy, speech therapy, and in advanced cases, CPAP for stridor and feeding tube placement for dysphagia. Prognosis is poor, with median survival of 6-10 years from diagnosis.

Myelopathy

– A general term for any neurological deficit resulting from spinal cord pathology, encompassing a wide range of causes and clinical presentations. The clinical features depend on the level and completeness of the spinal cord lesion and may include motor weakness (upper motor neuron pattern below the lesion, with spasticity, hyperreflexia, and extensor plantar responses), sensory loss (with a sensory level corresponding to the lesion), bladder and bowel dysfunction, and gait disturbance, spastic gait, sensory ataxia, or a combination. The sensory level is a key finding in myelopathy—the dermatomal level at which sensation changes from normal to abnormal below the level of the lesion. This helps localise the spinal cord lesion. Diagnosis is by MRI of the spinal cord, which demonstrates the underlying pathology (compression, inflammation, infarction, tumor, or demyelination). Management depends on the cause and may include surgical decompression for extramedullary compression (disc, tumor, abscess, haematoma), corticosteroids for inflammatory or demyelinating myelopathy, immunosuppression for autoimmune causes, and rehabilitation for functional recovery. Prognosis depends on the etiology, severity of the initial deficit, and timeliness of treatment.

Neglect Syndrome

– Hemispatial neglect (unilateral neglect, hemineglect) is a neurological condition characterized by failure to attend to, respond to, or orient toward stimuli on the side of space contralateral to the brain lesion, in the absence of primary sensory or motor deficits sufficient to explain the neglect. It is most commonly caused by damage to the right

hemisphere, particularly the right parietal lobe (especially the inferior parietal lobule and temporoparietal junction), right thalamus, or right basal ganglia. The patient fails to respond to stimuli on the contralateral (left) side, which may include visual, auditory, tactile, or even olfactory stimuli. Patients may fail to eat food on the left side of their plate, bump into objects on the left, shave only the right side of their face, and may even deny ownership of their left limbs (somatoparaphrenia). Neglect is more severe and persistent for left-sided stimuli after right hemisphere damage due to the right hemisphere's dominant role in spatial attention (both hemispheres attend to the right, but only the right attends to the left). The contralesional side is the left side. Diagnosis includes bedside tests such as line bisection (patient marks the middle of a horizontal line, bisecting it further to the right of center), cancellation tasks (patient fails to cancel targets on the left side of the page), and drawing tasks (patient omits left-sided details when drawing a clock or a daisy). The Behavioural Inattention Test (BIT) provides a standardised assessment. Management includes visual scanning training, limb activation therapy, prism adaptation, and dopamine agonists. The condition has a significant negative impact on functional recovery and rehabilitation outcomes, with less severe forms resolving over weeks to months.

Neurocysticercosis

– The most common parasitic infection of the central nervous system worldwide and is caused by the larval stage (cysticercus) of the pork tapeworm *Taenia solium*. It is endemic in Latin America, Asia, and Africa, and is an important cause of epilepsy in endemic regions. The larvae are ingested through fecal-oral transmission (ingestion of food or water contaminated with tapeworm eggs from an infected individual), and the oncospheres cross the intestinal wall, disseminate hematogenously to the brain, where they develop into cysticerci within the brain parenchyma, subarachnoid space, ventricles, or spinal cord. Clinical presentation depends on the location and number of cysts and the host immune response. Parenchymal neurocysticercosis commonly presents with seizures (the most common manifestation in endemic regions, accounting for up to 30 percent of epilepsy in endemic areas),

headache, and focal neurological deficits. Ventricular cysts can cause obstructive hydrocephalus, and subarachnoid cysts can cause arachnoiditis and communicating hydrocephalus. Diagnosis is by neuroimaging: CT shows calcified dead cysts (small hyperdense nodules) and viable cysts (hypodense lesions with a scolex visible as a hyperdense dot within the cyst). MRI is more sensitive, showing the cyst fluid intensity similar to CSF and the scolex as a mural nodule on T1-weighted imaging. Serological testing (enzyme-linked immunoelectrotransfer blot) in serum and CSF supports the diagnosis. Management includes antiparasitic drugs (albendazole, praziquantel) for active parenchymal cysts, corticosteroids to control inflammation and cerebral edema during antiparasitic treatment, anticonvulsants for seizure control, and surgical management of hydrocephalus (CSF shunting) and intraventricular or spinal cysts. Prognosis is generally good for parenchymal disease with treatment; ventricular and subarachnoid disease have worse outcomes. Prevention focuses on improved hygiene, sanitation, and meat inspection.

Neurological Examination

– The systematic clinical assessment of the nervous system: mental status/cognition, cranial nerves (I–XII), motor system (bulk, tone, power, pronator drift), reflexes (deep tendon reflexes, plantar/Babinski), coordination (finger–nose, heel–shin), gait, sensory examination (light touch, pinprick, vibration, proprioception, temperature), and autonomic signs. Localizes lesions (UMN vs LMN, hemisphere vs brainstem vs spinal cord vs peripheral nerve) and guides investigation (imaging, labs, EMG). Serial examinations monitor progression (e.g., GCS in head injury). A structured approach maximizes detection of deficits.

Neuromyelitis Optica

– Neuromyelitis optica spectrum disorder (NMOSD), formerly known as Devic disease, is an autoimmune, inflammatory demyelinating disorder of the central nervous system that preferentially targets the optic nerves and spinal cord. It is caused by pathogenic aquaporin-4 (AQP4) immunoglobulin G autoantibodies in approximately seventy-five to eighty percent of cases, which bind to AQP4 water channels on astrocyte foot processes, activating complement-

mediated astrocyte damage and secondary demyelination. Clinical presentation of NMOSD includes optic neuritis (acute or subacute vision loss, often bilateral or sequential, and more severe than in multiple sclerosis, with poor recovery), longitudinally extensive transverse myelitis (LETM, defined as spinal cord lesion extending three or more vertebral segments on MRI, causing paraplegia, sensory loss, and bladder dysfunction), area postrema syndrome (intractable nausea, vomiting, and hiccoughs due to involvement of the medullary area postrema, which is a highly characteristic presentation), and acute brainstem syndrome. The distinction from multiple sclerosis is critical because treatments differ: MS disease-modifying therapies (interferon-beta, fingolimod, natalizumab) are ineffective or may exacerbate NMOSD. Diagnosis is based on clinical criteria (IPND 2015 criteria) requiring at least one core clinical characteristic plus positive AQP4-IgG serology. In seronegative cases, myelin oligodendrocyte glycoprotein (MOG) antibody-associated disease should be considered. MRI findings include longitudinally extensive optic nerve involvement, LETM with central cord involvement, and periaqueductal and area postrema brain lesions. Acute treatment includes high-dose intravenous corticosteroids as first-line, with plasma exchange for steroid-resistant cases. Long-term immunosuppression to prevent relapses includes mycophenolate mofetil, azathioprine, rituximab, eculizumab (a complement C5 inhibitor), inebilizumab (anti-CD19 monoclonal antibody), and satralizumab (anti-IL-6 receptor monoclonal antibody). Prognosis is relapse-dependent, with most patients accumulating disability from recurrent attacks. Attacks are typically more severe than in MS, but progression is attack-related rather than gradual.

Neuropathic Pain

– Chronic pain caused by damage or disease affecting the somatosensory nervous system, including the peripheral nerves, dorsal root ganglia, spinal cord, or brain. It is characteristically described as burning, shooting, electric shock-like, tingling, or stabbing, and may be accompanied by allodynia (pain from a normally non-painful stimulus) and hyperalgesia (exaggerated pain from a normally painful stimulus). Common causes include diabetic peripheral

neuropathy, postherpetic neuralgia (the most common cause), painful diabetic peripheral neuropathy, trigeminal neuralgia, spinal cord injury pain, post-stroke central pain, chemotherapy-induced peripheral neuropathy, and HIV-associated neuropathy. Diagnosis is clinical, based on the characteristic pain descriptors and neurological examination findings. Screening tools such as the Douleur Neuropathique 4 (DN4) questionnaire and the Leeds Assessment of Neuropathic Symptoms and Signs (LANSS) scale help differentiate neuropathic from nociceptive pain. Nerve conduction studies and skin biopsy (quantifying intraepidermal nerve fibre density) may confirm small fibre neuropathy. Management follows a stepwise approach: first-line treatments include gabapentinoids (gabapentin, pregabalin), tricyclic antidepressants (amitriptyline, nortriptyline), and serotonin-noradrenaline reuptake inhibitors (duloxetine, venlafaxine). Topical treatments include lidocaine 5 percent patches and capsaicin 8 percent patches for localised neuropathic pain. Second-line options include tramadol and other opioid analgesics, which should be used cautiously due to the risk of dependence. Non-pharmacological treatments include transcutaneous electrical nerve stimulation (TENS), cognitive behavioural therapy, and spinal cord stimulation for refractory cases. Management of the underlying condition (e.g., glycaemic control in diabetes, antiviral therapy for herpes zoster) is also important.

NIH Stroke Scale

– The National Institutes of Health Stroke Scale (NIHSS) is a standardized, validated clinical assessment tool used to quantify the severity of acute ischemic stroke. It consists of fifteen items assessing level of consciousness, gaze, visual fields, facial palsy, motor strength in the arms and legs, limb ataxia, sensory function, language, dysarthria, and extinction/inattention. Each item is scored with a specific number of points, and the total score ranges from zero (no stroke symptoms) to forty-two (most severe stroke). Each item is assessed by a certified examiner, and the scale can be completed in approximately 5-8 minutes. The NIHSS is used to assess baseline stroke severity, guide treatment decisions (e.g., thrombolysis is generally recommended for NIHSS 4-25, though patients with severe strokes

may still benefit), monitor neurological changes during the acute phase, and predict outcomes. Higher scores predict poorer outcomes at 90 days. The NIHSS has well-established reliability and validity but has limitations, including poor sensitivity for posterior circulation stroke and right hemisphere stroke, and language barriers for aphasic patients. It is also less accurate for very mild (NIHSS 0-3) or very severe strokes.

Non communicating Hydrocephalus

– Non-communicating (obstructive) hydrocephalus is a type of hydrocephalus in which there is obstruction to the flow of cerebrospinal fluid (CSF) within the ventricular system, preventing CSF from reaching the arachnoid granulations for absorption. The obstruction can occur at any level of the ventricular system, causing dilation of the ventricles proximal to the obstruction. Common causes include tumors (particularly those obstructing the fourth ventricle or the aqueduct of Sylvius, such as posterior fossa tumors such as medulloblastoma, ependymoma, and brainstem glioma), aqueductal stenosis (congenital or acquired), intraventricular hemorrhage (particularly in premature infants causing post-hemorrhagic hydrocephalus), and intraventricular cysts or masses. Clinical presentation depends on the severity and rate of progression of the obstruction. Acute obstruction presents with severe headache, nausea and vomiting, papilloedema, and rapidly decreasing level of consciousness (life-threatening). Chronic obstruction presents with headache, developmental delay (in children), macrocephaly in infants, gait disturbance, cognitive decline, and the sunseting eye sign (upward gaze palsy due to pressure on the tectal plate from a dilated third ventricle). Diagnosis is by neuroimaging (CT or MRI) showing dilation of the ventricles proximal to the obstruction (lateral and third ventricles above the aqueduct, or fourth ventricle below the aqueduct if the obstruction is at the foramen of Luschka and Magendie), with normal or small ventricles distal to the obstruction. Aqueductal flow studies on MRI can confirm obstruction. Management includes urgent CSF diversion via endoscopic third ventriculostomy (ETV) for

aqueductal stenosis and selected obstructive causes, or ventriculoperitoneal (VP) shunt placement, with removal of the obstructing lesion if possible (e.g., tumor resection).

Normal Pressure Hydrocephalus

– A potentially reversible cause of dementia characterized by the classic triad of gait disturbance, urinary incontinence, and cognitive impairment, with enlarged cerebral ventricles on imaging despite normal cerebrospinal fluid pressure on lumbar puncture. NPH is classified as idiopathic (primary) or secondary to conditions such as subarachnoid hemorrhage, meningitis, or traumatic brain injury. The pathophysiology is thought to involve impaired CSF absorption at the arachnoid granulations due to reduced CSF conductance, leading to increased ventricular pressure that is not reflected by a single normal lumbar puncture opening pressure but may be detected by prolonged intracranial pressure monitoring. The classic clinical triad (Wet, Wacky, Wobbly) includes gait apraxia (the earliest and most prominent feature—difficulty initiating walking with a magnetic, shuffling gait described as feet feeling stuck to the floor), cognitive impairment (subcortical dementia with psychomotor slowing, inattention, and executive dysfunction rather than the prominent memory loss of Alzheimer disease), and urinary incontinence (urinary urgency and frequency progressing to complete incontinence, typically occurring last in the triad). Diagnosis is clinical with supportive imaging: MRI brain shows enlarged ventricles out of proportion to cortical atrophy (ventriculomegaly with Evan index greater than 0.3), periventricular white matter changes, and tight high-convexity sulci (disproportionately enlarged subarachnoid space hydrocephalus). Additional diagnostic tests include a positive response to CSF drainage via lumbar puncture (Tap test) or extended lumbar CSF drainage (ELD), where improvement in gait is the most predictive finding. CSF infusion studies may show reduced CSF conductance. Management is CSF diversion via a ventriculoperitoneal (VP) shunt. Response rates are variable, with gait improvement occurring in 70-80 percent of appropriately selected patients, cognitive improvement in 50-70 percent, and urinary improvement in 50-60 percent. The best outcomes are seen

in patients with dominant gait disturbance, known etiology (secondary NPH), and a positive response to CSF drainage.

Occipital Neuralgia

– A paroxysmal, severe, stabbing or electric shock-like pain in the distribution of the greater, lesser, or third occipital nerves (posterior scalp, from the nuchal line to the vertex). The pain is unilateral or bilateral, often described as 'ice pick' or 'stabbing', with tenderness over the occipital nerve and paraesthesias in the affected dermatome. Attacks last seconds to minutes but may be followed by a dull ache. Causes: entrapment or irritation of the occipital nerves (trauma, whiplash, cervical spine disease—C1–C3 facet arthropathy, tumors, vascular compression). Differential diagnosis: cervicogenic headache, migraine (especially occipital migraine), giant cell arteritis (must be excluded—check ESR, CRP, temporal artery biopsy), and tension-type headache. Diagnosis is clinical; occipital nerve block (injection of lidocaine and corticosteroid at the midpoint between the occipital protuberance and mastoid) is both diagnostic and therapeutic. Treatment: nerve blocks, NSAIDs, muscle relaxants, neuropathic pain agents (gabapentin, amitriptyline), and in refractory cases, pulsed radiofrequency ablation or occipital nerve stimulation.

Paranoia

– A thought process characterized by excessive or irrational suspiciousness and distrust of others, often manifesting as delusions of persecution, reference, or grandeur. Paranoia occurs across a spectrum: paranoid personality disorder (pervasive, lifelong pattern of distrust without the severity of delusions), delusional disorder (persecutory type—non-bizarre delusions in the absence of other psychotic symptoms), paranoid schizophrenia (prominent persecutory delusions with hallucinations and disorganised thinking), and secondary paranoia (due to dementia, substance use—cocaine, amphetamines, alcohol withdrawal, traumatic brain injury, or brain tumors). Paranoia may also occur in mood disorders (psychotic depression, bipolar mania). Treatment: antipsychotic medication, cognitive behavioural therapy, and treatment of underlying cause.

Paresthesia

– An abnormal sensation in the skin, described as

tingling, prickling, numbness, burning, or a pins-and-needles sensation, caused by dysfunction of the sensory nerves. It can be caused by any condition that affects the peripheral nerves, nerve roots, or central sensory pathways. Common causes include peripheral neuropathy (diabetes, alcohol, vitamin deficiencies), nerve compression (carpal tunnel syndrome, ulnar neuropathy, radiculopathy), multiple sclerosis, spinal cord lesions, stroke, transient ischemic attack, migraine with aura (sensory aura), anxiety and hyperventilation, and certain medications. Paresthesia is a symptom rather than a diagnosis and may be transient (e.g., pressure on a nerve causing the limb to fall asleep) or chronic (e.g., diabetic peripheral neuropathy). The distribution of the paresthesia is important for localising the lesion: peripheral nerve distribution suggests a mononeuropathy, stocking-and-glove distribution suggests a length-dependent polyneuropathy, dermatomal distribution suggests a radiculopathy, a hemi-body distribution suggests a central (brain) lesion, and bilateral leg involvement suggests a spinal cord lesion. Diagnosis involves identifying the underlying cause through history, neurological examination, electrodiagnostic studies, and appropriate laboratory tests. Management is directed at the underlying cause, with symptomatic treatment of neuropathic pain if the paresthesia is painful.

Parkinson Disease

– A progressive neurodegenerative disorder characterized by the loss of dopaminergic neurons in the substantia nigra pars compacta of the midbrain, leading to reduced dopamine levels in the striatum and the cardinal motor features of bradykinesia, resting tremor, rigidity, and postural instability. The cardinal motor features include bradykinesia (slowness of movement, the hallmark feature, with progressive reduction in amplitude and speed of repetitive movements), resting tremor (a pill-rolling tremor of the hand at 4-6 Hz that is present at rest and diminishes with voluntary movement, typically asymmetrical at onset), rigidity (lead-pipe or cogwheel resistance to passive movement), and postural instability (impaired balance and tendency to fall, typically occurring later in the disease course). Non-motor features are increasingly recognised and include hyposmia (reduced sense of smell, often a

prodromal feature that may precede motor symptoms by years), REM sleep behaviour disorder (acting out dreams), constipation, depression (the most common neuropsychiatric symptom), anxiety, apathy, cognitive impairment (executive dysfunction and bradyphrenia, progressing to dementia in up to 80 percent of patients with long-standing disease), autonomic dysfunction (orthostatic hypotension, urinary frequency, erectile dysfunction), and pain. Diagnosis is clinical using the UK Parkinson Disease Society Brain Bank criteria, which require bradykinesia plus at least one of rigidity, resting tremor, or postural instability. Dopamine transporter (DaT) SPECT scanning can confirm presynaptic dopaminergic denervation when the diagnosis is uncertain. The gold standard treatment is levodopa combined with a peripheral decarboxylase inhibitor (carbidopa or benserazide), which is the most effective symptomatic therapy, but long-term use is complicated by motor fluctuations (wearing-off phenomena, on-off fluctuations) and dyskinesias (involuntary choreiform movements). Other medications include dopamine agonists (pramipexole, ropinirole, rotigotine), monoamine oxidase B inhibitors (selegiline, rasagiline), catechol-O-methyltransferase inhibitors (entacapone, opicapone), anticholinergics (for tremor in younger patients), and amantadine (for dyskinesias). Deep brain stimulation of the subthalamic nucleus or globus pallidus internus is effective for advanced disease with motor fluctuations and dyskinesias. Multidisciplinary management including physiotherapy, occupational therapy, speech therapy, and specialist nursing is essential.

Parkinsonism

– A clinical syndrome characterized by bradykinesia, rigidity, tremor (resting, pill-rolling), and postural instability. Idiopathic Parkinson disease: most common cause, responds well to levodopa. Atypical parkinsonian disorders: multiple system atrophy (Parkinsonism plus cerebellar/autonomic), progressive supranuclear palsy (vertical gaze palsy, early falls), corticobasal degeneration (asymmetric apraxia, alien limb), dementia with Lewy bodies (Parkinsonism plus early dementia). Drug-induced parkinsonism: antipsychotics, resolves with drug withdrawal. Vascular parkinsonism: lower body predominance, poor levodopa response.

Peripheral Neuropathy

– A disorder of peripheral nerves causing sensory, motor, and/or autonomic symptoms in a distal, symmetric ‘stocking-glove’ pattern. Causes: diabetes (most common), alcohol, vitamin B12 deficiency, uremia, hypothyroidism, toxins, medications (chemotherapy, isoniazid), autoimmune (GBS, CIDP, vasculitis), infections (HIV, leprosy), paraproteinemia, and hereditary (Charcot-Marie-Tooth). Features: numbness, tingling, burning pain, weakness, atrophy, absent reflexes. Diagnosis: clinical, NCS/EMG (axonal vs. demyelinating), labs (B12, glucose/HbA1c, TSH, SPEP, B12), biopsy if needed. Management: treat cause, neuropathic pain agents (gabapentin, pregabalin, duloxetine, amitriptyline), foot care.

Pituitary Adenoma

– Pituitary adenomas are benign neoplasms arising from the adenohypophysis (anterior pituitary gland), accounting for approximately ten to fifteen percent of all intracranial neoplasms. They are classified by size as microadenomas (less than 10 millimeters) or macroadenomas (10 millimeters or greater), and by functional status as functioning (hormone-secreting) or non-functioning. Functioning adenomas include prolactinomas (most common functioning adenoma, causing galactorrhea, amenorrhea, and infertility). Non-functioning adenomas present with mass effect: visual field deficits (bitemporal hemianopia from compression of the optic chiasm), headache, hypopituitarism (from compression of the normal pituitary gland), and cranial nerve palsies from cavernous sinus invasion. Prolactinomas are treated medically with dopamine agonists (cabergoline is first-line, bromocriptine is second-line), which are highly effective in reducing prolactin levels and tumor size. Surgery (trans-sphenoidal adenomectomy) is indicated for non-functioning adenomas causing mass effect, functioning adenomas not responsive to medical therapy (except prolactinomas), and apoplexy (hemorrhagic infarction of a pituitary adenoma causing acute headache, visual loss, ophthalmoplegia, and altered consciousness—a pituitary emergency requiring urgent corticosteroid replacement and surgical decompression). Radiotherapy or radiosurgery (Gamma Knife) is used for residual, recurrent, or aggressive adenomas. Endocrine assessment and

replacement of deficient hormones are essential before and after treatment. Prognosis is excellent for microadenomas, and macroadenomas have good outcomes with surgical resection, though long-term endocrine follow-up is required.

Presyncope

– The sensation of imminent fainting (lightheadedness, weakness, visual blurring) without actual loss of consciousness, due to transient global cerebral hypoperfusion that resolves before LOC. Causes: orthostatic hypotension (volume depletion, autonomic failure, medications), vasovagal, cardiac (arrhythmias, aortic stenosis), and metabolic. Evaluation: orthostatic BP, ECG, cardiac workup if suspected, medications review. Distinguish from true syncope and from vertigo. Management: treat cause—volume, compression, medication adjustment, education about warning symptoms. Recurrent presyncope warrants evaluation like syncope.

Romberg Test

– The Romberg test is a clinical neurological test used to assess the integrity of the dorsal column-medial lemniscus pathway (proprioception) and the cerebellum in maintaining balance. The test is performed by asking the patient to stand with feet together and eyes open, and then to close the eyes. A positive Romberg test is indicated by loss of balance (increased sway or falling) when the eyes are closed, with the patient being stable with eyes open. A positive result indicates impaired proprioception (dorsal column dysfunction) causing sensory ataxia, with the patient able to maintain balance when visual input compensates for the loss of proprioception. A negative Romberg test (patient remains stable with eyes closed) suggests a cerebellar cause of ataxia rather than a sensory cause. The test should be performed with the patient standing on a firm, level surface with adequate lighting and within arm’s reach of a wall or examiner to prevent falls. The patient should be allowed to stand with eyes open initially, and if stable, then asked to close the eyes. The test is considered positive if the patient sways or falls within approximately 20-30 seconds of eye closure. A positive Romberg test indicates dysfunction of the dorsal columns of the spinal cord or peripheral nerves that carry proprioceptive information. Causes include tabes dorsalis (neurosyphilis),

vitamin B12 deficiency (subacute combined degeneration of the cord), diabetic peripheral neuropathy, Friedreich ataxia, and other causes of sensory neuropathy.

Sleep

– A naturally recurring physiological state characterized by altered consciousness, reduced sensory responsiveness, and distinct brain wave patterns that is essential for physical restoration, memory consolidation, and metabolic regulation. It is divided into non-rapid eye movement sleep, which includes light and deep restorative stages, and rapid eye movement sleep, which is associated with dreaming and emotional processing. Chronic sleep deprivation is linked to increased risks of obesity, cardiovascular disease, cognitive impairment, and weakened immune function, underscoring the critical role of adequate sleep in overall health.

Spinal Shock

– A state of transient physiological areflexia and flaccid paralysis occurring immediately after acute spinal cord injury, below the level of the lesion. It is characterized by loss of all somatic and autonomic nervous system function, including motor paralysis, sensory loss, areflexia, hypotension (from loss of sympathetic tone), bradycardia (from unopposed vagal tone), and loss of bladder and bowel function. The spinal shock phase typically begins immediately after injury and lasts days to several weeks, with gradual recovery of reflexes and autonomic function as spinal cord edema resolves and neuronal function returns. The duration of spinal shock is longer in more severe injuries. The development of hyperreflexia and spasticity marks the transition from spinal shock to the chronic phase of spinal cord injury. Management during the spinal shock phase includes aggressive hemodynamic support (maintaining mean arterial pressure >85 mmHg with IV fluids and vasopressors to prevent secondary ischemic injury to the spinal cord), immobilisation of the spine, and early surgical decompression for correctable compressive causes. The return of the bulbocavernosus reflex is the earliest sign of the end of spinal shock and is used as a clinical milestone.

Stroke

– A medical emergency caused by the interruption of blood flow to the brain, resulting in neuronal death

and neurological deficits. Ischemic stroke, accounting for approximately 87 percent of cases, occurs when a thrombus or embolus blocks a cerebral artery, while hemorrhagic stroke results from rupture of a blood vessel causing bleeding into or around the brain. Rapid recognition using the FAST acronym and immediate medical intervention with thrombolytic therapy or endovascular thrombectomy can significantly reduce disability and mortality, followed by rehabilitation and secondary prevention with antiplatelet agents, anticoagulation, and risk factor modification.

Stupor

– A state of reduced consciousness in which the patient is unresponsive to most environmental stimuli but can be temporarily aroused by vigorous, repeated stimulation (painful stimuli, loud shouting). Stupor is distinguished from coma (no response to any stimuli, no arousal), obtundation (reduced alertness but responds to verbal stimuli), and delirium (impaired attention and cognition with fluctuating consciousness). Causes: structural brain lesions (brainstem stroke—basilar artery occlusion, thalamic stroke, intracerebral hemorrhage, subdural haematoma, brain tumor, cerebral abscess), metabolic (hypoglycaemia, hyperosmolar hyperglycaemic state, hepatic encephalopathy, uraemia, hyponatraemia, hypercalcaemia, hypothyroidism, Wernicke encephalopathy), drug intoxication (opioids, benzodiazepines, barbiturates, alcohol, antipsychotics, antidepressants, carbon monoxide poisoning), CNS infection (meningitis, encephalitis, cerebral malaria), psychiatric (catatonia, dissociative stupor—rare). Assessment: ABCs, Glasgow Coma Scale (GCS <8 indicates severe brain injury, consider airway protection), pupillary response, eye movements (doll's eye, oculocephalic reflex, cold caloric testing), motor responses, and deep tendon reflexes. Emergent CT head, blood glucose, electrolytes, toxicology screen, ABG, and lumbar puncture if indicated. Management: stabilise airway, breathing, circulation; administer naloxone if opioid overdose suspected, thiamine (before glucose) for possible Wernicke, and 50% dextrose for hypoglycaemia. Treat underlying cause.

Subarachnoid Hemorrhage

– Bleeding into the subarachnoid space, the area

between the arachnoid membrane and the pia mater surrounding the brain, most commonly caused by rupture of a cerebral (berry) aneurysm. Approximately eighty-five percent of non-traumatic SAH cases are caused by aneurysm rupture, with the remaining cases due to perimesencephalic (benign) SAH, arteriovenous malformations, mycotic aneurysms, and other vascular pathologies. The classic presentation is thunderclap headache—the sudden onset of the worst headache of the patient’s life, reaching maximal intensity within seconds to minutes. Associated symptoms include nausea and vomiting, photophobia, nuchal rigidity (meningismus from blood in the subarachnoid space), loss of consciousness, seizures, and focal neurological deficits. The Ottawa SAH Rule and the classic presentation guide the need for urgent investigation. Diagnosis begins with a non-contrast CT head, which has 100 percent sensitivity for SAH within the first 6 hours and over 93 percent sensitivity within the first 24 hours; sensitivity declines to approximately 50 percent after one week. If CT is normal but clinical suspicion is high, a lumbar puncture is performed to detect CSF xanthochromia (yellow discolouration from bilirubin breakdown products), which is the gold standard for confirming SAH. CT angiography (CTA) or digital subtraction angiography (DSA) is used to identify the causative aneurysm. Management includes initial stabilisation in a neurosurgical critical care unit, securing the aneurysm via endovascular coiling or surgical clipping (to prevent rebleeding), management of delayed cerebral ischemia (vasospasm, which peaks at days 7-10 post-SAH, treated with nimodipine and hypertensive therapy), and management of complications including hydrocephalus (requiring external ventricular drain or VP shunt), rebleeding, and electrolyte disturbances. Prognosis is guarded, with mortality of approximately 50 percent and significant disability among survivors.

Subdural Hematoma

– A collection of blood between the dura mater and the arachnoid mater, caused by tearing of bridging veins that traverse the subdural space. It is classified as acute (symptoms within hours to three days), subacute (symptoms within three days to three weeks), or chronic (symptoms after three weeks), depend-

ing on the rate of bleeding and time from injury. Acute subdural hematoma is most commonly caused by severe head trauma, particularly in the elderly and alcoholics, and carries a high mortality rate (30-50 percent). Subacute and chronic subdural haematomas are more common in the elderly, alcoholics, epileptics, and patients on anticoagulation, where even minor or unrecognised head trauma can cause bleeding. Chronic subdural haematoma features a liquefied collection surrounded by an inflammatory neomembrane, which can rebleed and progressively enlarge, causing subacute or slowly progressive neurological deterioration. Clinical presentation varies: acute SDH presents with decreased consciousness, focal neurological deficit (hemiparesis), and ipsilateral pupillary dilation (from uncal herniation). Chronic SDH presents with headache, cognitive decline, gait disturbance, and personality changes, mimicking dementia or normal pressure hydrocephalus. Diagnosis is by CT head without contrast: acute SDH appears as a hyperdense, crescent-shaped collection along the convexity of the brain that does not cross the midline but can cross suture lines. Chronic SDH appears as a hypodense crescentic collection. Management: large acute SDH with mass effect requires emergency surgical evacuation via craniotomy or burr hole drainage. Chronic SDH is managed with burr hole drainage under local anesthesia or conservative observation for small asymptomatic collections. Anticoagulation reversal is critical in all cases. Prognosis: acute SDH has 30-50 percent mortality, while chronic SDH has good prognosis with treatment, though recurrence after burr hole drainage is approximately 10-20 percent.

Temporal Lobe

– One of the four major lobes of the cerebral hemisphere, located beneath the lateral fissure (Sylvian fissure) on the lateral surface of the brain, extending medially to the parahippocampal gyrus. The temporal lobe is involved in auditory processing, language comprehension, memory, and emotion. Key structures: primary auditory cortex (Heschl gyrus, Brodmann area 41/42—superior temporal gyrus), Wernicke area (posterior superior temporal gyrus—language comprehension, dominant hemisphere; lesions cause receptive aphasia/Wernicke aphasia), medial temporal lobe structures (hip-

pocampus—memory formation, consolidation, spatial navigation; amygdala—emotion processing, fear, aggression; parahippocampal gyrus—memory and visuospatial processing). Functions: auditory perception, phonemic and semantic processing (language), declarative memory (episodic and semantic—hippocampus-dependent), facial recognition (fusiform gyrus—inferior temporal), and emotional regulation (amygdala). Pathology: temporal lobe epilepsy (most common focal epilepsy), temporal lobe tumors (glioblastoma, meningioma), herpes simplex encephalitis (hemorrhagic necrosis of the medial temporal lobes), dementia (Alzheimer disease—hippocampal atrophy is an early feature), and traumatic brain injury (temporal lobe contusions are common).

Temporal Lobe Epilepsy

– The most common form of focal (partial) epilepsy, arising from the medial temporal lobe structures (hippocampus, amygdala, parahippocampal gyrus). Cause: hippocampal sclerosis (most common—neuronal loss and gliosis in the CA1 and CA3 regions of the hippocampus, associated with febrile seizures in childhood), tumors (low-grade gliomas, DNET), cortical dysplasia, vascular malformations, infections (herpes simplex encephalitis, neurocysticercosis), and trauma. Seizures: focal impaired awareness seizures (complex partial seizures)—characterized by an aura (epigastric rising sensation, déjà vu, jamais vu, olfactory/gustatory hallucinations, fear), followed by behavioural arrest, automatisms (lip smacking, chewing, fumbling), and postictal confusion/amnesia. Duration: 30 seconds to 2 minutes. Seizures may secondarily generalise to bilateral tonic-clonic seizures. Interictal EEG: anterior temporal sharp waves or spikes. MRI: high-resolution coronal T2/FLAIR images show hippocampal atrophy and increased T2 signal (hippocampal sclerosis). Treatment: antiseizure medications (first-line: lamotrigine, levetiracetam, carbamazepine, oxcarbazepine). Drug-resistant epilepsy (30%): anterior temporal lobectomy or selective amygdalohippocampectomy—seizure-free outcome in 60–80%. Vagus nerve stimulation and responsive neurostimulation are alternatives.

Tension Headache

– The most common headache type, characterized by bilateral, pressing/tightening head pain of mild-moderate intensity (like a band around the head), lasting 30 min to days, without nausea or vomiting; photophobia or phonophobia may be present but not both. Causes: stress, poor posture, sleep disturbance, muscle contraction (pericranial tenderness). Not associated with aura or activity exacerbation; examination normal. Management: analgesics (NSAIDs, paracetamol), stress reduction, relaxation, and avoidance of triggers; chronic tension headache warrants preventive therapy (amitriptyline). Distinguish from migraine and secondary causes (red flags: sudden onset, fever, focal deficits, neck stiffness).

Thrombolysis for Stroke

– Thrombolysis with intravenous alteplase (tPA) is the primary acute treatment for ischemic stroke when administered within the time window of symptom onset. Alteplase is a recombinant tissue plasminogen activator that converts plasminogen to plasmin, which degrades fibrin in the thrombus, restoring blood flow to the ischemic brain. The standard dose is 0.9 milligrams per kilogram (maximum 90 milligrams), with ten percent given as an intravenous bolus over one minute and the remainder infused over one hour. The therapeutic window is 0–4.5 hours from symptom onset for intravenous thrombolysis, with stricter criteria applied after 3 hours (age over 80, NIHSS >25, prior stroke plus diabetes, and anticoagulant use becoming relative contraindications). Treatment within 3 hours has the best benefit-risk profile (number needed to treat of 8 for improved outcome). Exclusion criteria include intracranial hemorrhage, recent major surgery, gastrointestinal or urinary tract bleeding, recent head trauma, uncontrolled hypertension (systolic >185 mmHg, diastolic >110 mmHg), current anticoagulation with INR >1.7, thrombocytopenia (platelets <100,000), blood glucose <2.8 or >22.2 mmol/L, and clinical presentation suggestive of subarachnoid hemorrhage even if CT is normal. The risk of symptomatic intracranial hemorrhage is approximately 6–7 percent within the first 36 hours, which limits the net benefit in patients treated later in the window. Endovascular thrombectomy with stent retrievers is indicated for large vessel occlusion (internal carotid artery, M1 segment of middle

cerebral artery, basilar artery) within 6 hours of onset, and may be extended to 24 hours in selected patients based on perfusion imaging (DAWN and DEFUSE-3 trial criteria).

Tics

– Sudden, rapid, recurrent, nonrhythmic stereotyped movements (motor tics) or vocalizations (vocal tics) that are usually brief and suppressible. Transient tics (most common in childhood) vs. chronic tic disorder; Tourette syndrome: multiple motor + at least one vocal tic for >1 year beginning before age 18. Preceded by a premonitory urge; exacerbated by stress/anxiety; may be associated with OCD and ADHD. Diagnosis: clinical. Management: education, behavioral therapy (habit reversal, CBIT); medication (alpha-agonists—clonidine, guanfacine; antipsychotics—risperidone, aripiprazole) for disabling tics; treat comorbidities.

Transient Ischemic Attack

– A transient ischemic attack (TIA) is a temporary episode of neurological dysfunction caused by focal brain, spinal cord, or retinal ischemia without acute infarction. Historically defined by an arbitrary time threshold of twenty-four hours, the modern tissue-based definition recognizes TIA as a brief episode of neurological symptoms caused by focal brain ischemia that resolves without evidence of acute infarction on neuroimaging (typically diffusion-weighted MRI). Most TIAs resolve within one hour, with the majority resolving within 10–60 minutes. The clinical presentation depends on the affected vascular territory and can include transient hemiparesis, hemisensory loss, aphasia, visual field defects, diplopia, vertigo, dysarthria, ataxia, and amaurosis fugax (transient monocular vision loss, the classic retinal TIA, which is a harbinger of ipsilateral carotid artery stenosis). The ABCD2 score is used to stratify the short-term risk of stroke after TIA: Age over 60 (1 point), Blood pressure >140/90 (1 point), Clinical features (unilateral weakness 2 points, speech impairment without weakness 1 point), Duration (10–59 minutes 1 point, 60+ minutes 2 points), and Diabetes (1 point). Patients with ABCD2 scores of 4 or higher or with cerebral ischemia on MRI (DWI-positive) are at higher risk and typically require urgent evaluation. The urgency of evaluation and treatment is critical be-

cause the risk of stroke is highest in the first 48 hours after a TIA, with approximately 10 percent of patients having a stroke within 90 days. Emergency management includes urgent neuroimaging (MRI brain with DWI, MRA of the head and neck), ECG and cardiac monitoring to detect atrial fibrillation, carotid Doppler ultrasound for significant carotid stenosis, and laboratory investigations for vascular risk factors. Secondary prevention includes antiplatelet therapy (aspirin plus clopidogrel for 21 days in high-risk patients, followed by single antiplatelet therapy), statin therapy (high-intensity), blood pressure control, smoking cessation, dietary modification, and carotid endarterectomy or stenting for significant ipsilateral carotid artery stenosis (70–99 percent). Anticoagulation is indicated for TIA associated with atrial fibrillation.

Tremor

– Involuntary, rhythmic oscillatory movement of a body part, classified by context: resting tremor (Parkinson disease—'pill-rolling', reduced with action), action/kinetic tremor (cerebellar, essential tremor—bilateral postural/action tremor, worsened by holding position), postural tremor (essential tremor, physiologic tremor, hyperthyroidism, drugs—beta-agonists, valproate, lithium), intention tremor (cerebellar—worse near target), and psychogenic. Diagnosis: history (onset, family, drugs), exam, and distinguishing features. Management: essential tremor—beta-blockers (propranolol), primidone; Parkinson—dopaminergics; treat cause. Red flags: asymmetric onset, rapid progression, focal findings.

Vertebrobasilar Insufficiency

– A condition of reduced blood flow through the vertebral arteries or basilar artery to the posterior circulation of the brain, including the brainstem, cerebellum, occipital lobes, and thalami. It is most commonly caused by atherosclerosis of the vertebral arteries or basilar artery, with risk factors including hypertension, diabetes, smoking, hyperlipidemia, and advanced age. The posterior circulation supplies vital structures including the brainstem (containing cranial nerve nuclei and vital autonomic centers), the cerebellum (controlling coordination and balance), the occipital lobes (vision), and the thalami (sensory and motor relay). Clinical presen-

tation of VBI includes dizziness and vertigo (the most common symptom), diplopia, dysarthria, dysphagia, ataxia, bilateral weakness or sensory loss, drop attacks (sudden loss of postural tone without loss of consciousness), visual disturbances (blurred vision, visual field defects, cortical blindness), and tinnitus. The diagnosis of VBI is distinguished from benign paroxysmal positional vertigo (which has positional triggers), Meniere disease (which has episodic vertigo with hearing loss and tinnitus), and migraine-associated vertigo. Diagnosis is by clinical assessment of posterior circulation symptoms and signs, with imaging including MRA or CTA of the vertebral and basilar arteries to assess for stenosis, occlusion, or dissection. Ultrasound of the vertebral arteries (extracranial segment) and transcranial Doppler of the basilar artery may demonstrate flow reduction. Management includes aggressive risk factor modification, antiplatelet therapy (aspirin or clopidogrel), and revascularisation (vertebral artery angioplasty and stenting, or vertebral artery endarterectomy) for selected patients with symptomatic severe stenosis refractory to medical therapy. Anticoagulation is indicated for embolism from the heart or proximal vertebral artery. Prognosis is poorer than for anterior circulation disease, with a higher risk of disabling or fatal stroke if large vessel disease is present.

Vestibular Neuritis

– Acute vestibular dysfunction due to inflammation of the vestibular nerve, typically viral in origin. Presents with acute onset of vertigo, nausea, vomiting, and nystagmus lasting days. Hearing is normal (unlike labyrinthitis). Diagnosis: clinical, HINTS exam (Head Impulse, Nystagmus, Test of Skew) to differentiate from central causes. Treatment: corticosteroids if early, vestibular suppressants acutely, and vestibular rehabilitation.

Vestibular Schwannoma

– Vestibular schwannoma, also known as acoustic neuroma, is a benign, slow-growing tumor arising from the Schwann cells of the vestibular portion of the eighth cranial nerve (vestibulocochlear nerve), typically from the superior vestibular nerve. It is the most common tumor of the cerebellopontine angle, accounting for approximately eighty percent of tumors in this location. The most common pre-

senting symptom is unilateral sensorineural hearing loss, which develops gradually over months to years and is often accompanied by tinnitus, vertigo or imbalance, and a sensation of fullness in the ear. Larger tumors compress the trigeminal nerve (causing facial numbness and paraesthesiae), the facial nerve (causing facial weakness or spasm), and the brainstem and cerebellum (causing ataxia, long tract signs, and hydrocephalus from compression of the fourth ventricle). The diagnosis is confirmed by MRI of the internal auditory meatus and brain with gadolinium showing an enhancing mass in the cerebellopontine angle that extends into and expands the internal auditory canal. The differential diagnosis includes meningioma, facial nerve schwannoma, epidermoid cyst, and trigeminal schwannoma. Audiometry shows unilateral sensorineural hearing loss with poor speech discrimination. Auditory brainstem response testing shows delayed latencies. Management options include observation with serial imaging for small tumors in elderly or medically unfit patients, fractionated stereotactic radiosurgery (Gamma Knife or linear accelerator) for small to medium tumors (less than 3 cm), and microsurgical resection via a translabyrinthine, retrosigmoid, or middle cranial fossa approach for large tumors causing significant mass effect or brainstem compression. The goal of radiosurgery is tumor control (prevention of growth) rather than complete elimination. Hearing preservation is possible in selected cases with small tumors and good pre-treatment hearing, but the likelihood of hearing preservation decreases with tumor size.

Wilson Disease

– An autosomal recessive inherited disorder of copper metabolism caused by mutations in the ATP7B gene on chromosome 13, which encodes a copper-transporting ATPase in hepatocytes. The defective ATP7B protein impairs incorporation of copper into apoceruloplasmin and biliary excretion of copper, leading to progressive copper accumulation in the liver, brain, cornea, and other organs. Clinical manifestations typically present between ages five and thirty-five and include hepatic disease (ranging from asymptomatic elevation of liver enzymes to acute hepatitis, cirrhosis, and fulminant hepatic failure), neurological disease (dysarthria, ataxia, dys-

tonia, parkinsonism, tremor—particularly a wing-beating tremor of the arms, chorea, and cognitive impairment with executive dysfunction), psychiatric symptoms (depression, personality changes, psychosis), and Kayser-Fleischer rings (golden-brown discolouration at the limbus of the cornea due to copper deposition in Descemet membrane, visible on slit-lamp examination and pathognomonic for Wilson disease when present). Diagnosis is based on a combination of clinical features, Kayser-Fleischer rings on slit-lamp examination, low serum caeruloplasmin (less than 0.2 g/L), elevated 24-hour urinary copper excretion (greater than 100 micrograms), elevated hepatic copper content on liver biopsy, and genetic testing for ATP7B mutations. Serum free copper (non-caeruloplasmin-bound copper) is elevated. Treatment involves lifelong copper chelation therapy with D-penicillamine (first-line, acts by chelating copper and promoting urinary excretion) or trientine, zinc acetate (which blocks intestinal absorption of copper and induces hepatic metallothionein, used as maintenance therapy or first-line for presymptomatic patients), and dietary restriction of copper-rich foods (shellfish, nuts, chocolate, mushrooms, organ meats). Liver transplantation is curative for severe hepatic failure or refractory neurological disease. Prognosis is excellent with early diagnosis and lifelong treatment; without treatment, Wilson disease is progressive and fatal. Patients who stop chelation therapy are at risk of irreversible neurological deterioration and hepatic decompensation.

23.2 Neurodegenerative & Movement Disorders

Acoustic Neuroma

– A benign, slow-growing schwannoma arising from the Schwann cells of the vestibular portion of the vestibulocochlear nerve (CN VIII), most commonly at the junction of the internal auditory canal and the cerebellopontine angle. Also known as vestibular schwannoma. Accounts for approximately 8 percent of intracranial tumors. Most are unilateral and sporadic; bilateral acoustic neuromas are pathognomonic of neurofibromatosis type 2 (NF2), an autosomal dominant condition caused by mu-

tations in the NF2 gene on chromosome 22q12.2. Clinical presentation includes ipsilateral sensorineural hearing loss (typically high-frequency), tinnitus, vertigo or imbalance, and facial numbness or weakness from compression of the trigeminal or facial nerve. Diagnosis is confirmed by MRI with gadolinium, demonstrating an enhancing mass at the cerebellopontine angle with extension into the internal auditory canal. Treatment options include observation with serial imaging for small or slow-growing tumors, stereotactic radiosurgery (Gamma Knife), or microsurgical resection via a translabyrinthine, retrosigmoid, or middle cranial fossa approach.

Agnosia

– A higher-order neurological deficit characterized by the inability to recognize or process sensory stimuli (visual, auditory, tactile) despite intact primary sensory organs and pathways. Caused by focal lesions in specific cortical association areas (parietal, temporal, or occipital lobes). Types: Visual agnosia (inability to recognize objects visually), Prosopagnosia (inability to recognize familiar faces; fusiform gyrus lesion), Astereognosis (inability to identify objects by touch; contralateral parietal lobe lesion), and Anosognosia (unawareness or denial of one's own neurological deficit; right parietal lobe lesion).

Agoraphobia

– Anxiety disorder characterized by fear and avoidance of situations where escape might be difficult or help unavailable during a panic-like episode. Common feared situations include public transportation, open spaces, enclosed spaces, standing in line, being in crowds, and being outside the home alone. Often develops after panic attacks and becomes self-reinforcing through avoidance behavior. Severe cases result in housebound patients unable to leave home. Diagnosis: DSM-5 criteria. Treatment: cognitive behavioural therapy (CBT) as first-line psychological intervention, SSRIs (particularly sertraline, paroxetine, escitalopram) as first-line pharmacotherapy, and combination therapy for moderate-to-severe cases. Prognosis is variable, but with appropriate treatment most patients achieve significant improvement.

Allodynia

– A form of neuropathic pain where a normally non-painful stimulus evokes pain. It is a key feature

of central and peripheral sensitization and can be categorized into tactile allodynia (pain from light touch or pressure), mechanical allodynia (pain from movement or stroking of the skin), and thermal allodynia (pain from normally non-painful temperature changes). Allodynia is commonly seen in postherpetic neuralgia, where the skin remains exquisitely sensitive to clothing or light touch. Diagnosis is clinical, supported by quantitative sensory testing and response to treatments. Management includes addressing the underlying cause, with pharmacological options including gabapentinoids (gabapentin, pregabalin), tricyclic antidepressants (amitriptyline, nortriptyline), serotonin-noradrenaline reuptake inhibitors (duloxetine, venlafaxine), lidocaine patches, capsaicin cream, and opioid analgesics as a last resort.

Anencephaly

– A fatal neural tube defect where the cerebral hemispheres and cranial vault fail to develop due to failed closure of the rostral neuropore during the fourth week of gestation. The brainstem and spinal cord are present, and reflex movements may occur, but there is no cognitive function. Associated with polyhydramnios (due to impaired swallowing) and elevated maternal serum alpha-fetoprotein. Diagnosis by prenatal ultrasound. Most cases are stillborn or die within hours to days after birth. Prevention with folic acid supplementation.

Anxiety Disorders

– Group of psychiatric disorders characterized by excessive fear, worry, and anxiety that cause significant distress and impairment. Types include generalized anxiety disorder (persistent, excessive worry about multiple topics), panic disorder (recurrent unexpected panic attacks with palpitations, sweating, trembling), social anxiety disorder (fear of social situations), specific phobias (irrational fear of specific objects/situations), and agoraphobia (fear of situations where escape may be difficult or embarrassing. Treatment includes CBT as first-line psychological treatment and SSRIs (sertraline, escitalopram, paroxetine) as first-line pharmacotherapy. Prognosis is generally favourable with treatment, though relapse rates are significant.

Balance Disorders and Vertigo

– Balance disorders encompass conditions that cause

dizziness, unsteadiness, or a sensation of motion, often arising from dysfunction in the inner ear, brain, or sensory pathways. Vertigo specifically describes the false sensation that the environment is spinning, commonly due to benign paroxysmal positional vertigo, vestibular neuritis, or Ménière's disease. Diagnosis involves history, physical exam, and vestibular testing; treatment includes repositioning maneuvers, medications, and vestibular rehabilitation.

Becker Muscular Dystrophy

– An X-linked recessive neuromuscular disorder caused by mutations in the dystrophin gene, similar to Duchenne muscular dystrophy (DMD), but with in-frame mutations that allow production of some functional dystrophin protein, albeit reduced in quantity or abnormal in size. The result is a milder clinical phenotype compared to DMD. The incidence is approximately one in 18,000 to 30,000 male births. Clinical features include progressive proximal muscle weakness, typically beginning in the hip girdle and thighs (difficulty climbing stairs, rising from chairs, and walking), calf hypertrophy (pseudohypertrophy due to fatty infiltration, which is characteristic), waddling gait, Gowers manoeuvre (using hands to push off the floor and climb up the legs to stand), and reduced or absent deep tendon reflexes. Progression is slower than DMD, with loss of ambulation typically occurring in the fourth decade or later. Cardiac involvement (dilated cardiomyopathy) is common and is the leading cause of death, requiring regular cardiac surveillance. Respiratory function declines with disease progression. Serum creatine kinase levels are elevated (typically 5-10 times normal). Diagnosis is confirmed by genetic testing showing in-frame dystrophin gene mutations, with muscle biopsy reserved for cases where genetic testing is inconclusive. Management involves multidisciplinary care including physiotherapy to maintain flexibility, corticosteroids to slow progression (although less evidence than in DMD), cardiac monitoring with ACE inhibitors or beta-blockers, respiratory support, and orthopaedic management for contractures and scoliosis.

Bell's Palsy

– See Bell Palsy.

Brain Abscess

– A focal, purulent infection within the brain

parenchyma, most commonly occurring in the frontal or temporal lobes. Sources of infection include direct contiguous spread (otitis media and mastoiditis causing temporal lobe abscess; sinusitis causing frontal lobe abscess; dental infection), hematogenous dissemination from a distant source (bacterial endocarditis, lung abscess, congenital heart disease with right-to-left shunt), penetrating head trauma, or post-neurosurgical infection. Common causative organisms include *Streptococcus milleri* group (most common), anaerobic bacteria (*Bacteroides*, *Fusobacterium*), *Staphylococcus aureus*, and aerobic Gram-negative bacilli. Clinical presentation includes headache, fever, focal neurological deficits (hemiparesis, aphasia, visual field defects), seizures, and signs of increased intracranial pressure (nausea, vomiting, decreased level of consciousness). Diagnosis is by contrast-enhanced CT or MRI brain showing a ring-enhancing lesion with surrounding edema and central necrosis. Management includes empiric broad-spectrum antibiotics (third-generation cephalosporin plus metronidazole covering aerobic and anaerobic organisms), stereotactic aspiration or surgical excision for definitive diagnosis and source control, corticosteroids for vasogenic edema, and anticonvulsants for seizure prophylaxis. Mortality is approximately 10-20 percent, with prompt treatment improving outcomes.

Brain Injuries

– Brain injuries range from mild concussions to severe traumatic brain injury caused by falls, motor vehicle accidents, sports impacts, or penetrating trauma. Symptoms depend on injury location and severity, including headache, confusion, memory loss, seizures, and altered consciousness. Recovery varies widely and may involve rest, rehabilitation, cognitive therapy, and long-term supportive care.

Brain Metastases

– The most common intracranial neoplasms, occurring in approximately ten to forty percent of patients with systemic cancer, and are more common than primary brain tumors. They result from hematogenous spread of tumor cells to the brain, with the most common primary sources being lung cancer (the most common source overall, particularly non-small cell lung cancer and small cell lung cancer), breast cancer, melanoma (highest propensity for

brain metastases), renal cell carcinoma, and colorectal cancer. Brain metastases typically occur at the gray-white matter junction, where the vascular supply changes from larger to smaller calibre vessels, and are most frequently located in the cerebral hemispheres (80 percent), cerebellum (15 percent), and brainstem (5 percent). Clinical presentation depends on the location and number of lesions but commonly includes headache, focal neurological deficits, seizures, cognitive impairment, and signs of increased intracranial pressure. Diagnosis is by contrast-enhanced MRI, which is more sensitive than CT for detecting small lesions. Management includes corticosteroids (dexamethasone) for vasogenic cerebral edema, whole-brain radiotherapy for multiple metastases, stereotactic radiosurgery for oligometastatic disease (typically 1-3 lesions), and surgical resection for single accessible lesions in patients with good performance status and controlled systemic disease.

Brain Tumor

– An abnormal growth of cells within the brain or its surrounding structures, classified as primary (originating from brain tissue or its coverings) or secondary/metastatic (spread from a cancer elsewhere in the body, which are more common, accounting for approximately 50 percent of all brain tumors). Primary brain tumors are classified by cell type and grade: meningiomas (most common primary brain tumor in adults, arising from the meninges, typically benign WHO grade 1), gliomas (arising from glial cells—including astrocytomas, oligodendrogliomas, glioblastomas (the most common and most malignant primary brain tumor, WHO grade 4), ependymomas, and mixed gliomas. Clinical presentation depends on the location, size, and rate of growth of the tumor but commonly includes progressive headache (often worse in the morning and worsened by Valsalva manoeuvre), seizures (focal or generalised), focal neurological deficits (hemiparesis, aphasia, visual field defects, sensory loss), cognitive and personality changes, and signs of increased intracranial pressure. Diagnosis is by neuroimaging: MRI with gadolinium is the imaging modality of choice, providing superior soft tissue resolution and demonstrating contrast enhancement, edema, mass effect, and relationship to adjacent structures.

Definitive diagnosis requires histopathological examination of tissue obtained by stereotactic biopsy or surgical resection. Management is multidisciplinary and depends on tumor type, grade, and location, and includes surgical resection (gross total resection when safely achievable), radiotherapy, and chemotherapy (temozolomide for glioblastoma). Prognosis varies widely by tumor type and grade: benign meningiomas have excellent prognosis with surgical resection, while glioblastoma multiforme carries a poor prognosis with median survival of approximately 15 months despite aggressive multimodality treatment.

Carpal Tunnel Syndrome

– The most common entrapment neuropathy, caused by compression of the median nerve as it passes through the carpal tunnel, a narrow fibro-osseous canal bounded by the carpal bones and the flexor retinaculum (transverse carpal ligament) at the wrist. The median nerve provides sensory innervation to the palmar aspect of the thumb, index finger, middle finger, and lateral half of the ring finger, and motor innervation to the thenar muscles (abductor pollicis brevis, opponens pollicis, and flexor pollicis brevis). The tunnel also contains nine flexor tendons (flexor digitorum profundus, flexor digitorum superficialis, and flexor pollicis longus) surrounded by synovial sheaths. Compression of the median nerve within the carpal tunnel results from any condition that reduces the volume of the tunnel or increases the volume of its contents: repetitive strain, obesity, pregnancy, diabetes, rheumatoid arthritis, hypothyroidism, acromegaly, amyloidosis, and wrist fractures. Clinical presentation includes numbness, tingling, and paraesthesiae in the median nerve distribution, typically occurring at night or with repetitive hand use. Patients may report waking with numb hands and shaking them for relief (flick sign). Motor weakness and thenar atrophy occur in advanced cases. Diagnosis is clinical, confirmed by nerve conduction studies showing prolonged distal motor and sensory latencies across the carpal tunnel. Treatment includes conservative measures (wrist splinting in neutral position at night, activity modification, NSAIDs, corticosteroid injection into the carpal tunnel) and surgical release (carpal tunnel release) for refractory or severe cases.

Cauda Equina Syndrome

– A neurosurgical emergency caused by compression of the cauda equina nerve roots below the level of the conus medullaris (typically at L1-L2 and below), resulting in bilateral lower extremity weakness, sensory loss, and bladder and bowel dysfunction. The most common cause is large lumbar disc herniation, but other causes include spinal tumors, epidural abscess, epidural hematoma, spinal stenosis, and trauma. Clinical features include severe low back pain, bilateral lower extremity weakness, bilateral sciatica, saddle anesthesia (loss of sensation in the perineal and perianal regions), loss of anal sphincter tone, urinary retention (painless, with overflow incontinence), and fecal incontinence. Urinary retention is an early and critical sign that is often missed; post-void residual volume greater than 100-200 mL is suggestive. Diagnosis is clinical, confirmed by urgent MRI of the lumbar spine showing compression of the cauda equina nerve roots. Management is a surgical emergency requiring urgent decompressive laminectomy and discectomy, ideally within 24-48 hours of symptom onset to maximise the chance of neurological recovery. Prognosis is better if surgery is performed early, particularly for urinary function, but long-term deficits may persist even with timely intervention.

Central Nervous System (CNS)

– The part of the nervous system comprising the brain and spinal cord, enclosed within the skull and vertebral column. The brain includes the cerebrum (consciousness, voluntary movement, sensation, language, cognition), cerebellum (coordination, balance, motor learning), and brainstem (vital autonomic centers, cranial nerve nuclei, ascending/descending pathways). The spinal cord extends from the foramen magnum to L1-L2, transmitting motor and sensory information between brain and periphery via ascending (spinothalamic, dorsal column) and descending (corticospinal) tracts, and housing reflex arcs. The CNS is protected by the skull and vertebral column, meninges (dura mater, arachnoid mater, pia mater), and cerebrospinal fluid. The blood-brain barrier regulates molecular exchange between blood and neural tissue.

Cervical Disc Herniation

– A common cause of neck pain and radiculopathy,

occurring when the nucleus pulposus of an intervertebral disc in the cervical spine herniates through the annulus fibrosus, compressing adjacent nerve roots or the spinal cord. The most commonly affected levels are C5-C6 and C6-C7, accounting for approximately ninety-five percent of cervical disc herniations. Cervical radiculopathy presents with dermatomal pain radiating from the neck into the shoulder, arm, or hand, along with sensory changes (numbness, tingling) and motor weakness in the corresponding myotome. C5-C6 disc herniation compresses the C6 nerve root, causing pain radiating to the lateral arm, thumb, and index finger, weakness of biceps, brachioradialis, and wrist extensors, and decreased biceps reflex. C6-C7 disc herniation compresses the C7 nerve root, causing pain radiating to the middle finger, weakness of triceps and finger extensors, and decreased triceps reflex. Diagnosis is by MRI of the cervical spine, which demonstrates the herniated disc and its relationship to the nerve root or spinal cord. Electromyography and nerve conduction studies may confirm the radiculopathy and exclude other causes. Management includes conservative treatment (analgesics, NSAIDs, muscle relaxants, physical therapy, cervical immobilisation) for most cases, with surgical intervention (anterior cervical discectomy and fusion, cervical disc replacement) indicated for progressive motor deficit, severe refractory pain, or spinal cord compression with myelopathy.

Chiari Malformation

– Chiari malformations are structural abnormalities of the posterior fossa and cerebellum characterized by downward displacement of the cerebellar tonsils through the foramen magnum. Type I is the most common variant, defined as cerebellar tonsillar ectopia of five millimeters or more below the foramen magnum. It may be asymptomatic or present with occipital headache (worsened by Valsalva maneuver, coughing, or straining), neck pain, lower cranial nerve palsies, cerebellar ataxia, myelopathy, and syringomyelia (a fluid-filled cavity within the spinal cord). Type II (Arnold-Chiari malformation) is a more severe variant associated with myelomeningocele and hydrocephalus. Diagnosis is made by MRI of the brain and cervical spine in the sagittal plane, which demonstrates tonsillar herniation. Surgical

decompression via suboccipital craniectomy and cervical laminectomy is indicated for symptomatic patients with brainstem compression, syringomyelia, or progressive neurological deficits.

Chronic Fatigue Syndrome

– A complex, debilitating disorder characterized by profound fatigue lasting >6 months that is not relieved by rest and is worsened by physical or mental exertion (post-exertional malaise). Associated symptoms: unrefreshing sleep, cognitive impairment (brain fog), orthostatic intolerance, joint pain, headaches, and sore throat. Also known as myalgic encephalomyelitis (ME/CFS). Diagnosis: clinical (CDC or Canadian Consensus criteria); exclusion of other causes. No FDA-approved treatment; management focuses on symptom relief, graded activity pacing, cognitive behavioral therapy for coping, and treating comorbid conditions (sleep disorders, orthostatic intolerance).

Chronic Inflammatory Demyelinating Polyneuropathy

– An acquired, immune-mediated peripheral neuropathy with a relapsing-remitting or progressive course. Presents with symmetric proximal and distal weakness, sensory loss, areflexia, and elevated CSF protein. Distinguishing from Guillain-Barre: progressive course >8 weeks (vs. rapid onset in GBS). Diagnosis: EMG/NCS shows demyelinating features (conduction block, temporal dispersion). Treatment: corticosteroids, IVIG, or plasmapheresis. Immunosuppressants (azathioprine, mycophenolate, rituximab) for refractory cases.

CIDP

– Chronic inflammatory demyelinating polyneuropathy (CIDP) is a chronic, immune-mediated, peripheral neuropathy characterized by progressive or relapsing symmetrical weakness and sensory loss in all four limbs, with areflexia or hyporeflexia, lasting for more than eight weeks. It is the chronic counterpart of GBS and is considered to be caused by an antibody-mediated attack on peripheral nerve myelin. The pathophysiology involves both humoral and cellular immune mechanisms targeting myelin and Schwann cells. Clinical presentation includes symmetrical proximal and distal weakness in all four limbs, with early loss of deep tendon reflexes, sensory loss (impaired vibration and proprioception),

and symptoms developing progressively over weeks to months. Diagnosis is made using the European Federation of Neurological Societies (EFNS) criteria, supported by nerve conduction studies showing demyelinating features (prolonged distal latencies, reduced conduction velocities, conduction block, temporal dispersion, prolonged F-wave latencies), CSF analysis showing elevated protein with normal cell count (cytoalbuminological dissociation), and MRI of the brachial or lumbosacral plexus showing nerve root thickening and gadolinium enhancement. Management includes corticosteroids (prednisolone), intravenous immunoglobulin (IVIG), and plasma exchange as first-line immunomodulatory therapies. Immunosuppressive agents (azathioprine, mycophenolate mofetil, cyclophosphamide, rituximab) are used for refractory or relapsing cases. Prognosis is variable; most patients require long-term immunomodulatory therapy to maintain function and prevent disability progression.

Cluster Headache

– A primary headache disorder characterized by severe, unilateral, strictly orbital or periorbital pain attacks lasting fifteen to one hundred eighty minutes, occurring with one of three autonomic symptoms on the same side as the pain: conjunctival injection, lacrimation, nasal congestion or rhinorrhea, eyelid edema, forehead or facial sweating, miosis, or ptosis. Attacks occur in clusters or cycles, typically one to eight attacks per day during a cluster period lasting weeks to months followed by remission periods lasting months to years. Cluster headache is the most severe primary headache disorder, often described as the most painful condition known to medicine, and is nicknamed suicide headache due to its intensity. The headache is accompanied by restlessness and agitation—patients typically pace the floor, rock back and forth, or bang their head during attacks, in contrast to migraine patients who prefer to lie still in a dark room. Diagnosis is clinical using ICHD-3 criteria. Acute treatment includes high-flow oxygen (100% at 12-15 L/min via non-rebreather mask) and subcutaneous sumatriptan or intranasal zolmitriptan, which cause vasoconstriction of dilated orbital vessels. Preventive treatment includes verapamil (first-line), lithium, topiramate, galcanezumab (a CGRP monoclonal antibody specif-

ically approved for cluster headache), and greater occipital nerve blockade. Transitional therapy with oral or intravenous corticosteroids is used at the onset of a cluster period to break the cycle while long-term preventatives take effect.

Complex Regional Pain Syndrome

– A chronic pain condition characterized by regional pain and sensory changes disproportionate to the inciting event. Type I (reflex sympathetic dystrophy): no identifiable nerve injury. Type II (causalgia): follows a major nerve injury. Presents with burning pain, allodynia, hyperalgesia, edema, vasomotor changes (temperature and color changes), sudomotor changes (sweating), and trophic changes (skin, hair, nail changes). Diagnosis: Budapest clinical criteria. Treatment: early physical therapy and occupational therapy; NSAIDs, gabapentinoids, tricyclic antidepressants, bisphosphonates; sympathetic nerve blocks for severe pain.

Corticobasal Degeneration

– A rare, progressive neurodegenerative disorder characterized by asymmetric cortical and basal ganglia dysfunction. Presents with asymmetric parkinsonism (rigidity, bradykinesia), apraxia (loss of learned motor skills), alien limb phenomenon (involuntary, purposeless movements), cortical sensory loss, myoclonus, and dystonia. Later: cognitive decline, behavioral changes, and aphasia. Diagnosis: clinical; MRI may show asymmetric frontoparietal atrophy. No disease-modifying treatment; symptomatic therapy with levodopa (poor response), botulinum toxin for dystonia, and supportive care.

Dandy-Walker Malformation

– A congenital hindbrain malformation characterized by hypoplasia or aplasia of the cerebellar vermis, cystic dilation of the fourth ventricle, and posterior fossa enlargement with upward displacement of the tentorium, transverse sinuses, and torcular herophili. Presents with hydrocephalus, developmental delay, ataxia, and cranial nerve palsies. Associated with agenesis of the corpus callosum and other CNS anomalies. Diagnosis by prenatal or postnatal MRI. Treatment: VP shunt or endoscopic third ventriculostomy for hydrocephalus. Prognosis depends on associated anomalies.

Diabetic Peripheral Neuropathy

– The most common complication of diabetes melli-

tus, affecting approximately fifty percent of patients with long-standing disease. It is a length-dependent, sensorimotor polyneuropathy that affects the distal lower extremities first, in a glove-and-stocking distribution, and progresses proximally over time. The pathophysiology involves multiple mechanisms including metabolic injury from hyperglycemia (polyol pathway, advanced glycation end products, oxidative stress, mitochondrial dysfunction, activation of the poly(ADP-ribose) polymerase pathway, and impaired axonal transport), microvascular disease (endoneurial capillary damage causing endoneurial hypoxia), and inflammatory mechanisms. Clinical presentation begins with numbness, tingling, and paraesthesiae in the toes and feet, progressing proximally over years. Pain is a common and disabling feature, often described as burning, shooting, or stabbing. Motor weakness (foot drop, intrinsic hand muscle weakness) develops in advanced stages. Physical examination reveals reduced vibration sense (the earliest finding), impaired pinprick and temperature sensation in a stocking distribution, loss of ankle reflexes, and eventually proprioceptive loss causing sensory ataxia. Autonomic involvement can cause orthostatic hypotension, gastroparesis, erectile dysfunction, and abnormal sweating. Diagnosis is clinical, supported by nerve conduction studies showing a length-dependent axonal sensorimotor polyneuropathy. Management involves optimising glycaemic control (the only intervention that slows progression), foot care to prevent ulceration, and symptomatic treatment of neuropathic pain with gabapentinoids, tricyclic antidepressants, or SNRIs (duloxetine).

Dysesthesia

– An unpleasant, abnormal sensation produced by a normally non-painful stimulus, or an unpleasant, exaggerated response to a normal stimulus. It is distinguished from paresthesia (which is simply an abnormal sensation that may or may not be unpleasant) by its consistently unpleasant quality. Dysesthesia is a feature of neuropathic pain and is caused by dysfunction of the somatosensory nervous system, including peripheral nerve damage, spinal cord lesions, or central brain lesions. Peripheral causes include compression neuropathies, radiculopathies, and polyneuropathies. The distinction

between dysesthesia and other sensory symptoms is important for diagnosis: dysesthesia is consistently unpleasant (a key distinguishing feature from paresthesia), allodynia is pain from a normally non-painful stimulus, hyperalgesia is an exaggerated response to a normally painful stimulus, and hyperpathia is a delayed, explosive, and unpleasant response to a stimulus, often with radiation beyond the stimulus site. Diagnosis is clinical, with neurological examination and nerve conduction studies to identify the underlying somatosensory pathway lesion. Management includes treating the underlying cause and symptomatic treatment of the dysesthetic pain with gabapentinoids, tricyclic antidepressants, or SNRIs.

Encephalitis

– Inflammation of the brain parenchyma, most commonly caused by viral infections (herpes simplex virus, arboviruses, enteroviruses). Presents with fever, headache, altered mental status, seizures, and focal neurological deficits. CSF shows lymphocytic pleocytosis. Diagnosis: CSF PCR, MRI, EEG. Treatment: acyclovir for HSV, supportive care. Complications: permanent neurological deficits, cognitive impairment.

Encephalocele

– A neural tube defect where brain tissue and meninges herniate through a skull defect, most commonly in the occipital region. The herniated sac contains cerebrospinal fluid, meninges, and often brain tissue. Associated with other CNS anomalies including hydrocephalus and Chiari malformation. Presents as a visible, pulsatile midline mass. Treatment: surgical repair with reduction of herniated contents and dural closure. Prognosis depends on the amount of herniated brain tissue.

Epilepsy

– A neurological disorder characterized by recurrent, unprovoked seizures due to abnormal electrical activity in the brain. Classification includes focal, generalized, and unknown onset seizures. Etiology: genetic, structural, metabolic, infectious, immune. Diagnosis: clinical history, EEG, neuroimaging. Treatment: antiseizure medications, epilepsy surgery, vagus nerve stimulation, ketogenic diet for refractory cases.

Epilepsy Surgery

– Indicated for patients with drug-resistant epilepsy who have a concordant, resectable seizure focus identified on comprehensive presurgical evaluation. Failure of two or more appropriately chosen and adequately dosed antiepileptic drugs to achieve sustained seizure freedom. The presurgical evaluation includes scalp EEG with video monitoring, high-resolution MRI, PET scan (typically showing hypometabolism in the seizure focus), SPECT scan (ictal SPECT showing hyperperfusion and interictal SPECT showing hypoperfusion in the epileptic focus), neuropsychological assessment, and functional MRI for language and motor mapping. Invasive EEG monitoring using subdural grid electrodes or stereoelectroencephalography (SEEG) may be required when non-invasive data are discordant or the seizure focus is in or near eloquent cortex. The type of surgery depends on the location and nature of the epileptic focus: temporal lobectomy (the most common and most successful procedure, with 60-80 percent seizure freedom rates), extratemporal resection, hemispherotomy or hemispherectomy (for large hemispheric pathologies such as Rasmussen encephalitis or Sturge-Weber syndrome), corpus callosotomy (for drop attacks in generalised epilepsy), and vagus nerve stimulation (for drug-resistant epilepsy not amenable to resective surgery). Responsive neurostimulation (RNS) and deep brain stimulation of the anterior nucleus of the thalamus are newer neuromodulation options.

GABA (Gamma-Aminobutyric Acid)

– The primary inhibitory neurotransmitter in the mammalian central nervous system, synthesised from glutamate via glutamic acid decarboxylase (GAD) with pyridoxal phosphate (vitamin B6) as cofactor. GABA acts on two classes of receptors: GABA-A (ionotropic, chloride ion channel, target of benzodiazepines, barbiturates, and ethanol) and GABA-B (metabotropic, G-protein coupled, modulates calcium and potassium channels). Functions: reduces neuronal excitability, regulates muscle tone, influences mood and anxiety. Implicated in: anxiety disorders (reduced GABAergic tone), epilepsy (GABA deficiency may contribute to seizures), Huntington disease (reduced GABA levels in basal ganglia), and spasticity (target of

baclofen, a GABA-B agonist).

Gargalesthesia

– The sensation of tickling. A complex sensory experience mediated by light tactile stimulation of sensitive skin areas (axillae, soles, flanks, ribcage). Involves both spinal reflexes (goosebumps, withdrawal) and emotional processing in the anterior cingulate cortex and somatosensory cortex. Ticklishness requires an intact somatosensory system and a social/emotional context; self-tickling does not produce the sensation due to cerebellar cancellation of self-generated movement. Loss of gargalesthesia may occur in peripheral neuropathy or spinal cord lesions.

Guillain-Barre Syndrome

– An acute, immune-mediated polyneuropathy typically presenting with ascending paralysis following an antecedent infection (Campylobacter jejuni, CMV, EBV, Zika). Variants: acute inflammatory demyelinating polyneuropathy (AIDP, most common in North America), acute motor axonal neuropathy (AMAN, more common in Asia). Presents with symmetric ascending weakness, areflexia, and paresthesias. Respiratory failure occurs in 20-30%. Diagnosis: CSF shows albuminocytologic dissociation (elevated protein, normal cell count); EMG/NCS. Treatment: IVIG or plasmapheresis (equally effective). Prognosis: most recover, but may have residual weakness.

Gyrus

– A ridge or convolution on the surface of the cerebral cortex, separated by sulci (grooves). The folded structure triples the surface area of the brain (approximately 2500 cm²) while fitting within the cranial vault. Major gyri: precentral gyrus (primary motor cortex, Brodmann area 4), postcentral gyrus (primary somatosensory cortex, areas 3,1,2), superior temporal gyrus (auditory cortex, area 41/42, includes Heschl gyrus), middle and inferior frontal gyri (prefrontal cortex, Broca area in dominant hemisphere), fusiform gyrus (face and object recognition), angular gyrus (reading and arithmetic), supramarginal gyrus (sensory integration), cingulate gyrus (limbic system, pain and emotion), hippocampal gyrus (parahippocampal, memory encoding). Gyral abnormalities may be seen in developmental disorders (polymicrogyria, pachygyria) and neu-

rodenerative diseases (gyral atrophy in Alzheimer disease).

Headache

– One of the most common neurologic symptoms, classified as primary (migraine, tension-type, cluster, and trigeminal autonomic cephalalgias) or secondary (attributed to an underlying structural, infectious, vascular, or metabolic cause). Tension-type headache is the most prevalent primary headache disorder, presenting as bilateral, pressing or tightening quality, mild to moderate intensity, lasting 30 minutes to 7 days, without nausea or photophobia/phonophobia. Migraine is the second most common primary headache disorder after tension-type headache. Secondary headaches have numerous causes, with red flags (SNOOP4: systemic symptoms, neurological signs, onset sudden, older age at onset, pattern change, prior headache history, precipitating factors, pregnancy, and postural aggravation) prompting investigation. Diagnosis is by careful history and neurological examination, with neuroimaging (CT or MRI) and lumbar puncture as indicated to exclude secondary causes. Management depends on the specific headache type: acute treatment includes simple analgesics, triptans, and antiemetics; preventive treatment includes beta-blockers, tricyclic antidepressants, antiepileptics, CGRP monoclonal antibodies, and nerve blocks.

Headache and Migraine

– Headaches are pain in the head or upper neck region, classified as primary (tension-type, migraine, cluster) or secondary to underlying conditions. Migraines are a neurological disorder characterized by recurrent episodes of moderate to severe throbbing pain, often accompanied by nausea, photophobia, and aura. Management includes acute treatments such as triptans and NSAIDs, plus preventive therapies including medications and lifestyle modifications.

Insomnia

– A sleep disorder characterized by difficulty falling asleep, staying asleep, or waking too early despite adequate opportunity for sleep, with resulting daytime impairment. It may be acute or chronic and is often triggered by stress, anxiety, depression, or poor sleep habits. Treatment includes cognitive behavioral therapy for insomnia (CBT-I) as first-line

therapy, with medications considered for short-term use.

Karnofsky Performance Status

– The Karnofsky Performance Status (KPS) scale is a widely used clinical tool for assessing the functional status of patients, particularly those with cancer, and quantifies the patient's ability to perform activities of daily living and tolerate treatments. The scale ranges from zero (dead) to one hundred (normal, no complaints, no evidence of disease) in increments of ten. KPS scores of eighty to one hundred indicate that the patient is able to carry on normal activity and work, with no special care needed; KPS 70 indicates that the patient is able to care for self but cannot carry on normal activity or do active work; KPS 50 indicates that the patient requires considerable assistance and frequent medical care; and KPS 20 indicates that the patient is very sick, requiring active supportive treatment. The scale was developed by Karnofsky and Burchenal in 1949 and is used in oncology to determine prognosis, guide treatment intensity, and assess eligibility for clinical trials. The KPS has been validated as an independent predictor of survival in many cancers. A score of 70 or higher is typically required for aggressive treatments such as combination chemotherapy or major surgery, while lower scores indicate the need for palliative and supportive care. The scale has limitations, including inter-rater variability and a lack of sensitivity to small changes in function.

Lissencephaly

– A severe brain malformation characterized by a smooth cerebral surface due to absent (agyria) or decreased (pachygyria) sulcation and gyration, caused by impaired neuronal migration during 12-16 weeks of gestation. Presents with severe developmental delay, intractable epilepsy (infantile spasms, Lennox-Gastaut), spasticity, and feeding difficulties. Facial features may include bitemporal hollowing, prominent forehead, and micrognathia. Diagnosis by MRI showing a smooth brain surface, thick cortex, and shallow or absent Sylvian fissures. Genetic causes include LIS1 (Miller-Dieker syndrome, 17p13.3 deletion) and DCX (X-linked) mutations. Prognosis is poor; most children have severe disabilities and shortened lifespan.

Lumbar Disc Herniation

– The most common cause of lumbar radiculopathy (sciatica), occurring when the nucleus pulposus of a lumbar intervertebral disc herniates through the annulus fibrosus, compressing adjacent nerve roots. The most commonly affected level is L4-L5 and L5-S1, accounting for approximately ninety-five percent of lumbar disc herniations. L4-L5 disc herniation typically compresses the L5 nerve root, causing pain radiating from the buttock down the lateral leg to the dorsum of the foot and great toe, weakness of ankle dorsiflexors and evertors (foot drop), and no reflex changes. L5-S1 disc herniation typically compresses the S1 nerve root, causing pain radiating from the buttock down the posterior leg to the heel and lateral foot, weakness of plantar flexion (gastrocnemius, soleus) and ankle eversion, and decreased ankle jerk reflex. Cauda equina syndrome is a surgical emergency requiring urgent MRI and neurosurgical referral. The majority of lumbar disc herniations resolve with conservative management including NSAIDs, activity modification, and physiotherapy. Indications for surgical intervention include cauda equina syndrome, progressive neurological deficit, and persistent radicular pain refractory to 6-12 weeks of conservative management. Surgical options include microdiscectomy, endoscopic discectomy, and minimally invasive tubular discectomy.

Meningioma

– The most common primary intracranial tumor, accounting for approximately thirty-seven percent of all primary brain tumors, and arises from arachnoid cap cells of the meninges. Most meningiomas are benign (WHO grade I), slow-growing, and well-circumscribed, with a whorled histopathological pattern and psammoma bodies. Atypical (grade II) and anaplastic (grade III) meningiomas are more aggressive with higher recurrence rates. Meningiomas are more common in women, with a female-to-male ratio of approximately 2-3:1, and their incidence increases with age. Most meningiomas are asymptomatic and discovered incidentally on neuroimaging. Symptomatic meningiomas present with symptoms related to mass effect on adjacent structures, including headache, seizures (focal or generalised), and focal neurological deficits. The most common locations are parasagittal/falcine region, cerebral convexities,

sphenoid wing, and olfactory groove. Sphenoid wing meningiomas may present with proptosis and visual disturbances. Diagnosis is by MRI with gadolinium, which shows a dural-based, extra-axial mass with homogeneous contrast enhancement and a dural tail sign. CT may show hyperostosis of the adjacent bone. Asymptomatic or small meningiomas with no mass effect are managed with observation and serial imaging. Symptomatic, growing, or large tumors are treated with surgical resection (Simpson grade I-V, with grade I meaning complete removal including dural attachment). Adjuvant radiotherapy or stereotactic radiosurgery is used for residual, recurrent, atypical, or malignant meningiomas. WHO grade I meningiomas have excellent prognosis, with 5-year recurrence rates of 5-10 percent after complete resection; grade II (atypical) have 30-40 percent recurrence; and grade III (anaplastic/malignant) have 50-80 percent recurrence.

Meningitis

– Inflammation of the meninges most commonly caused by bacterial infection (*Neisseria meningitidis*, *Streptococcus pneumoniae*, *Haemophilus influenzae*, Group B *Streptococcus*). Presents with fever, nuchal rigidity, photophobia, and altered mental status. Diagnosis: lumbar puncture with CSF analysis. Bacterial meningitis is a medical emergency requiring prompt empiric antibiotics and dexamethasone. Vaccination prevents several causes.

Migraine

– A primary headache disorder characterized by recurrent episodes of moderate to severe, typically unilateral, pulsating headache lasting 4-72 hours, associated with nausea, vomiting, photophobia, and phonophobia. Migraine is the second most disabling condition worldwide (second only to low back pain in years lived with disability), affecting 15-18 percent of women and 6-8 percent of men globally. The pathophysiology involves a complex neurovascular cascade: cortical spreading depression (a wave of neuronal depolarisation followed by prolonged suppression of cortical electrical activity that propagates across the cortex at 2-6 mm per minute), which is thought to be the pathophysiological substrate of the migraine aura, followed by activation of the trigeminovascular system (trigeminal nerve endings surrounding intracranial blood vessels re-

lease vasoactive neuropeptides such as CGRP, substance P, and neurokinin A), causing neurogenic inflammation and vasodilation of intracranial and extracranial blood vessels, which activates nociceptive pathways to the thalamus and cortex. Triggers include stress (the most common trigger), hormonal fluctuations (menstrual migraine), lack of sleep or excessive sleep, skipped meals, dehydration, alcohol (especially red wine), caffeine withdrawal, bright lights, loud noises, strong odours, and certain foods. Migraine is classified as episodic (fewer than 15 headache days per month) or chronic (15 or more headache days per month for more than 3 months, with at least 8 days meeting migraine criteria). Chronic migraine often evolves from episodic migraine and is associated with overuse of acute medications. Management of acute attacks includes simple analgesics (ibuprofen, paracetamol, aspirin), triptans (sumatriptan, rizatriptan, eletriptan—serotonin 5-HT_{1B/1D} receptor agonists that inhibit CGRP release and cause vasoconstriction), antiemetics (metoclopramide, domperidone), and gepants (ubrogepant, rimegepant—CGRP receptor antagonists). Preventive therapy is indicated for patients with frequent or disabling attacks and includes beta-blockers (propranolol, metoprolol), tricyclic antidepressants (amitriptyline), antiepileptics (topiramate, sodium valproate), CGRP monoclonal antibodies (erenumab, galcanezumab, fremanezumab, eptinezumab), and botulinum toxin type A (OnabotulinumtoxinA) for chronic migraine.

Migraine Without Aura

– A primary headache disorder characterized by recurrent attacks of moderate to severe, pulsating, unilateral headache lasting four to seventy-two hours, associated with nausea, vomiting, photophobia, and phonophobia. The International Classification of Headache Disorders (ICHD-3) diagnostic criteria require at least five attacks fulfilling the following: headache lasting four to seventy-two hours, with at least two of the following four characteristics: unilateral location, pulsating quality, moderate or severe pain intensity, and aggravation by or causing avoidance of routine physical activity, and during the headache attack at least one of nausea and/or vomiting or photophobia and phonophobia. The attack is not better accounted for by another diag-

nosis. Migraine without aura is the most common subtype of migraine, accounting for approximately 70-80 percent of all migraine attacks. The headache phase is thought to be mediated by activation of the trigeminovascular system, with release of vasoactive neuropeptides such as CGRP causing neurogenic inflammation of the meningeal blood vessels. The pathophysiology of migraine without aura is less well understood than migraine with aura, as cortical spreading depression is not thought to occur. Management of acute attacks includes stratified care based on headache severity: mild attacks are treated with simple analgesics (ibuprofen, paracetamol, aspirin, diclofenac) plus an antiemetic; moderate-to-severe attacks are treated with triptans (sumatriptan, rizatriptan, eletriptan) or gepants (rimegepant, ubrogepant). Triptans are most effective when taken early during the headache phase before central sensitisation develops. Preventive therapy is indicated for patients with frequent or disabling attacks and includes beta-blockers (propranolol, metoprolol), tricyclic antidepressants (amitriptyline), antiepileptics (topiramate, sodium valproate), and CGRP monoclonal antibodies.

Multiple Sclerosis

– A chronic autoimmune demyelinating disease of the central nervous system, most commonly presenting in young adults. Characterized by relapsing-remitting episodes of neurological dysfunction (optic neuritis, transverse myelitis, brainstem syndromes). Diagnosis: McDonald criteria with MRI dissemination in space and time. Disease-modifying therapies reduce relapse rate and disability progression.

Myasthenia Gravis

– An autoimmune disorder caused by antibodies against the nicotinic acetylcholine receptor (AChR, 85%) or MuSK at the neuromuscular junction, leading to fluctuating muscle weakness that worsens with use (fatigability). Presents with ptosis, diplopia, dysphagia, dysarthria, and proximal limb weakness. Ocular MG: limited to eye muscles. Generalized MG: bulbar and limb involvement. Myasthenic crisis: respiratory failure requiring ventilation. Diagnosis: AChR antibodies, repetitive nerve stimulation (decrement), single-fiber EMG, edrophonium test. Treatment: acetylcholinesterase inhibitors (pyridostigmine), corticosteroids, im-

munosuppressants (azathioprine, mycophenolate), thymectomy for thymoma, IVIG/plasmapheresis for crisis.

Myotonic Dystrophy

– The most common adult-onset muscular dystrophy, an autosomal dominant multisystem disorder caused by CTG trinucleotide repeat expansions in the DMPK gene (type 1, DM1) or CCTG tetranucleotide repeat expansions in the CNBP gene (type 2, DM2) on chromosome 19q13.3. DM1 is more common and more severe than DM2. The pathophysiology involves a toxic gain-of-function mechanism, where the expanded repeat RNA forms hairpin structures that sequester RNA-binding proteins (particularly muscleblind-like proteins MBNL1 and MBNL2), leading to dysregulation of alternative splicing of many downstream genes (spliceopathy). The expanded repeats can also be transcribed into toxic proteins through repeat-associated non-ATG (RAN) translation. Clinical features of DM1 include myotonia (delayed relaxation after muscle contraction, demonstrable by grip myotonia or percussion myotonia of the thenar eminence and tongue), progressive distal weakness (worse than proximal), facial weakness with a characteristic hatchet face and ptosis, frontal balding, cataracts (posterior subcapsular iridescent cataracts), cardiac conduction abnormalities (first-degree heart block, bundle branch block, complete heart block—a leading cause of death), insulin resistance, and excessive daytime somnolence. DM2 (proximal myotonic myopathy) is milder, with predominantly proximal weakness, less severe myotonia, fewer cardiac complications, and later onset. Myotonic dystrophy exhibits anticipation (earlier and more severe disease in successive generations) due to expansion of the CTG repeat during transmission, particularly through maternal inheritance. Diagnosis is clinical, confirmed by genetic testing showing expanded CTG repeats in DMPK (DM1) or CCTG repeats in CNBP (DM2). There is no disease-modifying treatment. Management is symptomatic and includes mexiletine for myotonia, cardiac monitoring with pacemaker insertion for conduction abnormalities, treatment of cataracts and endocrine dysfunction, and respiratory support for sleep-disordered breathing. Avoid depolarising muscle relaxants (suxamethonium) due

to risk of malignant hyperthermia. Prognosis in DM1 is variable; patients with severe congenital DM1 have poor outcomes, while milder adult-onset forms allow near-normal lifespan with appropriate surveillance.

Neuropathy (Peripheral Neuropathy)

– Damage to peripheral nerves causing sensory, motor, or autonomic dysfunction. Common causes: diabetes mellitus, alcohol use disorder, vitamin B12 deficiency, chemotherapy, autoimmune diseases, and hereditary conditions (Charcot-Marie-Tooth disease). Presents with numbness, tingling, burning pain, weakness, and gait instability. Treatment addresses the underlying cause, with symptomatic management including gabapentin, duloxetine, and tricyclic antidepressants.

Oligoclonal Bands

– Immunoglobulin G (IgG) proteins produced by a limited number of B-cell clones in the cerebrospinal fluid (CSF), detected by isoelectric focusing of CSF and serum samples. Oligoclonal bands represent intrathecal IgG synthesis and are present in approximately ninety to ninety-five percent of patients with multiple sclerosis, making them one of the most sensitive laboratory markers for the disease. The detection of OCBs in CSF but not in serum (type 2 pattern) indicates intrathecal IgG synthesis and supports the diagnosis of multiple sclerosis (MS). The presence of identical OCBs in both CSF and serum (type 3 pattern) indicates systemic IgG production with passive transfer into the CSF, which is less specific for MS. OCBs are detected in approximately 90-95 percent of MS patients, making them the most sensitive laboratory marker for the disease. They are also present in other inflammatory and infectious CNS conditions such as neuromyelitis optica, neurosarcoidosis, neurosyphilis, and neuroborreliosis, but with lower frequency. The absence of OCBs in a patient with typical MS clinical and MRI findings is associated with a milder disease course. OCB typing by isoelectric focusing of paired CSF and serum samples is considered the gold standard method.

Pachymeningitis

– Inflammation of the dura mater (pachymeninx), the outermost layer of the meninges. Pachymeningitis

is less common than leptomeningitis (inflammation of pia and arachnoid mater). Causes: infection (tuberculosis—most common in developing countries, syphilis, fungi—*Cryptococcus*, bacteria—direct spread from sinusitis/otitis/osteomyelitis), autoimmune (IgG4-related disease—hypertrophic pachymeningitis, granulomatosis with polyangiitis, sarcoidosis, rheumatoid arthritis), and neoplastic (meningeal carcinomatosis, lymphoma). Presentation: chronic headache (most common), cranial nerve palsies (II, III, VI, VII, VIII), radicular pain, and myelopathy (spinal pachymeningitis). Hypertrophic pachymeningitis: focal or diffuse dural thickening on MRI with contrast enhancement (pachymeningeal enhancement). CSF: lymphocytic pleocytosis, elevated protein. Diagnosis: MRI brain with contrast, CSF analysis, and biopsy if autoimmune or neoplastic cause suspected. Treatment: corticosteroids for autoimmune causes, antitubercular therapy for TB, antibiotics for bacterial infection. Prognosis depends on the underlying etiology.

Parinaud Syndrome

– A clinical condition caused by lesions of the dorsal midbrain, particularly the pretectal area and superior colliculi, resulting in a characteristic triad of vertical gaze palsy (particularly impaired upward gaze), convergence-retraction nystagmus (involuntary retraction of the eyeballs into the orbits with attempted upward gaze), and light-near dissociation (pupils that do not react to light but do react to accommodation). Other features include Collier sign (eyelid retraction, also known as the lid-lag sign or setting-sun sign), convergence-retraction nystagmus, and papilloedema. Parinaud syndrome is most commonly caused by compression of the dorsal midbrain by a pineal gland tumor (pinealoma, pineal germinoma, pineocytoma, pineoblastoma), which accounts for the classic presentation in young males. Other causes include midbrain infarction, hemorrhage, multiple sclerosis, arteriovenous malformations, neurocysticercosis, and hydrocephalus (which can cause dilation of the third ventricle with upward pressure on the tectum). Diagnosis is by MRI brain with particular attention to the pineal region and dorsal midbrain, including CSF cytology and tumor markers (alpha-fetoprotein, beta-human chorionic gonadotropin) for suspected germ cell tumors.

Management is directed at the underlying cause: surgical resection of pineal tumors, radiotherapy or chemotherapy for germinomas, ventriculoperitoneal shunting for hydrocephalus, and treatment of vascular or demyelinating causes. Prognosis depends on the underlying etiology and response to treatment.

Petit Mal

– See Absence Seizure.

Polymicrogyria

– A brain malformation characterized by an excessive number of abnormally small, fused gyri, resulting in an irregular, bumpy cortical surface with shallow sulci. Caused by abnormal late neuronal migration or post-migrational cortical organization. May be focal or diffuse, unilateral or bilateral, and symmetric or asymmetric. Presents with variable severity depending on extent: seizures (often focal epilepsy), developmental delay, motor deficits, and language impairment. Bilateral perisylvian polymicrogyria presents with pseudobulbar palsy, dysarthria, and cognitive impairment. Diagnosis by MRI (thin-section T1-weighted and T2-weighted imaging). No specific treatment; management is symptomatic.

Primary Lateral Sclerosis

– A rare neurodegenerative disorder confined to the upper motor neurons (corticospinal tract) of the motor cortex and brainstem. Presents with slowly progressive spasticity, hyperreflexia, Babinski sign, and pseudobulbar affect (emotional lability). Unlike ALS, there is no significant lower motor neuron involvement (no muscle atrophy or fasciculations) and survival is longer (10-15 years vs. 2-5 years for ALS). Diagnosis: clinical, EMG/NCS to exclude ALS mimics. No disease-modifying therapy; symptomatic management with baclofen, tizanidine, and speech therapy.

Progressive Supranuclear Palsy

– A neurodegenerative tauopathy characterized by the accumulation of tau protein in the basal ganglia, brainstem, and cerebral cortex, belonging to the family of Parkinson plus syndromes. The cardinal clinical features include progressive vertical supranuclear gaze palsy (particularly impairment of voluntary downward gaze, which is the hallmark feature), early postural instability with recurrent unexplained falls (typically backwards), axial rigidity greater than in the limbs (axial rigidity), bradyki-

nesia, and early cognitive decline (including frontal lobe dysfunction with apathy, disinhibition, and executive impairment, which helps distinguish PSP from Parkinson disease). Other common features include dysphagia, dysarthria (hypokinetic or spastic), pseudobulbar affect (emotional lability with pathological laughing or crying), and eyelid opening apraxia (difficulty opening the eyes voluntarily). The classic PSP phenotype is Richardson syndrome (RS), but other variants include PSP-parkinsonism (PSP-P, resembling Parkinson disease with moderate levodopa response), PSP-progressive gait freezing (PSP-PGF), and PSP-corticobasal syndrome (PSP-CBS). The pathophysiology involves abnormal aggregation of the microtubule-associated protein tau, predominantly the 4-repeat (4R) tau isoform, in neurons and glia, forming globose neurofibrillary tangles and tufted astrocytes. The H1 haplotype of the MAPT gene is the major genetic risk factor. Diagnosis is clinical (MDS-PSP criteria) with supportive MRI findings including the hummingbird sign (midbrain atrophy on sagittal T1-weighted MRI showing a flat or concave superior profile of the midbrain resembling a hummingbird) and the Mickey Mouse sign (preserved pons with atrophied midbrain on axial MRI, giving the appearance of Mickey Mouse ears). Midbrain-to-pons area ratio of less than 0.2 is highly suggestive. There is no disease-modifying treatment; management is symptomatic with levodopa for parkinsonism (limited response, usually modest and transient), botulinum toxin for blepharospasm and eyelid apraxia, speech therapy, swallowing assessment, and fall prevention strategies. Prognosis is poor, with median survival of 6-9 years from symptom onset, with falls, dysphagia, and aspiration pneumonia as common causes of death.

Rippling Muscle Disease

– A rare, benign myopathy characterized by mechanically-induced muscle contractions that spread across the muscle as a visible wave (rippling), typically triggered by stretch, percussion, or movement. Rippling muscle disease is caused by mutations in the CAV3 gene (encoding caveolin-3), inherited as an autosomal dominant trait with variable expressivity. Caveolin-3 is a structural protein in the sarcolemma membrane of skeletal muscle,

involved in membrane stabilisation and signalling. Onset can occur at any age from childhood to adulthood. Clinical features: muscle rippling (percussion-induced or stretch-induced visible wave of muscle contraction, lasting 1–5 seconds), muscle mounding (percussion-induced localised muscle swelling, lasting up to 30 seconds), myoedema (localised dimpling on percussion), muscle stiffness/cramps after exercise, and mild proximal weakness in some patients. Serum creatine kinase is elevated (2–10 times normal). EMG shows no myotonic discharges (distinguishing from myotonic dystrophy and channelopathies). Muscle biopsy: normal or mild non-specific changes; caveolin-3 immunostaining shows reduced sarcolemmal caveolin-3. Treatment: symptomatic—avoidance of triggering stimuli, mexiletine or carbamazepine may reduce muscle stiffness. Prognosis: benign, non-progressive, normal life expectancy. Consider genetic counseling.

Schizencephaly

– A rare brain malformation characterized by a full-thickness, gray matter-lined cleft extending from the pial surface to the lateral ventricle. Caused by early focal neuronal migration abnormalities, often associated with prenatal vascular disruption or COL4A1 mutations. Closed-lip (Type I): the cleft walls are apposed. Open-lip (Type II): there is a CSF-filled space between the cleft walls. May be unilateral or bilateral. Presents with seizures, motor deficits (hemiparesis, spasticity), developmental delay, and hydrocephalus. Diagnosis by MRI. Treatment includes seizure management, physical/occupational therapy, and hydrocephalus management if needed.

Sciatica

– Pain radiating along the distribution of the sciatic nerve (L4-S3), from the lower back through the buttock and down the posterior thigh to the foot. Most commonly caused by lumbar disc herniation compressing the nerve root (L4-L5 or L5-S1). Other causes: spinal stenosis, spondylolisthesis, piriformis syndrome, and epidural abscess. Presents with sharp, burning pain, paresthesias, and sometimes motor weakness (foot drop). Positive straight leg raise test. Diagnosis: clinical; MRI if red flags (cauda equina, progressive weakness, trauma, infection). Management: conservative (NSAIDs, physical therapy, activity modification); epidural steroid

injections; surgical discectomy for refractory or severe cases.

Seizure

– A transient occurrence of signs and/or symptoms due to abnormal, excessive, or synchronous neuronal activity in the brain. Provoked seizures have an identifiable acute cause (fever, electrolyte disturbance, drug toxicity, withdrawal). Unprovoked seizures occur without an acute trigger. Classification: focal onset, generalized onset, unknown onset. Evaluation: EEG, neuroimaging, laboratory studies. Management depends on etiology and recurrence risk.

Sleep Studies (Polysomnography)

– Sleep tests, most commonly polysomnography, are diagnostic studies used to evaluate sleep architecture and identify sleep disorders. Polysomnography records brain waves, eye movements, heart rate, breathing patterns, blood oxygen levels, and limb movements throughout the night in a controlled laboratory setting. Home sleep apnea tests are simpler devices that primarily measure breathing and oxygen saturation to screen for obstructive sleep apnea, while multiple sleep latency tests assess daytime sleepiness by measuring how quickly a person falls asleep in a quiet environment.

Spasm

– A sudden, involuntary, sustained or repetitive contraction of a muscle or group of muscles. Types: (1) Skeletal muscle spasm—muscle cramps (common, benign—nocturnal leg cramps, exercise-associated), muscle strain, tetany (hypocalcaemia—perioral paraesthesias, carpopedal spasm, Trousseau sign, Chvostek sign), tetanus (generalised rigidity, risus sardonicus, opisthotonos), dystonia (sustained muscle contractions causing twisting/repetitive movements—cervical dystonia, blepharospasm, writer's cramp), and myoclonus (brief, shock-like jerks). (2) Smooth muscle spasm—bronchospasm (asthma, COPD exacerbation), esophageal spasm (chest pain, dysphagia), ureteric colic (kidney stone—severe flank pain radiating to groin), and biliary colic (gallstone obstruction of cystic duct). Treatment: directed at the underlying cause; muscle relaxants (baclofen, tizanidine, benzodiazepines) for skeletal muscle spasm; antispasmodics (hyoscine butylbromide/Buscopan) for smooth muscle spasm; calcium

channel blockers for esophageal spasm; analgesics and NSAIDs for ureteric colic.

Spina Bifida Meningocele

– A form of spina bifida where the meninges (but not neural tissue) herniate through a vertebral defect, forming a CSF-filled sac. The spinal cord remains in its normal position and is not involved. Presents as a visible, fluid-filled, translucent sac on the back, typically without neurologic deficits. Surgical repair involves reduction and closure. Prognosis is excellent with normal neurologic function expected.

Spina Bifida Myelomeningocele

– The most severe form of spina bifida, where both the meninges and neural tissue (spinal cord and nerve roots) herniate through a vertebral defect. Presents as a visible, flat or sac-like lesion on the back with neurologic deficits below the level of the lesion (paralysis, sensory loss, bowel/bladder dysfunction). Associated with hydrocephalus (in 80-90% of cases) and Arnold-Chiari malformation type II. Diagnosis by prenatal ultrasound and elevated maternal serum alpha-fetoprotein. Treatment: surgical closure within 24-48 hours of birth, ventriculoperitoneal shunt for hydrocephalus, and lifelong multidisciplinary care.

Spinocerebellar Ataxias

– A group of autosomal dominant neurodegenerative disorders characterized by progressive cerebellar ataxia, often with additional neurological features. Over forty different SCA types have been identified, with SCA1, SCA2, SCA3 (Machado-Joseph disease, the most common worldwide), SCA6, and SCA7 being the most prevalent. Most SCAs are caused by CAG trinucleotide repeat expansions encoding polyglutamine (polyQ) tracts in the affected proteins, similar to Huntington disease, with anticipation (earlier onset in successive generations) observed in some SCA types due to repeat instability, especially with paternal transmission. Clinical features include progressive gait and limb ataxia, dysarthria, and eye movement abnormalities (nystagmus, saccadic intrusions). Additional features vary by SCA type: SCA1 includes pyramidal signs, peripheral neuropathy, and dysphagia; SCA2 includes slow saccades, peripheral neuropathy, and cognitive decline; SCA3 (Machado-Joseph disease) includes dystonia, parkinsonism, and spasticity in

addition to ataxia; SCA6 is a pure cerebellar ataxia with later onset; and SCA7 includes retinal degeneration causing progressive vision loss. Diagnosis is based on clinical presentation, family history (autosomal dominant inheritance), and genetic testing identifying the specific CAG repeat expansion in the relevant gene. MRI brain shows progressive cerebellar atrophy, particularly of the vermis and cerebellar hemispheres, with brainstem atrophy in some types. There is no disease-modifying treatment; management is symptomatic and supportive, including physical and occupational therapy, speech therapy, and treatment of specific complications. Prognosis is variable but most SCAs lead to severe disability and reduced lifespan over 10-30 years.

Syringomyelia

– A condition characterized by the formation of a fluid-filled cyst (syrinx) within the spinal cord, which can expand and elongate over time, compressing and destroying the surrounding spinal cord tissue. The most common cause is Chiari malformation type I (see separate entry), where cerebellar tonsillar ectopia obstructs CSF flow at the foramen magnum, leading to syrinx formation. Other causes include spinal cord trauma, spinal cord tumors, arachnoiditis, and spinal dysraphism. The syrinx typically expands within the central canal of the spinal cord (dilating it) in a segmental pattern, most commonly in the cervical region, and can extend rostrally into the brainstem (syringobulbia) or caudally down the entire cord. Clinical presentation depends on the location and extent of the syrinx. Typical symptoms include a capelike distribution of dissociated sensory loss (loss of pain and temperature sensation with preserved touch and vibration sensation) over the shoulders and upper back (due to crossing spinothalamic fibers being affected first in the central cord), segmental weakness and atrophy in the arms and hands (from damage to anterior horn cells), and in advanced cases, spastic paraparesis, bladder dysfunction, and Horner syndrome (if the syrinx expands laterally). Pain is common, often described as a deep, aching, or burning sensation in the neck, shoulders, and arms. Diagnosis is by MRI of the spinal cord, which demonstrates a CSF-filled cavity within the spinal cord and any associated Chiari malformation or

other pathology. Management is directed at the underlying cause: for Chiari-related syringomyelia, posterior fossa decompression (suboccipital craniectomy and cervical laminectomy with duraplasty) is the treatment of choice. For post-traumatic syringomyelia, the treatment is syrinx shunting or untethering of the spinal cord. Patients with stable, asymptomatic syringomyelia can be managed conservatively with serial MRI monitoring. The natural history is variable: some syringes remain stable while others progress insidiously over years, leading to increasing neurological deficit.

Syrinx

– A syrinx is a fluid-filled cavity within the spinal cord, typically containing cerebrospinal fluid or a similar fluid, that develops as a result of abnormal CSF flow dynamics within the spinal cord. Syringomyelia: a syrinx in the central spinal cord. Hydromyelia: dilation of the central canal. In practice, the terms are often used interchangeably. The most common cause of syrinx formation is Chiari malformation type I, where cerebellar tonsillar ectopia obstructs CSF flow at the foramen magnum, causing abnormal CSF pressure dynamics within the central canal of the spinal cord, leading to cyst formation. Other causes include spinal cord trauma, spinal cord tumors (especially intramedullary tumors such as ependymomas and haemangioblastomas, which can cause syrinx formation through altered CSF flow dynamics), and arachnoiditis (inflammation of the arachnoid mater due to infection, hemorrhage, or previous surgery). The syrinx may be asymptomatic if small, or may cause progressive myelopathy depending on its size and location. Symptoms include central cord syndrome with dissociated sensory loss (loss of pain and temperature with preserved touch and vibration in a cape-like distribution over the shoulders and upper back), segmental weakness and atrophy (from anterior horn cell damage), spastic paraparesis (from corticospinal tract involvement), and neuropathic pain. Diagnosis is by MRI of the spinal cord, which shows the CSF-filled cavity. Management depends on the cause and symptoms: asymptomatic syringes may be observed with serial imaging, while symptomatic syringes may require surgical treatment including posterior fossa decompression for Chiari malformations, cyst

drainage or shunting, or tumor resection. Prognosis is variable; timely treatment of the underlying cause may stabilise or improve symptoms, but neurological deficits may be irreversible if the syrinx has caused significant cord damage.

Tethered Cord Syndrome

– A congenital or acquired condition where the spinal cord is abnormally attached (tethered) to surrounding tissues, restricting its normal upward movement within the spinal canal. Caused by a thickened filum terminale, lipomeningomyelocele, diastematomyelia, or previous myelomeningocele repair. Presents with back pain, leg weakness, sensory loss, gait abnormalities, urinary incontinence, and foot deformities. Symptoms may worsen with growth, flexion, or trauma. Diagnosis by MRI showing a low-lying conus medullaris (below L2-L3). Treatment: surgical detethering to prevent progressive neurologic deterioration.

Tic Douloureux

– See Trigeminal Neuralgia.

Transverse Myelitis

– An inflammatory disorder of the spinal cord causing acute or subacute motor, sensory, and autonomic dysfunction. It results from immune-mediated inflammation of the spinal cord parenchyma and can occur as a isolated condition or as part of a systemic autoimmune disease or demyelinating disorder such as multiple sclerosis or neuromyelitis optica. Clinical features include bilateral lower extremity weakness, a sensory level (a dermatome below which sensation is impaired), urinary retention (more common than incontinence in the acute phase, progressing to bladder and bowel incontinence), and a sensory level (a transverse band-like boundary below which there is loss of pain, temperature, and light touch sensation). The sensory level is typically in the mid-thoracic region, as the thoracic spinal cord is the longest and most vulnerable segment. Fever or a recent history of infection or vaccination may precede the onset. If the inflammation occurs as part of multiple sclerosis, it is typically shorter (less than one vertebral segment) and more asymmetrical, whereas NMOSD-related transverse myelitis is typically longitudinally extensive (three or more vertebral segments). Diagnosis is by MRI of the spinal cord, which shows a central T2-hyperintense

intramedullary lesion with gadolinium enhancement in the acute phase. CSF analysis typically shows a lymphocytic pleocytosis (elevated white cell count) and elevated protein, with positive oligoclonal bands if associated with multiple sclerosis. Treatment of acute attacks includes high-dose intravenous corticosteroids (methylprednisolone 1 gram daily for 5 days), with plasma exchange for steroid-resistant cases. Long-term treatment depends on the underlying cause: immunosuppression for NMOSD, disease-modifying therapy for MS, and observation for monophasic idiopathic cases. Prognosis is variable: approximately one-third of patients recover fully, one-third have moderate residual disability, and one-third have severe disability.

Trigeminal Neuralgia

– A chronic pain condition characterized by recurrent, sudden, severe, electric shock-like pain in the distribution of the trigeminal nerve (typically V2/V3). Often triggered by light touch, chewing, or brushing teeth. Most cases are caused by vascular compression of the trigeminal nerve root. First-line treatment: carbamazepine or oxcarbazepine. Surgical options: microvascular decompression, gamma knife radiosurgery, percutaneous rhizotomy.

Tuberous Sclerosis Complex

– An autosomal dominant genetic disorder caused by mutations in TSC1 (hamartin) or TSC2 (tuberin) genes, leading to mTOR pathway activation. Features: cortical tubers, subependymal nodules, cardiac rhabdomyomas, angiomyolipomas, facial angiofibromas, and seizures (often infantile spasms). Intellectual disability and autism spectrum disorder are common. Treatment: mTOR inhibitors (everolimus) for angiomyolipomas and subependymal giant cell astrocytomas.

Unconsciousness

– See Coma.

Chapter 24

Nuclear Medicine & Molecular Imaging

Biological Half-Life

- Time required for the human body to eliminate half the administered quantity of a drug or radiopharmaceutical through physiological excretory pathways (renal, fecal, pulmonary, hepatic), independent of radioactive decay.

Collimator

- Lead or tungsten shielding device mounted on a gamma camera or SPECT detector containing precision holes that permit only gamma rays traveling along specific geometric trajectories to reach the scintillation detector, preventing scattered photons from blurring the image.

Cyclotron

- Particle accelerator used in nuclear medicine radiopharmacies to bombard stable target nuclei with high-energy protons or deuterons to manufacture short-lived positron-emitting radionuclides such as Fluorine-18 (^{18}F), Carbon-11 (^{11}C), Nitrogen-13 (^{13}N), and Oxygen-15 (^{15}O).

DaTscan (Ioflupane I-123)

- Radiopharmaceutical (^{123}I -ioflupane) SPECT imaging agent that binds to presynaptic dopamine transporters (DaT) in the striatum; used to differentiate Essential Tremor (normal uptake) from Parkinsonian Syndromes (Parkinson disease, Multiple System Atrophy, Progressive Supranuclear Palsy showing reduced striatal uptake).

DMSA Renal Scan

- Nuclear medicine imaging procedure using Technetium-99m dimercaptosuccinic acid ($^{99\text{m}}\text{Tc}$ -DMSA) which binds to cortical renal tubular cells; gold standard for evaluating static renal cortical mass, detecting cortical scarring from recurrent pyelonephritis, and assessing differential renal function.

Dose Calibrator

- Ionization chamber instrument utilized in radiopharmacies to measure the radioactivity (Bequerels or Curies) of radiopharmaceutical doses prior to administration to patients.

DTPA Renal Scan

- Dynamic renal scintigraphy using Technetium-99m diethylenetriaminepentaacetic acid ($^{99\text{m}}\text{Tc}$ -DTPA), an agent excreted exclusively by glomerular filtration; used to measure Glomerular Filtration Rate (GFR) and assess renal arterial perfusion.

Effective Half-Life

- Net rate of clearance of a radiopharmaceutical from the body combining both physical radioactive decay half-life (T_p) and biological clearance half-life (T_b), calculated by $(T_p \times T_b)/(T_p + T_b)$.

Fluorodeoxyglucose (18F-FDG)

- Positron-emitting radiopharmaceutical and glucose analog (^{18}F -FDG) widely utilized in Positron Emission Tomography (PET) imaging. Pathophysiology: FDG is transported into cells via GLUT transporters and phosphorylated by hexokinase into FDG-6-phosphate; because FDG-6-phosphate cannot be further metabolized in the glycolytic pathway, it becomes metabolic trapped inside hypermetabolic cells. Clinical utility: Oncology (detection, staging, and therapy response monitoring of primary and metastatic malignancies, which exhibit high glucose utilization via the Warburg effect), Neurology (evaluation of Alzheimer's disease showing parietotemporal hypometabolism, and localization of epileptic foci), and Cardiology (assessment of myocardial viability).

Fluorodeoxyglucose PET-CT (FDG-PET/CT)

- Hybrid molecular imaging modality combining

high-sensitivity Positron Emission Tomography (PET) tracking glucose metabolism with high-resolution Computed Tomography (CT) providing precise anatomical localization. Essential in modern clinical oncology for tumor staging (TNM), restaging following therapy, detecting occult recurrence, guiding biopsy of hypermetabolic tissue, and planning radiation therapy fields. Standardized Uptake Value (SUV) is a quantitative measurement of radiotracer uptake used to differentiate malignant from benign lesions.

Gallium-68 PSMA (68Ga-PSMA)

- Positron-emitting radiopharmaceutical targeting Prostate-Specific Membrane Antigen (PSMA), highly expressed on prostate adenocarcinoma cells; utilized in PET-CT for restaging prostate cancer with biochemical recurrence (elevated PSA) and detecting occult micrometastases.

Gamma Camera

- Core imaging detector in conventional nuclear medicine, designed to detect gamma rays emitted from radiopharmaceuticals administered to patients and convert them into two-dimensional projection images (scintigrams). Major components: lead collimator (discriminates gamma ray direction), sodium iodide (NaI) scintillation crystal (converts gamma photons into visible light flashes), photomultiplier tubes (PMTs—convert light into electrical signals), and positioning electronics. Used for planar imaging and rotated around the patient to perform Single-Photon Emission Computed Tomography (SPECT).

Gastric Emptying Study

- Diagnostic nuclear medicine procedure where a patient ingests a radiolabeled standardized meal (e.g., egg whites labeled with ^{99m}Tc -sulfur colloid) and sequential gamma camera images are acquired to measure gastric retention percentage over 4 hours; gold standard for diagnosing gastroparesis.

HIDA Scan (Cholescintigraphy)

- Dynamic hepatobiliary nuclear imaging using Technetium-99m iminodiacetic acid analogs (^{99m}Tc -mebrofenin or ^{99m}Tc -disofenin); excreted by hepatocytes into bile, allowing visualization of gallbladder, biliary tree, and duodenum. Non-visualization of gallbladder at 4 hours indicates acute cholecystitis due to cystic duct obstruction.

Indium-111 WBC Scan

- Diagnostic imaging technique where patient leukocytes are harvested, labeled in vitro with Indium-111 oxine (^{111}In -WBC), and reinjected; highly specific for localizing occult intra-abdominal abscesses, osteomyelitis in complicated diabetic feet, and inflammatory bowel disease.

Iodine-123 MIBG (123I-MIBG)

- Radiopharmaceutical structural analog of norepinephrine concentrated in sympathetic adrenergic tissue; used in SPECT imaging to detect neuroblastoma, pheochromocytoma, and paraganglioma, and assess cardiac sympathetic innervation.

Krypton-81m (81mKr)

- Ultra-short half-life (13 seconds) inert radioactive gas generated on-site from a Rubidium-81 generator; inhaled to perform real-time continuous pulmonary ventilation scintigraphy paired with perfusion imaging.

Lutetium-177 DOTATATE (177Lu-DOTATATE)

- Targeted peptide receptor radionuclide therapy (PRRT) utilizing a beta-emitting radioisotope linked to a somatostatin analog; indicated for the treatment of somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumors (GEP-NETs).

Lymphoscintigraphy

- Nuclear medicine procedure mapping lymphatic drainage pathways following intradermal injection of ^{99m}Tc -sulfur colloid or ^{99m}Tc -tilmanocept around a primary malignancy (melanoma, breast cancer) to identify and guide surgical biopsy of the Sentinel Lymph Node.

MAG3 Renal Scan

- Dynamic renal scintigraphy using Technetium-99m mercaptoacetyltriglycine (^{99m}Tc -MAG3), excreted predominantly by renal tubular secretion; ideal radiotracer for evaluating urinary tract obstruction (hydronephrosis) and renal dysfunction in patients with impaired renal function.

Meckel Scintigraphy

- Nuclear medicine scan following intravenous injection of Technetium-99m pertechnetate ($^{99m}\text{TcO}_4^-$), which selectively accumulates in ectopic gastric mucosa; gold standard diagnostic test for detecting Meckel's diverticulum presenting with lower gastrointestinal bleeding.

Myocardial Perfusion Imaging (MPI)

– Diagnostic nuclear cardiology test used to evaluate myocardial blood flow at rest and during physiological or pharmacological stress (adenosine, regadenoson, dobutamine). Radiopharmaceuticals used: Technetium-99m sestamibi (^{99m}Tc -sestamibi), Technetium-99m tetrofosmin, or Thallium-201 (^{201}Tl). Images captured using SPECT camera allow detection of inducible ischemia (reversible perfusion defect: normal at rest, reduced during stress—indicating significant coronary artery disease) versus myocardial infarction (fixed perfusion defect: reduced at both rest and stress—indicating scar tissue).

Nuclear Medicine & Molecular Imaging

– Specialized branch of medical imaging and therapeutics that utilizes small amounts of radioactive substances (radiopharmaceuticals or radiotracers) to diagnose, stage, evaluate, and treat human diseases. Unlike anatomical imaging (plain X-ray, CT, MRI) which visualizes structure, nuclear medicine visualizes functional physiological processes at the cellular and molecular level (organ perfusion, cell metabolism, receptor density, bone turnover). Encompasses diagnostic modalities (SPECT, PET, planar scintigraphy) and targeted radionuclide therapy (Theranostics).

Parathyroid Scintigraphy

– Subtractive or dual-phase SPECT/CT imaging utilizing Technetium-99m sestamibi (^{99m}Tc -sestamibi) which washes out rapidly from normal thyroid tissue but is retained in hyperfunctioning parathyroid adenomas or hyperplasia, guiding minimally invasive parathyroidectomy.

PET-MRI

– Hybrid diagnostic imaging modality combining the high metabolic sensitivity of Positron Emission Tomography (PET) with the superior soft-tissue contrast and non-ionizing anatomical imaging of Magnetic Resonance Imaging (MRI).

Positron Decay

– Mode of radioactive decay (β^+ decay) occurring in proton-rich unstable nuclei, where a proton converts into a neutron, emitting a positron (e^+) and a neutrino (ν).

Positron Emission Tomography (PET)

– Advanced 3D tomographic molecular imaging technique based on the detection of annihilation photon pairs. When a positron-emitting radiotracer (e.g., Fluorine-18, Carbon-11, Gallium-68) decays, emitted positrons travel a short distance before colliding with an electron, resulting in an annihilation event that produces two 511 keV gamma ray photons traveling in opposite directions (180° apart). Detectors surrounding the patient register these simultaneous coincidence events to construct high-resolution functional images.

Radioactive Iodine Therapy (^{131}I)

– Targeted radionuclide therapy utilizing Iodine-131 (^{131}I), a beta- and gamma-emitting isotope, to selectively destroy functioning thyroid tissue. Thyroid follicular cells actively trap circulating iodide via the sodium-iodide symporter (NIS). Emitted beta particles (mean range 1–2 mm) deliver localized cytotoxic radiation while sparing adjacent neck structures. Clinical indications: definitive treatment of hyperthyroidism (Graves' disease, toxic multinodular goiter) and adjuvant ablation of residual normal thyroid tissue or metastatic disease following surgery for differentiated thyroid cancer (papillary and follicular carcinoma).

Radioimmunoassay (RIA)

– In vitro quantitative laboratory technique utilizing radiolabeled antigens (^{125}I) and specific antibodies to measure extremely low concentrations of hormones, drugs, and proteins in blood plasma.

Radionuclide Bone Scan

– Highly sensitive nuclear medicine imaging procedure used to evaluate bone turnover and osteoblastic activity throughout the skeleton. Radiopharmaceutical: Technetium-99m labeled diphosphonates (^{99m}Tc -MDP), which adsorb directly onto hydroxyapatite crystals in areas of active bone remodeling. Three-phase bone scan (flow phase, blood pool phase, delayed skeletal phase) differentiates osteomyelitis from cellulitis. Highly sensitive for detecting skeletal metastases (prostate, breast, lung cancer—appearing as multiple asymmetrical "hot spots"), stress fractures, occult trauma, and Paget disease of bone.

Radiopharmaceutical

– Pharmaceutical drug compound containing one or more radioactive isotopes (radionuclides) suitable for human administration, used for medical diagnosis or targeted therapy. Composed of two parts: a targeting molecule (antibody, peptide, metabolic substrate, or ligand) that binds to specific cellular receptors or physiological pathways, linked to a radionuclide that emits detectable radiation (gamma or positron for imaging; beta or alpha for therapy). Common radionuclides: Technetium-99m (^{99m}Tc), Fluorine-18 (^{18}F), Iodine-131 (^{131}I), Gallium-68 (^{68}Ga), Lutetium-177 (^{177}Lu), and Yttrium-90 (^{90}Y).

Radium-223 Dichloride (^{223}Ra)

– Alpha-emitting targeted radiopharmaceutical that acts as a calcium mimetic, selectively targeting areas of high bone turnover; approved for improving overall survival in castration-resistant prostate cancer with symptomatic bone metastases.

Samarium-153 Lexidronam (^{153}Sm)

– Beta-emitting radiopharmaceutical complexed with tetramethylene phosphonate, concentrating in osteoblastic bone lesions; used for palliative pain relief in widespread painful skeletal metastases.

Schilling Test

– Historical classic radioisotope absorption test utilizing Cobalt-57 labeled Vitamin B12 ($^{57}\text{Co-B12}$) to elucidate the underlying etiology of megaloblastic anemia (differentiating intrinsic factor deficiency / pernicious anemia from ileal malabsorption).

Secular Equilibrium

– Radioactive equilibrium established in a parent-daughter isotope pair when the physical half-life of the parent radionuclide is extremely long compared to that of the daughter (e.g., Radium-226 decaying to Radon-222).

Single-Photon Emission Computed Tomography (SPECT)

– 3D tomographic nuclear imaging technique where one or more gamma cameras rotate around the patient, acquiring multiple 2D projection images from different angles that are computer-reconstructed into cross-sectional axial, coronal, and sagittal slices. Utilizes single-photon gamma-emitting radiotracers (primarily Technetium-99m, Iodine-123, Indium-111). Frequently combined with CT (hybrid

SPECT/CT) for precise anatomical registration. Used extensively in myocardial perfusion imaging, bone scans, brain SPECT (DaTscan for Parkinsonism), and neuroendocrine tumor localization.

Standardized Uptake Value (SUV)

– Semi-quantitative measurement of radiotracer concentration in a region of interest normalized to injected dose and patient body weight, calculated during PET imaging to differentiate malignant (high SUV) from benign lesions.

Strontium-89 Chloride (^{89}Sr)

– Beta-emitting radioisotope and calcium analog that deposits in active osteoblastic bone lesions; utilized for long-term palliative relief of bone pain caused by osseous metastases.

Technetium-99m (^{99m}Tc)

– The most widely used diagnostic radionuclide in modern nuclear medicine, accounting for over 80% of all nuclear imaging procedures globally. Ideal physical properties: emits pure 140 keV gamma rays (optimal energy for gamma camera detection with minimal radiation dose to patient), has a convenient physical half-life of 6.0 hours (short enough to minimize radiation exposure, long enough for complex imaging protocols), and decays by isomeric transition to Technetium-99 without emitting particulate (beta/alpha) radiation. Produced on-site in hospital radiopharmacies using a Molybdenum-99 / Technetium-99m generator ("moly cow").

Technetium-99m HMPAO

– Lipophilic radiopharmaceutical (^{99m}Tc -hexamethylpropyleneamine oxime) that crosses the blood-brain barrier and becomes intracellularly trapped in brain tissue in proportion to regional cerebral blood flow; utilized in SPECT brain imaging to confirm Brain Death.

Technetium-99m MAA

– Technetium-99m labeled Macroaggregated Albumin (^{99m}Tc -MAA), consisting of radiolabeled albumin particles (20 – 90 μm) that temporarily lodge in pulmonary capillaries; used for pulmonary perfusion imaging and pre-transarterial radioembolization (TARE) planning.

Technetium-99m Sestamibi

– Lipophilic cationic radiopharmaceutical (^{99m}Tc -sestamibi) that passively diffuses into cells and concentrates in mitochondrial membranes;

used extensively in myocardial perfusion imaging, parathyroid imaging, and breast imaging.

Thallium-201 (201Tl)

- Cyclotron-produced potassium analog radionuclide emitting low-energy X-rays; historically used for myocardial perfusion imaging and differentiating cerebral lymphoma from toxoplasmosis in immunocompromised patients.

Theranostics

- Emerging paradigm in nuclear medicine and oncology that combines targeted diagnostic imaging and targeted radionuclide therapy using the same molecular vector or paired radiotracers. A diagnostic radiotracer (e.g., Gallium-68 PSMA for prostate cancer, or ^{68}Ga -DOTATATE for neuroendocrine tumors) is first used with PET-CT to visualize, localize, and quantify target receptor expression on tumor cells. If positive, the same targeting vector is labeled with a therapeutic beta- or alpha-emitting radionuclide (e.g., Lutetium-177 PSMA, or ^{177}Lu -DOTATATE) to deliver destructive ionizing radiation selectively to tumor sites while sparing healthy tissue.

Thyroid Scintigraphy (123I / 99mTc)

- Diagnostic nuclear imaging procedure evaluating the anatomical structure and functional activity of the thyroid gland. Radiotracers: Iodine-123 (^{123}I) or Technetium-99m pertechnetate ($^{99\text{m}}\text{TcO}_4^-$). Clinical indications: differential diagnosis of hyperthyroidism—diffuse homogeneous increased uptake (Graves' disease), toxic nodular goiter (multiple hot nodules), toxic adenoma (single hyperfunctioning "hot" nodule suppressing rest of gland), or subacute thyroiditis (suppressed, absent uptake); and evaluation of thyroid nodules ("cold" non-functioning nodules carry a 15–20% risk of malignancy and require fine-needle aspiration).

Transient Equilibrium

- Radioactive equilibrium condition occurring when the physical half-life of the parent radionuclide is slightly longer than that of the daughter radionuclide, as seen in Molybdenum-99 ($T_{1/2} = 66 \text{ h}$) decaying to Technetium-99m ($T_{1/2} = 6 \text{ h}$).

Ventilation-Perfusion Scan (V/Q Scan)

- Nuclear medicine study evaluating pulmonary ventilation and blood perfusion to diagnose pulmonary embolism (PE), particularly in patients with contraindications to CT Pulmonary Angiography (e.g., severe contrast allergy, renal failure, pregnancy). Ventilation phase: inhalation of Radioactive Xenon-133 gas or $^{99\text{m}}\text{Tc}$ -Technegas aerosol. Perfusion phase: intravenous injection of Technetium-99m macroaggregated albumin ($^{99\text{m}}\text{Tc}$ -MAA), which microembolizes in pulmonary capillaries. Classic PE finding: one or more segmental "mismatched" defects (normal ventilation with absent perfusion).

Xenon-133 (133Xe)

- Inhaled radioactive inert gas emitting 81 keV gamma rays; used in planar nuclear ventilation imaging to evaluate regional pulmonary airflow and trapped gas in chronic obstructive pulmonary disease.

Yttrium-90 Microspheres (90Y)

- Radioembolization selective internal radiation therapy (SIRT) utilizing glass or resin microspheres loaded with Yttrium-90 (^{90}Y), delivered via hepatic artery catheterization to treat primary hepatocellular carcinoma or unresectable liver metastases.

Chapter 25

Obstetrics and Gynecology

25.1 Obstetrics & Maternal-Fetal Medicine

Abdominal Circumference (AC)

- The circumference of the fetal abdomen measured at the level of the stomach, umbilical vein (portal sinus), and spine (ribs not visible). The best single parameter for estimating fetal weight. AC is also the most sensitive measurement for detecting IUGR (the liver is the first organ affected by placental insufficiency). AC growth: 1-1.5 cm per week. A declining AC percentile (or growth arrest) strongly suggests placental insufficiency.

Abdominal Pregnancy

- A very rare ectopic pregnancy (1%) implanted in the peritoneal cavity outside the fallopian tubes, ovaries, and uterus. Risk factors: prior ectopic, tubal damage, ART. Diagnosis: ultrasound (empty uterus, gestational sac outside the uterus, fetal parts adjacent to maternal organs). High maternal mortality (hemorrhage from placental separation). Treatment: surgical removal. The placenta may be left in situ (risks of infection, hemorrhage) if adherence to vital organs prevents safe removal.

Abortion

- The termination of a pregnancy by medical or surgical means before the fetus reaches viability (typically before 24 weeks gestation in the UK). Medical abortion uses mifepristone (antiprogesterone) followed by misoprostol (prostaglandin analog) to induce uterine contractions and expel pregnancy tissue. Surgical abortion involves vacuum aspiration (suction evacuation) or dilatation and evacuation (D&E). In the UK, abortion is regulated under the Abortion Act 1967, requiring two doctors to certify that the grounds for abortion are met. Complica-

tions are rare: infection, hemorrhage, uterine perforation, and incomplete evacuation. Psychological outcomes are generally positive with appropriate support.

Abruptio Placentae

- Premature separation of the placenta from the uterine wall before delivery, occurring in approximately 0.5-1% of pregnancies. Classified as revealed (vaginal bleeding present, blood tracks downward) or concealed (bleeding remains behind the placenta, no visible bleeding, higher risk of coagulopathy). Risk factors include hypertension, preeclampsia, maternal smoking, cocaine use, abdominal trauma, thrombophilia, prior abruption, and advanced maternal age. Clinical features include vaginal bleeding (may be absent in concealed abruption), abdominal pain, uterine tenderness and hypertonicity (board-like abdomen), and fetal distress or demise. Complications include maternal hemorrhage, disseminated intravascular coagulation (DIC) from release of thromboplastin into the maternal circulation, fetal hypoxia, preterm delivery, and perinatal death. Diagnosis is primarily clinical; ultrasound has limited sensitivity for detecting retroplacental clot. Management depends on gestational age and severity: immediate delivery (usually by caesarean) is indicated for maternal or fetal compromise irrespective of gestational age, with aggressive blood product replacement and coagulopathy management.

Active Management of Third Stage

- A bundle of interventions to reduce the risk of postpartum hemorrhage: (1) administration of oxytocin (10 IU IM/IV) immediately after delivery of the baby, (2) controlled cord traction (Brandt-Andrews maneuver) to deliver the placenta, and (3) uterine massage after placental delivery. Reduces the inci-

dence of PPH by 50-60%, reduces mean blood loss, and shortens the third stage. The WHO recommends active management for all vaginal deliveries. Misoprostol (600-800 mcg sublingual/rectal) is an alternative in settings where oxytocin is unavailable.

Active Phase of Labor

– The part of the first stage of labor from 6 cm to full dilatation (10 cm). Characterized by more rapid cervical change (minimum: 1 cm/hour in nulliparas, 1.2 cm/hour in multiparas). The cervix dilates more rapidly as labor progresses. Arrest of active phase: no cervical change for ≥ 4 hours with adequate contractions (≥ 200 Montevideo units for 2 hours) or ≥ 6 hours with inadequate contractions. Management: oxytocin augmentation for inadequate contractions, cesarean delivery for failed progress despite adequate contractions.

Acute Fatty Liver of Pregnancy (AFLP)

– A rare (1:7000-1:15,000) but life-threatening pregnancy complication characterized by microvesicular fatty infiltration of the liver leading to hepatic failure. Occurs in the third trimester (most commonly 35-37 weeks). Risk factors: primiparity, multiple gestation, male fetus, and disorders of fatty acid oxidation (LCHAD deficiency in the fetus, transmitted to the mother). Presents: nausea, vomiting, abdominal pain, jaundice, and encephalopathy. Lab findings: markedly elevated LFTs (though often mild relative to disease severity), elevated bilirubin, hypoglycemia, elevated ammonia, leukocytosis, DIC (prolonged PT/aPTT, low fibrinogen), and renal impairment. The Swansea criteria are used for diagnosis: ≥ 6 features in the setting of no other cause. Treatment: immediate delivery (regardless of gestational age), aggressive supportive care (glucose, coagulation factors, dialysis, and ICU), and liver transplantation if not improving within days. Maternal mortality: 10-20%. Fetal mortality: 10-20%.

Adhesions

– Bands of fibrous scar tissue that form between organs or tissues, most commonly following abdominal or pelvic surgery. In gynecology, adhesions can develop after cesarean section, myomectomy, ovarian cystectomy, or treatment of endometriosis. Adhesions can cause pelvic pain, bowel obstruction, and female infertility by distorting tubo-ovarian

anatomy and impairing oocyte pickup. Diagnosis is made at laparoscopy (the gold standard). Prevention: gentle tissue handling, meticulous hemostasis, minimizing operative time, and use of adhesion barriers (e.g., Interceed, Seprafilm). Treatment: laparoscopic adhesiolysis for symptomatic adhesions, though adhesions can reform.

Advanced Maternal Age

– Maternal age ≥ 35 years at the time of delivery. Associated with increased risks: aneuploidy (trisomy 21: 1:350 at age 35, 1:100 at age 40, 1:25 at age 45), miscarriage, gestational diabetes, preeclampsia, preterm birth, IUGR, placenta previa, and stillbirth. Management: offers of genetic counseling and prenatal diagnosis (NIPT, CVS, amniocentesis). Older mothers also have increased medical comorbidities that require management.

Amenorrhea

– Absence of menstruation. Primary amenorrhea: no menarche by age 15 with normal secondary sexual development, or by age 13 without. Secondary amenorrhea: absence of menses for ≥ 3 cycles or ≥ 6 months in women with prior menstruation. Causes: pregnancy (most common), hypothalamic suppression (stress, exercise, weight loss), PCOS, hyperprolactinemia, premature ovarian insufficiency, thyroid disorders, outflow obstruction. Evaluation: pregnancy test, FSH, LH, prolactin, TSH, and imaging.

Amniocentesis

– An invasive prenatal diagnostic procedure involving the aspiration of amniotic fluid from the uterine cavity under ultrasound guidance, typically performed between 15 and 20 weeks of gestation for diagnostic indications and after 32 weeks for fetal lung maturity assessment. A thin needle is inserted through the maternal abdomen and uterus into the amniotic sac, avoiding the fetus and placenta, to collect 20-30 milliliters of fluid. The procedure is indicated for advanced maternal age (greater than 35 years), abnormal maternal serum screening, abnormal ultrasound findings (structural anomalies, nuchal translucency greater than 3 mm), previous child with chromosomal abnormality or neural tube defect, and fetal lung maturity testing. Fetal cells in the amniotic fluid are cultured for chromosomal analysis (karyotype or chromosomal microarray) to detect aneuploidies (trisomy 21, 18, 13, sex chromo-

some abnormalities) and structural chromosomal rearrangements. Amniotic fluid alpha-fetoprotein (AFP) levels are measured to screen for neural tube defects (elevated in open spina bifida and anencephaly).

Amnion

– The innermost fetal membrane, lining the amniotic cavity and containing the amniotic fluid. A thin, avascular membrane composed of a single layer of cuboidal epithelium overlying a basement membrane and connective tissue. The amnion produces and resorbs amniotic fluid. It fuses with the chorion by 12-14 weeks. Amniotic membranes rupture spontaneously during labor (spontaneous ROM) or are artificially ruptured (AROM). Amniotic bands are rare complications of amnion rupture.

Amniotic Fluid

– The fluid surrounding the fetus in the amniotic cavity, providing cushioning, temperature regulation, and allowing fetal movement, breathing, and swallowing. Composed of water, electrolytes, and fetal components (urine, cells); volume increases with gestation (peak 800-1000 mL at 34-36 weeks). Abnormalities: oligohydramnios (low—PROM, fetal renal anomaly, IUGR, postterm) and polyhydramnios (high—GI obstruction, neural tube defects, maternal diabetes, twin transfusion). Assessed by ultrasound (amniotic fluid index, deepest vertical pocket). Amniocentesis samples fluid for karyotype/genetic testing and lung maturity.

Amniotic Fluid Embolism

– A rare, catastrophic obstetric emergency where amniotic fluid enters the maternal circulation, causing acute cardiovascular collapse. Characterized by sudden respiratory distress, hypotension, coagulopathy, and seizure. Mortality rate 20-60% among survivors; 50% of affected mothers die. Treatment is supportive: cardiopulmonary resuscitation, mechanical ventilation, and management of disseminated intravascular coagulation. High association with mortality and severe maternal morbidity.

Amniotic Fluid Index

– A semi-quantitative assessment of amniotic fluid volume using ultrasound. The uterus divided into four quadrants, and the single deepest vertical pocket measured in each quadrant, then summed. Normal range is 5-24 cm at 16-40 weeks. Less than

5 cm indicates oligohydramnios; greater than 24 cm indicates polyhydramnios. Used in conjunction with fetal growth assessment and Doppler studies to evaluate fetal well-being.

Anatomy Survey (Level II Ultrasound)

– A comprehensive fetal ultrasound performed at 18-22 weeks to evaluate fetal anatomy and screen for structural anomalies. Standard views: fetal head (BPD, HC, lateral ventricles, choroid plexus, cerebellum, cisterna magna), face (lips, orbits, nasal bone), chest (heart rate, rhythm, four-chamber view, outflow tracts, lungs), abdomen (stomach, AC, kidneys, bladder, bowel, anterior abdominal wall), spine (longitudinal and transverse), extremities (femur, humerus, hands, feet), and placenta (location, grade, cord insertion) and amniotic fluid (AFI or single deepest pocket). Sensitivity for major anomalies: 60-80% depending on BMI, gestational age, and operator experience.

Antenatal

– The period before birth, also called prenatal. The medical supervision and screening provided to pregnant women to monitor the health of the mother and fetus, detect complications early, and provide health education. Antenatal appointments typically follow a schedule: booking appointment (8-12 weeks), anomaly scan (18-21 weeks), and regular follow-ups. Key components: blood pressure monitoring, urine testing, fundal height measurement, fetal heart rate auscultation, and screening for gestational diabetes, pre-eclampsia, and fetal anomalies.

Antepartum Fetal Surveillance

– The monitoring of fetal well-being in the third trimester for high-risk pregnancies. Methods: fetal kick counts (daily maternal counting of fetal movements), non-stress test (NST), biophysical profile (BPP, AFI, fetal tone, movement, breathing), and Doppler (umbilical artery, MCA). Indications: postterm pregnancy, IUGR, preeclampsia, diabetes (pregestational), decreased fetal movement, maternal medical conditions (SLE, antiphospholipid syndrome), and prior stillbirth. Timing: weekly or twice-weekly starting at 32-34 weeks (earlier for severe conditions).

Antihypertensives in Pregnancy

– Medications used to treat hypertension in preg-

nancy. First-line agents: labetalol (combined alpha/beta blocker, 100-1200 mg BID-TID PO, or IV push for acute hypertension), nifedipine (calcium channel blocker, immediate-release 10-20 mg PO q30min for urgent, or XL 30-60 mg daily for maintenance), and methyldopa (central alpha agonist, 250-1000 mg BID, historically safest, first-line for chronic hypertension). Second-line: hydralazine (direct vasodilator, 5-10 mg IV q20min for acute hypertension). Contraindicated: ACE inhibitors and ARBs (fetal renal agenesis, oligohydramnios, fetal death), atenolol (IUGR), and nitroprusside (cyanide toxicity).

APGAR Score

– A scoring system developed by Virginia Apgar in 1952 to assess the newborn's immediate condition at 1 and 5 minutes after birth. Five components (each scored 0, 1, or 2): Appearance (skin color), Pulse (heart rate), Grimace (reflex irritability), Activity (muscle tone), and Respiration (breathing effort). Score 7-10: normal; 4-6: moderately depressed (may require stimulation or oxygen); 0-3: severely depressed (requires full resuscitation). The 5-minute score is more predictive of neonatal outcome. A low APGAR score does not equate to birth asphyxia.

Artificial Rupture of Membranes (AROM)

– Also called amniotomy. The intentional rupture of the amniotic sac with a small hook (Amnihook) during a cervical exam. Indications: induction or augmentation of labor, placement of internal monitors (fetal scalp electrode, intrauterine pressure catheter), and assessment of amniotic fluid (meconium staining). Risks: cord prolapse (especially with high presenting part), chorioamnionitis (with prolonged ROM), fetal injury, umbilical cord compression, and variable decelerations. AROM alone may augment labor by releasing prostaglandins.

Assisted Breech Delivery

– Vaginal breech delivery with operator assistance after spontaneous delivery to the umbilicus. Maneuvers: delivery of the legs (pinch them at the knees and deliver one at a time), delivery of the arms (Løvset maneuver: rotate the body to deliver the posterior arm, then the anterior arm), and delivery of the aftercoming head (Mauriceau-Smellie-Veit

maneuver: the operator's hand supports the head flexed while traction is applied to the shoulders; or Piper forceps). The head must be delivered flexed to enter the pelvis with its smallest diameter. Episiotomy is generally performed.

Assisted Reproductive Technology

– ART: fertility treatments involving manipulation of oocytes/sperm/embryos: in vitro fertilization (IVF), intracytoplasmic sperm injection (ICSI), intrauterine insemination (IUI, some definitions), embryo cryopreservation, gamete donation, and surrogacy. Indications: tubal disease, male factor, unexplained infertility, endometriosis, genetic screening (PGT), and same-sex/single parenthood. IVF: ovarian stimulation (gonadotropins + GnRH analogues), oocyte retrieval, fertilization, embryo culture, transfer, luteal support. Complications: multiple pregnancy, ovarian hyperstimulation syndrome (OHSS), and procedural risks. Success depends on age, cause, and center; significant cost; ethical/legal considerations (embryos, gametes).

Asymptomatic Bacteriuria in Pregnancy

– The presence of >100,000 CFU/mL of bacteria on a clean-catch urine culture without urinary symptoms. Occurs in 2-10% of pregnancies. Risk factors: prior UTI, diabetes, sickle cell trait, and multiparity. If untreated, 20-40% develop pyelonephritis. Screening: urine culture at the first prenatal visit. Treatment: nitrofurantoin (100 mg BID x 5-7 days, avoid near term), cephalexin (500 mg QID x 5-7 days), or amoxicillin (500 mg TID x 5-7 days). Recurrence is common; monthly surveillance cultures and suppression may be needed.

Augmentation of Labor

– The stimulation of spontaneous contractions that are judged to be inadequate to achieve progressive cervical dilatation. Most commonly uses oxytocin (Pitocin) infusion. Also includes artificial rupture of membranes (AROM, amniotomy). Indications: arrest of active phase (no cervical change for ≥ 4 hours with adequate MVUs), or prolonged latent phase. Pitocin is started at 1-2 mU/min and titrated every 15-30 minutes (up to 40 mU/min) until achieving adequate uterine activity (200-250 Montevideo units). Hyperstimulation (>5 contractions in 10 minutes or contractions lasting >2 minutes) is managed by

reducing or stopping oxytocin.

Bacterial Vaginosis

– BV: replacement of normal vaginal lactobacilli by an overgrowth of mixed anaerobes (*Gardnerella vaginalis*, *Mobiluncus*, etc.), the most common cause of vaginal discharge in reproductive-age women. Risk: new/multiple partners, douching, smoking. Features: thin, gray-white, fishy-smelling (amine) discharge, pH >4.5, no significant inflammation; many asymptomatic. Diagnosis: clinical, clue cells on wet mount, positive whiff (KOH) test, and Amsel criteria or Nugent score. Complications: increased risk of STI acquisition, PID, and preterm birth. Management: metronidazole (oral or intravaginal) or clindamycin; recurrence is common (maintenance, probiotics); screen/treat in pregnancy. Not sexually transmitted per se but partner treatment not required.

Bartholin Cyst

– A cyst of the Bartholin gland (paired mucus-secreting glands at the posterolateral introitus) due to obstruction of the duct; if infected, a Bartholin abscess. Features: painless (cyst) or painful, tender (abscess) swelling at the posterior labium minus; may cause dyspareunia or labial discomfort; abscess: fluctuant, erythematous, painful. Diagnosis: clinical. Management: small asymptomatic cysts—observation; symptomatic/abscess—incision and drainage with marsupialization or Word catheter insertion (abscess), antibiotics for cellulitis; recurrence may require excision; biopsy of cyst in older women (exclude malignancy). Refer to gynecology.

Betamethasone

– A corticosteroid administered to pregnant women at risk of preterm delivery to accelerate fetal lung maturation. Indications: all pregnancies between 24-36 weeks 6 days at risk for preterm delivery within 7 days. Also for late preterm (34-36 weeks) if not previously given and delivery anticipated in ≤7 days. Dose: two doses of 12 mg IM, 24 hours apart. Mechanism: stimulates surfactant production in type II pneumocytes, induces structural maturation of the lungs (thinner alveolar walls), and reduces risk of RDS (by 40-50%), IVH, and NEC. Optimal benefit: 24 hours to 7 days after the first dose. Can be repeated (rescue course) if delivery is still

imminent >14 days after the initial course.

Bile Acids

– Substances produced in the liver that aid digestion of fats and absorption of fat-soluble vitamins. In pregnancy, elevated bile acids ($\geq 10 \mu\text{mol/L}$) indicate intrahepatic cholestasis of pregnancy (obstetric cholestasis), a liver disorder characterized by pruritus (itching, typically palms and soles) and elevated serum bile acids. ICP is associated with increased risks of preterm birth, meconium-stained amniotic fluid, and stillbirth. Treatment: ursodeoxycholic acid reduces pruritus and improves bile acid levels. Delivery is typically planned at 37-39 weeks to reduce stillbirth risk.

Biophysical Profile

– A non-stress test combined with ultrasound assessment of five fetal parameters, each scored 0 or 2 for a total of 0-10. Parameters include non-stress test (fetal heart rate reactivity), fetal breathing movements, fetal tone, fetal movement, and amniotic fluid volume. Score of 8-10 is normal; 6 is equivocal; 4 or less is abnormal and may warrant delivery. Used to assess fetal well-being in high-risk pregnancies.

Biparietal Diameter (BPD)

– The transverse diameter of the fetal skull measured at the level of the thalami and cavum septum pellucidum. Used for dating (14-26 weeks, $\pm 7-10$ days) and assessing growth. Normal growth: 2-4 mm per week. BPD is less reliable after 26 weeks and in abnormal fetal head shapes (dolichocephaly, brachycephaly). The cephalic index (BPD/OFD ratio, normal 0.74-0.84) helps identify head shape abnormalities.

Birth Control

– Contraception; see Contraception. Methods to prevent unintended pregnancy: hormonal contraceptives (pill, patch, ring, injection, implant), intrauterine devices (copper, levonorgestrel), barrier methods (condoms, diaphragm), emergency contraception, fertility awareness, and sterilization. Effectiveness varies; LARC (IUDs, implant) is most effective (>99 percent). Considerations: efficacy, side effects, non-contraceptive benefits (cycle regulation, dysmenorrhea, acne, endometriosis), and medical eligibility (WHO MEC—thrombosis risk with estrogen, etc.). Counseling, STI prevention,

and follow-up are essential components.

Bishop Score

– A pre-induction cervical scoring system that predicts the success of labor induction. Five components: cervical dilatation (0-3), effacement (0-3), station (-3 to +2, scored 0-3), consistency (firm, medium, soft; scored 0-2), and position (posterior, mid, anterior; scored 0-2). Total score: 0-13. Favorable ($\geq 6-8$): high likelihood of successful induction. Unfavorable (≤ 5): cervical ripening needed (prostaglandins or mechanical dilation with a Foley balloon). The Bishop score is used to choose the induction method and predict the risk of failed induction.

B-Lynch Suture

– A surgical technique for controlling postpartum hemorrhage due to uterine atony unresponsive to medical management. A compressive suture placed around the uterus to mechanically compress the uterine walls and reduce blood flow. The suture creates a brace-like effect. Can be combined with other compression sutures (Cho, Hayman). Often successful in avoiding hysterectomy. Requires laparotomy and is performed under general anesthesia.

Braxton Hicks Contractions

– Irregular, painless uterine contractions occurring throughout pregnancy, becoming more frequent in the third trimester. Usually last 30-60 seconds and are felt as a tightening of the abdomen. Distinguished from true labour contractions by their irregularity, lack of cervical change, and resolution with rest or hydration. Named after John Braxton Hicks, the English physician who first described them in 1872. They do not cause progressive cervical dilatation or effacement. Often confused with prodromal labour or preterm labour, especially in primiparous women. Increased frequency at the end of the day or with physical activity. No treatment is necessary; reassurance and hydration are sufficient.

BRCA

– BReast CAncer gene: BRCA1 and BRCA2 are tumor suppressor genes involved in DNA double-strand break repair via homologous recombination. Mutations in these genes confer a significantly increased lifetime risk of breast cancer (up to 70-80% for BRCA1, 40-70% for BRCA2) and ovarian cancer (up to 40-50% for BRCA1, 10-20% for

BRCA2). In obstetrics and gynecology, BRCA testing is offered to women with a strong family history of breast or ovarian cancer. Management options for mutation carriers: enhanced breast surveillance (MRI and mammography), risk-reducing salpingo-oophorectomy (RRSO, typically after childbearing is complete, around age 35-40 for BRCA1, 40-45 for BRCA2), and risk-reducing mastectomy.

Breast Engorgement

– Overfilling of the breasts with milk, causing bilateral pain, firmness, warmth, and nipple flattening. Occurs 3-5 days postpartum. Pathophysiology: vascular congestion and edema before milk secretion is established. Management: frequent feeding or pumping, cold compresses between feedings, warm compresses before feeding, and NSAIDs for pain relief. Differentiate from mastitis (usually unilateral, with fever and erythema). Engorgement is a common cause of early breastfeeding cessation if not managed properly.

Breastfeeding

– The feeding of an infant with breast milk, recommended exclusively for the first 6 months and continued with complementary foods to 2 years and beyond. Benefits: infant (nutrition, immune protection—IgA, reduced infection/allergy/obesity, bonding) and maternal (uterine involution, contraception, reduced breast/ovarian cancer). Physiology: prolactin (milk production) and oxytocin (milk ejection); demand feeding. Challenges: latch difficulties, sore nipples, engorgement, mastitis, insufficient milk, and work/social barriers. Contraindications: maternal HIV (in high-resource settings), active TB, chemotherapy/radiation, and infant galactosemia; some medications contraindicated. Support: lactation consultants, positioning, frequent feeding.

Breech Delivery

– Vaginal delivery of a breech presentation. Types: assisted breech (the baby delivers spontaneously to the umbilicus, then the operator assists delivery of the shoulders and head) and total breech extraction (the operator delivers the entire baby by grasping the feet and pulling). Total breech extraction is reserved for the second twin or extreme prematurity. Prerequisites for planned breech delivery: frank or complete breech, estimated fetal weight 2000-3800 g, adequate pelvis, head flexed, and no fetal

anomalies. The Term Breech Trial (2000) showed increased perinatal mortality with planned vaginal breech delivery, leading to a sharp decline in vaginal breech births.

Breech Presentation

– A fetal presentation where the buttocks or feet are positioned to deliver first. Types include frank breech (hips flexed, knees extended, most common), complete breech (hips and knees flexed), and footling breech (one or both feet presenting). Associated with increased risk of cord prolapse, head entrapment, and birth trauma. External cephalic version attempted at 36-38 weeks. Cesarean delivery recommended for persistent breech at term.

Brow Presentation

– A fetal presentation where the fetal head is in a military position between full flexion (vertex) and hyperextension (face). The presenting diameter is the largest (occipitofrontal, 13.5 cm). Incidence: 1:1000-1:2000. Vaginal delivery is impossible with a persistent brow in a term fetus unless it converts to vertex or face. Diagnosis: palpation of the anterior fontanelle and orbital ridges side by side. Management: conversion to vertex by applying fundal pressure and flexing the head or conversion to face by encouraging hyperextension. If conversion fails, cesarean delivery.

CA125

– Cancer Antigen 125, a protein tumor marker used primarily in the evaluation of ovarian cancer. CA125 is elevated in approximately 80% of epithelial ovarian cancers but can also be elevated in benign conditions (endometriosis, pelvic inflammatory disease, uterine fibroids, pregnancy, menstruation) and other cancers (pancreatic, breast, lung). In premenopausal women, the positive predictive value of CA125 for ovarian cancer is low due to frequent false positives. The Risk of Malignancy Index combines CA125, ultrasound findings, and menopausal status to stratify ovarian cancer risk. CA125 is also used to monitor response to ovarian cancer treatment and detect recurrence.

Caesarean Birth

– An operative procedure in which a baby is delivered through an incision in the abdominal wall and uterus. Indications: fetal distress, failure to progress in labor, breech presentation, placenta praevia, mul-

tiple pregnancy, previous cesarean, and maternal request. Types: planned (elective) cesarean, typically performed at 39 weeks; emergency cesarean, performed when urgent delivery is needed for maternal or fetal compromise. Procedure: Joel-Cohen or Pfannenstiel skin incision, lower uterine segment transverse incision (isthmic), delivery of the baby, delivery of the placenta, and closure in layers. Regional anesthesia (spinal or epidural) is preferred. Recovery: 2-4 day hospital stay, 6-week activity restriction.

Cardiotocography (CTG)

– A continuous electronic recording of the fetal heart rate and uterine contractions used to assess fetal well-being during pregnancy and labor. The CTG machine uses two transducers placed on the maternal abdomen: an ultrasound transducer records the fetal heart rate, and a tocodynamometer records uterine contractions. CTG interpretation uses the four features of the fetal heart rate: baseline rate (normal 110-160 bpm), baseline variability (normal 5-25 bpm), accelerations (increase of ≥ 15 bpm for ≥ 15 seconds, reassuring), and decelerations (early, late, or variable). CTG is categorized as normal (reassuring), suspicious (one non-reassuring feature), or pathological (two or more non-reassuring or abnormal features). Fetal blood sampling may be used to confirm acidosis in suspicious/pathological CTG.

Cardiovascular Changes in Pregnancy

– Plasma volume increases 40-50% (total volume 5 L), red cell mass increases 20-30% (physiologic anemia of pregnancy due to dilution). Cardiac output increases 30-50% by 32 weeks (stroke volume increases initially, then heart rate). Systemic vascular resistance decreases (progesterone-mediated vasodilation) causing a slight decrease in blood pressure despite increased cardiac output. Supine hypotensive syndrome: the gravid uterus compresses the IVC, reducing venous return and cardiac output. Auscultation: S3 gallop, systolic flow murmur. ECG: left axis deviation.

Category I Fetal Heart Tracing

– A normal fetal heart rate tracing by NICHD 2008 criteria. All three characteristics present: baseline 110-160 bpm, moderate variability (6-25 bpm), and no late or variable decelerations. May have accel-

erations. Category I tracings are associated with normal fetal acid-base status. Routine management: continue labor management; no intervention needed. Predictive of normal fetal oxygenation.

Category II Fetal Heart Tracing

– An indeterminate fetal heart rate tracing that falls between Category I and III. Includes a wide range of patterns: baseline tachycardia or bradycardia (100-110 bpm), minimal or absent variability without decelerations, absent variability with recurrent decelerations, marked variability, variable decelerations with slow return to baseline or with other concerning features, and prolonged decelerations. Category II tracings are the most common in labor (70-80%). Management: intrauterine resuscitation (position change, maternal oxygen, IV fluids, reduce or stop oxytocin), further evaluation (fetal scalp stimulation, scalp pH), and continued close observation. Progression to Category III warrants intervention.

Category III Fetal Heart Tracing

– An abnormal fetal heart rate tracing indicating potential fetal hypoxia or acidosis. Two specific patterns: (1) absent baseline variability with recurrent late decelerations, (2) absent baseline variability with recurrent variable decelerations, and (3) sinusoidal pattern. Category III tracings require prompt evaluation and intervention: intrauterine resuscitation measures, and if the pattern does not resolve, immediate delivery (operative vaginal or cesarean) to prevent fetal acidemia and neurologic injury.

Cell-Free Fetal DNA (cfDNA) Screening

– Also known as noninvasive prenatal testing (NIPT). Analyzes cell-free fetal DNA (cffDNA) circulating in maternal blood, derived from placental trophoblast apoptosis. Performed from 10 weeks onward. Highly sensitive and specific for trisomy 21 (>99%, FPR <0.1%), trisomy 18 (>97%), and trisomy 13 (>90%). Also screens for sex chromosome aneuploidies and microdeletions (22q11.2, 1p36, Prader-Willi/Angelman). False positives can occur from placental mosaicism, vanishing twin, or maternal chromosomal abnormalities. NIPT is a screening test, not diagnostic; positive results require confirmatory diagnostic testing (CVS or amniocentesis).

Cephalhaematoma

– A collection of blood between the periosteum and the skull bone, caused by rupture of blood vessels during childbirth, most commonly associated with ventouse (vacuum) delivery. Unlike caput succedaneum, a cephalhaematoma does not cross suture lines and is limited by the periosteal attachments. It presents as a firm, unilateral swelling on the newborn's scalp, appearing within hours to days after birth. It resolves spontaneously over weeks to months as the blood is reabsorbed. Complications: jaundice (from breakdown of red blood cells), anemia, and rarely infection or calcification. No treatment is required unless complications develop.

Cerclage

– A surgical placement of a suture around the cervix to prevent preterm delivery in patients with cervical insufficiency. Types include transvaginal (McDonald or Shirodkar) and transabdominal. Usually placed at 12-14 weeks gestation and removed at 36-37 weeks. Indicated for history of painless second trimester loss, cervical dilatation on exam, or short cervix on ultrasound. Emergency cerclage performed when dilatation occurs in the second trimester.

Cerebroplacental Ratio (CPR)

– The ratio of the middle cerebral artery (MCA) pulsatility index to the umbilical artery (UA) pulsatility index. CPR <5th percentile (or <1.0-1.1) suggests fetal brain-sparing effect (vasodilation of cerebral vessels in response to hypoxemia) due to placental insufficiency. A low CPR in IUGR fetuses predicts adverse perinatal outcomes (stillbirth, acidosis, NICU admission) better than UA Doppler alone. CPR may also be abnormal in small-for-gestational-age fetuses before UA Doppler becomes abnormal.

Cervical Cerclage

– Surgical placement of a non-absorbable suture around the cervix to provide mechanical support and prevent preterm delivery in patients with cervical insufficiency. Most commonly performed using the McDonald technique (purse-string suture at the cervicovaginal junction without bladder dissection) or the Shirodkar technique (with bladder and rectal dissection to place the suture at the internal os). Elective cerclage is placed at 12-14 weeks gestation, with removal at 36-37 weeks or at the

onset of labour. Emergency or rescue cerclage may be performed in the second trimester if cervical dilation is detected before 24 weeks. Contraindications include chorioamnionitis, active vaginal bleeding, preterm labour, preterm prelabour rupture of membranes, and fetal demise. Risks include membrane rupture, chorioamnionitis, cervical trauma, and preterm labour.

Cervical Dilatation

- Progressive opening of the cervical os during labor, measured in centimeters from 0 (closed) to 10 cm (fully dilated). The cervix must also efface (thin out) before significant dilatation occurs. Cervical status assessed by digital vaginal examination during labor.

Cervical Dilation

- The opening of the cervical canal during labor, measured in centimeters from closed (0 cm) to fully dilated (10 cm); required for vaginal delivery. Occurs with effacement (thinning/shortening of the cervix) during the first stage of labor, driven by effective uterine contractions. Assessed by vaginal examination (digital—dilation, effacement, station, position). Progress: active phase typically dilates 1-1.2 cm/hour (nullipara) and 1.5 cm/hour (multipara); abnormal dilation (protracted/arrested) indicates labor dystocia, requiring augmentation, reassessment for cephalopelvic disproportion, or cesarean.

Cervical Effacement

- Thinning and shortening of the cervix during labor, measured as a percentage from 0% (thick, normal length) to 100% (paper thin). Effacement precedes and accompanies cervical dilatation. Nulliparous women often efface before dilating; multiparous women may efface and dilate simultaneously. Effacement occurs as the internal os and external os are pulled upward into the lower uterine segment. Assessed by digital vaginal examination. In nulliparous women, effacement typically occurs before significant dilatation; in multiparous women, effacement and dilatation often occur concurrently. Contributes to the Bishop score for predicting labor induction success.

Cervical Exam in Labor

- Serial digital vaginal examinations to assess cervical dilatation (cm), effacement (%), station (relationship to ischial spines, -5 to +5), consistency (firm, medium, soft), and position (posterior, mid, ante-

rior). Performed every 2-4 hours in active labor. In the second stage, assessing fetal head position and asynclitism. Risks: infection with frequent exams (especially with ruptured membranes). Current guidelines: minimize exams after ROM, limit to q4h in active labor unless clinically indicated.

Cervical Incompetence

- The inability of the cervix to maintain pregnancy in the second trimester due to painless cervical dilatation. Results in recurrent second trimester pregnancy loss or preterm delivery. Risk factors include prior cervical trauma, cone biopsy, and congenital anomalies. Management includes cerclage (McDonald or Shirodkar) typically placed at 12-14 weeks and removed at 36-37 weeks. Cervical length screening by transvaginal ultrasound in high-risk patients.

Cervical Length Screening

- Transvaginal ultrasound measurement of the cervix between 18-24 weeks to assess risk of spontaneous preterm birth. Normal cervix measures greater than 25 mm. Short cervix (less than 25 mm) increases preterm delivery risk. Cervical funneling and dilatation are additional concerning findings. Interventions for short cervix include progesterone supplementation, cerclage, and cervical pessary. Most beneficial in asymptomatic women with prior preterm birth.

Cervical Mucus

- Secretions from the cervical glands that change throughout the menstrual cycle under hormonal influence. Estrogen produces thin, clear, stretchy mucus favorable for sperm transport around ovulation (spinnbarkeit). Progesterone produces thick, sticky, opaque mucus that forms a plug in the cervical canal during pregnancy. The mucus plug (operculum) protects against ascending infection throughout gestation.

Cervical Pregnancy

- A rare ectopic pregnancy (0.1-1%) implanted in the cervical canal. Presents with painless vaginal bleeding in the first trimester. Diagnosis: ultrasound (hourglass-shaped uterus, gestational sac in the cervix with absent sliding sign, empty uterine cavity). High risk of severe hemorrhage. Treatment: methotrexate (systemic or local injection), uterine artery embolization, dilation and curettage with Foley balloon tamponade, or hysterectomy for

uncontrolled bleeding.

Cervical Ripening Agents

– Medications or mechanical devices used to soften and dilate the cervix before induction of labor when the Bishop score is unfavorable (≤ 5). Pharmacologic: prostaglandin E1 (misoprostol/Cytotec, 25 mcg PV q4h), prostaglandin E2 (dinoprostone/Cervidil vaginal insert 10 mg over 12 hours, or Prepidil gel 0.5 mg intracervical q6h). Mechanical: transcervical Foley catheter (16-30 Fr, 30-60 mL balloon), osmotic dilators (laminaria, Dilapan-S). Membrane stripping (sweeping) is a low-risk office procedure. Combination of pharmacologic and mechanical methods is common. Contraindication: prior classical cesarean (risk of uterine rupture with prostaglandins). Misoprostol has the highest risk of tachysystole.

Cervicitis

– Inflammation of the uterine cervix, most commonly caused by sexually transmitted infections (*Chlamydia trachomatis* and *Neisseria gonorrhoeae*) but also by other organisms (*Mycoplasma genitalium*, *Trichomonas vaginalis*, herpes simplex virus), or non-infectious causes (chemical irritation, foreign body, allergy). Presents with mucopurulent vaginal discharge, cervical friability (bleeding on touch), intermenstrual or postcoital bleeding, and dyspareunia. Many cases are asymptomatic. Diagnosis: microscopic examination of cervical secretions showing increased polymorphonuclear leukocytes, nucleic acid amplification tests (NAATs) for *Chlamydia* and *Neisseria gonorrhoeae*, and cervical cultures. Treatment includes appropriate antibiotics (azithromycin or doxycycline for *Chlamydia*, ceftriaxone for gonorrhea). Sexual partners require treatment and screening. Untreated cervicitis can ascend to cause pelvic inflammatory disease, leading to tubal factor infertility, ectopic pregnancy, and chronic pelvic pain. Barrier contraception reduces transmission risk.

Cervix

– The lower, narrow part of the uterus that opens into the vagina. The cervix is approximately 3-4 cm long in the non-pregnant state and consists of two parts: the ectocervix (visible portion protruding into the vagina, covered by stratified squamous epithelium) and the endocervical canal (lined by

columnar epithelium). The transformation zone (squamocolumnar junction) is where cervical cell changes and cancer typically arise. Functions: produces cervical mucus that changes in consistency during the menstrual cycle to facilitate or impede sperm transport; dilates during labor to allow passage of the baby; and provides mechanical support to maintain pregnancy.

Cesarean Delivery

– Surgical delivery of the fetus through abdominal and uterine incisions. Performed when vaginal delivery is contraindicated or fails. Indications include malpresentation, placenta previa, previous cesarean, fetal distress, and failed induction. Most common uterine incision is low transverse (classical for very preterm or transverse lie). Regional anesthesia preferred. Complications include infection, hemorrhage, thromboembolism, and injury to adjacent organs.

Cesarean Section

– C-section: surgical delivery of the infant through incisions in the abdominal wall and uterus. Indications: fetal distress, failure to progress, malpresentation (breech, transverse), placenta previa, abruption, previous cesarean (some), multiple pregnancy, preeclampsia, cord prolapse, and maternal conditions. Types: lower segment (transverse, most common—less blood loss) vs. classical (vertical). Procedure: regional (spinal/epidural) or general anesthesia, Pfannenstiel incision, bladder reflection, uterine incision, delivery, placental removal, and layered closure. Complications: hemorrhage, infection (wound, endometritis), thrombosis, adhesions, placenta accreta in future pregnancies, and neonatal respiratory issues. Recovery longer than vaginal delivery.

Chignon

– A temporary swelling (edema) on the baby's scalp caused by the vacuum cap used during ventouse (vacuum) assisted delivery. The chignon forms as the vacuum creates negative pressure pulling the scalp tissue into the cup. It settles within 24-48 hours after birth without any treatment. It should be distinguished from cephalhaematoma (subperiosteal bleed) and caput succedaneum (generalized scalp edema). No specific management is needed; parents should be reassured.

Chorioamnionitis

– Infection of the chorion and amnion, typically due to ascending bacterial infection from the genital tract. Risk factors include prolonged rupture of membranes, multiple vaginal exams, and preterm labor. Presents with maternal fever, uterine tenderness, and fetal tachycardia. Diagnosis is clinical; amniocentesis for confirmation. Treatment includes intravenous antibiotics (ampicillin and gentamicin) and delivery. Neonatal sepsis is a major concern.

Chorion

– The outermost fetal membrane, derived from the trophoblast. The chorion frondosum (villous chorion) develops into the fetal portion of the placenta. The chorion laeve (smooth chorion) is the non-villous portion. Chorionic villi contain fetal blood vessels and are bathed in maternal blood. Chorionic villus sampling (CVS) biopsies these villi for prenatal genetic diagnosis. The chorion is separated from the amnion by the extraembryonic coelom until the amnion fuses with it at 12-14 weeks.

Chorionic Villus Sampling (CVS)

– A first-trimester invasive prenatal diagnostic procedure (10-13 weeks) that samples chorionic villi for genetic analysis. Transcervical (catheter through the cervix into the placenta under ultrasound guidance) or transabdominal (needle through the abdominal wall). Advantages over amniocentesis: earlier results (24-48 hours for rapid FISH, 7-14 days for karyotype). Indications: advanced maternal age, abnormal NIPT, prior aneuploidy, family history of genetic disorders, and abnormal ultrasound findings. Risks: miscarriage (0.2-0.5% above background), and limb reduction defects (rare, associated with CVS before 10 weeks). Confined placental mosaicism (CPM, 1-2%): karyotype differs between placenta and fetus, requiring amniocentesis for confirmation.

Choroid Plexus Cyst (CPC)

– A sonolucent fluid-filled cyst within the choroid plexus of the lateral cerebral ventricle, seen in 1-3% of second-trimester fetuses. In isolation, it is a normal variant with no clinical significance. CPC is associated with trisomy 18 (30-50% of trisomy 18 fetuses have CPC, but most fetuses with CPC are normal). If isolated, the risk of trisomy 18 is very low, particularly if NIPT is normal. No further

workup is needed for isolated CPC after 22 weeks gestation.

Chromosomal Abnormality

– Any deviation from the normal number (46 chromosomes, 23 pairs) or structure of chromosomes. Numerical abnormalities: aneuploidy (trisomy 21/Down syndrome, trisomy 18/Edwards syndrome, trisomy 13/Patau syndrome, monosomy X/Turner syndrome), polyploidy (triploidy, tetraploidy). Structural abnormalities: deletions (Cri-du-chat, 22q11.2 deletion), duplications, translocations (Robertsonian, reciprocal), inversions, and ring chromosomes. Screening: combined test (nuchal translucency, hCG, PAPP-A), NIPT (cell-free fetal DNA), quadruple test. Diagnosis: chorionic villus sampling (11-14 weeks), amniocentesis (15+ weeks).

Chronic Hypertension in Pregnancy

– Hypertension (BP $\geq 140/90$ mmHg) that predates pregnancy or is diagnosed before 20 weeks gestation. Affects 1-5% of pregnancies. Increased risk of superimposed preeclampsia (20-50%), IUGR, preterm birth, and placental abruption. Management: continue or adjust antihypertensives (avoid ACE inhibitors and ARBs during pregnancy; labetalol, nifedipine, and methyldopa are safe). Low-dose aspirin (81 mg daily) from 12-36 weeks reduces the risk of preeclampsia. Delivery timing depends on blood pressure control and fetal status.

Clavicle Fracture (Intentional)

– Intentional fracture of the fetal clavicle as a last resort to reduce the bisacromial diameter in shoulder dystocia. The operator applies upward pressure on the midportion of the anterior fetal clavicle with a finger, fracturing it. The clavicle heals without long-term sequelae. Usually unnecessary because the posterior arm delivery and Gaskin maneuver are more effective and less traumatic. Accidental clavicle fracture occurs in 0.5-2% of normal deliveries.

Colostrum

– The thick, yellowish fluid produced by the mammary glands in late pregnancy and the first few days postpartum. Rich in immunoglobulins (especially IgA), proteins, leukocytes, and growth factors.

Combined Spinal-Epidural (CSE)

Analgesia

– A neuraxial analgesia technique for labor that combines a spinal injection (short-acting opioid or opioid + low-dose local anesthetic) with an epidural catheter. Advantages: rapid onset of pain relief (3-5 minutes from the spinal component), minimal motor block, and the ability to dose through the epidural catheter for prolonged labor. The spinal block provides immediate relief for women in active labor; the epidural provides sustained relief. The CSE may be associated with more maternal pruritus (from intrathecal opioids) and a higher rate of fetal bradycardia than epidural alone.

Compound Presentation

– A fetal presentation where an extremity (hand, arm, foot) presents alongside the vertex or breech. Most common: hand alongside the head. Incidence: 1:300-1:1000. Fetal prognosis is generally good; the prolapsed extremity often retracts as labor progresses. Management: expectant management in most cases. The prolapsed hand may be gently pushed back after descent. The cord should be assessed for prolapse. Cesarean if labor fails to progress or the extremity causes obstruction.

Conception (Fertilization)

– The fusion of a sperm and an ovum in the ampulla of the fallopian tube, forming a zygote. The sperm penetrates the corona radiata and zona pellucida (acrosome reaction). After fertilization, the zygote undergoes cleavage (mitotic division) as it travels toward the uterus. Implantation occurs approximately 6-10 days after ovulation. Conception timing is critical for dating pregnancy and determining the window of fertility.

Conjoined Twins

– Monozygotic, monochorionic, monoamniotic twins who are physically connected at birth, resulting from incomplete fission of the fertilized ovum after day 13 of fertilization. Incidence: 1 in 50,000-100,000 births. Classification by the site of union: thoracopagus (chest, most common, 40%, often with shared heart — poor prognosis), omphalopagus (abdomen, 33%), pygopagus (sacrum/buttocks, 19%), ischiopagus (pelvis, 6%), craniopagus (head, 2%), and parapagus (lateral fusion). Determination of shared vital organs (especially the heart) is critical for prognosis and surgical planning. Diagnosis

by prenatal ultrasound and MRI. Delivery is typically by planned cesarean at 34-36 weeks. Surgical separation after birth is complex and requires a multidisciplinary team. Prognosis depends on the degree of organ sharing.

Continuous Electronic Fetal Monitoring (EFM)

– The continuous recording of fetal heart rate (FHR) and uterine contractions using external transducers (Doppler ultrasound and tocodynamometer) or internal devices (fetal scalp electrode and intrauterine pressure catheter). Used intrapartum to detect fetal hypoxia. The NICHD 2008 classification categorizes tracings as Category I (normal), II (indeterminate), or III (abnormal). EFM is associated with an increased rate of cesarean and operative vaginal delivery without clear reduction in cerebral palsy (false positives are common). Recommended for high-risk labor and women who choose augmentation. Intermittent auscultation is appropriate for low-risk labor.

Contraception

– Methods to prevent pregnancy. Hormonal: combined oral contraceptive pill (COC), progestin-only pill, depot medroxyprogesterone, implant (etonogestrel), vaginal ring, patch; IUDs (copper, levonorgestrel); barrier (male/female condom, diaphragm, cervical cap, spermicide); emergency contraception (levonorgestrel, ulipristal, copper IUD); fertility awareness; and permanent (sterilization—tubal ligation, vasectomy). Selection: efficacy, reversibility, side effects, and medical eligibility (WHO MEC). Long-acting reversible contraception (LARC—IUDs, implant) has the highest effectiveness. Counseling includes STI protection (condoms), risk assessment (thrombosis—COC, migraine with aura), and patient preference.

Contraception and Birth Control

– Contraception encompasses methods used to prevent pregnancy, including hormonal options like oral contraceptives, patches, rings, injections, and implants, as well as non-hormonal methods like copper IUDs, barrier methods, diaphragms, and permanent sterilization. Emergency contraception is available for use shortly after unprotected intercourse. Method selection considers effectiveness, side effects, reversibility, and individual health factors.

Contractions

– Rhythmic uterine muscular contractions of labor that produce cervical dilation and effacement, driving descent of the fetus. Characterized by frequency, duration, and intensity; progress is monitored by partogram and tocography (CTG). Braxton Hicks contractions: irregular, non-progressive, painless prelabor contractions. Abnormalities: inadequate/hypotonic (dystocia—augmentation with oxytocin), hypertonic/tetanic (fetal distress, placental abruption risk), and preterm contractions (threatened preterm labor). Management: assess cervical change to confirm labor, monitor fetal well-being during contractions (CTG), analgesia, and address abnormalities (augmentation, tocolysis for preterm labor if indicated).

Contraction Stress Test

– An antepartum fetal surveillance technique assessing fetal heart rate response to induced uterine contractions. Oxytocin or nipple stimulation produces contractions. A negative test shows no late decelerations. A positive CST demonstrates late decelerations with more than 50% of contractions. Equivocal results show intermittent late decelerations. Contraindications include preterm labour, placenta previa, previous classical caesarean, multiple gestation, and preterm prelabour rupture of membranes. The CST has largely been replaced by the biophysical profile and modified BPP as first-line antepartum surveillance due to its higher false-positive rate, greater time requirement, and need for intravenous access. However, it remains useful when BPP is equivocal or when fetal status is uncertain.

Contraction Stress Test (CST)

– An antepartum test that evaluates the fetal heart rate response to uterine contractions. Contractions are induced with oxytocin or nipple stimulation (until 3 contractions in 10 minutes). Negative (normal): no late or significant variable decelerations. Positive (abnormal): late decelerations with $\geq 50\%$ of contractions. Equivocal: intermittent late decelerations. The CST is less commonly used due to the higher success and lower risk of the BPP. Indications: when BPP is equivocal or maternal perception of decreased movement.

Controlled Cord Traction (CCT)

– A technique for active management of third-stage labor: gentle, steady traction on the umbilical cord with one hand while the other hand applies suprapubic counter-pressure (to prevent uterine inversion). Performed after signs of placental separation. The Brandt-Andrews maneuver and the Finocchetti technique are CCT methods. CCT reduces the duration of the third stage and the risk of postpartum hemorrhage. Contraindication: signs of uterine inversion.

Cord Presentation

– The presence of the umbilical cord between the presenting fetal part and the cervix, with intact membranes. Risk factors: malpresentation, unstable lie, low-lying placenta, and long cord. If the membranes rupture, the cord may prolapse (umbilical cord prolapse). Diagnosis: digital exam (palpation of a pulsating cord through intact membranes) or ultrasound. Management: admit to the hospital, strict bed rest, avoid vaginal exams, and cesarean delivery before membrane rupture.

COVID-19 in Pregnancy

– Pregnant women with COVID-19 are at increased risk of severe illness (ICU admission, mechanical ventilation, death) compared to non-pregnant women. Risks to the fetus: preterm birth, cesarean delivery, and possibly stillbirth. Vertical transmission is rare but possible. Management: vaccination is recommended (no increased risk of miscarriage or adverse outcomes). Treatment: remdesivir, dexamethasone (for oxygen requirement), and anticoagulation as indicated. Pregnant women should be offered vaccination at any stage of pregnancy.

Crowning

– The stage of the second stage of labor when the fetal head (widest diameter) distends the perineum and becomes visible at the introitus and is no longer receding between contractions. At crowning, controlled delivery of the head (guard the perineum, support, or episiotomy if needed) minimizes perineal trauma; the mother is guided not to push forcefully and to pant to allow controlled expulsion. Following the head, shoulders and body deliver. Complete breech and other presentations differ. Crowning precedes imminent delivery; neonatal and maternal readiness is required.

Crown-Rump Length (CRL)

- The measurement from the top of the fetal head (crown) to the bottom of the buttocks (rump), the most accurate method for establishing gestational age in the first trimester. Measured at 7-13 weeks. Accuracy: ± 3 -5 days. The EDD is set using CRL if the difference from LMP dating exceeds 7 days. CRL growth: approximately 1 mm per day. CRL < 7 mm without cardiac activity: uncertain viability, repeat in 1 week. Absent cardiac activity at CRL ≥ 7 mm is diagnostic of pregnancy failure.

Cystocele

- Anterior vaginal wall prolapse: herniation of the bladder into the anterior vaginal wall due to weakening of the pubocervical fascia, most commonly after childbirth and menopause. Features: vaginal bulge/pressure, difficulty voiding, incomplete emptying, urinary urgency/frequency, and stress urinary incontinence; worse with standing/straining. Grades by POP-Q. Diagnosis: clinical. Management: pelvic floor physiotherapy, pessary, and surgical repair (anterior colporrhaphy) for symptomatic prolapse; treat urinary symptoms and address contributing factors (obesity, constipation). Complications of surgery: recurrence, dyspareunia, and urinary symptoms.

Decidua

- The transformed endometrium of pregnancy, shed after delivery. Three regions: decidua basalis (under the placenta, site of trophoblast invasion), decidua capsularis (over the gestational sac, covering the embryo), and decidua parietalis (the remainder of the uterine lining). The decidua provides nutrition to the early embryo and produces hormones (prolactin, relaxin). Decidual cells and natural killer cells play key roles in immune tolerance of the fetus.

Delayed Cord Clamping

- The practice of delaying umbilical cord clamping for ≥ 30 -60 seconds after delivery, allowing placental transfusion of blood to the newborn. Benefits: increases neonatal blood volume by 30%, improves iron stores (ferritin, hemoglobin) for the first 6 months, reduces anemia, and improves transitional circulation. For preterm infants (< 34 weeks), delayed clamping for 30-60 seconds reduces intraventricular hemorrhage, necrotizing enterocolitis, and need for blood transfusion. Contraindications: need for immediate resuscitation, cord avulsion, pla-

cental abruption with hemorrhage, and maternal instability.

Delivery

- The process of childbirth: vaginal delivery (spontaneous vertex most common; assisted—vacuum, forceps) or cesarean delivery (abdominal). Stages of labor culminate in delivery of the infant and placenta. Considerations: fetal presentation (vertex, breech, face), position, and station; maternal pushing and expulsive forces; perineal trauma (tears/episiotomy); and immediate neonatal care (Apgar, cord clamping). Complications: shoulder dystocia, postpartum hemorrhage, retained placenta, cord prolapse. Management: preparation (delivery pack, neonatal resuscitation), controlled delivery of head/shoulders, third-stage management (oxytocin to reduce hemorrhage), and documentation. Facility-based delivery with skilled attendance reduces maternal/neonatal mortality.

Delivery of Posterior Arm

- A shoulder dystocia maneuver: the operator's hand enters the posterior vagina along the fetal chest, finds the fetal hand, grasps the forearm, sweeps it across the chest and face, and delivers the posterior arm and hand over the perineum. This reduces the bisacromial diameter by 20% and is often highly effective. Flexing the elbow helps retrieve the hand. Risk: humerus fracture (treat with immobilization; heals well). Often the definitive maneuver after McRoberts and rotational maneuvers fail.

Dexamethasone

- An alternative corticosteroid for fetal lung maturation, similar to betamethasone. Dose: four doses of 6 mg IM, 12 hours apart. While betamethasone is the preferred agent in the US (more evidence for RDS reduction), dexamethasone is used in some settings and is effective. Both cross the placenta and induce fetal lung surfactant production. Dexamethasone has slightly more evidence for long-term neurodevelopmental outcomes in certain studies. WHO recommends either agent.

Dichorionic Twins

- Twins each having their own chorion and amnion, occurring in approximately 30% of monozygotic twins and all dizygotic twins. Each twin has its own placenta, though placentas may be adjacent. Complications include growth restriction, preterm

delivery, and preeclampsia, but not twin-to-twin transfusion syndrome. Require regular ultrasound monitoring for growth discordance.

Dinoprostone (Cervidil, Prepidil)

– A synthetic prostaglandin E2 (PGE2) used for cervical ripening and induction. Forms: Cervidil (10 mg vaginal insert, slow-release over 12 hours, removed if tachysystole occurs), Prepidil (0.5 mg intracervical gel, may be repeated q6h), and Prostin E2 (vaginal suppository). Indications: unfavorable cervix (Bishop ≤ 5). Side effects: tachysystole (5-10%), fever, nausea, vomiting, and diarrhea. Contraindications: prior uterine surgery (including classical cesarean), active vaginal bleeding, and fetal compromise. Remove promptly if tachysystole or nonreassuring FHR occurs.

Donor Insemination

– A fertility treatment in which sperm from a donor (anonymous or known) is placed into a woman's vagina, cervix, or uterus to achieve pregnancy. Indications: male factor infertility (azoospermia, severe oligospermia), genetic disorders in the male partner, single women, and same-sex female couples. In the UK, donor insemination is regulated by the Human Fertilization and Embryology Authority, requiring donor screening for infectious diseases, genetic disorders, and medical conditions. Recipients may require ovulation induction or intrauterine insemination (IUI) to optimize timing.

Douche

– A stream of water or solution directed into a body cavity, most commonly the vagina, for cleansing, therapeutic, or contraceptive purposes. Medical use: therapeutic douches with antiseptic solutions (povidone-iodine, vinegar, chlorhexidine) for treating specific vaginal infections (trichomoniasis, bacterial vaginosis) as adjunctive therapy. Routine vaginal douching is not recommended and is associated with adverse outcomes: disruption of normal vaginal flora (increased risk of bacterial vaginosis, candida overgrowth), pelvic inflammatory disease, ectopic pregnancy, and increased HIV transmission risk.

Doula Support

– A trained non-medical birth companion who provides continuous emotional, physical, and informational support to the laboring mother. Ser-

vices: massage, positioning guidance, breathing techniques, advocacy, and reassurance. Doula support has Level 1 evidence for improved outcomes: reduced duration of labor (by 40 minutes), reduced need for cesarean (by 25%), reduced epidural requests, reduced Pitocin use, and higher satisfaction. Doulas do not perform clinical tasks (vaginal exams, FHR monitoring). They complement but do not replace midwives or physicians.

Early Decelerations

– A fetal heart rate pattern with a gradual decrease (onset to nadir >30 seconds) that mirrors the contraction and returns to baseline as the contraction ends. Caused by fetal head compression during contractions (vagal response). A benign, physiologic finding associated with normal fetal acid-base status. No intervention required. Early decelerations are characteristic of active labor and descent of the fetal head.

Echogenic Bowel

– Increased echogenicity of the fetal bowel relative to adjacent bone (iliac wing). Identified in 0.1-0.5% of second-trimester ultrasounds. Associations: aneuploidy (trisomy 21, 18, 13), cystic fibrosis (echogenic bowel may be the first sign of meconium ileus), congenital infection (CMV, toxoplasmosis, parvovirus B19), IUGR, and swallowing of intra-amniotic blood. Workup: NIPT, cystic fibrosis carrier screening, infection serologies (TORCH), and serial growth scans.

Echogenic Intracardiac Focus (EIF)

– A small bright spot (calcification) in the fetal heart, typically in the left ventricle (papillary muscle). Seen in 3-5% of normal pregnancies. In isolation, it is a normal variant with minimal aneuploidy risk. However, EIF is more common in trisomy 21 fetuses (10-30%), particularly when combined with other soft markers. If isolated and NIPT/low-risk serum screen, no further action is needed.

Eclampsia

– The occurrence of generalized tonic-clonic seizures in a patient with preeclampsia, representing a medical emergency. Complications include aspiration, placental abruption, disseminated intravascular coagulation, and maternal/fetal death. Prevention and treatment involves intravenous magnesium sulfate (4-6 g IV bolus followed by 1-2 g/hour mainte-

nance), which reduces the risk of seizures by 50%. Management includes airway protection, seizure control (magnesium sulfate first-line; benzodiazepines if magnesium fails), blood pressure control with antihypertensives (labetalol or hydralazine for BP $\geq 160/110$ mmHg), and delivery once maternal stability is achieved. Eclampsia can occur antepartum (50%), intrapartum (25%), or postpartum (25%, most within 48 hours). Recurrence risk in future pregnancies is approximately 2%. Maternal mortality is approximately 2-5% in high-resource settings.

Ectopic Pregnancy

– Implantation of a fertilized ovum outside the uterine cavity, most commonly in the fallopian tube (95%). Risk factors: prior ectopic, PID, tubal surgery, IUD, smoking, and assisted reproductive technology. Presents with lower abdominal pain, amenorrhea, and vaginal bleeding. Rupture causes hemodynamic instability. Diagnosis: transvaginal ultrasound (no intrauterine pregnancy with hCG >discriminatory zone), serial hCG monitoring. Treatment: methotrexate for early, unruptured ectopic; salpingectomy or salpingostomy for surgical management.

Effacement

– Thinning (shortening) of the cervix during labor, expressed as a percentage (0-100 percent), as the cervix is taken up into the lower uterine segment, enabling dilation. Occurs with cervical dilation in the first stage of labor, driven by contractions and the presenting part. Assessed digitally on vaginal examination along with dilation and station. Effacement precedes or accompanies dilation, particularly in nulliparas (effacement first), whereas multiparas may dilate with less effacement. Abnormal (lack of progress) indicates dystocia.

Embryo

– The developing human organism from fertilization (conception) through the eighth week of gestation (10th week by last menstrual period). After fertilization, the zygote undergoes cleavage (cell division) as it travels through the fallopian tube, reaching the morula stage (16 cells) and then the blastocyst stage (5–6 days), which implants in the endometrium. During the embryonic period, all major organ systems develop (organogenesis): gastrulation forms the three germ layers (ectoderm, mesoderm,

endoderm), neurulation forms the neural tube, and the heart begins beating at 5–6 weeks. The embryonic period is the most vulnerable to teratogens (medications, infections, radiation, alcohol), which can cause major structural malformations. After 8 weeks, the developing human is called a fetus.

Endometritis

– Infection of the endometrium, the most common cause of puerperal fever after cesarean delivery. Risk factors include prolonged labor, multiple vaginal examinations, premature rupture of membranes, and cesarean section. Presents with fever, uterine tenderness, foul-smelling lochia, and leukocytosis. Treatment with broad-spectrum IV antibiotics (ampicillin and gentamicin plus clindamycin) for polymicrobial infection including anaerobes.

Engagement

– The descent of the fetal presenting part into the pelvis, typically occurring 2-3 weeks before labor in nulliparas or at the onset of labor in multiparas.

Epidural

– Regional analgesia (or anesthesia) delivering local anesthetic/opioid via a catheter in the epidural space (lumbar), used for pain relief during labor and for cesarean (higher dose) anesthesia. Provides excellent analgesia while allowing maternal mobility and pushing; reduces catecholamine stress. Complications: hypotension (sympathetic block), postdural puncture headache, motor block, back pain, urinary retention, infection/hematoma (rare), and fetal effects (transient). Contraindications: coagulopathy, infection at site, patient refusal, and severe hypovolemia. Alternatives: spinal (single dose), combined spinal-epidural, nitrous oxide, and systemic opioids.

Epidural Analgesia for Labor

– A neuraxial technique for labor analgesia: a catheter is placed in the epidural space (L3-L4 or L2-L3 interspace) and local anesthetic (bupivacaine 0.0625-0.125%) with opioid (fentanyl 2 µg/mL) is infused continuously or in patient-controlled epidural analgesia (PCEA) boluses. Produces segmental analgesia (T10-L1 for the first stage, T10-S4 for the second stage). Benefits: excellent pain relief, mother can rest, and can be converted to surgical anesthesia for cesarean. Side effects: hypotension, motor block (reduced with low-dose solutions), fever (can increase the diagnosis of chorioamnionitis), pruritus,

and urinary retention. Contraindications: maternal coagulopathy, infection at the insertion site, and untreated maternal hypovolemia.

Episiotomy

– A surgical incision of the perineum to enlarge the vaginal outlet during delivery. Two types: mediolateral (most common worldwide) and median/midline. Previously performed routinely; current evidence supports selective use. Indications include operative vaginal delivery, fetal distress requiring expedited delivery, and shoulder dystocia. Classified with perineal lacerations as first degree (vaginal mucosa only), second degree (mucosa and perineal muscles), third degree (involving the anal sphincter complex), or fourth degree (extending through the rectal mucosa). Healing occurs over 2-4 weeks. Complications include pain, infection, dyspareunia, and wound dehiscence. The mediolateral episiotomy is preferred over midline because it is associated with a lower risk of third- and fourth-degree tears involving the anal sphincter. Modern obstetrics recommends restrictive rather than routine use of episiotomy.

Episiotomy Repair

– Surgical repair of an episiotomy incision after delivery. Technique: continuous suturing of the vaginal mucosa (2-0 chromic), interrupted sutures for the perineal muscles, and subcuticular closure of the perineal skin. The rectum should be examined after repair (suture inadvertently through the rectal mucosa). Mediolateral episiotomy is repaired in the same fashion. Pain management: ice packs, topical anesthetics, sitz baths, NSAIDs. Avoid prolonged sitting and constipation.

Estimated Due Date (EDD)

– The expected date of delivery, calculated as 40 weeks (280 days) from the first day of the last menstrual period. Confirmed or adjusted by first-trimester ultrasound crown-rump length measurement (most accurate $\pm 5-7$ days). Second-trimester ultrasound is less accurate ($\pm 10-14$ days). Third-trimester is least accurate ($\pm 21-30$ days). Only 5% of women deliver on their exact EDD; most deliver within 2 weeks before or after. Used to determine gestational age for prenatal screening, timing of interventions, and postterm management.

Estimated Fetal Weight (EFW)

– An ultrasound-derived estimate of fetal weight,

calculated using formulas that combine BPD, HC, AC, and FL. The Hadlock formula (using HC, AC, FL) is the most commonly used. Accuracy: $\pm 10-15\%$. Indications: assess fetal growth, determine size for gestational age, and plan delivery. EFW < 10 th percentile: SGA/IUGR. EFW > 90 th percentile: LGA/macrosomia. EFW > 4500 g may influence delivery decisions (consider cesarean).

External Cephalic Version (ECV)

– A procedure to manually rotate a breech or transverse fetus to a cephalic (head-down) presentation from outside the abdomen. Performed after 36-37 weeks (term, with adequate amniotic fluid). Success rate: 30-80% (higher with prior vaginal delivery, transverse lie, adequate fluid, and non-anterior placenta). Contraindications: non-reassuring fetal status, oligohydramnios, uterine anomaly, multiple gestation, and contraindications to vaginal delivery. Fetal monitoring before and after. RhoGAM for Rh-negative patients. Tocolysis (terbutaline) may increase success.

Extrauterine Pregnancy

– A pregnancy in which the fertilized ovum implants outside the uterine cavity, an alternative term for ectopic pregnancy. By far the most common site is the fallopian tube (ampulla 70%, isthmus 12%, fimbria 11%, cornual/interstitial 2-4%). Other extrauterine sites: ovary, cervix, cesarean scar, abdominal cavity, and the rudimentary horn of a bicornuate uterus. Risk factors: prior ectopic pregnancy, tubal surgery, pelvic inflammatory disease, endometriosis, smoking, assisted reproductive technology, and IUD in situ. Presentation: abdominal pain, amenorrhea, vaginal bleeding—classic triad; rupture causes hemoperitoneum, hypovolemic shock. Diagnosis: quantitative beta-hCG and transvaginal ultrasound. Treatment: medical (methotrexate for unruptured, low hCG, no fetal cardiac activity) or surgical (salpingectomy or salpingostomy by laparoscopy).

Face Presentation

– A fetal presentation where the neck is hyperextended and the face is the presenting part. Incidence: 1:500-1:1000. Types: mentum anterior (chin toward pubis, delivers vaginally), mentum posterior (chin toward the sacrum, cannot deliver vaginally unless rotates to anterior). Diagnosis: ultrasound or palpation (feel nose, eyes, mouth, and chin during

vaginal exam). Management: if mentum anterior, labor may proceed; if mentum posterior and persistent, cesarean. Preterm and anencephalic fetuses have a higher rate of face presentation.

Failed Induction of Labor

- The inability to achieve active labor and progressive cervical change after an adequate trial of induction. Definition: no active labor (cervical change) after ≥ 12 -18 hours of oxytocin with ruptured membranes and adequate contractions. Management: the latent phase may be prolonged (up to 24 hours or more). If the cervix does not change after adequate contractions with a favorable Bishop score and ROM, cesarean delivery is indicated. Failed induction is more common in nulliparas and with unfavorable cervical status at the beginning.

Fecundity

- The biological ability to conceive and produce a live birth. Fecundity is influenced by age (declines significantly after 35), ovarian reserve, tubal patency, uterine factors, and male fertility (sperm count, motility, morphology). Fecundability: the probability of achieving pregnancy in a single menstrual cycle. Normal fecundability is approximately 20-25% per cycle in healthy couples. Infertility is defined as failure to conceive after 12 months of regular unprotected intercourse.

Female Genital Mutilation

- FGM: the partial or total removal of female external genitalia for non-medical reasons, a human rights violation practiced in parts of Africa, the Middle East, and Asia (types I-IV). Immediate complications: severe pain, hemorrhage, infection, urinary retention. Long-term: chronic infection, scarring, painful menstruation, sexual dysfunction, and obstetric complications (prolonged labor, perineal tears, fistula, increased maternal/neonatal mortality). Legal/ethical: illegal in most countries; mandatory reporting and safeguarding. Management: multidisciplinary care (gynecology, urology, psychosexual), deinfibulation for obstetric/functional indications, counseling, and community education/prevention. Support survivors with sensitive, non-judgmental care.

Femur Length (FL)

- The length of the fetal femur (diaphysis), measured from the greater trochanter to the distal femoral

metaphysis. Used for dating (14-26 weeks) and growth assessment. Normal growth: 2 mm per week. Short femur: can be constitutional (especially with short parents), associated with aneuploidy (trisomy 21, skeletal dysplasias), or IUGR. The FL/AC ratio helps differentiate IUGR (increased ratio) from constitutional smallness.

Fertility

- The biological capacity to conceive and produce offspring. Fertility depends on the proper functioning of the reproductive system in both males and females, including ovulation, sperm production, and hormonal regulation. Infertility affects a significant proportion of couples and may require medical evaluation and assisted reproductive technologies such as in vitro fertilization (IVF).

Fetal Acid-Base Status

- The assessment of fetal oxygenation and acid-base balance during labor, reflecting fetal metabolic condition. Normal: umbilical artery pH 7.25-7.35, pCO₂ 40-50 mmHg, base excess 0 to -5. Fetal acidosis: pH <7.20 (mild), pH <7.00 (severe, associated with neonatal encephalopathy). Respiratory acidosis: elevated pCO₂ from cord compression (rapidly reversible). Metabolic acidosis: decreased base excess from prolonged hypoxia (associated with neurologic injury). Fetal scalp pH: direct measurement from fetal blood; pH >7.25 = normal, <7.20 = acidosis.

Fetal Alcohol Spectrum Disorder (FASD)

- A broad spectrum of physical, behavioral, and cognitive impairments caused by prenatal alcohol exposure. The most severe form is fetal alcohol syndrome (FAS): characteristic facial features (smooth philtrum, thin vermilion border, small palpebral fissures), growth deficiency (prenatal or postnatal), and central nervous system abnormalities (microcephaly, developmental delay, intellectual disability). No amount of alcohol is considered safe in pregnancy. Diagnosis: based on confirmed maternal alcohol use, dysmorphology exam, and neurodevelopmental assessment. Prevention: screening and counseling in pregnancy.

Fetal Alcohol Syndrome

- A collection of birth defects resulting from exposure of the fetus to alcohol during pregnancy,

representing the most severe form of fetal alcohol spectrum disorder (FASD). Characteristic features include distinctive facial dysmorphology (smooth philtrum, thin vermilion border, small palpebral fissures), prenatal and postnatal growth deficiency, and central nervous system abnormalities (microcephaly, developmental delay, intellectual disability, behavioral problems). No amount of alcohol is considered safe during pregnancy. Diagnosis requires confirmed prenatal alcohol exposure, characteristic facial features, growth deficits, and neurodevelopmental impairment. Management is supportive with early intervention services.

Fetal Attitude

- The relationship of fetal body parts to one another, describing the degree of flexion or extension of the fetal head and extremities. Normal attitude is full flexion (vertex presentation with chin tucked to chest). attitudes include deflexion (less flexion), military (neutral position), brow, face, or complete extension. Deflexed attitudes result in larger presenting diameters, potentially complicating vaginal delivery.

Fetal Bradycardia

- A baseline fetal heart rate <110 bpm for ≥ 10 minutes. Moderate (100-110 bpm): often benign, especially in post-term fetuses. Severe (<100 bpm): concerning for fetal hypoxia, acidosis, congenital heart block (SLE, anti-Ro/anti-La antibodies), cord accident, placental abruption, or maternal seizures. A prolonged deceleration lasting >2 minutes is managed as an emergency. Congenital heart block: fixed bradycardia 50-80 bpm, unrelated to contractions, diagnosed prenatally by fetal echocardiography.

Fetal Heart Rate

- Normal fetal heart rate ranges from 110-160 beats per minute. Monitored via auscultation with a fetoscope, Doppler ultrasound, or continuous electronic fetal monitoring. Baseline FHR is determined over a 10-minute window and is modulated by the autonomic nervous system. Variability (fluctuations in baseline) is classified as absent, minimal (≤ 5 bpm), moderate (6-25 bpm), or marked (>25 bpm) and reflects fetal acid-base status. Accelerations (transient increases of ≥ 15 bpm for ≥ 15 seconds in fetuses beyond 32 weeks) are reassuring signs of fetal well-being. Decelerations are classified as early

(head compression, benign), variable (cord compression, most common), or late (uteroplacental insufficiency, concerning). Fetal tachycardia (>160 bpm) may indicate maternal fever, infection, or hypoxia; bradycardia (<110 bpm) may suggest fetal distress, congenital heart block, or maternal hypotension.

Fetal Kick Counts (Fetal Movement Counting)

- A method of antepartum fetal surveillance where the mother counts fetal movements (kicks, rolls, stretches) daily. Cardiff count (10 kicks in 2 hours): lie on the left side, record the time until 10 movements are felt. Normal: 10 movements in ≤ 2 hours. Decreased fetal movement is associated with increased risk of stillbirth and IUGR. A single episode of decreased fetal movement warrants NST/BPP. Maternal perception of fetal movement is generally reliable and may be the earliest sign of fetal compromise.

Fetal Lie

- The relationship of the long axis of the fetus to the long axis of the mother. Longitudinal lie (parallel, 99%) or transverse lie (perpendicular, 1%). Most common is left occiput transverse or left occiput anterior. Transverse lie at term is abnormal and requires cesarean delivery if not corrected. Lie determined by palpation and ultrasound, particularly important for planning delivery route and management of labor.

Fetal Presentation

- The relationship of the fetal presenting part to the maternal pelvis. Includes cephalic (head first, most common at 97%), breech (buttocks or feet first), shoulder/oblique, and transverse lie. Cephalic presentations include vertex, face, brow, and compound. Breech presentations include complete, frank, and footling. Presentation assessed by Leopold maneuvers and confirmed with ultrasound. External cephalic version may be attempted for breech at 36-38 weeks.

Fetal Scalp Electrode (FSE)

- A spiral wire electrode placed on the fetal scalp through the cervix to directly record the fetal heart rate. Provides a more accurate FHR signal than external Doppler, particularly in obese patients or when external monitoring is inadequate. Indications: poor-quality external tracing, need for internal mon-

itoring. Contraindications: HIV and hepatitis C (risk of vertical transmission), placenta previa, and scalp infection at the electrode site. The electrode is placed after membrane rupture, with cervical dilatation ≥ 2 cm.

Fetal Scalp Stimulation

- A test of fetal well-being during labor by digitally rubbing or pinching the fetal scalp during a vaginal exam. A reactive acceleration (increase of ≥ 15 bpm for ≥ 15 seconds) in the FHR in response to stimulation is a reassuring sign of normal fetal acid-base status (negative predictive value 95% for fetal acidosis). If no acceleration, fetal scalp pH may be indicated. The test is noninvasive and can be performed repeatedly.

Fetal Tachycardia

- A baseline fetal heart rate >160 bpm for ≥ 10 minutes. Mild (161-180 bpm) or severe (>180 bpm). Causes: maternal fever (most common, often from chorioamnionitis), medications (terbutaline, atropine, scopolamine), maternal hyperthyroidism, fetal infection (myocarditis), fetal hypoxia (compensatory response), and fetal tachyarrhythmia (SVT, atrial flutter, 200-300 bpm). Management: identify and treat the cause (maternal cooling, antibiotics for chorioamnionitis). Persistent tachycardia with minimal variability is concerning.

Fetal Viability

- The gestational age at which a fetus has the potential to survive outside the uterus with medical support, generally considered to be 23-24 weeks of gestation. Survival rates increase significantly with each additional week: approximately 30-50% at 23 weeks, 50-70% at 24 weeks, and over 90% by 27-28 weeks. Factors influencing viability include birth weight, sex, multiple gestation, access to neonatal intensive care, and presence of congenital anomalies. The limit of viability is defined by each country's legal and ethical framework. In the UK, the upper limit for termination of pregnancy is 24 weeks for most grounds. Prognosis for intact survival without severe neurodevelopmental impairment remains guarded at the earliest gestational ages, with approximately 40% of survivors at 23 weeks having moderate to severe disability.

Fetomaternal Hemorrhage

- Transplacental passage of fetal red blood cells into

the maternal circulation. Occurs in small amounts during normal pregnancy but can be massive during trauma, placental abruption, or cesarean delivery.

Fetus

- An unborn offspring from the 9th week of gestation (after the embryonic period) until birth. The fetal period is characterized by rapid growth, maturation of organ systems, and increasing complexity of function. Key fetal milestones: 12 weeks — sex distinguishable, kidneys begin producing urine; 20 weeks — fetal movements felt by mother (quickening); 24 weeks — viability (potential to survive outside the womb with intensive neonatal support); 28-32 weeks — lung surfactant production increases; 37-42 weeks — term.

First Stage of Labor

- From the onset of regular contractions to full cervical dilatation. Two phases: latent (0-6 cm, slow progress, 6-12 hours in nulliparas) and active (6-10 cm, faster progress, 1-2 cm/hour in nulliparas). Active phase begins at 6 cm (the Friedman curve was revised: the old 4 cm threshold was updated to 6 cm by ACOG/NICHD in 2014). Arrest of first stage: no cervical change for ≥ 4 hours with adequate contractions or ≥ 6 hours with inadequate contractions.

First Trimester

- The period from conception to 12 weeks gestational age. Characterized by rapid embryonic organogenesis, rising hCG levels, and establishment of the placenta. Common symptoms include nausea, vomiting, fatigue, and breast tenderness. Dating ultrasound performed to confirm gestational age. Risk of miscarriage highest during this trimester. Prenatal vitamins with folic acid recommended.

Folic Acid Supplementation

- Daily folic acid (400-800 mcg) taken before conception and during the first trimester to prevent neural tube defects (NTDs: spina bifida, anencephaly, encephalocele). Folic acid is a B vitamin (folate) essential for DNA synthesis and cell division. Higher doses (4-5 mg daily) are recommended for women with a prior NTD-affected pregnancy, diabetes, obesity, or those taking antiepileptic medications (valproate, carbamazepine). NTDs occur at 21-28 days post-conception, often before pregnancy is recognized, making preconceptional supplementa-

tion critical.

Forceps-Assisted Delivery

– Operative vaginal delivery using forceps (two curved blades applied to the fetal head). Types: outlet (forceps applied at the introitus, fetal scalp visible), low (station $\geq +2$, not at outlet), midpelvic (station $\geq +2$ but head above ischial spines), and rotational (forceps used to rotate from OP to OA). Most common types: Simpson (for molded heads), Elliot (for unmolded heads), and Piper (for after-coming head in breech delivery). Prerequisites: full dilatation, ROM, engaged head, known position, adequate pelvis, and consent. Neonatal risks: facial nerve palsy, brachial plexus injury, bruising, and cephalohematoma. Maternal risks: third/fourth-degree lacerations (higher than vacuum).

Forceps Delivery

– Assisted vaginal delivery using forceps (curved blades applied to the fetal head) to expedite delivery for maternal or fetal indications (prolonged second stage, fetal distress, maternal exhaustion, medical conditions limiting pushing). Requires: full dilatation, engaged vertex (station and position known), ruptured membranes, empty bladder, and adequate analgesia; contraindications: fetal malpresentation, suspected cephalopelvic disproportion. Complications: maternal (vaginal/perineal lacerations, episiotomy, incontinence) and fetal (facial bruising, cephalohematoma, nerve injury—rare serious injury). Compared with vacuum, forceps have higher maternal trauma but lower fetal scalp trauma. Increasingly replaced by cesarean for difficult cases.

Fourth-Degree Tear

– The most severe type of perineal tear during childbirth, extending through the anal sphincter (both internal and external) and into the rectal mucosa. Fourth-degree tears occur in approximately 0.5-1% of vaginal deliveries and are associated with forceps delivery, shoulder dystocia, large baby, and episiotomy. Repair requires expert surgical reconstruction in the operating room: layered closure of rectal mucosa, internal anal sphincter, external anal sphincter, and perineal muscles. Complications: anal incontinence (flatus and fecal), rectovaginal fistula, and dyspareunia.

Friedman Curve

– The classic labor curve described by Emanuel Fried-

man in the 1950s, plotting cervical dilatation against time. Defined the latent and active phases, with active phase beginning at 4 cm. The Friedman curve was the standard for labor management for decades. Modern revisions (Consortium on Safe Labor, Zhang 2010) showed that labor progresses more slowly than Friedman described, particularly in nulliparas and with epidural anesthesia. The active phase now starts at 6 cm. The new paradigm recommends more patience before diagnosing arrest of labor.

Fundal Height

– The distance from the symphysis pubis to the top of the uterus measured in centimeters. Used to estimate gestational age and fetal growth. Generally correlates with weeks of gestation between 20-36 weeks (e.g., 24 cm at 24 weeks). Discrepancies may suggest fetal growth restriction, macrosomia, polyhydramnios, or multiple gestation. Measured with patient supine using a tape measure.

Gestation

– The period of development of a fetus from fertilization to birth. Human gestation averages 280 days (40 weeks) from the first day of the last menstrual period (LMP) or 266 days (38 weeks) from conception. Trimesters: first (weeks 1-12: organogenesis, highest vulnerability to teratogens), second (weeks 13-27: fetal growth and maturation, quickening at 18-22 weeks), third (weeks 28-40: rapid weight gain, lung maturation, acquisition of immune competence). Gestational age is assessed by: LMP, early ultrasound (crown-rump length at 11-13 weeks most accurate), symphysis-fundal height measurement after 20 weeks, and clinical assessment. Gestational age categories: preterm (<37 weeks), term (37-41 weeks), post-term (>41 weeks).

Gestational Age

– The age of pregnancy measured in weeks from the first day of the last menstrual period (LMP). Also called menstrual age. Typically 2 weeks longer than fertilization age. Calculated using LMP or firsttrimester ultrasound. Used to estimate due date (40 weeks from LMP). Preterm is less than 37 weeks; post-term is beyond 42 weeks. Key metric for fetal development milestones and management decisions.

Gestational Diabetes

– Glucose intolerance first diagnosed during pregnancy, affecting 6-9% of pregnancies. Risk factors include obesity, advanced maternal age, family history, and prior gestational diabetes. Complications include macrosomia, birth trauma, neonatal hypoglycemia, and preeclampsia. Screening by 50g glucose challenge test at 24-28 weeks, with confirmatory 100g oral glucose tolerance test. Management includes dietary modification, glucose monitoring, and insulin therapy when diet fails.

Gestational Hypertension

– New-onset hypertension (BP $\geq 140/90$ mmHg) after 20 weeks of gestation in a woman with previously normal blood pressure, without proteinuria or other features of preeclampsia. Affects 6-8% of pregnancies. Management: monitoring blood pressure, screening for preeclampsia progression (proteinuria, labs, symptoms). Delivery at term (37-40 weeks) is typical. Some patients progress to preeclampsia. Treatment with antihypertensives (labetalol, nifedipine, methyldopa) is recommended for BP $\geq 160/110$ mmHg.

Gestational Sac

– The first sonographic sign of an intrauterine pregnancy, visible on transvaginal ultrasound at approximately 4.5-5 weeks gestational age. A fluid-filled structure within the decidua, surrounded by the chorionic ring. Mean sac diameter (MSD) correlates with gestational age. The yolk sac is visible within the gestational sac at 5-6 weeks, and the embryo with cardiac activity at 6-7 weeks. Abnormal findings: empty gestational sac without yolk sac (pseudogestational sac in ectopic, anembryonic pregnancy).

Gestational Trophoblastic Disease

– A spectrum of conditions arising from abnormal trophoblast proliferation, including complete and partial hydatidiform moles and gestational choriocarcinoma. Complete mole has 46,XX karyotype (all paternal origin); partial mole is triploid (69 chromosomes). Presents with elevated hCG, uterus large for dates, and vaginal bleeding. Diagnosis by ultrasound (snowstorm pattern) and histology. Managed by uterine evacuation and hCG monitoring.

Group B Streptococcus

– A gram-positive bacterium (*Streptococcus agalactiae*) colonizing the genitourinary and gastrointestinal

tracts. Asymptomatic vaginal colonization occurs in 20-30% of pregnant women. Screening is performed at 36-37 weeks gestation via rectovaginal swab culture. Intrapartum antibiotic prophylaxis (IV penicillin G or ampicillin) is indicated for women with positive GBS screening, prior infant with GBS disease, or GBS bacteriuria during the current pregnancy. Penicillin-allergic women receive cefazolin (if low risk) or clindamycin/vancomycin (if high risk). Prophylaxis reduces early-onset neonatal GBS disease (sepsis, pneumonia, meningitis) by 80%. Early-onset GBS disease occurs in the first 7 days of life and has a mortality rate of 5-10% in term infants.

Growth Scan

– An ultrasound performed in the third trimester (usually 28-32 weeks and/or 36-38 weeks) to assess fetal growth. Measurements: BPD, HC, AC, FL, and estimated fetal weight (EFW). Growth percentiles plotted on a growth curve. Abnormal: <10 th percentile (SGA/IUGR) or >90 th percentile (LGA/macrosomia). Amniotic fluid volume and Doppler studies (umbilical artery, MCA) often included. Indications: suspected growth abnormality, multiple gestation, maternal diabetes, hypertension, prior IUGR, and postterm surveillance.

Gynaecologist

– A medical doctor who specializes in the health of the female reproductive system (vagina, cervix, uterus, fallopian tubes, ovaries) and breasts. Gynecologists diagnose and treat conditions including menstrual disorders, pelvic pain, endometriosis, fibroids, ovarian cysts, pelvic organ prolapse, incontinence, infections, and gynecologic cancers. They perform procedures including colposcopy, hysteroscopy, laparoscopy, and surgery. Many gynecologists also practice obstetrics (obstetrician-gynecologists, OB/GYNs). Subspecialties: gynecologic oncology, reproductive endocrinology and infertility, urogynecology, and pediatric/adolescent gynecology.

Hand Prolapse

– Prolapse of a fetal hand or arm alongside or below the presenting part. May occur spontaneously or after manual rotation. The prolapsed arm may be mistaken for a cord or foot. Management: if the hand is above the presenting part (compound

presentation), it may be gently pushed back during contractions. If it presents beside the head after full dilatation, spontaneous delivery may occur, but rotation may be impeded. If vaginal delivery is obstructed, cesarean is performed.

Head Circumference (HC)

- The circumference of the fetal skull, measured at the same level as BPD (thalami, cavum septum pellucidum). Used for dating (second trimester) and for assessing head growth. HC is more reliable than BPD for dating when head shape is abnormal. Microcephaly: HC <3rd percentile (workup for infection, aneuploidy, genetic syndromes). Macrocephaly: HC >97th percentile.

HELLP Syndrome

- A severe variant of preeclampsia characterized by Hemolysis, Elevated Liver enzymes, and Low Platelets. Occurs in 10-20% of patients with severe preeclampsia. Diagnostic criteria include haemolysis (LDH >600 U/L, schistocytes on peripheral smear), elevated liver enzymes (AST $\geq$ 70 U/L), and low platelets (<100,000/ μ L). HELLP can develop before or after delivery and may present without classic preeclampsia features (15-20% of cases). Symptoms include right upper quadrant or epigastric pain, nausea, vomiting, headache, and malaise. Complications include DIC, placental abruption, hepatic rupture or infarction, acute kidney injury, pulmonary edema, and maternal death. Management: delivery is indicated regardless of gestational age. Corticosteroids (dexamethasone) may improve platelet count but are not recommended as routine treatment. Plasma exchange may be considered for persistent thrombocytopenia postpartum.

HELPERR Mnemonic

- A mnemonic for the sequential management of shoulder dystocia: H — Help (call for additional personnel, anesthesia, and pediatrics). E — Evaluate for episiotomy (generous episiotomy to provide more room). L — Legs (McRoberts maneuver: hyperflex maternal legs onto the abdomen). P — Suprapubic pressure (downward pressure on the maternal suprapubic area to dislodge the anterior shoulder). E — Enter internal rotation (Rubin II or Woods screw maneuver: rotate the fetal shoulders 180 degrees). R — Remove the posterior arm (sweep the posterior arm across the chest and deliver it).

R — Roll the patient (Gaskin maneuver: onto all fours). If all maneuvers fail: Zavanelli maneuver (replace the fetal head and proceed with emergency cesarean).

Hematologic Changes in Pregnancy

- Plasma volume increases 40-50% while red cell mass increases 20-30%, resulting in physiologic anemia (Hb 10-11 g/dL). Leukocytosis (WBC up to 15,000-16,000/ μ L, predominantly neutrophils) is normal. The coagulation cascade shifts to a prothrombotic state: increased fibrinogen (factor I, 300-600 mg/dL), factors VII, VIII, IX, X, XII, and von Willebrand factor. Decreased protein S activity (free S decreases). The overall effect is an increased risk of venous thromboembolism (5-10 fold) and the utility of DVT prophylaxis in certain populations.

hemorrhage

- Excessive or severe bleeding. In obstetrics, hemorrhage is classified by timing: antepartum hemorrhage (bleeding after 24 weeks of pregnancy before birth, causes include placenta praevia, placental abruption, vasa praevia) and postpartum hemorrhage (bleeding >500 mL after vaginal delivery or >1000 mL after cesarean, causes include uterine atony, retained placenta, genital tract trauma, coagulopathy). Postpartum hemorrhage is a leading cause of maternal mortality worldwide. Management: uterine massage, oxytocin, ergometrine, carboprost, tranexamic acid, intrauterine balloon tamponade, uterine compression sutures (B-Lynch), and emergency hysterectomy.

Herpetic Whitlow

- A painful viral infection of the finger caused by the herpes simplex virus (typically HSV-1), characterized by swelling, redness, and painful vesicular lesions on the finger. In obstetrics, healthcare workers (midwives, obstetricians) are at risk when attending deliveries of women with genital herpes, as the virus can enter through breaks in the skin of the gloved hand. Treatment: oral antiviral medication (acyclovir, valacyclovir). Prevention: wearing double gloves during vaginal examinations and deliveries of women with active genital herpes lesions.

Heterotopic Pregnancy

- Simultaneous intrauterine and ectopic pregnancy. Rare in spontaneous conception (1:30,000) but more common with ART (1:100-1:500). Risk factors: ovu-

lation induction, IVF with multiple embryo transfer. The presence of an intrauterine pregnancy does not exclude an ectopic pregnancy. Diagnosis: ultrasound showing intrauterine and extrauterine gestational sacs. Treatment: surgical removal of the ectopic pregnancy (salpingectomy) with preservation of the intrauterine pregnancy (which can proceed normally).

High-Dependency Unit

– A ward or area within a hospital that provides a level of care between a general ward and an intensive care unit, for patients who require intensive observation or treatment but not mechanical ventilation. In obstetrics, women may be admitted to HDU for: severe pre-eclampsia, postpartum hemorrhage, sepsis, or medical complications in pregnancy. HDU provides continuous monitoring (pulse oximetry, ECG, invasive blood pressure), one-to-one or one-to-two nursing, and the ability to administer vasoactive drugs or blood products.

Hormone Replacement Therapy

– HRT (menopause hormone therapy): estrogen $\pm$ progestin to relieve menopausal symptoms (vasomotor, vaginal atrophy, sleep, mood) and prevent osteoporosis. Regimens: estrogen-only (post-hysterectomy) or combined (with progestin for endometrial protection in uterus-intact women); routes: oral, transdermal, vaginal. Benefits: symptom relief, bone protection, and improved quality of life. Risks: VTE, stroke, breast cancer (estrogen+progestin; duration-dependent), and gallbladder disease. Selection: lowest effective dose, shortest duration, personalized (transdermal for VTE risk), timing (within 10 years of menopause for benefit). Contraindications: breast/endometrial cancer, VTE, liver disease, unexplained bleeding. Alternatives for vaginal/osteoporosis indications.

Hot Flashes

– Vasomotor symptoms: sudden sensations of intense heat, sweating, flushing, and palpitations, most commonly from estrogen withdrawal around menopause; also in hypogonadism, chemotherapy-induced ovarian failure, and some medications (SERMs, GnRH agonists). Mechanism: hypothalamic thermoregulatory dysfunction. Features: episodic (30 s-several min), often at night with disrupted sleep. Diagnosis: clinical; exclude secondary causes. Management:

lifestyle (avoid triggers, cooling), non-hormonal (SSRIs/SNRIs—paroxetine, venlafaxine, gabapentin, clonidine, exercise), hormonal (HRT—estrogen for symptomatic menopause in appropriate candidates) as most effective; weigh risks (breast cancer, thrombosis); alternative/complementary options.

Human Chorionic Gonadotropin

– A glycoprotein hormone produced by trophoblast cells after implantation. Detectable in serum 8-11 days post-conception and in urine 12-14 days. Levels double approximately every 48-72 hours in early pregnancy, peaking at 8-11 weeks then plateauing. Used in pregnancy testing, ectopic pregnancy diagnosis (abnormal rise), and molar pregnancy monitoring. Beta-hCG subunit measured quantitatively for clinical decisions.

Hydatidiform Mole

– A type of gestational trophoblastic disease characterized by abnormal proliferation of trophoblastic tissue. Complete mole: 46,XX (all paternal), no fetal tissue, diffuse vesicular swelling; risk of malignant transformation (15-20%). Partial mole: triploid (69,XXX), some fetal tissue, focal swelling; lower risk. Presents with vaginal bleeding in first trimester, excessive uterine size, theca lutein cysts, hyperemesis, and very high hCG. Diagnosis: ultrasound (snowstorm appearance, no fetal parts), markedly elevated hCG. Treatment: suction curettage with careful hCG monitoring until undetectable. Chemotherapy (methotrexate, actinomycin D) for persistent or malignant disease.

Hydrops Fetalis

– Abnormal accumulation of fluid in two or more fetal compartments, including pleural effusion, pericardial effusion, ascites, and subcutaneous edema. Causes include Rh isoimmunization, chromosomal abnormalities, cardiac defects, infections (parvovirus B19), and twin-to-twin transfusion syndrome. Often associated with severe fetal anemia or cardiac failure. Mortality rate high; management depends on etiology. May require intrauterine transfusion.

Hymen

– A thin fold of mucous membrane that partially covers the external opening of the vagina. The hymen is a remnant of fetal development, with no known physiological function in postnatal life. Shape and

configuration vary widely: annular (most common), crescentic, cribriform (multiple small openings), septate, redundant, imperforate (complete closure, requiring surgical incision). The hymen typically has a central or crescentic opening of variable size that allows passage of menstrual blood. Rupture (tearing) of the hymen was traditionally associated with first vaginal intercourse (defloration), but the hymen can be stretched or torn by: tampon use, vigorous exercise, horseback/bicycle riding, gynaecological examination, or trauma. Its appearance does not reliably indicate virginity or sexual activity. Clinical significance: (1) Imperforate hymen: presents in adolescents with primary amenorrhoea and cyclic pelvic pain due to haematocolpos (accumulated menstrual blood in the vagina), treated by hymenotomy (cruciate incision). (2) Hymenal tags or polyps. (3) Hymenal tears in sexual abuse cases (forensic examination). (4) Hymenal stenosis or scarring. The concept of the hymen as a marker of virginity is a cultural and social construct, not a reliable anatomical indicator.

Hyperemesis Gravidarum

– Severe, persistent nausea and vomiting during pregnancy resulting in weight loss greater than 5%, dehydration, electrolyte imbalances, and ketosis. Occurs in 0.3-2% of pregnancies, typically presenting in the first trimester. Differentiated from normal morning sickness by severity and metabolic derangement. Management includes IV fluids, antiemetics (ondansetron, promethazine), thiamine supplementation to prevent Wernicke encephalopathy, and dietary modification. May require hospitalisation for IV hydration and electrolyte correction. Risk factors include female fetus, multiple gestation, molar pregnancy, and history of hyperemesis in a prior pregnancy. Complications include Wernicke encephalopathy (from thiamine deficiency), hypokalaemia, hyponatraemia, and vitamin deficiencies. Prognosis is generally good with symptoms improving by 16-20 weeks, though some women experience symptoms throughout pregnancy.

Hyperprolactinaemia

– Elevated levels of the hormone prolactin in the blood, above the normal range (typically >500 mIU/L in women). Causes: physiological (pregnancy, breastfeeding, stress, exercise), pharmaco-

logical (antipsychotics, metoclopramide, SSRIs, verapamil), and pathological (prolactinoma — pituitary adenoma, hypothyroidism, polycystic ovary syndrome, chronic renal failure). In women, hyperprolactinaemia causes galactorrhoea (milk production), oligomenorrhea or amenorrhea, anovulation, and infertility. Diagnosis: serum prolactin measurement (fasting, morning, avoid venipuncture stress), thyroid function tests, and pituitary MRI for macroprolactinoma. Treatment: dopamine agonists (cabergoline first-line due to better tolerability, bromocriptine second-line).

Hysterectomy

– The surgical removal of the uterus, the second most common major surgical procedure in women after cesarean section in the United States. The types of hysterectomy are classified as total (complete removal of the uterus and cervix, the most common), subtotal or supracervical (removal of the uterine body, leaving the cervix in place, preserving pelvic support and potentially reducing operative complications but requiring continued cervical cancer screening), radical (removal of the uterus, cervix, upper vagina, parametrial tissue, and pelvic lymph nodes, reserved for cervical and uterine malignancies), and total hysterectomy with bilateral salpingoophorectomy (removal of the uterus, cervix, fallopian tubes, and ovaries, inducing surgical menopause).

Implantation

– The embedding of the blastocyst into the endometrium, occurring approximately 6-10 days after ovulation. The blastocyst hatches from the zona pellucida, and the trophoblast invades the decidua. Implantation triggers hCG production, which maintains the corpus luteum. Failure of implantation is a common cause of early pregnancy loss. Ectopic implantation occurs outside the uterus, most commonly in the fallopian tube.

Induction of Labor

– The artificial initiation of uterine contractions before the onset of spontaneous labor. Indications: postterm pregnancy (>41-42 weeks), hypertensive disorders (preeclampsia, gestational hypertension), maternal medical conditions (diabetes, renal disease), fetal compromise (IUGR, oligohydramnios), PROM, chorioamnionitis, and elective reasons (shared decision-making after 39 weeks). Methods:

cervical ripening agents (prostaglandins, mechanical dilation with Foley balloon), followed by oxytocin if needed. Contraindications: placenta previa, vasa previa, transverse lie, prior classical cesarean, active genital herpes, and absolute cephalopelvic disproportion.

Influenza Vaccination in Pregnancy

– Annual inactivated influenza vaccine recommended for all pregnant women. Pregnancy increases the risk of severe influenza (pneumonia, ICU admission, death) due to changes in immune function and cardiopulmonary physiology. Maternal vaccination also protects the newborn during the first 6 months of life (transplacental antibody transfer) and reduces the risk of influenza-like illness in the infant by 50-70%. The vaccine is safe at any trimester.

Intensive Care Unit

– A specialist hospital unit providing continuous monitoring and life support for critically ill patients. In obstetrics, women may require ICU admission for: severe pre-eclampsia or eclampsia, massive postpartum hemorrhage, amniotic fluid embolism, sepsis, cardiac disease in pregnancy, or complications of anesthesia. ICU provides mechanical ventilation, continuous hemodynamic monitoring (invasive arterial pressure, central venous pressure), renal replacement therapy, and vasoactive drug support. Multidisciplinary care involves intensivists, obstetricians, and midwives.

Intermittent Auscultation (IA)

– The periodic auscultation of the fetal heart rate with a fetoscope or Doppler ultrasound during labor, without continuous electronic monitoring. Protocol: auscultate after a contraction for 60 seconds, during the active phase every 15-30 minutes in the first stage and every 5-15 minutes in the second stage. Used for low-risk pregnancies (no meconium, normal labor progress, no maternal risk factors). Advantages: less restricted mobility, lower intervention rate. Disadvantages: requires one-to-one nursing, may miss subtle changes. ACOG supports IA for low-risk patients.

Internal Podalic Version

– A maneuver where the operator inserts a hand into the uterus, grasps one or both fetal feet, and converts a transverse lie or cephalic presentation to a breech, then delivers by total breech extraction.

Indication: delivery of the second twin (transverse lie) or severe fetal distress in the second stage. Rare in modern obstetrics. Contraindications: contracted pelvis, uterine scar, ruptured uterus, and fetal distress from other causes.

Interstitial (Cornual) Pregnancy

– A rare ectopic pregnancy (2-4%) implanted in the intramural portion of the fallopian tube within the uterine wall. Higher morbidity than tubal ectopic because the myometrial layer expands, allowing later rupture (12-16 weeks) with massive hemorrhage. Risk factors: prior ipsilateral salpingectomy, IVF. Diagnosis: ultrasound (eccentric gestational sac surrounded by <5 mm myometrium), interstitial line sign. Treatment: cornual resection (wedge resection of the uterine horn) or hysterectomy for rupture. Methotrexate may be considered for early diagnosis with low hCG.

Intimate Partner Violence (IPV) in Pregnancy

– Physical, sexual, or psychological abuse by a current or former partner during pregnancy. Prevalence: 3-9% of pregnancies. Risk factors: unplanned pregnancy, late prenatal care, substance use, and young age. IPV increases the risk of miscarriage, preterm birth, low birth weight, placental abruption, and maternal death. Screening: universal screening with validated tools (HITS, AAS, PRISMA). All positive screens require safety assessment, referral to domestic violence resources (hotline, shelter), and documentation. Mandatory reporting varies by state.

Intrahepatic Cholestasis of Pregnancy (ICP)

– A pregnancy-specific liver disorder characterized by pruritus (palms and soles, often nocturnal, with no rash) and elevated serum bile acids (>10-40 $\mu\text{mol/L}$). Incidence: 0.5-2% of pregnancies. Risk factors: prior ICP, multiple gestation, hepatitis C, and high estrogen states. Onset: third trimester (after 28 weeks), resolves within 48 hours of delivery. Diagnosis: elevated total bile acids (fasting), elevated liver enzymes (AST, ALT, GGT). Fetal risks: preterm birth (spontaneous and iatrogenic), meconium-stained amniotic fluid, and stillbirth (with bile acids >40-100 $\mu\text{mol/L}$). Management: ursodeoxycholic acid (UDCA, 10-15 mg/kg/day) for

pruritus, vitamin K supplementation (coagulopathy risk from fat malabsorption), and planned delivery at 36-39 weeks depending on bile acid level. Fetal surveillance advised.

Intrapartum

– The period during labor and childbirth, from the onset of regular uterine contractions leading to cervical dilation until delivery of the baby and placenta. Intrapartum care includes: monitoring maternal vital signs and fetal wellbeing (CTG), pain relief (epidural, gas and air, opioids), management of labor progress (partogram), assisted delivery if needed (forceps, ventouse), and active management of the third stage (oxytocin for placental delivery). Intrapartum complications include fetal distress, failure to progress, shoulder dystocia, and postpartum hemorrhage.

Intrauterine Device

– IUD: a long-acting reversible contraceptive (LARC) device placed in the uterus. Types: copper IUD (ParaGard—hormone-free, up to 10-12 years, also emergency contraception) and levonorgestrel-releasing IUS (Mirena/Skyla—progestin, up to 3-8 years, reduces bleeding). Mechanisms: copper—spermicidal/inflammatory; LNG—thickens cervical mucus, endometrial changes. Insertion by trained clinician; expulsion and perforation are rare. Benefits: highly effective, reversible, no systemic hormones (copper), reduced menstrual bleeding (LNG). Side effects: cramping, spotting, irregular bleeding; risk of PID is low. Contraindications: current PID, pregnancy, uterine anomaly, some. Used for contraception and for menorrhagia/endometriosis.

Intrauterine Fetal Demise (IUFD) / Stillbirth

– Fetal death before complete expulsion or extraction from the mother, at ≥ 20 weeks gestation. Affects 1:160 pregnancies in the US (25,000 annually). Causes: placental abruption, umbilical cord accidents, infection, genetic abnormalities, maternal medical conditions (diabetes, hypertension, SLE), and unexplained ($>25\%$). Evaluation: fetal autopsy, placental pathology, karyotype/microarray, and maternal testing (Kleihauer-Betke, lupus anticoagulant, anticardiolipin, thrombophilia, HbA1c, infection screen, thyroid). Management: induction

of labor or D&E. Grief support and counseling for subsequent pregnancy.

Intrauterine Growth Restriction

– IUGR: a fetus with estimated weight below the 10th percentile (or growth velocity decline), usually with placental insufficiency or maternal/fetal factors. Causes: maternal (preeclampsia, hypertension, chronic disease, malnutrition, smoking, drugs), placental (insufficiency, abruption), and fetal (chromosomal, congenital infection, multiple pregnancy). Types: symmetric (early onset, affects head and body—anomaly/infection) vs. asymmetric (head-sparing, later onset—placental insufficiency). Complications: perinatal mortality, hypoxia, meconium aspiration, hypoglycemia, and long-term metabolic effects. Diagnosis: serial ultrasound (fundal height, estimated fetal weight, Dopplers—UA/MCA). Management: surveillance, Doppler monitoring, treat cause, and timed delivery for fetal compromise.

Intrauterine Pressure Catheter (IUPC)

– A fluid-filled catheter inserted into the uterine cavity alongside the fetus to measure the intensity and frequency of contractions in mm Hg (Monte-video units, MVU). Indications: inadequate labor progress despite oxytocin, need to assess contraction adequacy, determining if tachysystole is present, and when external tocodynamometer cannot provide adequate data. MVU: sum of peak contraction pressures (minus resting tone) over 10 minutes. Adequate labor: ≥ 200 -250 MVU. Placed through the cervix after ROM, typically during active labor.

Intrauterine Transfusion

– Ultrasonically guided intravascular or intraperitoneal transfusion of fetal red blood cells to treat severe fetal anemia, most commonly from Rh isoimmunization. Performed through the umbilical vein using a 22-25 gauge needle. Packed red blood cells, CMV-negative and crossmatched, are transfused slowly. Risks include bradycardia, infection, preterm labor, and fetal death. May need repeated transfusions until delivery.

In Vitro Fertilisation (IVF)

– An assisted reproductive technology in which eggs are retrieved from the ovaries, fertilized with sperm in a laboratory, and resulting embryos are transferred to the uterus. Stages: ovarian stimulation

(FSH injections for 10-14 days), oocyte retrieval (transvaginal ultrasound-guided aspiration under sedation), insemination (conventional or ICSI), embryo culture (3-6 days), and embryo transfer (1-2 embryos placed in the uterine cavity, typically at blastocyst stage). Success rates: approximately 30-40% live birth per cycle for women under 35, declining with age.

Involution

- The process by which the uterus returns to its prepregnancy size after delivery. The uterus weighs approximately 1000 grams immediately postpartum and returns to approximately 60 grams by 6 weeks. Fundal height decreases approximately 1 cm per day.

IVF

- In vitro fertilization: the assisted reproductive technology in which oocytes are retrieved, fertilized by sperm outside the body (in vitro), and the resulting embryos transferred to the uterus. Indications: tubal factor, male factor (with ICSI), endometriosis, unexplained, ovulation disorders, genetic testing, and same-sex parenthood. Steps: controlled ovarian stimulation, ovulation trigger, oocyte retrieval (transvaginal ultrasound-guided), fertilization, embryo culture (days 3-6, blastocyst), embryo transfer (fresh or frozen), and luteal phase support. Success: live birth per cycle depends on maternal age (40-50 percent <35, declining after). Risks: OHSS, multiple pregnancy, ectopic, and cost. PGT screens embryos.

Kangaroo Care (Skin-to-Skin Contact)

- Holding a newborn against the mother's bare chest, typically for at least 60 minutes, promoting physiologic stability, thermoregulation, bonding, and breastfeeding initiation. Especially beneficial for preterm and low-birth-weight infants: reduces mortality (by 40%), hypothermia, and hospital-acquired infections. Improves maternal confidence and reduces postpartum depression. Now standard practice for all newborns, including term infants in the immediate postpartum period.

Karyotyping

- A laboratory technique that produces an image (karyotype) of an individual's complete set of chromosomes, arranged in pairs by size, centromere

position, and banding pattern. Karyotyping is used to detect chromosomal abnormalities: aneuploidy (trisomy 21, 18, 13), sex chromosome abnormalities (Turner, Klinefelter), structural abnormalities (deletions, duplications, translocations), and marker chromosomes. In obstetrics, karyotyping is performed on samples obtained by chorionic villus sampling or amniocentesis, or on products of conception after miscarriage.

Ketones

- Acidic byproducts produced when the body breaks down fat for energy instead of glucose (ketogenesis). Ketones can be detected in blood and urine. In pregnancy, ketones may be elevated due to: hyperemesis gravidarum (prolonged vomiting and starvation), gestational diabetes or poorly controlled pre-existing diabetes (diabetic ketoacidosis), and prolonged labor with inadequate caloric intake. Testing for ketones (urine dipstick or blood ketone meter) is part of the assessment of women with vomiting, diabetes, or reduced oral intake in pregnancy. Significant ketonuria may indicate dehydration or metabolic decompensation requiring IV fluids and glucose.

Labor

- The process of uterine contractions leading to progressive cervical dilation and effacement and delivery of the fetus. Stages: first (latent—cervical dilation to 3-4 cm, then active—3-10 cm), second (full dilation to delivery of the infant), third (delivery of the placenta), fourth (first hour postpartum). Features of normal labor: regular contractions, cervical change, rupture of membranes. Onset: may begin spontaneously (with prelabor: engagement, bloody show, Braxton Hicks). Abnormal labor: prolonged/protracted (dystocia), requiring augmentation, operative delivery, or cesarean. Management: maternal/fetal monitoring (CTG), analgesia (nitrous, epidural), progress evaluation (partogram), and support of the second stage; immediate newborn and third-stage care.

Labour

- The process of childbirth, consisting of regular uterine contractions that cause progressive cervical effacement and dilation, leading to delivery of the baby and placenta. Three stages: First stage — from onset of labor to full cervical dilation (10 cm), divided into latent (slow dilation to 4-6 cm)

and active (rapid dilation from 4-6 cm to 10 cm) phases. Second stage — from full dilation to delivery of the baby, with passive descent and active pushing. Third stage — delivery of the placenta and membranes, active management (oxytocin + controlled cord traction) recommended. The partogram records labor progress and alerts to abnormalities.

Lactation (Breastfeeding)

– The production of milk by the mammary glands stimulated by the hormone prolactin. Colostrum is produced for the first 2-5 days (rich in IgA, proteins, and growth factors). Mature milk appears at day 5-7. The milk ejection reflex (let-down) is mediated by oxytocin. Benefits to the baby: optimal nutrition, passive immunity (IgA, lactoferrin, lysozyme), reduced risk of infections (otitis, gastroenteritis, pneumonia), SIDS, and long-term protection against obesity and diabetes. Benefits to mother: reduced risk of breast and ovarian cancer, postpartum weight loss, and uterine involution from oxytocin release.

Laparoscopy

– A minimally invasive surgical technique using a laparoscope (a thin, lighted telescope) inserted through a small incision (typically at the umbilicus) to visualize the abdominal and pelvic organs. Carbon dioxide gas is insufflated to create a working space. Additional small incisions (ports) allow insertion of instruments. In gynecology, laparoscopy is used for diagnosis and treatment of: endometriosis, ovarian cysts, ectopic pregnancy, pelvic adhesions, and tubal infertility. Also used for sterilization (tubal occlusion) and hysterectomy.

Laparotomy

– A surgical incision into the abdominal cavity, typically a midline vertical or transverse (Pfannenstiel) incision, providing wide access to the abdominal and pelvic organs. In obstetrics and gynecology, laparotomy is performed for: emergency cesarean delivery, ectopic pregnancy (ruptured), ovarian tumor (suspected malignant), pelvic abscess, hysterectomy for large fibroids or cancer, and repair of uterine rupture. Laparotomy carries greater morbidity than laparoscopy: longer recovery, more pain, higher infection risk, and increased adhesion formation.

Last Menstrual Period (LMP)

– The first day of the last normal menstrual pe-

riod, used to estimate gestational age and the due date. Requires regular menstrual cycles and reliable recall. Limitations: irregular cycles, recent oral contraceptive use, early pregnancy bleeding mistaken for menses, and poor recall. Discriminatory zone: if ultrasound dating differs from LMP dating by more than 7 days in the first trimester, 14 days in the second trimester, or 21 days in the third trimester, ultrasound dating is preferred.

Late Decelerations

– A fetal heart rate pattern with a gradual decrease (onset to nadir >30 seconds) that starts at or after the peak of the contraction and returns to baseline after the contraction ends. Associated with uteroplacental insufficiency (reduced oxygen transfer across the placenta). Recurrent late decelerations (>50% of contractions) with moderate variability require intrauterine resuscitation. Late decelerations with absent variability are Category III and indicate potential fetal acidosis. Management: maternal oxygen, position change (left lateral), IV fluids, reduce oxytocin.

Latent Phase of Labor

– The early part of the first stage of labor, from the onset of regular contractions to 6 cm cervical dilation. Characterized by slow, progressive cervical change (usually <1 cm/hour). Duration is highly variable: up to 20 hours in nulliparas and 14 hours in multiparas. Active-phase labor arrest cannot be diagnosed during the latent phase. Prolonged latent phase (>20 hours nullipara, >14 hours multipara) is managed with rest, hydration, and observation or oxytocin augmentation.

Late Preterm (34-36 weeks)

– Preterm births between 34 weeks 0 days and 36 weeks 6 days, accounting for 70% of all preterm births. Late preterm infants are at increased risk compared to term infants: respiratory distress (TTN, RDS), temperature instability, hypoglycemia, jaundice, feeding difficulties, and hospital readmission. The risk of adverse outcomes is inversely related to gestational age. Antenatal corticosteroids (betamethasone) are recommended for all preterm births <37 weeks within 7 days of expected delivery.

Laxatives

– Medications used to treat constipation by stimulating bowel movements or softening stool. In ob-

stetrics, constipation is common in pregnancy (progesterone slows bowel motility, iron supplements, and later mechanical compression) and postpartum (perineal pain, fear of damaging sutures, opioid pain relief). Types: bulk-forming (psyllium, Fybogel) — increase stool water content; osmotic (lactulose, polyethylene glycol/macrogol) — draw water into the bowel; stimulant (senna, bisacodyl) — increase peristalsis; and stool softeners (docusate). Safe in pregnancy and breastfeeding.

Leiomyoma

– Uterine fibroid: a benign smooth muscle tumor of the uterus (estrogen/progesterone-sensitive), the most common pelvic tumor in women. Locations: subserosal, intramural, submucosal (most symptomatic). Features: often asymptomatic; abnormal uterine bleeding (menorrhagia), pelvic pain/pressure, bulk symptoms (urinary frequency, constipation), infertility, pregnancy complications (pain, abruption, malpresentation). Diagnosis: pelvic exam, ultrasound (gold standard imaging), MRI. Management: asymptomatic—observation; symptomatic—medical (tranexamic acid, NSAIDs, hormonal—progestins, GnRH agonists, LNG-IUS) or surgical (myomectomy, hysterectomy), UAE (embolization), and MR-guided focused ultrasound; sarcoma risk is low.

Leopold Maneuvers

– A systematic abdominal palpation technique used to determine fetal position and presentation. Four maneuvers: (1) fundal grip identifies fetal lie (head vs breech), (2) umbilical grip locates the fetal back, (3) Pawlik grip identifies the presenting part and its position, (4) pelvic grip confirms presentation and attitude. Performed after 36 weeks with an empty bladder. Helps determine need for ultrasound confirmation.

Libido

– Sexual desire or drive, influenced by biological, psychological, and social factors. In women, libido is affected by hormonal changes (menstrual cycle, pregnancy, menopause), medical conditions (depression, thyroid disorders, PCOS), medications (SSRIs, hormonal contraceptives), and life circumstances (stress, relationship issues, fatigue). Low libido (hypoactive sexual desire disorder) is the most common female sexual complaint. Management: address un-

derlying causes, relationship counseling, psychosexual therapy, and consider testosterone therapy in selected cases (postmenopausal women).

Linea Nigra

– A dark brown or black vertical line appearing on the abdomen during pregnancy, extending from the pubic symphysis to the umbilicus or beyond. Caused by hormonal stimulation of melanocytes, resulting in hyperpigmentation. More prominent in darker-skinned women. Usually appears in the second trimester and fades weeks to months after delivery. One of many normal dermatologic changes of pregnancy along with melasma and striae gravidarum.

Listeriosis in Pregnancy

– Infection with *Listeria monocytogenes*, a foodborne Gram-positive rod. Pregnant women are 10-20 times more susceptible than the general population. Ingestion of contaminated food (deli meats, soft cheeses, unpasteurized dairy, raw sprouts). Maternal symptoms: fever, myalgias, GI symptoms (nausea, diarrhea). Fetal/neonatal infection: chorioamnionitis, preterm labor, miscarriage, stillbirth, and neonatal sepsis/granulomatosis infantiseptica. Diagnosis: blood culture, placental culture. Treatment: IV ampicillin (high dose) + gentamicin. Prevention: avoid high-risk foods during pregnancy.

Local anesthetic

– A medication that causes reversible loss of sensation in a specific area of the body without affecting consciousness. Local anesthetics work by blocking voltage-gated sodium channels in nerve cell membranes, preventing the propagation of action potentials and transmission of pain signals. Common agents: lidocaine (1-2%, most widely used), bupivacaine (longer-acting), and ropivacaine. Onset: 2-5 minutes (infiltration). Duration: 30 minutes to several hours depending on agent, dose, and use of vasoconstrictor (epinephrine prolongs action and reduces bleeding). In obstetrics: used for perineal infiltration before episiotomy repair, pudendal block, and as part of epidural/spinal anesthesia.

Lochia

– Vaginal discharge following delivery that undergoes characteristic changes over the puerperium. Lochia rubra (days 1-4): red, bloody discharge containing blood, decidual tissue, and fetal membranes. Lochia

serosa (days 5-10): pinkish-brown discharge with serous fluid, leukocytes, and organisms. Lochia alba (days 11-42): yellowish-white discharge containing mucus, leukocytes, and bacteria. The sequence reflects progressive uterine involution and healing of the placental site. Foul-smelling lochia suggests endometritis or retained products of conception. Prolonged or heavy lochia warrants evaluation for retained tissue or subinvolution. Normal total volume is approximately 200-500 mL over the first 2 weeks.

Macrosomia

- Birth weight exceeding 4000 grams (8 pounds 13 ounces) regardless of gestational age. Risk factors include maternal diabetes, obesity, post-term pregnancy, and prior macrosomia. Complications include shoulder dystocia, brachial plexus injury, clavicular fracture, and neonatal hypoglycemia. Cesarean delivery may be considered for estimated fetal weight over 4500 grams in diabetic patients or over 5000 grams in non-diabetic patients.

Magnesium Sulfate for Neuroprotection

- Intravenous magnesium sulfate administered to women in imminent preterm labor (<32 weeks) to reduce the risk of cerebral palsy and major motor dysfunction in the child. Dose: 4-6 g IV bolus, followed by 1-2 g/hour maintenance for up to 24 hours or until delivery. Mechanism: thought to stabilize cerebral blood flow, prevent excitotoxic injury, and reduce inflammation. The BEAM trial showed a 30-45% reduction in the risk of moderate-to-severe cerebral palsy. Side effects: flushing, warmth, nausea, dizziness, and respiratory depression (monitor deep tendon reflexes and respiratory rate). Contraindication: myasthenia gravis.

Malpresentation

- Any fetal presentation other than vertex (cephalic) at term. Includes breech (buttocks or feet first), face, brow, and shoulder presentations. Breech presentation occurs in 3-4% of term pregnancies and increases the risk of cord prolapse and difficult delivery. External cephalic version may be attempted at 36-38 weeks. Persistent breech presentation typically managed with cesarean delivery.

Manual Removal of Placenta

- The manual extraction of a retained placenta from

the uterine cavity. Indication: retained placenta beyond 30-60 minutes. Technique: under adequate anesthesia (regional or general), one hand inserts into the uterine cavity with fingers together (like a knife hand), and the placenta is gently separated from the uterine wall using a sweeping motion. The other hand is placed on the abdomen to stabilize the uterus. After removal, the uterus is explored to ensure complete evacuation. Oxytocin is given. Complications: hemorrhage, infection, perforation, and Asherman syndrome.

Mastitis

- Inflammation of the breast tissue, most commonly occurring during lactation (lactational mastitis, affecting 5-20 percent of breastfeeding women), typically within the first 6-12 weeks postpartum. Lactational mastitis results from milk stasis combined with bacterial infection, most frequently *Staphylococcus aureus* (including MRSA) entering through cracked or fissured nipples. Clinical presentation includes localized breast pain, erythema, warmth, swelling, induration, and systemic symptoms of fever, chills, and malaise. Diagnosis is primarily clinical. Treatment includes milk removal through continued breastfeeding or pumping (emptying the affected breast is essential), supportive measures (cold compresses between feedings, warm compresses before feedings, NSAIDs for pain), and antibiotics if symptoms are severe or persist beyond 12-24 hours of conservative management (dicloxacillin or cephalexin for 10-14 days; clindamycin for penicillin-allergic or MRSA-suspected cases). The mother should continue breastfeeding or pumping to maintain milk flow, as abrupt cessation worsens the condition and increases the risk of breast abscess. Preventive measures include proper latch technique, frequent feeding, and hand hygiene. Recurrent mastitis may require investigation for underlying ductal abnormalities or milk supply issues.

Maternal Physiologic Changes in Pregnancy

- Extensive adaptive changes across all organ systems to support the growing fetus. Key changes: plasma volume increases 40-50% (hemodilution), cardiac output increases 30-50%, heart rate increases 10-15 bpm, systemic vascular resistance decreases, tidal volume and minute ventilation increase (chronic res-

piratory alkalosis), renal blood flow increases 50% (increased GFR, decreased creatinine and BUN), and insulin resistance increases (mediated by human placental lactogen, cortisol, and growth hormone). These changes impact medication dosing, interpretation of lab values, and response to illness.

Maternal Pushing (Second Stage)

– Maternal expulsive efforts during the second stage of labor to facilitate fetal descent. Directed (closed-glottis, Valsalva) pushing: sustained breath-hold for 10 seconds with three pushes per contraction. Spontaneous (open-glottis) pushing: shorter pushes with the mother pushing when she feels an urge. Evidence: spontaneous pushing results in less perineal trauma, less fatigue, and better fetal acid-base status. Directed pushing may slightly shorten the second stage but increases perineal injury and is associated with lower umbilical cord pH.

MCA Peak Systolic Velocity (PSV)

– Doppler measurement of the peak systolic velocity in the fetal middle cerebral artery. An indicator of fetal anemia: elevated MCA PSV (>1.5 MoM) correlates with moderate-to-severe anemia. The most important application is surveillance of Rh-sensitized pregnancies (detect anemia before hydrops develops). Also used to assess fetal anemia due to parvovirus B19 infection or fetomaternal hemorrhage. MCA PSV is also used as part of the cerebroplacental ratio (CPR = MCA PI / umbilical artery PI) to assess brain sparing in IUGR.

McDonald Cerclage

– A transvaginal cervical cerclage using a purse-string suture (Mersilene tape or Prolene) placed at the cervicovaginal junction, without bladder dissection. The most common cerclage technique. Indications: cervical insufficiency (history-indicated or ultrasound-indicated short cervix <25 mm before 24 weeks). Placed at 12-14 weeks. The suture is removed at 36-37 weeks or at the onset of labor. Suture around the cervix, not through it. No flap of the bladder or rectum is created. Success rate: 80-90% for term delivery in selected patients.

Meconium Aspiration

– Meconium aspiration syndrome (MAS): aspiration of meconium-stained amniotic fluid into the fetal/neonatal airway causing airway obstruction, chemical pneumonitis, and surfactant dysfunction—respiratory distress in term/post-term infants.

Risk: fetal distress/hypoxia (passage of meconium in utero). Features: meconium-stained skin/nails, respiratory distress at birth, tachypnea, cyanosis, hyperinflation on X-ray. Management: at birth, if depressed—suction of oropharynx (routine suction not recommended for vigorous infants); support ventilation, oxygen, surfactant, and possibly ECMO for severe; complications: pneumothorax, persistent pulmonary hypertension, death. Prevention: fetal monitoring and timely intervention for distress.

Melasma

– A common hyperpigmentation disorder characterized by brown or gray-brown patches on the face, particularly the cheeks, forehead, nose, and upper lip. Also called chloasma or the mask of pregnancy.

Menstrual Cycle

– The monthly hormonal and uterine changes preparing for pregnancy, typically 21-35 days. Phases: follicular (FSH stimulates follicle growth and estradiol; endometrium proliferates), ovulation (LH surge mid-cycle, day 14, releases the oocyte), luteal (progesterone from corpus luteum supports endometrium; if no pregnancy, corpus luteum regresses), and menstruation (shedding). Hormonal control: hypothalamus GnRH $\rightarrow$ pituitary FSH/LH $\rightarrow$ ovary estradiol/progesterone $\rightarrow$ feedback. Abnormalities: anovulation, cycle irregularity (PCOS, thyroid, perimenopause), and bleeding disorders. Tracking (calendar, basal body temperature, LH kits) assists fertility or contraception; hormonal methods modify the cycle for contraception.

Menstruation

– Menses: the cyclic shedding of the endometrial lining (menstrual period) as part of the menstrual cycle, occurring with the fall in estrogen/progesterone when implantation does not occur. Normal: interval 21-35 days, duration 2-7 days, blood loss 30-80 mL. First menses = menarche (12-13 years); cessation = menopause (51 years). Abnormalities: amenorrhea (absence), oligomenorrhea, menorrhagia (heavy), metrorrhagia (irregular), dysmenorrhea (painful), and polymenorrhea. Physiology: regulated by the HPO axis (GnRH, FSH/LH, ovarian steroids). Evaluation for abnormalities: pregnancy, hormonal, structural (fibroids, polyps), and systemic causes. Hygiene, pain management, and cycle

tracking support.

Midtrimester

– The middle third of pregnancy, from 14 to 28 weeks gestation. The midtrimester is when many women feel their best: nausea and fatigue of the first trimester resolve, and the physical discomforts of the third trimester have not yet developed. Key events: fetal movements felt (quickening, around 18-20 weeks), anomaly scan (18-21 weeks), maternal serum screening, and the fetus grows rapidly. By 24 weeks, the fetus reaches viability. Midtrimester complications include miscarriage (late), cervical insufficiency, and preterm labor.

Miscarriage

– Also known as spontaneous abortion, the spontaneous loss of a pregnancy before 20 weeks of gestation, occurring in 15-20 percent of clinically recognized pregnancies. The majority (80 percent) occur in the first trimester, with risk decreasing significantly after visualization of fetal cardiac activity. Chromosomal abnormalities account for 50-60 percent of first-trimester miscarriages, most commonly autosomal trisomies (trisomy 16, trisomy 22, trisomy 21, trisomy 18, trisomy 13), monosomy X, and triploidy. Risk increases with advancing maternal age: 10 percent at age 20, 15-20 percent at age 35, 25-40 percent at age 40, and greater than 50 percent at age 45. Other causes include uterine anatomic abnormalities (septate uterus, fibroids, adhesions), maternal disorders (diabetes, thyroid disease, antiphospholipid syndrome, thrombophilias), infections (*Listeria*, *Toxoplasma*, rubella, parvovirus B19), cervical insufficiency, and environmental factors (smoking, alcohol, high caffeine). Diagnosis is classified as threatened (bleeding, closed cervix, viable pregnancy), inevitable (open cervix with bleeding), incomplete (partial tissue passage), complete (empty uterine cavity), or missed (fetal demise without expulsion). Management is expectant, medical (misoprostol), or surgical (suction evacuation) depending on clinical presentation and patient preference.

Misoprostol (Cytotec)

– A synthetic prostaglandin E1 analog used off-label for cervical ripening and labor induction. Dose: 25-50 mcg vaginally or 25-100 mcg orally q4-6h. Advantages: inexpensive, stable at room temperature, and

multiple routes of administration. Risks: uterine tachysystole (with and without FHR changes), the highest rate among induction agents. Contraindicated in patients with prior cesarean or uterine scar (increased risk of uterine rupture). The oral route has less tachysystole than vaginal. The buccal/sublingual route is also used.

Modified Biophysical Profile (Modified BPP)

– A simplified antepartum test combining the non-stress test (NST) with the amniotic fluid index (AFI). The NST assesses acute fetal status (heart rate reactivity over 20-40 minutes) and the AFI assesses chronic uteroplacental function (oligohydramnios suggests chronic hypoxia or placental insufficiency). Scoring: NST (reactive: 2, nonreactive: 0), AFI (>5 cm: 2, ≤ 5 cm: 0). The total modified BPP score is 4 (normal), 2 (equivocal, repeat in 24 hours), or 0 (abnormal, consider delivery). Equivalent to the full BPP for outcome prediction in most settings.

Molar Pregnancy

– See Hydatidiform Mole.

Montevideo Units (MVU)

– A quantitative measure of uterine contraction intensity, calculated by summing the peak contraction pressures (in mm Hg) minus the resting tone for each contraction in a 10-minute window. Adequate labor: ≥ 200 MVU (spontaneous) or ≥ 250 MVU (augmented). Measured with an intrauterine pressure catheter (IUPC). Low MVU may prompt oxytocin augmentation. The concept helps distinguish true arrest of labor from inadequate contractions.

Montgomery Tubercles

– Small, raised sebaceous glands visible on the areola of the breast during pregnancy and lactation. They appear as small bumps surrounding the nipple and secrete an oily substance that lubricates the nipple and areola, protecting against infection. Their prominence increases during pregnancy under hormonal influence. Often mistaken for pathological lesions but are normal anatomic structures. First described by William Fetherston Montgomery in 1837.

Morning Sickness

– Nausea and vomiting of pregnancy (NVP): nausea (and sometimes vomiting) commonly in the

first trimester (6-12 weeks), typically resolving by 14-16 weeks; multifactorial (hCG, estrogen, progesterone, odor sensitivity). Management: dietary changes (small frequent meals, ginger, bland foods, avoid triggers), pyridoxine (vitamin B6) $\pm$ doxylamine (first-line pharmacotherapy), and reassurance. Severe/persistent vomiting with weight loss, dehydration, and electrolyte disturbance = hyperemesis gravidarum—requires IV fluids, antiemetics (ondansetron, metoclopramide), electrolyte replacement, thiamine, and monitoring; exclude other causes (multiple pregnancy, molar pregnancy, GI/hepatic disease, thyroid).

Multiple Pregnancy

- Gestation with more than one fetus: twins (most common), triplets, higher order. Types: dizygotic (two eggs, two placentas—fraternal, more common, familial and increased with IVF) vs. monozygotic (one egg split—identical, sharing determined by timing: dichorionic-diamniotic, monochorionic-diamniotic, monoamniotic, conjoined). Risks: preterm birth, low birth weight, preeclampsia, gestational diabetes, twin-twin transfusion syndrome (monochorionic), IUGR, congenital anomalies, and fetal loss. Diagnosis: ultrasound (chorionicity critical). Management: high-risk antenatal care, serial growth scans, prevention/treatment of preterm labor, planned delivery (vaginal for low-risk vertex twins; cesarean for others), and postpartum surveillance.

Naegele Rule

- A formula for estimating the due date (estimated date of delivery, EDD): add 7 days to the first day of the last menstrual period (LMP), then add 9 months (or subtract 3 months). Example: LMP January 1 yields EDD October 8. Assumes a 28-day cycle with ovulation on day 14. The rule is most accurate with regular cycles and confirmed LMP. First-trimester ultrasound dating is more accurate and preferred when LMP is uncertain or cycles are irregular.

Neonatal Resuscitation

- The systematic approach to stabilizing a newborn after delivery, guided by the Neonatal Resuscitation Program (NRP). Steps: (1) initial steps (warm, dry, stimulate, position, clear airway if needed), (2) assess breathing, heart rate, and color, (3) posi-

tive pressure ventilation (PPV) with a bag-mask if gasping or HR <100 bpm, (4) chest compressions (3:1 ratio with ventilations) if HR <60 bpm despite PPV, (5) endotracheal intubation if needed, (6) epinephrine (IV or ET) if HR remains <60 bpm, and (7) volume expansion if suspected hypovolemia. The transition from fetal to neonatal circulation requires successful lung aeration and closure of fetal shunts.

Nitrous Oxide for Labor

- A 50:50 mixture of nitrous oxide and oxygen (Entonox) inhaled by the mother during labor for analgesia. Self-administered via a mask or mouthpiece; the woman controls her own dosing, taking a breath 30 seconds before a contraction. Advantages: noninvasive, rapid onset and offset, no effect on the baby at low concentrations, and the mother can ambulate. Disadvantages: incomplete pain relief (does not eliminate pain, only modulates it), can cause nausea, dizziness, and drowsiness. Contraindications: pneumothorax, bowel obstruction, and vitamin B12 deficiency. Widely used in the UK and Canada; increasingly available in US hospitals.

Noninvasive Prenatal Testing (NIPT)

- See Cell-Free Fetal DNA (cfDNA) Screening.

Non-Stress Test

- A fetal heart rate monitoring technique assessing fetal heart rate reactivity over 20-40 minutes. Normal (reactive) tracing shows at least 2 fetal heart rate accelerations of 15 beats per minute above baseline lasting at least 15 seconds within a 20-minute period. Non-reactive tracings may indicate fetal hypoxia or sleep cycle. Used for antepartum surveillance in high-risk pregnancies, including post-dates pregnancy and maternal conditions affecting fetal well-being.

Nuchal Translucency (NT) Screening

- An ultrasound measurement of the fluid-filled space at the posterior fetal nuchal region, performed at 11-14 weeks (crown-rump length 45-84 mm). Increased NT (>95th percentile or >3.0-3.5 mm) is associated with trisomies 21, 18, 13, Turner syndrome, and cardiac defects. Combined with maternal serum biomarkers (PAPP-A, free β -hCG) in the first-trimester combined screen, it detects 85-90%

of Down syndrome. NT measurement requires certified training and quality assurance (Fetal Medicine Foundation).

Nutrition in Pregnancy

– A balanced diet providing adequate calories, protein, vitamins, and minerals to support maternal and fetal health. Additional caloric needs: 300 kcal/day in the second and third trimesters. Key nutrients: folic acid (400 mcg/day), iron (27 mg/day), calcium (1000 mg/day), vitamin D (600 IU/day), iodine (220 mcg/day), DHA (200-300 mg/day). Foods to avoid: raw/undercooked meat and fish (listeriosis, toxoplasmosis), high-mercury fish (shark, swordfish, king mackerel), unpasteurized dairy, and excess caffeine (<200 mg/day).

Obstetric Anal Sphincter Injury (OASIS)

– Third- and fourth-degree perineal lacerations involving the anal sphincter complex. Incidence: 0.5-5% of vaginal deliveries. Risk factors: midline episiotomy (increases risk 2-3 fold), operative vaginal delivery, primiparity, macrosomia, and occiput posterior position. Repair: immediate repair in the delivery room under adequate anesthesia (regional or general). End-to-end or overlap repair of the EAS (3-0 PDS), repair of the IAS if involved. Post-operative: broad-spectrum antibiotics, stool softeners (lactulose, docusate), and avoid constipation. Follow-up: pelvic floor physiotherapy, ultrasound, or MRI for persistent symptoms.

Obstetrician

– A medical doctor who specializes in the care of women during pregnancy, labor, and the postpartum period (obstetrics). Obstetricians manage normal and high-risk pregnancies, perform cesarean deliveries and assisted vaginal deliveries, and treat pregnancy complications (pre-eclampsia, gestational diabetes, hemorrhage, preterm labor). In the UK, obstetrics and gynecology are combined as a single specialty (O&G). Training: 2 years foundation training + 7 years specialty training to become a consultant obstetrician and gynecologist.

Obstetrics

– The branch of medicine and surgery concerned with the care of women during pregnancy, childbirth, and the postpartum period. Obstetricians manage normal and high-risk pregnancies, perform

antenatal screening and diagnosis, conduct deliveries (spontaneous vaginal, assisted vaginal—forceps, ventouse, and caesarean section), and manage obstetric emergencies (pre-eclampsia/eclampsia, hemorrhage, sepsis, shoulder dystocia, cord prolapse, uterine rupture). Antenatal care in the UK follows a schedule of 10 appointments for nulliparous women and 7 for multiparous, including ultrasound dating (10–13 weeks), anomaly scan (18–21 weeks), screening for aneuploidy, gestational diabetes, and infections. Maternal medicine deals with pre-existing medical conditions in pregnancy (diabetes, hypertension, cardiac disease, epilepsy). The specialty has close links with midwifery (midwife-led care for low-risk pregnancies), neonatology, and fetal medicine.

Occiput Posterior (OP) Position

– The fetal head presenting with the occiput oriented toward the maternal sacrum (back-to-back position). Occurs in 15-20% of labors, about half rotate spontaneously to OA by delivery. Persistent OP is associated with prolonged labor (especially the second stage), arrest of descent, severe back pain (back labor), and higher rate of operative vaginal delivery and cesarean. Management: maternal positioning (hands and knees, pelvic rocking), manual rotation (hands or forceps), and vacuum or forceps delivery if needed.

Occiput Transverse (OT) Position

– The fetal head presenting with the sagittal suture oriented transversely. Usually the normal descent position; most rotate to OA with contractions. When persistent, it can cause protracted descent and prolonged second stage. Management: maternal position changes, and if persistent, manual rotation to OA or direct OP extraction with forceps/vacuum. Deep transverse arrest: OT at the outlet, more common with an android pelvis and requires rotation before delivery.

Oestrogen

– The primary female sex hormone, produced mainly by the ovaries (granulosa cells of developing follicles) and in smaller amounts by adipose tissue, the adrenal glands, and the placenta during pregnancy. The three major forms: estradiol (E2, most potent, predominant in reproductive-age women), estrone (E1, predominant after menopause), and estriol (E3, produced by the placenta). Functions: development

of secondary sexual characteristics, regulation of the menstrual cycle, endometrial proliferation, breast development, bone density maintenance, and cardiovascular health. Used in HRT, combined oral contraceptives, and treatment of anovulation.

Oligohydramnios

– Insufficient amniotic fluid volume, defined as amniotic fluid index less than 5 cm or single deepest pocket less than 2 cm. Causes include fetal renal anomalies, post-term pregnancy, premature rupture of membranes, maternal dehydration, and placental insufficiency. Complications include umbilical cord compression, fetal growth restriction, and pulmonary hypoplasia. Management includes amniotic fluid infusion, maternal hydration, and delivery when indicated.

One-Hour Glucose Challenge Test (GCT)

– A screening test for gestational diabetes mellitus (GDM) performed at 24-28 weeks. The patient drinks 50 g of glucose (regardless of fasting state), and plasma glucose is measured at 1 hour. Threshold: ≥ 130 -140 mg/dL (7.2-7.8 mmol/L) is considered positive, warranting diagnostic 3-hour oral glucose tolerance test (OGTT). Sensitivity: 80-90% depending on the threshold used. A negative test (glucose < 130 mg/dL) excludes GDM. Earlier testing (first trimester) is performed in high-risk women (obesity, prior GDM, family history of diabetes).

Operative Vaginal Delivery

– Vaginal delivery assisted by vacuum or forceps. Indications: prolonged second stage, suspected fetal compromise, need to shorten the second stage for maternal benefit (exhaustion, cardiac disease, hypertensive crisis). Prerequisites: full dilatation, ruptured membranes, engaged head (station $\geq +2$), known fetal position, adequate pelvis, and consent. Vacuum: soft or rigid cup applied to the fetal occiput. Forceps: two blades applied to the fetal head (outlet, low, or mid-pelvic). Success rate: 80-95%. Complications: maternal (perineal lacerations, anal sphincter injury, vaginal lacerations, hematoma) and neonatal (cephalohematoma, subgaleal hemorrhage with vacuum, facial nerve palsy with forceps).

Oral Contraceptive

– Birth control pill: combined oral contraceptive (COC—ethinylestradiol + progestin) or progestin-

only pill (POP/minipill). Mechanisms: ovulation inhibition, cervical mucus thickening, endometrial change. Benefits: effective (91-99 percent with typical/perfect use), cycle regulation, reduced dysmenorrhea/menorrhagia, acne, ovarian/endometrial cancer prevention, and PMDD. Risks: VTE (estrogen—higher with smoking, age > 35 , obesity, migraine with aura), hypertension, and rare hepatic effects. Contraindications: VTE history, thrombophilia, migraine with aura, estrogen-sensitive cancer, liver disease, and smokers > 35 . POP is safe during breastfeeding. Prescribed with counseling and follow-up; missed pills reduce efficacy (backup contraception).

Oral Contraceptives

– Hormonal medications taken orally to prevent pregnancy. Combined oral contraceptive pills (COCP) contain oestrogen (ethinylestradiol 20–35 μ g) and a progestogen (levonorgestrel, norethisterone, drospirenone, desogestrel). Mechanisms: inhibit ovulation (suppression of LH surge), thicken cervical mucus (impedes sperm penetration), and alter endometrial receptivity. Perfect-use failure rate: 0.3% per year; typical-use failure rate: 7–9%. Benefits: cycle regulation, reduced dysmenorrhoea, decreased ovarian/endometrial cancer risk (protective effect persists > 30 years after stopping), reduced acne, and improved bone density. Contraindications (WHO categories 3–4): age ≥ 35 and smoking ≥ 15 cigarettes/day, uncontrolled hypertension, migraine with aura, history of VTE, breast cancer, liver disease. Cardiovascular risks: increased VTE risk (3–9 per 10,000 woman-years vs 1–5 in non-users). Progestogen-only pill (POP, 'mini-pill') contains desogestrel 75 μ g or norethisterone 350 μ g; strict timing required (within 3-hour window); safe for use during breastfeeding and in women with contraindications to oestrogen.

Ovarian Cyst

– A fluid-filled sac within or on the ovary, most commonly functional (follicular or corpus luteum cysts) related to the menstrual cycle. Usually asymptomatic; can present with pelvic pain, pressure, and bloating. Complications: rupture, hemorrhage, torsion (sudden severe pain with nausea/vomiting). Diagnosis: transvaginal ultrasound (assess size, morphology, septations, solid components, and vascular-

ity). Simple cysts <5 cm in reproductive-age women are usually benign. Treatment: observation for simple cysts; surgical removal for complex/malignant features or persistent large cysts.

Ovarian Pregnancy

– A rare ectopic pregnancy (0.5-3%) implanted on the ovary. Diagnosis: Spiegelberg criteria (ipsilateral fallopian tube intact, gestational sac on the ovary, connected to the ovary by the uteroovarian ligament, ovarian tissue in the sac wall). Treatment: ovarian wedge resection or oophorectomy.

Ovarian Torsion

– Twisting of the ovary (and often the fallopian tube) on its vascular pedicle, causing obstruction of blood flow—a gynecologic emergency. Risk: ovarian cysts/tumors (especially >5 cm), longer utero-ovarian ligament, younger women, pregnancy. Features: sudden severe unilateral lower abdominal/pelvic pain, nausea/vomiting, and a palpable adnexal mass; may be intermittent (partial torsion) or with fever/infection. Diagnosis: clinical suspicion; ultrasound with Doppler (absent/reduced arterial or venous flow, enlarged ovary), CT/MRI. Management: urgent surgery (laparoscopy/laparotomy) with detorsion (ovarian preservation) ± oophoropexy; necrosis requires oophorectomy. Delayed treatment risks ovarian loss and infertility.

Oxytocics

– A class of medications that stimulate uterine contractions, used for induction and augmentation of labor and prevention/treatment of postpartum hemorrhage. Oxytocin (Syntocinon) — synthetic analog of endogenous oxytocin, administered IV infusion for labor induction or IM/IV for PPH prevention. Ergometrine — causes sustained tetanic uterine contraction, used IM for PPH, contraindicated in hypertension and preeclampsia. Carboprost (Hemabate) — prostaglandin F₂-alpha analog, IM for refractory PPH. Misoprostol (Cytotec) — PGE₁ analog, oral/sublingual/rectal for PPH prevention and treatment in resource-limited settings.

Oxytocin Infusion

– Synthetic oxytocin (Pitocin) administered intravenously for induction or augmentation of labor. Standard dosing: start at 1-2 mU/min, increase by 1-2 mU/min every 15-30 minutes to achieve 200-250

Montevideo units (MVU, measured by IUPC). Maximum dose: 40 mU/min. After achieving adequate labor, the dose may be maintained or decreased. Complications: uterine tachysystole (>5 contractions/10 min, leading to fetal hypoxia), hyperstimulation (tachysystole with nonreassuring FHR), water intoxication (antidiuretic effect at high doses), and uterine rupture (rare, increased risk with prior cesarean). Stop or reduce oxytocin if hyperstimulation occurs.

Pap Smear

– Papanicolaou test (cervical cytology): a screening test collecting cervical cells (conventional or liquid-based) to detect precancerous cervical changes (CIN) and cancer, usually combined with HPV DNA testing (co-testing). Screening: start at 21-25 years (age varies), every 3-5 years depending on modality and age; cytology alone or cytology + HPV. Abnormal results: ASC-US, LSIL, HSIL, AGC—managed by HPV triage, colposcopy, or repeat testing per guidelines; CIN2-3 treated (LEEP, cryotherapy, conization). HPV vaccination prevents most cervical cancers. Reduced incidence/mortality from screening programs. Follow-up and surveillance after abnormal results are essential.

Partograph (Partogram)

– A graphic record of cervical dilatation, fetal descent, and uterine contractions over time, used to monitor labor progress and identify labor abnormalities. The WHO partograph has an alert line (1 cm/hour dilatation) and an action line (4 hours after the alert line, indicating need for intervention). Components: cervical dilatation (plotted against time), fetal descent (station), contractions (frequency and duration), FHR, and maternal vital signs. The partograph reduces prolonged labor, augmentation rates, and intrapartum stillbirths in low-resource settings. Modern use: most centers now use the Zhang labor curve (active phase at 6 cm).

Parturition (Childbirth)

– The process of giving birth, encompassing three stages: (1) First stage: from the onset of regular uterine contractions (cervical effacement and dilatation) to full dilation (10 cm). Latent phase—slow dilation (0-4 cm) over hours, variable duration. Active phase—more rapid dilation (4-10 cm), typically 1-

1.5 cm/hour in nulliparous women. (2) Second stage: from full dilation to delivery of the baby. Passive phase—descent of the presenting part without active pushing. Active phase—maternal pushing with contractions. Duration: up to 2 hours in nulliparous (3 hours with epidural), 1 hour in multiparous (2 hours with epidural). (3) Third stage: delivery of the placenta and membranes. Active management (oxytocin, controlled cord traction) reduces the risk of postpartum hemorrhage. Signs of labour: regular painful contractions, cervical dilation and effacement, show (blood-stained mucus), and spontaneous rupture of membranes (SROM). Induction of labour (IOL) is indicated for post-term pregnancy, pre-eclampsia, diabetes, intrauterine growth restriction, and premature rupture of membranes. Methods: prostaglandins (dinoprostone, misoprostol), balloon catheter, amniotomy, and oxytocin infusion. Assisted vaginal delivery: forceps or ventouse (vacuum) for prolonged second stage, fetal distress, or maternal exhaustion. Caesarean section: for failed IOL, fetal distress, malpresentation, placenta praevia, and previous caesarean section (VBAC may be attempted).

Pelvic Floor Health and Disorders

– The pelvic floor is a musculofascial sling (levator ani, coccygeus, and surrounding fascia) spanning the pelvic outlet, supporting the pelvic organs (bladder, uterus, rectum), maintaining continence, and facilitating urination, defecation, and sexual function. Pelvic floor disorders include pelvic organ prolapse (cystocele, rectocele, uterine prolapse, vaginal vault prolapse—affecting up to 50% of parous women), stress urinary incontinence (leakage with cough, sneeze, exercise—treated with pelvic floor muscle training/Kegel exercises, pessaries, or midurethral sling), overactive bladder (urgency, frequency, urge incontinence—treated with behavioral modification, anticholinergics, beta-3 agonists), and pelvic pain syndromes (levator ani spasm, pudendal neuralgia). Risk factors: pregnancy/childbirth (vaginal delivery, especially with forceps or prolonged second stage), aging, obesity, chronic constipation, and heavy lifting. Diagnosis: Pelvic Organ Prolapse Quantification (POP-Q) system, urodynamic studies, and MRI defecography for complex prolapse. Treatment progresses from conservative (pelvic floor phys-

ical therapy, biofeedback, vaginal pessaries, lifestyle modification) to surgical (native tissue repair, sacrocolpopexy, colpocleisis for frail patients, sling procedures for SUI).

Pelvic Inflammatory Disease

– Infection and inflammation of the upper female genital tract (uterus, fallopian tubes, ovaries, and peritoneum), most commonly caused by sexually transmitted infections (*Chlamydia trachomatis*, *Neisseria gonorrhoeae*). Presents with lower abdominal pain, cervical motion tenderness, adnexal tenderness, and fever. Complications: tubo-ovarian abscess, infertility, ectopic pregnancy, and chronic pelvic pain. Diagnosis: clinical criteria (CDC minimal criteria: cervical motion, uterine, or adnexal tenderness). Treatment: empiric broad-spectrum antibiotics (ceftriaxone + doxycycline +/- metronidazole).

Pelvic Inlet

– The superior opening of the true pelvis, bounded by the sacral promontory posteriorly, the arcuate lines of the ilia laterally, and the symphysis pubis anteriorly. Its anteroposterior diameter (true conjugate) normally measures at least 11 cm. The transverse diameter is typically 13 cm. Contraction of the pelvic inlet (cephalopelvic disproportion) may prevent engagement of the fetal head, necessitating cesarean delivery.

Pelvic Organ Prolapse

– POP: descent of the pelvic organs through the vagina due to pelvic floor weakness. Types: cystocele (anterior—bladder), rectocele (posterior—rectum), uterine prolapse (apical), enterocele, and vault prolapse (post-hysterectomy). Risk factors: vaginal delivery (especially instrumental), multiparity, aging/menopause, obesity, chronic cough/constipation, and heavy lifting. Features: vaginal bulge/pressure, urinary incontinence/voiding difficulty, fecal symptoms, dyspareunia, and back pain; graded by POP-Q. Management: asymptomatic—observation; symptomatic—pelvic floor physiotherapy, pessary, and surgery (repair, sacrocolpopexy, hysterectomy); address contributing factors.

Pelvic Outlet

– The inferior opening of the true pelvis, bounded by the pubic symphysis, ischial tuberosities, sacrotuberous ligaments, and coccyx. Normal anteroposterior

diameter is 11-13 cm (from the lower border of the pubic symphysis to the tip of the coccyx), and the transverse diameter (between the ischial tuberosities) is approximately 10-11 cm. A narrow pelvic outlet can cause shoulder dystocia or obstructed labour. Assessment of the pelvic outlet is part of clinical pelvimetry examination during prenatal care and is relevant when planning vaginal delivery, particularly in cases of suspected cephalopelvic disproportion.

Pelvic Pain

– Pain localized to the lower abdomen, pelvis, or perineum, lasting <3 months (acute) or >3–6 months (chronic), and can arise from gynecologic, urologic, gastrointestinal, musculoskeletal, or psychologic causes. Acute causes: ectopic pregnancy (life-threatening emergency), pelvic inflammatory disease (PID—sexually transmitted, polymicrobial; treated with antibiotics), ovarian torsion (sudden severe pain, adnexal mass; surgical emergency), acute cystitis, appendicitis, and diverticulitis. Chronic pelvic pain (CPP) affects 15% of women, with common etiologies: endometriosis (endometrial glands outside uterus, cyclic pain, dyspareunia, dysmenorrhea; laparoscopy for diagnosis; medical or surgical management), interstitial cystitis/bladder pain syndrome (bladder pressure/pain with filling, urgency, frequency), irritable bowel syndrome, pelvic floor myofascial pain, vulvodynia, and adenomyosis. Evaluation: bimanual exam, pregnancy test, imaging (transvaginal ultrasound, MRI, CT), laparoscopy for suspected endometriosis, and multidisciplinary assessment. Multimodal treatment: NSAIDs, hormones (OCPs, GnRH agonists for endometriosis), physical therapy, trigger point injections, CBT, and nerve blocks.

Percutaneous Umbilical Blood Sampling (PUBS)

– Also called cordocentesis. An invasive procedure for fetal blood sampling (cardocentesis) from the umbilical vein under ultrasound guidance, typically performed after 18-20 weeks. Indications: fetal anemia (Rh isoimmunization, parvovirus B19, hemoglobin Bart), fetal platelet disorders (immune thrombocytopenia), rapid karyotyping (late gestation), and fetal infection assessment (toxoplasmosis, CMV, parvovirus). Risks: fetal loss (1-2%), bleeding from the

puncture site, bradycardia, and cord hematoma.

Perineal Laceration

– Tearing of the perineum during vaginal delivery. First degree: skin only (perineal skin, fourchette). Second degree: perineal muscles (bulbocavernosus, transverse perineal) without anal sphincter involvement. Third degree: anal sphincter injury—3a (<50% of EAS), 3b (>50% of EAS), 3c (both EAS and IAS). Fourth degree: extends through the anal sphincter into the rectal mucosa. Risk factors: primiparity, operative vaginal delivery, midline episiotomy, large baby, and precipitous delivery. Repair: absorbable sutures, layers corresponding to the injury.

Perineal Protection

– Techniques used during the second stage to minimize perineal trauma (lacerations, episiotomy). Manual protection: the attendant's hand applies gentle pressure to the fetal head to control the speed of delivery (not too fast), supporting the perineum and flexing the fetal head. Warm compresses applied to the perineum during crowning may reduce third- and fourth-degree lacerations. Maternal pushing efforts should be gentle during crowning to allow the perineum to stretch gradually. Perineal massage in the second stage may reduce trauma.

Perineal Tear

– Laceration of the perineum during vaginal delivery, classified by degree: first degree (skin only), second degree (perineal muscles), third degree (sphincter complex involvement), and fourth degree (rectal mucosa). Most deliveries involve first or second degree tears. Third and fourth degree tears risk fecal incontinence. Risk factors include nulliparity, operative delivery, and midline episiotomy. Repair under local anesthesia with absorbable suture.

Perineum

– The diamond-shaped area between the pubic symphysis, coccyx, and ischial tuberosities, containing the urogenital and anal triangles. The urogenital triangle contains the external genitalia and urethral opening; the anal triangle contains the anus and coccygeus muscles. During delivery, the perineum stretches to allow passage of the fetus. Perineal tears classified as first through fourth degree.

Peripartum Cardiomyopathy

– See Postpartum Cardiomyopathy.

Placental Abruptio

– Premature separation of the placenta from the uterine wall before delivery, occurring in 0.5-1% of pregnancies. Risk factors: hypertension, preeclampsia, smoking, cocaine use, trauma, prior abruptio, and thrombophilia. Presents with vaginal bleeding (concealed or revealed), abdominal pain, uterine tenderness, and uterine hypertonicity (board-like abdomen). Fetal distress may be present. Complications: maternal hemorrhage, DIC (due to release of thromboplastin), fetal hypoxia, and fetal death. Diagnosis: clinical; ultrasound (retroplacental clot, sensitivity limited). Management: immediate delivery regardless of gestational age if maternal or fetal compromise. Severe abruptio: emergency cesarean, blood transfusion, and coagulopathy management.

Placental Accreta Spectrum

– Abnormal placental attachment to the myometrium, ranging from accreta (adherent to decidua basalis) to increta (invading myometrium) to percreta (invading through serosa). Major risk factor is prior cesarean section with anterior placenta previa. Diagnosis by prenatal ultrasound or MRI, with findings including loss of the clear zone between the placenta and myometrium, abnormal placental lacunae, turbulent flow on Doppler, and increased vascularity. Management requires a multidisciplinary team approach with planned cesarean hysterectomy, as attempted manual removal of the placenta leads to massive hemorrhage. Conservative management (leaving the placenta in situ) may be considered in carefully selected cases but carries risks of infection, delayed hemorrhage, and sepsis. Maternal mortality is approximately 5-10%, primarily from hemorrhage. The rising incidence parallels the increasing cesarean delivery rate.

Placental Separation Signs

– Clinical signs indicating the placenta has separated from the uterine wall and is ready for delivery. Classic signs: lengthening of the umbilical cord (cord lengthens as the placenta descends), a sudden gush of blood, and uterine elevation and firming (the uterus rises and becomes globular as the placenta moves into the lower segment). The mother may feel an urge to push. Manual exam may show the placenta in the vagina. The Brandt-Andrews maneuver (controlled cord traction) is performed after

signs of separation are observed.

Placenta Praevia

– Placental implantation over or near the internal cervical os, affecting approximately 0.5% of pregnancies at term. Risk factors: previous cesarean section (risk increases with number of CS), placenta praevia in a prior pregnancy, multiple gestation, advanced maternal age (>35), smoking, cocaine use, and IVF. Classification per ultrasound: complete (placenta covers the os completely), partial (covers the os partially when dilated), marginal (placental edge reaches but does not cover the os), and low-lying (placental edge within 20 mm of the os). Presentation: painless, bright red vaginal bleeding in the second half of pregnancy (typically after 28 weeks—sentinel bleed). Diagnosis is by transvaginal ultrasound (accurate, safe—no risk of provoking bleeding). Management: (1) Antepartum: hospitalisation for significant bleeding, corticosteroids (betamethasone 12 mg IM $\times 2$, 24 hours apart) for fetal lung maturity if preterm, anti-D immunoglobulin for Rh-negative women, avoid vaginal examination until placenta praevia is excluded. (2) Delivery: elective cesarean section at 36–37 weeks (increased bleeding risk), or earlier if bleeding is heavy. If the placenta is anterior and there is a prior CS scar, assess for placenta accreta spectrum (MRI or Doppler ultrasound). Complications: massive obstetric hemorrhage (blood transfusion often required), placenta accreta/increta/percreta, preterm delivery, and disseminated intravascular coagulation.

Placenta Previa

– A condition where the placenta implants in the lower uterine segment, partially or completely covering the internal cervical os. Classified as complete (total), partial, marginal, or low-lying. Major risk factor is prior cesarean section. Presents with painless, bright red vaginal bleeding in the third trimester. Diagnosis by transvaginal ultrasound. Management includes pelvic rest, corticosteroids for lung maturity, and cesarean delivery for complete previa.

Polyhydramnios

– Excess amniotic fluid volume, defined as amniotic fluid index greater than 24 cm or single deepest pocket greater than 8 cm. Occurs in 1-2% of pregnancies. Causes include gestational diabetes, fetal

anomalies (GI atresia, neural tube defects), chromosomal abnormalities, and idiopathic. Complications include preterm labor, preterm premature rupture of membranes, cord prolapse, and malpresentation. Mild cases managed expectantly; severe cases may require amnioreduction.

Postpartum Blues

– A transient, self-limited condition affecting 50-80% of women, characterized by mood swings, tearfulness, irritability, and anxiety beginning 2-4 days after delivery and resolving within 2 weeks. No psychomotor disturbance or suicidal ideation. Treatment: reassurance, support, and rest. No pharmacotherapy needed. Differentiated from PPD by timing, duration, and lack of functional impairment. Women with postpartum blues are at increased risk of developing PPD and should be followed closely.

Postpartum Cardiomyopathy (Peripartum Cardiomyopathy)

– An idiopathic dilated cardiomyopathy presenting with heart failure in the last month of pregnancy or within 5 months of delivery. Incidence: 1:1000-1:4000 live births. Risk factors: advanced maternal age, African descent, multiple gestation, hypertension, and preeclampsia. Presents: dyspnea, orthopnea, edema, fatigue, and chest pain. Diagnosis: echocardiography (LVEF <45%, LV dilatation). Management: standard heart failure therapy (beta-blockers, diuretics, ACE inhibitors/ARBs after delivery). Bromocriptine may improve outcomes (prolactin inhibition). Recovery: 50-60% recover LVEF within 6 months. Prognosis: worse in those with LVEF <30% at diagnosis.

Postpartum Depression (PPD)

– A major depressive episode occurring within 4 weeks of delivery, affecting 10-15% of postpartum women. Symptoms persist >2 weeks and include depressed mood, anhedonia, sleep disturbance (insomnia despite exhaustion), appetite changes, fatigue, impaired concentration, guilt, and thoughts of harming self or the baby. Onset: most common within the first 3 months. Risk factors: prior depression, PPD in a previous pregnancy, stressful life events, lack of social support, and infant difficulties. Screening: Edinburgh Postnatal Depression Scale (EPDS, cutoff ≥ 10). Treatment: cognitive behavioral therapy (CBT), SSRIs (sertraline, citalopram,

fluoxetine — compatible with breastfeeding), and social support.

Postpartum Hemorrhage

– Blood loss >500 mL after vaginal delivery or >1000 mL after cesarean section, the leading cause of maternal mortality worldwide. Causes: uterine atony (most common, 80%), retained placenta, genital tract trauma (lacerations, episiotomy), and coagulopathy. Presents with heavy vaginal bleeding, hypotension, tachycardia, and pallor. Management: uterine massage, bimanual compression, uterotonic medications (oxytocin, misoprostol, methylergonovine, carboprost), balloon tamponade, uterine artery embolization, and surgical interventions (B-lynch suture, hysterectomy) for refractory cases.

Postpartum Hemorrhage (Secondary)

– Excessive bleeding occurring between 24 hours and 12 weeks postpartum. Causes: retained products of conception (most common), endometritis, subinvolution of the placental site, and coagulopathy. Presents with heavy or prolonged bleeding, cramping, and passing clots. Diagnosis: ultrasound (retained tissue, thickened endometrium). Management: uterine evacuation (D&C), antibiotics, uterotonics, and rarely, uterine artery embolization. Retained products of conception can be missed if the ultrasound is performed too early (endometrial stripe not reliable before 2 weeks).

Postpartum Infection

– Infections occurring after delivery, a leading cause of maternal morbidity. Types: endometritis (most common, especially after cesarean), wound infection (cesarean incision, episiotomy, perineal laceration), urinary tract infection, mastitis, septic pelvic thrombophlebitis, and pneumonia. Risk factors: prolonged ROM, multiple vaginal exams, cesarean section, chorioamnionitis, and retained products of conception. Presentation: fever ($\geq 38^\circ\text{C}$ after the first 24 hours postpartum), uterine tenderness, foul lochia, and wound erythema/drainage. Treatment: broad-spectrum antibiotics (gentamicin + clindamycin for endometritis, cephalexin for wound infection).

Postpartum Psychosis

– A rare but severe psychiatric emergency (1-2 per 1000 deliveries) characterized by the acute onset

of delusions, hallucinations, disorganized behavior, confusion, and mood swings (mania or depression) within 1-4 weeks postpartum. Risk factors: bipolar disorder (50% risk of recurrence in the postpartum period), prior postpartum psychosis, and a family history of bipolar disorder. High risk of infanticide and suicide requiring immediate psychiatric hospitalization. Treatment: mood stabilizers (lithium), antipsychotics (olanzapine, haloperidol), and ECT for severe cases. Breastfeeding considerations: lithium is relatively contraindicated; antipsychotics are preferred.

Postpartum Thyroiditis

– Autoimmune thyroid inflammation presenting within the first year postpartum (typically 2-6 months). Incidence: 5-10% of women, especially those with positive TPO antibodies (50-70% risk). Triphasic pattern: thyrotoxic phase (2-4 months, due to destructive release of stored thyroid hormone), followed by hypothyroid phase (4-8 months), followed by return to euthyroid (80%). The thyrotoxic phase may be mistaken for postpartum depression (fatigue, palpitations, heat intolerance). Treatment: beta-blockers for thyrotoxic symptoms, levothyroxine for hypothyroidism. Up to 30% develop permanent hypothyroidism. Recurrence in future pregnancies is common (70%).

Postterm Pregnancy

– Pregnancy that extends beyond 42 weeks (294 days) of gestation, occurring in 5-10% of pregnancies. Risk factors: prior postterm pregnancy, inaccurate dating, male fetus, and obesity. Complications: increased perinatal mortality (2-3 fold), meconium aspiration syndrome, macrosomia with shoulder dystocia, oligohydramnios (leading to cord compression), and placental insufficiency. Management: accurate dating (first-trimester ultrasound), antepartum surveillance (BPP, NST, AFI) starting at 41 weeks. Induction of labor is recommended by 41-42 weeks to reduce perinatal complications.

Preconception Counseling

– Counseling provided to women of reproductive age before pregnancy to optimize outcomes. Components: folic acid supplementation (400 mcg, 4-5 mg for high risk), confirmation of immunity (rubella, varicella), management of chronic conditions (diabetes HbA1c <6.5%, hypertension, epilepsy, thy-

roid disease), medication review (stop teratogens: isotretinoin, valproate, ACE inhibitors), vaccinations (MMR, varicella, hepatitis B, Tdap, influenza), healthy weight, smoking/alcohol cessation, genetic carrier screening (cystic fibrosis, spinal muscular atrophy, hemoglobinopathies per ethnicity), and reproductive life planning.

Preeclampsia

– A pregnancy-specific hypertensive disorder defined as new-onset hypertension (blood pressure 140/90 mmHg or higher) after 20 weeks gestation with proteinuria or other end-organ damage. Risk factors include nulliparity, advanced maternal age, obesity, chronic hypertension, diabetes, multiple gestation, preeclampsia in a prior pregnancy, and thrombophilia. Pathophysiology involves abnormal placentation, endothelial dysfunction, and systemic inflammatory response. Diagnosis requires BP $\geq 140/90$ on two occasions at least 4 hours apart with proteinuria ≥ 300 mg/24 hours or protein/creatinine ratio ≥ 0.3 . In the absence of proteinuria, preeclampsia is diagnosed if new-onset hypertension is accompanied by thrombocytopenia, renal insufficiency, impaired liver function, pulmonary edema, or cerebral/visual symptoms. Management includes antihypertensives for BP $\geq 160/110$ mmHg (labetalol, nifedipine, hydralazine), magnesium sulfate for seizure prophylaxis, and delivery for gestational age ≥ 37 weeks or for severe features. Low-dose aspirin (81 mg daily) from 12-36 weeks reduces the risk in high-risk women.

Preeclampsia with Severe Features

– Preeclampsia (BP $\geq 140/90$ + proteinuria/end-organ dysfunction) with one or more severe criteria: BP $\geq 160/110$ mmHg, thrombocytopenia ($<100,000/\mu\text{L}$), impaired liver function (AST/ALT $>2\times$ normal, epigastric/RUQ pain), progressive renal insufficiency (creatinine >1.1 mg/dL), pulmonary edema, new-onset cerebral or visual symptoms (headache, scotomata, blurred vision). Management: antihypertensives for BP $\geq 160/110$ (labetalol, hydralazine, nifedipine), magnesium sulfate for seizure prophylaxis, and delivery (regardless of gestational age if maternal/fetal instability, otherwise at 34-37 weeks with corticosteroids).

Pregnancy

– The physiological state in which a developing em-

bryo or fetus grows within the female uterus, typically lasting approximately 40 weeks from the last menstrual period to childbirth. It involves complex hormonal and anatomical changes that support fetal development, including increased blood volume, altered metabolism, and growth of the placenta. Regular prenatal care is essential for monitoring maternal health and fetal growth, as well as identifying potential complications such as gestational diabetes, preeclampsia, or preterm labor.

Pregnancy-Induced Hypertension

– Hypertension developing after 20 weeks gestation without other features of preeclampsia. Blood pressure 140/90 mmHg or higher on two readings at least 4 hours apart. Affects 6-8% of pregnancies. Managed with antihypertensive therapy (labetalol, nifedipine, methyldopa) when blood pressure exceeds 160/110 mmHg. Close monitoring for progression to preeclampsia. May resolve postpartum or persist as chronic hypertension.

Premature Rupture of Membranes

– PROM: spontaneous rupture of the amniotic membranes before the onset of labor; preterm PROM (PPROM) occurs before 37 weeks. Features: gush or leakage of fluid per vaginam; confirmed by sterile speculum (pooling, ferning, nitrazine pH test) or amniotic fluid biomarkers (IGFBP-1, PAMG-1). Risks: ascending infection (chorioamnionitis), cord prolapse, placental abruption, preterm birth. Management: confirm gestational age; for term—induction if not laboring (risk of infection); for PPRM—antenatal corticosteroids (lung maturity), latency antibiotics (erythromycin/azithromycin), magnesium sulfate (neuroprotection), and monitoring for chorioamnionitis; delivery for infection or fetal compromise.

Prenatal Care

– Regular medical care during pregnancy to monitor maternal and fetal health. Includes history and physical exam, weight and blood pressure monitoring, urine testing, blood work, fundal height measurements, fetal heart rate auscultation, and ultrasound. Schedules visits monthly in first trimester, biweekly in second, and weekly in third trimester. Screens for gestational diabetes, preeclampsia, anemia, infections, and fetal anomalies.

Prenatal Vitamins

– Multivitamin supplements formulated for pregnancy, containing folic acid (400-800 mcg), iron (27-60 mg), calcium (200-300 mg), vitamin D (400-600 IU), DHA (200 mg), and iodine (150-220 mcg). Started preconceptionally or at the first prenatal visit. Evidence supports NTD reduction from folic acid. Iron prevents maternal anemia. Additional screening detects deficiencies (vitamin D, B12, iron). Gummy vitamins may lack iron and calcium.

Preterm Birth

– Delivery before 37 weeks gestation, occurring in 10% of pregnancies worldwide. Subtypes: spontaneous preterm labor (50%), preterm PROM (30%), and medically indicated preterm birth (20%, for maternal or fetal indications). Risk factors: prior preterm birth (strongest), short cervix, multiple gestation, smoking, infection, periodontal disease, and socioeconomic factors. Complications: respiratory distress syndrome (RDS), intraventricular hemorrhage (IVH), necrotizing enterocolitis (NEC), sepsis, and neurodevelopmental impairment. Prevention: progesterone supplementation, cervical cerclage, and screening for short cervix.

Preterm Labor

– Regular uterine contractions causing cervical change before 37 weeks gestation. Risk factors include prior preterm delivery, multiple gestation, infection, and cervical insufficiency. Diagnosis requires regular contractions with documented cervical change. Tocolytic therapy may delay delivery to allow corticosteroid administration for fetal lung maturity. Magnesium sulfate for neuroprotection if delivery anticipated before 32 weeks. Antenatal corticosteroids reduce respiratory distress syndrome.

Preterm Premature Rupture of Membranes

– Rupture of the amniotic membranes before the onset of labor at <37 weeks gestation. Causes: infection (subclinical chorioamnionitis), cervical insufficiency, and prior PPRM. Presents with sudden gush or leakage of fluid per vagina. Diagnosis: sterile speculum exam (pooling of amniotic fluid), ferning pattern on microscopy, and nitrazine test (turns blue, pH >6.5). Management: depends on gestational age. <24 weeks: counseling for expectant management or induction. 24-34 weeks: expectant management with corticosteroids (betamethasone

for fetal lung maturity), antibiotics (ampicillin + erythromycin to prolong latency and reduce neonatal complications), and monitoring for chorioamnionitis. At term: induction of labor.

Progesterone Supplementation

– Administration of progesterone to prevent preterm birth in high-risk women. Natural progesterone (17-alpha hydroxyprogesterone caproate) shown to reduce preterm birth rate in women with prior spontaneous preterm delivery. Also beneficial for short cervix detected on screening. Typically started in the second trimester. Route options include weekly intramuscular injections or vaginal suppositories.

Progestogen

– A synthetic form of progesterone, the hormone that maintains the uterine lining in the secretory phase of the menstrual cycle and supports early pregnancy. Progestogens are used in: combined oral contraceptives (with estrogen), progestogen-only contraceptives (mini-pill, Depo-Provera injection, implant, Mirena IUS), HRT (with estrogen to protect the endometrium), treatment of menstrual disorders (heavy bleeding, endometriosis), and luteal phase support in IVF. Examples: norethisterone, levonorgestrel, medroxyprogesterone acetate, and micronized progesterone.

Prolonged Deceleration

– A fetal heart rate deceleration lasting ≥ 2 minutes but < 10 minutes. If the deceleration persists ≥ 10 minutes, it is a baseline change. Causes: maternal hypotension (epidural-induced aortocaval compression), uterine hyperstimulation, umbilical cord prolapse, placental abruption, and maternal seizure. Management: immediate intrauterine resuscitation (position change, maternal oxygen, IV fluids, stop oxytocin, treat hypotension). Vaginal exam to exclude cord prolapse. If not resolved in minutes, emergency delivery (cesarean or operative vaginal).

Prolonged Second Stage

– Second stage of labor exceeding the time limits: nulliparas — 3 hours with regional anesthesia (2 hours without); multiparas — 2 hours with regional (1 hour without). Management: reassess position, contractions, and fetal status. For inadequate contractions: oxytocin augmentation. For malposition (OP, OT): manual rotation. For inadequate maternal effort: coaching or rest. If vaginal delivery is not

imminent after a reasonable trial, operative vaginal delivery or cesarean is indicated. Prolonged second stage increases maternal (hemorrhage, chorioamnionitis, lacerations) and neonatal (acidosis, low APGAR, NICU admission) risks.

Prostaglandins

– Lipid compounds involved in labor initiation and cervical ripening. Endogenous prostaglandins (PGE2, PGF2alpha) stimulate uterine contractions and promote cervical softening. Synthetic analogs used clinically: misoprostol (PGE1) and dinoprostone (PGE2 gel or insert) for cervical ripening and labor induction. Also used for postpartum hemorrhage management. Contraindicated in patients with previous cesarean section due to uterine rupture risk.

Pudendal Block

– A local anesthetic block of the pudendal nerve (S2-S4) used for perineal anesthesia during the second stage of labor, outlet forceps delivery, or perineal repair. Technique: transvaginal approach — a needle guide is placed on the ischial spine, and the needle is advanced through the sacrospinous ligament. 1% lidocaine (10 mL on each side) is injected. Provides perineal and lower vaginal analgesia. Does not provide uterine pain relief. Rarely used today because epidural analgesia provides superior pain relief. Complications: intravascular injection (seizures, cardiac toxicity), ischiorectal hematoma, and sciatic nerve block.

Puerperal Fever

– Fever higher than 38 degrees Celsius occurring during the first 10 days postpartum, not including the first 24 hours. Most common cause is endometritis, particularly after cesarean delivery. Other causes include urinary tract infection, wound infection, mastitis, and thrombophlebitis. Evaluation includes blood cultures, urinalysis, wound assessment, and pelvic exam. Treatment depends on suspected source; broad-spectrum antibiotics for endometritis.

Puerperium

– The period following delivery during which the reproductive organs return to their prepregnancy state, approximately 6 weeks in duration. Characterized by uterine involution, cervical closure, lochial discharge changes, and hormonal shifts. Physi-

cal recovery includes perineal healing, breast engorgement, and metabolic readjustment. Emotional changes common; screening for postpartum depression recommended. Return of ovulation variable, particularly with breastfeeding.

Quickening

– The first perception of fetal movement by the mother, typically felt between 16-20 weeks in multiparous women and 18-22 weeks in nulliparous women. Described initially as a subtle fluttering sensation that becomes stronger and more regular as pregnancy progresses. Factors affecting the timing include maternal body habitus, placental location (anterior placenta may delay perception), and gestational age. Quickening was historically used to estimate gestational age before ultrasound became available. The relationship between maternal perception and fetal activity patterns informs kick-count protocols for antepartum surveillance. Absence of perceived movement by 24 weeks warrants ultrasound evaluation for fetal wellbeing.

Rectum

– The final straight section of the large intestine, approximately 12-15 cm long, extending from the sigmoid colon to the anal canal. The rectum stores feces before defecation. In obstetrics, the rectum is relevant for: perineal tears (third- and fourth-degree involve the anal sphincter and rectal mucosa), rectocele (prolapse of the rectum into the posterior vaginal wall), and rectal examination (assessing descent of the fetal head or performing an enema).

Renal Changes in Pregnancy

– Renal blood flow increases 50-80% by the second trimester, and GFR increases 50% (creatinine decreases to 0.4-0.6 mg/dL, BUN to 8-10 mg/dL). Glycosuria and aminoaciduria are normal due to decreased tubular reabsorption. The ureters dilate (hydronephrosis of pregnancy, more prominent on the right) due to progesterone and mechanical compression by the gravid uterus. Proteinuria up to 300 mg/day is normal. The kidney increases in size (1-1.5 cm). Serum uric acid decreases due to increased clearance.

Reproductive Organs

– The organs involved in reproduction. Female: ovaries (produce eggs and hormones), fallopian tubes (transport eggs, site of fertilization), uterus

(nurtures the developing fetus), cervix (lower part of uterus, dilates during labor), vagina (passage for sperm and baby), and vulva (external genitalia). Male: testes (produce sperm and testosterone), epididymis (sperm maturation), vas deferens (sperm transport), seminal vesicles and prostate (produce seminal fluid), and penis (delivers sperm). Reproductive years: the period from menarche to menopause during which a woman is capable of conceiving.

Reproductive Years

– The period of a woman's life during which she is capable of conceiving, typically from menarche (first menstrual period, average age 12-13) to menopause (final menstrual period, average age 51). During the reproductive years, women experience regular menstrual cycles, ovulation, and fertility that peaks in the mid-20s and declines after age 35. The most fertile window is approximately 5-6 days before ovulation. Contraception may be used to prevent pregnancy during the reproductive years.

Respiratory Changes in Pregnancy

– Functional residual capacity (FRC) decreases by 20% due to elevated diaphragm from the gravid uterus. Tidal volume increases 30-40%, minute ventilation increases 50% (due to progesterone-mediated increase in respiratory drive). Result: chronic respiratory alkalosis (PaCO_2 28-32 mmHg) with compensatory renal bicarbonate excretion (serum HCO_3 18-22 mEq/L). PO_2 is slightly increased (100-110 mmHg). Oxygen consumption increases 20%. The decreased FRC means pregnant women desaturate faster during apnea (important for airway management).

Retained Placenta

– Failure of the placenta to deliver spontaneously within 30 minutes after delivery of the baby. Incidence: 1-3% of deliveries. Types: placenta adherens (failure of separation due to inadequate myometrial contractions) and trapped placenta (separated but trapped behind a closed cervix). Risk factors: prior retained placenta, uterine anomaly, placenta previa, and preterm delivery. Management: manual removal of the placenta under anesthesia, oxytocin, and gentle cord traction. Retained placenta increta/percreta may require hysterectomy. Complications: hemorrhage, infection, and Asherman

syndrome.

Retained Products of Conception (RPOC)

– Fragments of placental or fetal tissue retained in the uterus after delivery, miscarriage, or abortion. Causes: incomplete placental separation, succenturiate lobe, and placenta accreta. Presents: persistent or heavy bleeding, pain, and fever in the postpartum period. Diagnosis: ultrasound (echogenic mass in the uterine cavity, Doppler shows vascularity). Management: dilation and curettage (D&C) or hysteroscopic resection. Antibiotics if febrile. RPOC is a common cause of secondary postpartum hemorrhage.

Rh Isoimmunization

– Maternal alloantibody production against fetal Rh D-positive red blood cells in an Rh D-negative mother, occurring when fetal RBCs enter the maternal circulation (fetomaternal hemorrhage). Sensitization typically occurs at delivery of an Rh-positive infant, but may also follow miscarriage, ectopic pregnancy, amniocentesis, chorionic villus sampling, abdominal trauma, or antepartum hemorrhage. The maternal immune system produces anti-D antibodies (IgG) that cross the placenta and cause haemolysis of fetal RBCs, leading to fetal anemia, hydrops fetalis, and potentially fetal death in subsequent pregnancies. Prevention with RhoGAM (anti-D immune globulin) at 28 weeks gestation and within 72 hours of potential sensitising events has reduced the incidence from 10-15% to less than 0.1%. Affected pregnancies are managed with serial middle cerebral artery Doppler monitoring and intrauterine transfusions if fetal anemia develops.

RhoGAM

– Rh immune globulin containing anti-D antibodies, used to prevent Rh isoimmunization in Rh-negative mothers. Administered intramuscularly at 28 weeks gestation and within 72 hours after delivery of an Rh-positive infant. Also given after amniocentesis, chorionic villus sampling, miscarriage, ectopic pregnancy, or abdominal trauma. Works by coating and clearing fetal Rh-positive red blood cells before the maternal immune system can respond.

Rubin Maneuver

– An internal rotational maneuver for shoulder dystocia: the operator inserts a hand and applies pressure

to the posterior aspect of the anterior fetal shoulder, rotating it toward the fetal chest (adducting the shoulders). This reduces the bisacromial diameter and disimpacts the anterior shoulder from the pubic symphysis. Often performed in sequence: Rubin I (external suprapubic pressure), Rubin II (internal pressure on the posterior aspect of the anterior shoulder). Performed after McRoberts and suprapubic pressure.

Salpingectomy

– Surgical removal of a fallopian tube, the definitive treatment for tubal ectopic pregnancy and for hydrosalpinx. Laparoscopic approach is standard (three-port technique). Indications: ruptured ectopic, hemodynamic instability, failed medical management, contralateral tube is healthy, and patient desires sterilization. Salpingectomy preserves ovarian function if the blood supply (ovarian artery anastomosis) is preserved. Methotrexate is an alternative for early, unruptured ectopic pregnancy.

Salpingitis

– Inflammation of the fallopian tubes, most commonly caused by ascending infection from the lower genital tract. Salpingitis is a component of pelvic inflammatory disease and is often bilateral. etiology: sexually transmitted infections—Chlamydia trachomatis (most common), Neisseria gonorrhoeae, and bacterial vaginosis-associated organisms (Gardnerella vaginalis, anaerobes—Bacteroides, Peptostreptococcus, Atopobium vaginae). Clinical: bilateral lower abdominal pain, abnormal vaginal/cervical discharge, fever, dysmenorrhoea, deep dyspareunia, intermenstrual bleeding, and cervical motion tenderness (chandelier sign) on bimanual examination. Diagnosis: clinical (CDC diagnostic criteria—minimum: cervical motion, uterine, or adnexal tenderness + one of: cervical mucopurulent discharge, increased WBC on saline microscopy of vaginal fluid, positive chlamydia/gonorrhea NAAT). Ultrasound may show thickened, fluid-filled tubes (tubo-ovarian complex or abscess). Complications: tubo-ovarian abscess, Fitz-Hugh-Curtis syndrome (perihepatitis—right upper quadrant pain), infertility (tubal factor—risk increases with number of episodes: 10% after 1 episode, 25% after 2, 50% after 3), ectopic pregnancy (6–10-fold increased risk), and chronic pelvic pain. Treatment: antibiotics

(regimen: ceftriaxone 500 mg IM single dose + doxycycline 100 mg PO BD for 14 days + metronidazole 500 mg PO BD for 14 days). Hospitalise if severe disease, pregnancy, tubo-ovarian abscess, or failure of oral therapy. Sexual partner(s) must be treated. Prevention: barrier contraception (condoms), chlamydia/gonorrhea screening in sexually active women <25.

Salpingostomy (Salpingotomy)

– A fertility-preserving surgical procedure for tubal ectopic pregnancy: a linear incision on the antimesenteric border of the fallopian tube to remove the ectopic gestation, leaving the tube in situ. Indications: unruptured ectopic, desire for future fertility, contralateral tubal damage or absence. Risk: persistent trophoblast (up to 15%, requires hCG monitoring and possibly methotrexate). The tube may heal with scarring, reducing patency (50-60% patency rate). Fertility rates after salpingostomy are similar to salpingectomy if the contralateral tube is normal.

Second Stage of Labor

– From full cervical dilatation (10 cm) to delivery of the baby. The mother feels the urge to push as the presenting part descends. Pushing: closed-glottis (Valsalva) or open-glottis. Duration: up to 3 hours in nulliparas with regional anesthesia (2 hours without), and 2 hours in multiparas (1 hour without). Prolonged second stage: longer than these limits. Management: continued maternal effort, operative vaginal delivery (vacuum or forceps), or cesarean delivery if vaginal delivery is not imminent.

Second Trimester

– The period from 13 to 27 weeks gestational age. Fetal growth accelerates, mother begins to feel quickening (fetal movement) between 16-20 weeks. Anatomy ultrasound at 18-22 weeks screens for structural anomalies. Maternal serum screening offered. Nausea typically resolves. Uterus becomes palpable above the symphysis pubis. Amniocentesis may be performed between 15-20 weeks. Risk of miscarriage decreases substantially after the first trimester. Cervical length screening by transvaginal ultrasound is performed in high-risk women between 18-24 weeks to assess preterm birth risk.

Sexual Dysfunction

– Persistent difficulty in sexual activity causing distress. In women: low sexual desire (hypoac-

tive), arousal disorder, orgasmic disorder (anorgasmia), and genito-pelvic pain/penetration disorder (dyspareunia, vaginismus). Causes: psychological (stress, relationship, depression, anxiety), endocrine (menopause, hypogonadism, thyroid, prolactin), vascular/neurologic (diabetes, MS), medication (SSRIs, antihypertensives), gynecologic (endometriosis, vaginismus, pelvic floor, infection, atrophy), and surgery (pelvic, breast cancer). Evaluation: history (medical, psychosexual, medication), exam, and labs (hormones). Management: treat underlying cause, counseling/sex therapy, lubricants, estrogen (atrophy), flibanserin/ testosterone (selected), and address relationship factors.

Sexual Intercourse (Coitus)

– The insertion of a penis into a partner's body for sexual pleasure, reproduction, or both. Most commonly vaginal intercourse (penile-vaginal penetration) but may also include anal intercourse. Sexual intercourse is a key component of human pair bonding and reproduction. From a medical perspective, it is associated with risks including sexually transmitted infections (STIs), unintended pregnancy, and physical injury (e.g., vaginal or penile trauma). Safe sex practices (condoms, contraception, PrEP, vaccination) reduce these risks. Sexual dysfunction can affect any stage of the sexual response cycle (desire, arousal, orgasm).

Sheehan Syndrome (Postpartum Pituitary Necrosis)

– Ischemic necrosis of the anterior pituitary gland due to severe postpartum hemorrhage (PPH) and hypotension. The pituitary enlarges during pregnancy and is vulnerable to ischemia from hypotensive episodes. Clinical features: failure of lactation (first sign, most common), amenorrhea, loss of axillary and pubic hair, breast atrophy, fatigue, hypoglycemia, and hypotension. Diagnosis: low serum cortisol, low TSH/T4, low LH/FSH, low prolactin, and MRI (empty sella). Treatment: lifelong hormone replacement (glucocorticoids first, thyroid hormone, estrogen, and growth hormone as needed).

Shirodkar Cerclage

– A transvaginal cervical cerclage technique that involves dissection of the bladder and rectum to place the suture (Mersilene tape) as high as possible at the level of the internal os. Technically more dif-

difficult than McDonald cerclage with higher risk of hemorrhage and bladder injury. Indications: cervical insufficiency when the cervix is too short for McDonald placement, or failed McDonald cerclage. The suture is buried below the vaginal mucosa. Removed at 36-37 weeks.

Shoulder Dystocia

- An obstetric emergency where the fetal head delivers but the anterior shoulder is impacted behind the maternal symphysis pubis. Defined as head-to-body delivery time exceeding 60 seconds or need for ancillary maneuvers. Risk factors include macrosomia, diabetes, prior shoulder dystocia, and operative vaginal delivery. Management follows HELPER mnemonic: call for help, episiotomy, legs (McRoberts), suprapubic pressure, internal rotation (Woods screw), delivery of posterior arm, and clavicle fracture.

Sinusoidal Fetal Heart Rate Pattern

- A rare, ominous FHR pattern characterized by a smooth, sine-wave-like undulation with a fixed frequency (2-5 cycles/minute) and absent variability. Strongly associated with severe fetal anemia (Rh isoimmunization, fetomaternal hemorrhage, parvovirus B19), fetal hypoxia, and fetal acidosis. Differential: pseudo-sinusoidal pattern (from maternal Demerol administration, usually resolves). A true sinusoidal pattern is a Category III tracing requiring immediate evaluation, intrauterine resuscitation, and urgent delivery.

Soft Markers for Aneuploidy

- Sonographic findings in the second trimester that are common in normal fetuses but have a statistically higher prevalence in aneuploid fetuses (especially trisomy 21). Common soft markers: echogenic intracardiac focus (EIF), echogenic bowel, renal pyelectasis (4-7 mm), short femur/humerus, nuchal fold ≥ 6 mm, choroid plexus cyst, and sandal gap. Each marker has a likelihood ratio (LR) for trisomy 21 (1.5-5). In isolation and with low-risk serum screening, no further workup is needed. Multiple markers increase risk and warrant genetic counseling.

Sonographer

- A healthcare professional trained to perform ultrasound scans (sonography). In obstetrics, sonographers perform:

dating scans (first trimester), nuchal translucency measurement (11-14 weeks), anomaly scans (18-21 weeks), growth scans (serial assessment of fetal size and amniotic fluid), and Doppler studies (umbilical artery, middle cerebral artery). Sonographers also perform gynecological scans (pelvic ultrasound for ovarian cysts, fibroids, endometriosis). They work closely with obstetricians and radiologists to interpret findings.

Spinal Anesthesia for Cesarean Delivery

- A neuraxial anesthetic technique used for elective and many emergency cesarean deliveries. A small dose of local anesthetic (hyperbaric bupivacaine 12-15 mg) with opioid (fentanyl 15-25 mcg, morphine 0.15-0.25 mg) is injected into the subarachnoid space. Produces rapid surgical anesthesia (T4 sensory level for cesarean). Advantages: minimal fetal drug exposure (compared to general anesthesia), the mother is awake for delivery, and excellent postoperative analgesia with intrathecal morphine. Disadvantages: maternal hypotension (from sympathectomy — prevent with left uterine displacement, IV fluids, vasopressors), pruritus, nausea, and PDPH (post-dural puncture headache, 1-2% with pencil-point needles).

Stages of Labor

- Four stages describing the progression from uterine contractions to delivery of the placenta. First stage: onset of regular contractions to full cervical dilatation (10 cm). Second stage: full dilatation to delivery of the baby. Third stage: delivery of the baby to delivery of the placenta. Fourth stage: the first 1-2 hours after placental delivery (immediate postpartum, highest risk of hemorrhage). Normal labor requires coordinated uterine contractions, progressive cervical change, and descent of the fetal presenting part.

Station

- The relationship of the fetal presenting part to the level of the ischial spines, measured in centimeters.

Sterilisation

- A permanent method of contraception. Female sterilization (tubal occlusion): the fallopian tubes are blocked or cut to prevent the egg from reaching the uterus, performed by laparoscopy (clip or diathermy) or at the time of cesarean delivery. Male sterilization (vasectomy): the vas deferens is cut or

sealed to prevent sperm from entering the ejaculate. Both are highly effective (>99%) and intended to be permanent, though reversal is sometimes possible through microsurgery.

Stillbirth

– Intrauterine fetal death (IUFD) at or after 20-24 weeks (definition varies by country); fetal death before viability (<20 weeks) is miscarriage. Causes: placental abruption, placental insufficiency, preeclampsia, fetal anomalies, infection (Listeria, parvovirus, CMV, syphilis), umbilical cord accidents, diabetes, IUGR, maternal disease (antiphospholipid, lupus), and unexplained (25 percent). Diagnosis: absent fetal heart tones/ultrasound. Management: confirm death, discuss delivery options (induction), psychological support, investigations (autopsy, placental pathology, karyotype, TORCH, thrombophilia), and prevention of recurrence counseling. Bereavement support and follow-up are essential.

Striae Gravidarum

– Stretch marks developing on the abdomen, breasts, thighs, and buttocks during pregnancy due to mechanical stretching of the dermis combined with hormonal effects on collagen. Initially appear as red or purple striae (striae rubrae) and eventually fade to silver-white (striae albae). Occur in 50-90% of pregnancies. Prevention with oils and creams has limited evidence. Do not affect fetal development.

Stripping of Membranes (Membrane Sweep)

– A procedure performed during a cervical exam where the examiner inserts a finger through the internal os and sweeps the membranes circumferentially, separating them from the lower uterine segment. Releases endogenous prostaglandins, promoting cervical ripening and potentially initiating labor. Performed at 38-41 weeks to reduce the need for formal induction. Discomfort: moderate cramping and spotting. Contraindications: low-lying placenta, placenta previa, and active bleeding. Studies show reduced postterm pregnancy and induction rates with serial sweeping. Nipple stimulation may also augment endogenous oxytocin.

Substance Use in Pregnancy

– Use of alcohol, tobacco, marijuana, opioids, cocaine, and other drugs during pregnancy. Tobacco:

increased risk of IUGR, preterm birth, placental abruption, SIDS, and low birth weight. Opioids: neonatal abstinence syndrome (NAS, withdrawal in 60-80% of exposed newborns), treated with morphine or methadone. Alcohol: FASD. Marijuana: limited evidence but possible impact on fetal neurodevelopment. Cocaine: abruption, IUGR, preterm birth. Screening: urine drug screen with patient consent (universal screening recommended, but risk of legal/social consequences).

Succenturial Lobe

– An accessory lobe of the placenta, connected to the main placenta by blood vessels that traverse the membranes. If undetected after delivery, the succenturial lobe may be retained in the uterus, causing postpartum hemorrhage or infection. Diagnosis: careful inspection of the placenta and membranes after delivery. A succenturial lobe can also be associated with vasa praevia (fetal vessels running across the internal cervical os), which can cause life-threatening fetal hemorrhage when membranes rupture.

Superimposed Preeclampsia

– Preeclampsia developing in a woman with pre-existing chronic hypertension. Diagnosis: sudden worsening of hypertension, new-onset proteinuria or a sudden increase in proteinuria, or new-onset thrombocytopenia, elevated liver enzymes, or symptoms (headache, visual changes). Occurs in 20-50% of women with chronic hypertension. Higher risk of adverse maternal and fetal outcomes compared to preeclampsia alone. Requires close monitoring and early delivery if severe features develop.

Supine Hypotensive Syndrome

– Compression of the inferior vena cava by the gravid uterus when the pregnant woman lies flat on her back after 20 weeks gestation. Results in decreased venous return, reduced cardiac output, and maternal hypotension, dizziness, pallor, and syncope. Uteroplacental perfusion may be compromised, potentially causing fetal bradycardia and distress. The syndrome typically occurs after 20 weeks gestation when the uterus is large enough to compress the great vessels. Prevention involves avoiding the supine position and maintaining left lateral tilt during labour, surgery, and transport. Treatment includes repositioning to the left lateral decubitus

position and IV fluid bolus. The syndrome is especially relevant during regional anesthesia (spinal or epidural) where loss of sympathetic tone compounds the hemodynamic effect.

Sutures

- Surgical threads or stitches used to close wounds or surgical incisions. In obstetrics, sutures are used for: episiotomy repair, perineal tear repair (1st-4th degree), cesarean section closure (uterine, fascial, and skin layers), and cervical cerclage. Absorbable sutures (Vicryl, Monocryl, chromic catgut) dissolve over time and do not require removal. Non-absorbable sutures (nylon, Prolene) require removal. Continuous suturing is faster; interrupted sutures may provide better wound edge apposition.

Tachysystole (Uterine Hyperstimulation)

- More than 5 contractions in 10 minutes averaged over 30 minutes, or contractions lasting ≥ 2 minutes. Tachysystole with fetal heart rate changes (late decelerations, prolonged deceleration, loss of variability) is more concerning. Causes: oxytocin (most common), prostaglandins (misoprostol $>$ dinoprostone), and cocaine. Management: stop oxytocin (if running), administer a tocolytic (terbutaline 0.25 mg SQ for persistent tachysystole with nonreassuring FHR), maternal position change, IV fluids, and oxygen. Uterine hypertonus: increased resting tone between contractions.

Tdap Vaccination in Pregnancy

- Administration of tetanus, diphtheria, and acellular pertussis (Tdap) vaccine during each pregnancy, optimally at 27-36 weeks. The goal: boost maternal antibodies to protect the newborn from pertussis (whooping cough) before the infant can be vaccinated at 2 months. Transplacental transfer of anti-pertussis antibodies provides passive immunity to the infant. Tdap is safe in pregnancy. The cocooning strategy (vaccinating family members) is no longer recommended as a primary strategy; maternal vaccination is more effective.

Third Stage of Labor

- From delivery of the baby to delivery of the placenta. The placenta separates from the uterine wall and is expelled spontaneously or with gentle cord traction. Normal duration: 5-30 minutes. Active management of the third stage: administration of

oxytocin immediately after delivery of the baby, controlled cord traction, and uterine massage. This reduces the risk of postpartum hemorrhage by 60%. Retained placenta: failure to deliver the placenta within 30 minutes; management includes manual removal or curettage.

Third Trimester

- The period from 28 weeks to delivery. Rapid fetal weight gain occurs, lungs mature with surfactant production. Fetal movements become regular and countable. Braxton Hicks contractions begin. Group B Streptococcus screening at 36 weeks. Fetal positioning assessed for delivery. Viability generally considered at 23-24 weeks. Cesarean section rate highest in this trimester.

Thrush

- A common vaginal infection caused by the yeast *Candida albicans* (also called candidiasis, vaginal thrush, or candida vulvovaginitis). Symptoms: itching, soreness, white discharge (like cottage cheese), dyspareunia, and external dysuria. Risk factors: pregnancy, antibiotic use, diabetes, immunosuppression, and high estrogen states. Diagnosis: clinical and confirmed by vaginal swab (microscopy and culture showing budding yeast and pseudohyphae). Treatment: topical clotrimazole or oral fluconazole (single dose). Recurrent thrush (>4 episodes/year) may require maintenance therapy.

Tocolysis

- The use of medications to suppress uterine contractions and delay preterm labor, providing time for corticosteroid administration (fetal lung maturity) and in utero transfer to a unit with appropriate neonatal facilities. First-line: nifedipine (calcium channel blocker) or atosiban (oxytocin receptor antagonist). Second-line: indomethacin (NSAID, short-term). Beta-agonists (terbutaline, ritodrine) are no longer first-line due to maternal side effects. Maintenance tocolysis beyond 48 hours is not recommended.

Tocolytic Therapy

- Medications used to inhibit uterine contractions temporarily to prolong pregnancy, allowing time for corticosteroid administration and transport to a tertiary care center. Indications: preterm labor with intact membranes, 24-34 weeks. First-line: nifedipine (calcium channel blocker, 20-30 mg PO

q3-4h) or indomethacin (NSAID, 50-100 mg PR/PO then 25-50 mg PO q6h, limited to 48 hours due to oligohydramnios and premature ductus arteriosus closure). Second-line: terbutaline (beta-agonist, SQ, not for prolonged use). Atosiban (oxytocin receptor antagonist) is used in Europe. Tocolysis should not delay delivery in the setting of chorioamnionitis, severe preeclampsia, or fetal compromise.

Total Breech Extraction

– A maneuver where the operator grasps the fetal feet and delivers the entire baby in breech presentation. The most common indication is delivery of the second twin (malpresentation). Contraindicated for term singleton breech due to high risk of head entrapment, nuchal arms, and birth trauma. Technique: identify the feet, grasp them at the ankles, and apply gentle traction. Deliver the legs, trunk, shoulders, and head sequentially. Anesthesia: adequate relaxation (regional or general) is needed.

Toxemia

– An older term for pre-eclampsia (also called toxemia of pregnancy), reflecting the now-outdated theory that the condition was caused by toxins in the blood. Pre-eclampsia is a multisystem disorder of pregnancy characterized by hypertension and proteinuria developing after 20 weeks gestation, affecting 2-8% of pregnancies. Features: elevated blood pressure ($\geq 140/90$ mmHg), proteinuria (≥ 300 mg/24h), and potentially headache, visual disturbances, epigastric pain, and seizures (eclampsia). The term toxemia has been largely replaced by pre-eclampsia in modern practice.

Transabdominal Scan

– An ultrasound scan performed with the transducer placed on the maternal abdomen. A full bladder improves visualization of pelvic structures. Used in early pregnancy to confirm viability and gestational age, and throughout pregnancy to assess fetal growth, anatomy, amniotic fluid volume, and placental location. Transabdominal scans provide a wider field of view than transvaginal scans but have lower resolution for early pregnancy (before 10-12 weeks) and detailed assessment.

Transcervical Foley Catheter for Cervical Ripening

– A mechanical method for cervical ripening: a Foley catheter (16-30 Fr) is inserted through the cervix,

the balloon is inflated with 30-60 mL of saline, and traction is applied (or the catheter is taped to the thigh with gentle tension). The balloon applies direct pressure to the internal os, stimulating endogenous prostaglandin release. Advantages: no increased risk of uterine tachysystole (unlike pharmacologic agents), safe in patients with prior cesarean, and minimal systemic side effects. Often combined with oxytocin after the balloon falls out. Typically <12 hours from insertion to expulsion.

Transverse Lie

– A fetal lie where the long axis of the fetus is perpendicular to the long axis of the mother. The presenting part is a shoulder or arm. Occurs in approximately 1% of term pregnancies. Risk of cord prolapse and obstructed labor. Cesarean delivery required as vaginal delivery is not possible. Version may be attempted to convert to longitudinal lie but often recurs. More common in multiparous women with lax abdominal walls.

TRAP Sequence

– Twin Reversed Arterial Perfusion sequence, a complication of monochorionic twin gestations where one twin (the pump twin) perfuses the other (the acardiac twin) via arterioarterial anastomoses. The acardiac twin receives retrograde, deoxygenated blood through its umbilical artery, resulting in severe anomalies (acardia, acephaly, rudimentary limbs) and no functional heart. The pump twin is structurally normal but at risk for high-output cardiac failure, polyhydramnios, and hydrops from the hemodynamic burden of perfusing the acardiac twin. Diagnosis by ultrasound showing a structurally abnormal twin with absent cardiac activity lacking the visible heartbeat. Doppler demonstrates reverse umbilical artery flow to the acardiac twin. Risk to the pump twin: mortality up to 50% without intervention. Treatment: fetoscopic laser coagulation or radiofrequency ablation of the acardiac twin's umbilical cord to stop perfusion. Outcomes for the pump twin are excellent with early intervention.

Trial of Labor After Cesarean (TOLAC)

– The attempt at vaginal birth in a woman with a prior cesarean, which may result in VBAC or a failed TOLAC (requiring repeat cesarean). Candidates: one prior low-transverse cesarean, clini-

cally adequate pelvis, no contraindications. Counseling: success rate 60-80%, uterine rupture risk 0.5-0.9%, perinatal mortality from rupture <0.1%. Induction of labor increases rupture risk (especially prostaglandins, avoid misoprostol). Oxytocin may be used with caution. Patients must deliver at hospitals capable of emergency cesarean within 30 minutes.

Triplets

– A multiple pregnancy with three fetuses (trichorionic, dichorionic, or monochorionic combinations); commonly results from assisted reproductive technology. High-risk: preterm delivery (average 32-33 weeks), low birth weight, preeclampsia, gestational diabetes, growth restriction, and complications of monochorionicity (TTTS). Antenatal: frequent monitoring, growth scans, corticosteroid prophylaxis, and planned cesarean delivery (usually). Neonatal: high rates of NICU admission, respiratory distress, and long-term neurodevelopmental concerns. Antenatal counseling, maternal nutrition, and multidisciplinary management are essential.

Tubal Pregnancy

– An ectopic pregnancy implanted in the fallopian tube, accounting for >95% of ectopic pregnancies. Most common site: ampulla (70%). Risk factors: prior ectopic, PID (chlamydia), tubal surgery, smoking, IUD, and ART. Presents with lower abdominal pain, amenorrhea, and vaginal bleeding. Diagnosis: transvaginal ultrasound (no intrauterine pregnancy with hCG above discriminatory zone, typically 1500-3000 IU/L), adnexal mass, or tubal ring. Unruptured: treated with methotrexate (single-dose regimen: 50 mg/m² IM) or salpingectomy/salpingostomy. Ruptured: surgical emergency with hemorrhagic shock requiring salpingectomy.

Twin-to-Twin Transfusion Syndrome

– See complete definition in the Multiple Gestation section above.

Twin-Twin Transfusion Syndrome

– A complication of monochorionic diamniotic twin pregnancies where placental vascular anastomoses (arteriovenous connections) cause unbalanced blood flow from one twin (the donor) to the other (the recipient). The donor twin becomes hypovolemic, anemic, and growth-restricted with oligohydramnios

("stuck twin"). The recipient twin becomes hypervolemic, polycythemic, and develops polyhydramnios, cardiac dysfunction, and hydrops. Quintero staging (I-V): I — oligohydramnios/polyhydramnios sequence without Doppler abnormalities; II — bladder not visible in donor; III — abnormal Doppler studies (absent/reversed end-diastolic flow in donor or reverse flow in ductus venosus in recipient); IV — hydrops in recipient; V — intrauterine fetal demise of one or both twins. Diagnosis by ultrasound in monochorionic twins. Treatment: fetoscopic laser photocoagulation of the placental anastomoses (first-line for Quintero II-IV). Severe TTTS without treatment has a mortality rate exceeding 80%.

Umbilical Artery Doppler

– Ultrasound assessment of blood flow in the umbilical arteries to evaluate placental resistance. Normal flow shows a pulsatility index decreasing throughout pregnancy with forward diastolic flow. Absent or reversed end-diastolic flow indicates severe placental dysfunction and is associated with increased perinatal morbidity and mortality. Used in management of intrauterine growth restriction to guide timing of delivery.

Umbilical Cord

– The connection between the fetus and the placenta, containing two umbilical arteries (carrying deoxygenated blood from the fetus to the placenta) and one umbilical vein (carrying oxygenated blood from the placenta to the fetus). The vessels are embedded in Wharton jelly, a mucopolysaccharide matrix that prevents compression. Normal length: 55-60 cm. The cord inserts centrally into the placenta in most cases. Abnormalities: velamentous insertion (vessels insert into the membranes), vasa previa (vessels cross the internal os), true knots, nuchal cord (around the fetal neck), and single umbilical artery (two-vessel cord).

Umbilical Cord Prolapse

– Descent of the umbilical cord through the cervix alongside or past the presenting fetal part, occurring when the membranes rupture. Risk factors: malpresentation (transverse lie, breech), preterm/low birth weight, polyhydramnios, multiparity, and artificial ROM with high presenting part. Presents as cord palpable on vaginal exam or visible at the introitus after ROM, often with sudden fetal bradycardia.

Management: immediate cesarean delivery. While preparing for delivery, relieve cord compression by elevating the presenting part (knee-chest position, Trendelenburg, or manual elevation). Keep the cord inside the vagina to prevent vasospasm. Tocolysis may be used.

Upright Labor Positions

– Maternal positions during labor that use gravity to promote fetal descent: walking, standing, squatting, kneeling, and sitting upright on a birth stool. Benefits of upright vs. recumbent positions: shorter first stage (1 hour), less epidural use, fewer operative deliveries, less perineal trauma, and less severe pain. The supine position is discouraged because it decreases uterine blood flow and cardiac output. Upright positions increase pelvic diameters and contraction efficiency. Water immersion (hydrotherapy) in the first stage is also beneficial.

Urinary Tract Infection in Pregnancy

– Asymptomatic bacteriuria (2-10% of pregnancies) and symptomatic UTI (cystitis, pyelonephritis). Pregnancy increases the risk of pyelonephritis due to hormonally mediated ureteral dilatation and stasis. Asymptomatic bacteriuria: screening and treatment (nitrofurantoin, cephalexin, amoxicillin) reduce the risk of pyelonephritis and preterm birth. Cystitis: dysuria, frequency, urgency. Pyelonephritis: fever, flank pain, nausea, higher risk of preterm labor/preterm delivery. Treatment: IV antibiotics (ceftriaxone, gentamicin, ampicillin+gentamicin) for pyelonephritis.

Uterine Atony

– Failure of the uterus to contract adequately after delivery, resulting in postpartum hemorrhage. The most common cause of PPH. Risk factors include prolonged labor, multiple gestation, macrosomia, oxytocin augmentation, and uterine fibroids. Diagnosis is clinical: boggy, soft uterus with excessive bleeding. Management: uterine massage, oxytocin, methylergonovine, carboprost, misoprostol, balloon tamponade, and surgical interventions (B-Lynch suture, uterine artery ligation) for refractory cases.

Uterine Balloon Tamponade

– A minimally invasive technique for managing postpartum hemorrhage due to uterine atony when uterotonics fail. A balloon (Bakri Postpartum Bal-

loon, 500-1000 mL capacity) is inserted transvaginally into the uterine cavity and inflated with saline until bleeding stops. The balloon provides mechanical compression against the uterine wall. Success rate: 70-90%. The balloon is left in place for 12-24 hours, then gradually deflated. If bleeding continues despite balloon tamponade, surgical intervention (uterine artery embolization, B-Lynch suture, hysterectomy) is indicated. Uterine rupture must be excluded before balloon placement.

Uterine Inversion

– A rare but life-threatening obstetric emergency where the uterus turns inside out, protruding through the cervix or vaginal introitus. Occurs in 1:2000-1:20,000 deliveries. Causes: fundal pressure, excessive cord traction (especially with fundal placenta), uterine atony, and fundal fibroids. Presents: sudden massive hemorrhage, shock out of proportion to blood loss, and a mass at the introitus or vagina. Management: Johnson maneuver (push the fundus back through the cervix with an open palm), tocolytics (terbutaline, magnesium) to relax the uterus, and if manual replacement fails, a surgical approach (Huntington or Hautlain procedure). IV fluids, blood products, and uterotonics after replacement.

Uterine Prolapse

– Descent of the uterus into the vaginal canal due to weakening of the uterosacral/cardinal ligaments and pelvic floor, most commonly after childbirth and menopause. Grades 1-3 based on descent. Risk: vaginal delivery, obesity, aging, chronic straining, heavy lifting. Features: vaginal bulge/pressure, backache, urinary symptoms (incontinence, retention), sexual dysfunction; worse with standing. Diagnosis: clinical (POP-Q). Management: conservative—pelvic floor physiotherapy, pessary, weight loss, treat constipation; surgical—hysterectomy with apical suspension, sacrocolpopexy, or Manchester repair for symptomatic prolapse; counseling for future pregnancy.

Uterine Rupture

– A full-thickness tear through the uterine wall, potentially life-threatening to both mother and fetus. Risk factors include prior cesarean section (especially classical incision), oxytocin augmentation, and operative vaginal delivery. Presents with sudden

abdominal pain, loss of fetal heart rate, and maternal hemorrhage. Requires emergent caesarean delivery and surgical repair. Risk is approximately 0.5% in women with a prior low-transverse caesarean attempting trial of labour after caesarean (TOLAC). The risk is higher with classical or T-shaped uterine incisions (5-10%), multiple prior caesareans, short interpregnancy interval, labour induction with prostaglandins (especially misoprostol), and traumatic delivery. Complete rupture involves full-thickness separation through serosa; incomplete rupture (dehiscence) involves separation of the myometrium with intact serosa. Management: emergency caesarean delivery and surgical repair or hysterectomy. Maternal mortality is less than 1%, but perinatal mortality ranges from 5-20%.

Vacuum-Assisted Delivery

– Operative vaginal delivery using a vacuum extractor applied to the fetal scalp. Types: soft cup (Kiwi OmniCup, Mityvac, for outlet and low deliveries) and rigid cup (metal Kiwi, for posterior positions and midpelvic deliveries). Steps: confirm position, cup placed over the flexion point (3 cm anterior to the posterior fontanelle), vacuum is created to 600-650 mm Hg, traction is applied during contractions with maternal pushing. Descent should be progressive; if no descent after three pulls, abandon. Cup pops-off: reposition after inspection. Contraindications: face presentation, <34 weeks (fragile skull), unengaged head. Neonatal risks: cephalohematoma, subgaleal hemorrhage (life-threatening, monitor), retinal hemorrhage.

Vacuum Delivery

– Assisted vaginal delivery using a vacuum extractor (cup applied to the fetal scalp with negative pressure) to expedite delivery for prolonged second stage, fetal distress, or maternal indications. Requires full dilation, engaged presenting part, ruptured membranes, and informed consent; contraindicated for face/brow presentation, <34 weeks, suspected fetal coagulopathy or macrosomia with cephalopelvic disproportion. Procedure: cup placement (over the flexion point), traction with contractions/pushing, and careful popping/descent. Complications: fetal scalp laceration, cephalohematoma, subgaleal hemorrhage (serious), retinal hemorrhage, and maternal perineal trauma; failed vacuum converts to

forceps/cesarean.

Vaginal Birth After Cesarean (VBAC)

– Vaginal delivery in a woman who has had a prior caesarean delivery. Success rate: 60-80% in appropriately selected candidates. Contraindications: prior classical or T-incision, prior uterine rupture, vertical uterine incision, more than 2 prior caesareans, and other contraindications to vaginal delivery. Factors favoring success: prior vaginal delivery (especially VBAC), spontaneous labor, non-recurrent indication for prior caesarean. Risk: uterine rupture (0.5-0.9%, higher with labor induction). Resources: continuous EFM, in-hospital capability for emergency caesarean.

Vaginal Delivery (Spontaneous)

– The spontaneous passage of the fetus through the birth canal without the use of operative instruments (vacuum or forceps). Typically occurs in the second stage of labor with maternal pushing. Includes crowning of the fetal head, delivery of the head (with restitution and external rotation), delivery of the anterior shoulder, delivery of the posterior shoulder, and delivery of the body. The umbilical cord is clamped and cut. The baby is placed on the mother's abdomen or chest for skin-to-skin contact. APGAR scores are assigned at 1 and 5 minutes.

Vaginal Intercourse

– The insertion of the penis into the vagina for sexual pleasure or reproduction. The most common form of sexual intercourse. Vaginal intercourse can lead to pregnancy if sperm are deposited in the vagina. From a medical perspective, it carries risks of STIs (HIV, gonorrhea, chlamydia, HPV, herpes, syphilis), unintended pregnancy, and rarely trauma (vaginal lacerations, especially in postmenopausal women or with inadequate lubrication). Contraception (condoms, hormonal methods, IUDs) and safe sex practices reduce these risks. Normal physiologic changes during vaginal intercourse include vaginal lubrication (Bartholin glands), vasocongestion, and orgasm.

Variable Decelerations

– A common fetal heart rate pattern characterized by an abrupt decrease in FHR (onset to nadir <30 seconds) with a variable shape, typically caused by umbilical cord compression. Variable decelerations

are classified as mild (<30 sec duration, >80 bpm), moderate (30-60 sec, 70-80 bpm), or severe (>60 sec, <70 bpm). Recurrent variable decelerations (>50% of contractions) with moderate variability are reassuring. Management for repetitive/severe variable decels: maternal position change, amnioinfusion, and reduction of oxytocin.

VEAL CHOP Mnemonic

– A memory aid for interpreting fetal heart rate patterns. VEAL: Variable decelerations → Cord compression, Early decelerations → Head compression, Accelerations → OK (fetal well-being), Late decelerations → Placental insufficiency. CHOP: Cord compression → Change position, Head compression → (no intervention needed), OK → (reassuring), Placental insufficiency → Oxygen. A quick reference for nurses and residents to correlate FHR patterns with their causes and guide initial interventions.

Venous Thromboembolism in Pregnancy

– Pregnancy increases the risk of VTE (DVT and PE) by 5-10 fold due to a hypercoagulable state (increased fibrinogen, factors VII-XII, vWF, decreased protein S, and venous stasis from the gravid uterus). Risk factors: prior VTE, thrombophilia (factor V Leiden, prothrombin G20210A, antithrombin deficiency, protein C/S deficiency), obesity, age >35, and cesarean section. DVT: most commonly left leg (by 3:1), proximal (iliofemoral rather than calf). Diagnosis: compression ultrasonography (DVT), CT pulmonary angiography (PE). Treatment: LMWH (enoxaparin 1 mg/kg BID for full-dose, 40 mg daily for prophylaxis), anticoagulate for entire pregnancy and at least 6 weeks postpartum.

Vitamin K Prophylaxis

– Intramuscular administration of vitamin K (1 mg, 0.5 mg for preterm) to all newborns at birth to prevent vitamin K deficiency bleeding (VKDB, formerly hemorrhagic disease of the newborn). Newborns have low stores of vitamin K (limited placental transfer, sterile gut, low in breast milk). VKDB presents with intracranial, GI, or umbilical bleeding. Oral vitamin K is less effective, especially for late VKDB (2-12 weeks). The IM route is superior and standard in most countries.

Vulvar Cancer

– Malignancy of the vulva, most commonly squa-

mous cell carcinoma (90 percent), related to HPV (younger women, with VIN) or lichen sclerosus (older women); also melanoma, basal cell, Paget disease, Bartholin gland adenocarcinoma. Risk: age, HPV infection, smoking, immunosuppression, chronic vulvar dermatoses. Features: persistent vulvar lump, ulcer, itching, pain, bleeding, and enlarged inguinal nodes; often diagnosed late. Diagnosis: biopsy. Management: surgical excision (wide local excision, vulvectomy) with sentinel node staging/inguinal lymphadenectomy for early; chemoradiation for advanced or node-positive; HPV vaccination prevents many cases. Prognosis depends on stage, nodal involvement.

Water Birth (Underwater Delivery)

– Delivery of a baby in a tub of warm water. Proponents claim: reduced pain, fewer perineal lacerations, and a gentler transition for the baby. Water birth is used in many birth centers and some hospitals. Criteria: low-risk pregnancy, term, clear fluid, and no signs of fetal distress. Risks: maternal or neonatal infection, newborn aspiration (the baby does not breathe until exposed to air), umbilical cord avulsion, difficulty assessing blood loss, and water embolism. The AAP and ACOG state that water birth should be offered only in the context of clinical trials.

Weight Gain in Pregnancy

– Recommended gestational weight gain according to the Institute of Medicine (IOM) guidelines, based on prepregnancy BMI. Underweight (BMI <18.5): 28-40 lbs (12.5-18 kg). Normal weight (BMI 18.5-24.9): 25-35 lbs (11.5-16 kg). Overweight (BMI 25-29.9): 15-25 lbs (7-11.5 kg). Obese (BMI ≥30): 11-20 lbs (5-9 kg). Twin gestations: higher weight gain recommended. Inadequate weight gain is associated with IUGR and preterm birth; excessive gain is associated with macrosomia, gestational diabetes, cesarean delivery, and postpartum weight retention.

Wharton Jelly

– A gelatinous substance (mucopolysaccharide matrix) surrounding the umbilical cord vessels, composed primarily of hyaluronic acid and chondroitin sulfate. It protects the umbilical vessels from compression and kinking during fetal movement and uterine contractions. Its elastic properties allow

the cord to maintain blood flow despite external pressure. Depletion of Wharton jelly is associated with oligohydramnios and cord accidents.

Whites (Leucorrhoea)

– A non-bloody, physiological or pathological vaginal discharge. Physiological leucorrhoea: normal, clear to whitish, odourless discharge that varies with the menstrual cycle (increased at ovulation, premenstrually, during pregnancy, sexual arousal, and with oral contraceptive use). It consists of desquamated epithelial cells, cervical mucus (from endocervical glands), vaginal flora (lactobacilli producing lactic acid, pH 3.8-4.5), and transudate. Pathological leucorrhoea: abnormal discharge in color, odour, or consistency. Causes: vulvovaginal candidiasis (white, thick, curd-like discharge, pruritus, erythema, pH normal 4-4.5, KOH-positive for pseudohyphae), bacterial vaginosis (thin, gray-white, fishy odour, elevated pH >4.5, clue cells on microscopy, positive whiff test with KOH), *Trichomonas vaginalis* (yellow-green, frothy, malodorous, pruritus, dysuria, strawberry cervix, pH >5, motile trichomonads on wet mount), *Chlamydia trachomatis* (mucopurulent cervicitis, yellow discharge, cervical friability), *Neisseria gonorrhoeae* (purulent discharge, PID risk), and atrophic vaginitis (thin, watery, sometimes blood-tinged, pH >5, in menopause). Diagnosis: history, speculum examination, pH testing, wet mount microscopy, KOH preparation, NAAT for *Chlamydia*/gonorrhea/*Trichomonas*. Management: treat underlying infection (antifungals for *Candida*, metronidazole for BV and *Trichomonas*, antibiotics for STIs). Recurrent or persistent leucorrhoea requires evaluation for cervical pathology and retained foreign body (tampon).

Womb

– The common term for the uterus, the muscular organ in the female pelvis where a fetus develops during pregnancy. The womb is pear-shaped, approximately 7.5 cm long, 5 cm wide, and 2.5 cm thick in the non-pregnant state. It consists of three layers: perimetrium (outer serosa), myometrium (thick muscular layer, responsible for uterine contractions during labor), and endometrium (inner lining, shed during menstruation and the site of implantation). The womb expands dramatically during pregnancy, increasing in capacity from 10

mL to 5 L.

Woods Corkscrew Maneuver

– An internal rotation maneuver for shoulder dystocia where the operator inserts a hand and rotates the fetal shoulders 180 degrees by applying pressure to the posterior aspect of the anterior shoulder. This disimpacts the shoulder from behind the symphysis pubis. Can be repeated if the shoulder re-impacts in the new position. Used when McRoberts maneuver and suprapubic pressure fail to resolve the dystocia.

Yeast Infection

– Vulvovaginal candidiasis: infection by *Candida albicans* (most common), causing vulvar and vaginal itching, burning, thick white 'cottage cheese' discharge, dyspareunia, and erythema; more common in pregnancy, diabetes, antibiotic use, and immunosuppression. Diagnosis: clinical; wet mount (budding yeast/hyphae), KOH, or culture. Management: topical azoles (clotrimazole, miconazole) or oral fluconazole (single/3-day dose) for uncomplicated; complicated (recurrent, severe, non-albicans, immunocompromised) needs longer therapy, culture-directed treatment, and maintenance/suppression; treat predisposing factors. Distinguish from bacterial vaginosis and trichomoniasis.

Yolk Sac

– The first extraembryonic structure visible on ultrasound at 5-6 weeks gestation. It provides early nutrition to the embryo before the placental circulation is established, produces blood cells until the fetal liver takes over, and forms the primitive gut. A normal yolk sac is 3-6 mm in diameter. Abnormal size (large >6 mm or small <2 mm) or shape is associated with early pregnancy failure. The yolk sac degenerates by the end of the first trimester.

Zavanelli Maneuver

– The final, rarely performed maneuver for an irreducible shoulder dystocia: the fetal head is replaced into the vagina (cephalic replacement) and the patient undergoes emergency cesarean delivery. Technique: the head is flexed and pushed back into the vagina, then into the birth canal under tocolysis (terbutaline, magnesium, or general anesthesia for uterine relaxation). High rates of fetal morbidity and mortality. The maneuver is used only when all other maneuvers have failed.

Zygote

– The single diploid cell formed by the fusion of male and female gametes (spermatozoon and secondary oocyte) at fertilization. The zygote contains 46 chromosomes (23 from each parent) and represents the beginning of a new, genetically unique individual. After fertilization, the zygote undergoes a series of mitotic cell divisions (cleavage) as it travels through the fallopian tube toward the uterine cavity. The first cleavage produces two blastomeres, then four, eight, and sixteen cells (morula), which then develops into a blastocyst (with inner cell mass → embryo and outer trophoblast → placenta) and implants in the endometrium approximately 5-6 days after fertilization. The zygote stage lasts approximately 24-30 hours, after which it becomes a 2-cell embryo. Abnormal zygote formation can result from polyspermy (fertilization by multiple sperm, resulting in triploidy), parthenogenesis (activation of the oocyte without sperm, not viable in humans), or chromosomal nondisjunction (leading to aneuploidy). In assisted reproductive technology (IVF/ICSI), the zygote is assessed for pronuclear morphology (2 pronuclei = normal fertilization) before embryo culture and transfer. Physiological leucorrhoea: normal, clear to whitish, odourless discharge that varies with the menstrual cycle (increased at ovulation, premenstrually, during pregnancy, sexual arousal, and with oral contraceptive use). It consists of desquamated epithelial cells, cervical mucus (from endocervical glands), vaginal flora (lactobacilli producing lactic acid, pH 3.8-4.5), and transudate. Pathological leucorrhoea: abnormal discharge in color, odour, or consistency. Causes: vulvovaginal candidiasis (white, thick, curd-like discharge, pruritus, erythema, pH normal 4-4.5, KOH-positive for pseudohyphae), bacterial vaginosis (thin, gray-white, fishy odour, elevated pH >4.5, clue cells on microscopy, positive whiff test with KOH), *Trichomonas vaginalis* (yellow-green, frothy, malodorous, pruritus, dysuria, strawberry cervix, pH >5, motile trichomonads on wet mount), *Chlamydia trachomatis* (mucopurulent cervicitis, yellow discharge, cervical friability), *Neisseria gonorrhoeae* (purulent discharge, PID risk), and atrophic vaginitis (thin, watery, sometimes blood-tinged, pH >5, in menopause). Diagnosis: history, speculum examination, pH testing, wet mount microscopy, KOH preparation, NAAT for

Chlamydia/*gonorrhea*/*Trichomonas*. Management: treat underlying infection (antifungals for *Candida*, metronidazole for BV and *Trichomonas*, antibiotics for STIs). Recurrent or persistent leucorrhoea requires evaluation for cervical pathology and retained foreign body (tampon).

25.2 Gynecologic Oncology & Disorders

Adenomyosis

– A condition in which endometrial glands and stroma are present within the myometrium (uterine muscle). Most common in multiparous women in their 40s and 50s. Presents with heavy menstrual bleeding (menorrhagia), severe dysmenorrhea, chronic pelvic pain, and uterine enlargement. Diagnosis: transvaginal ultrasound shows diffuse or focal myometrial thickening with heterogeneous echogenicity; MRI is more specific (junctional zone thickening >12 mm). Treatment: NSAIDs, hormonal contraceptives, levonorgestrel IUD, GnRH agonists, endometrial ablation, and hysterectomy for definitive management.

Anal Intercourse

– The insertion of the penis into the anus and rectum for sexual pleasure. The anal canal is rich in nerve endings, making it a sensitive erogenous zone. The rectum lacks natural lubrication, so artificial lubricants are essential to prevent mucosal trauma. Risks: STI transmission is higher than with vaginal intercourse (especially HIV, HPV, hepatitis A/B, gonorrhea, chlamydia, and syphilis) due to the fragile rectal mucosa and increased HIV target cells (CD4+ T-cells) in the rectal tissue. Condom use significantly reduces STI risk. Other risks: anal fissures, fecal incontinence (rare with healthy sphincter), and foreign body retention. Anal intercourse does not cause hemorrhoids.

Breast Health

– Breast health involves routine self-awareness, clinical examinations, and mammographic screening to detect abnormalities such as lumps, pain, or skin changes that may indicate benign conditions or breast cancer. Risk factors include genetics, age, hormone exposure, and lifestyle factors. Early detection through regular screening significantly improves

treatment outcomes and survival.

Cervical Dysplasia

– Abnormal growth of cervical epithelial cells, representing a premalignant condition that may progress to cervical cancer if untreated. Also known as cervical intraepithelial neoplasia (CIN). CIN is caused by persistent infection with high-risk human papillomavirus (HPV) types, most commonly HPV 16 and 18. Grading: CIN 1 (mild dysplasia, involves the lower one-third of the epithelium, high rate of spontaneous regression), CIN 2 (moderate dysplasia, lower two-thirds), and CIN 3 (severe dysplasia/carcinoma in situ, full-thickness involvement). Most CIN 1 lesions regress spontaneously; CIN 2 and 3 require treatment. Diagnosis: abnormal Pap smear followed by colposcopy with directed biopsy and endocervical curettage. Treatment: CIN 1 may be observed; CIN 2/3 is treated with excisional procedures (loop electrosurgical excision procedure, cold knife conization) or ablative therapy (cryotherapy, laser ablation) depending on lesion size, location, and patient factors. Follow-up is essential as recurrence can occur. Prevention: HPV vaccination.

Clear Margins

– A histological finding indicating that no abnormal cells (e.g., cervical intraepithelial neoplasia or cancer cells) are present at the edge of a tissue specimen removed during a procedure such as LLETZ, cone biopsy, or surgical excision. Clear margins suggest that the entire abnormal area has been removed, reducing the risk of persistent or recurrent disease. Positive margins (abnormal cells at the edge) indicate incomplete excision and require closer follow-up or repeat treatment. Clear margins are the goal of excisional treatment for cervical cell changes and other gynecologic conditions.

Diathermy

– The use of high-frequency electrical current to generate heat for surgical purposes, including cutting tissue, coagulating blood vessels to stop bleeding (hemostasis), and destroying abnormal tissue (electrocautery, electrocoagulation). In gynecologic surgery, diathermy is used in laparoscopic procedures (ovarian drilling for PCOS, endometriosis ablation, myomectomy), hysteroscopic surgery (endometrial ablation, polypectomy, fibroid resection), and colposcopy (treatment of cervical intraepithe-

lial neoplasia). Monopolar diathermy: current flows from electrode through patient to grounding pad. Bipolar diathermy: current flows between two forceps tips, safer for use near delicate structures.

Dysmenorrhea

– Painful menstruation with cramping pelvic pain. Primary dysmenorrhea: no underlying pathology, associated with prostaglandin release, starts within 3 years of menarche. Secondary dysmenorrhea: due to underlying pathology (endometriosis, fibroids, adenomyosis, PID). Treatment: NSAIDs (ibuprofen, naproxen), hormonal contraceptives (pills, IUD, implant), and treatment of underlying cause. Severe cases may require GnRH agonists or surgical intervention.

Dysmenorrhoea

– Painful menstruation, classified as primary (no identifiable pelvic pathology) or secondary (underlying structural or inflammatory condition). Primary dysmenorrhoea is caused by prostaglandin-induced uterine contractions and occurs in the first 2-3 years after menarche, typically starting 6-12 hours before menstruation and lasting 1-3 days. Secondary dysmenorrhoea is associated with endometriosis, adenomyosis, fibroids, or pelvic inflammatory disease. Treatment: NSAIDs (inhibit prostaglandin synthesis), combined oral contraceptives (reduce menstrual volume and prostaglandin production), Mirena IUS, and treatment of underlying cause.

Electrocoagulation

– A surgical technique using high-frequency electrical current to destroy tissue or stop bleeding by coagulating proteins, also known as diathermy or cauterization. In gynecology, electrocoagulation is used in laparoscopic treatment of endometriosis (ablation of implants), polycystic ovary syndrome (ovarian drilling), and hysteroscopic endometrial ablation. It may be monopolar or bipolar. Complications are rare but include thermal injury to adjacent organs (bowel, ureter, bladder) and infection.

Endometrial Cancer

– The most common gynecologic malignancy in developed countries, arising from the lining of the uterine cavity, typically in postmenopausal women. Type I (endometrioid) carcinomas account for 80 percent of cases and are estrogen-driven, associated with endometrial hyperplasia, obesity, diabetes, polycystic

ovary syndrome, unopposed estrogen therapy, and tamoxifen use; they are generally low-grade with a favorable prognosis. Type II (non-endometrioid) carcinomas (serous, clear cell, carcinosarcoma) are not estrogen-driven, arise in atrophic endometrium, and are aggressive with a poor prognosis. The lifetime risk is approximately 3 percent in the general population. Clinical presentation: postmenopausal bleeding is the cardinal symptom (occurring in 90 percent of cases), along with abnormal uterine bleeding in premenopausal women, watery or bloody vaginal discharge, and pelvic pain in advanced disease. Diagnosis is by endometrial biopsy or dilation and curettage, with transvaginal ultrasound showing endometrial thickness greater than 4-5 mm in postmenopausal women requiring further evaluation. Histologic grading (FIGO grade 1-3 based on glandular architecture), subtype determination, and molecular classification (POLE ultramutated, microsatellite instability-high, copy number low, copy number high) guide prognosis and treatment. Staging is surgical according to the FIGO system, based on depth of myometrial invasion, cervical stromal involvement, adnexal spread, lymph node metastasis, and peritoneal cytology. Treatment: total hysterectomy with bilateral salpingo-oophorectomy is the mainstay; lymph node assessment is performed for high-risk histologies. Adjuvant radiotherapy and/or chemotherapy are indicated for high-stage or high-grade disease. Prognosis is generally favourable due to early presentation with postmenopausal bleeding; five-year survival exceeds 95% for stage I disease.

Endometriosis

– A chronic, estrogen-dependent gynecologic disorder characterized by the presence of endometrial-like tissue (glands and stroma) outside the uterine cavity, most commonly implanted on the pelvic peritoneum, ovaries, uterosacral ligaments, and rectovaginal septum. The ectopic endometrial tissue responds to hormonal stimulation, proliferating and shedding cyclically, causing local inflammation, adhesion formation, and fibrosis. The prevalence is 6-10 percent of women of reproductive age, rising to 35-50 percent in women with infertility and chronic pelvic pain. The exact pathogenesis remains unclear, but leading theories include retrograde menstruation (Sampson theory, with menstrual debris

transported through the fallopian tubes into the peritoneal cavity), coelomic metaplasia (transformation of peritoneal mesothelium into endometrial tissue), lymphatic or hematogenous dissemination, and immune dysregulation (impaired clearance of endometrial cells from the peritoneal cavity). Genetic factors contribute, with a 6-9 fold increased risk in first-degree relatives. Clinical presentation includes chronic pelvic pain (often cyclic but may become continuous), severe dysmenorrhea, dyspareunia (painful intercourse), infertility, and dyschezia (painful defecation). Physical examination may reveal tender nodularity in the posterior vaginal fornix, fixed retroverted uterus, and adnexal masses (endometriomas). Diagnosis is definitively made by direct visualization at laparoscopy, with histological confirmation of endometrial glands and stroma in biopsy specimens. Treatment includes analgesics (NSAIDs), hormonal therapy (combined oral contraceptives, progestins, GnRH agonists, levonorgestrel IUS), and surgical excision or ablation of implants. Fertility management ranges from expectant management to assisted reproductive technologies.

Fibrocystic Breast Changes

– A benign condition characterized by lumpy, painful breast tissue, most common in women aged 20-50, driven by hormonal fluctuations during the menstrual cycle (estrogen and progesterone). Microscopic features include stromal fibrosis, cyst formation (macrocyts and microcyts), and adenosis (increased glandular tissue). Palpable breast lumps may be tender and fluctuate in size with the menstrual cycle. Diagnosis relies on clinical breast exam, mammography (showing dense breast tissue and cysts), and ultrasound (anechoic simple cysts), with biopsy (core needle or fine-needle aspiration) reserved for suspicious or complex cysts or solid areas to exclude malignancy. Fibrocystic changes do not increase breast cancer risk except when associated with proliferative changes with atypia (columnar cell change with atypia or atypical ductal hyperplasia), which warrants increased surveillance. Management includes supportive bras, NSAIDs, oral contraceptives (suppressing hormonal fluctuations), and avoiding dietary methylxanthines (caffeine) if symptomatic, though evidence for dietary modification is weak.

Fibroids, Cysts, and Polyps

- Benign growths that can develop in the reproductive organs. Fibroids are smooth muscle tumors of the uterus; cysts are fluid-filled sacs that commonly form on the ovaries; and polyps are tissue overgrowths in the endometrium or cervix. Although typically noncancerous, they can cause symptoms such as pain, abnormal bleeding, and fertility issues, often requiring monitoring or surgical removal.

Fimbriae

- The finger-like projections at the distal end of each fallopian tube that sweep over the ovary during ovulation to capture the released egg and guide it into the fallopian tube. The fimbriae are lined with ciliated epithelium that creates a current to draw the egg into the tube. At the center of the fimbriae is the abdominal ostium, the opening into the fallopian tube. Damage to the fimbriae from infection (pelvic inflammatory disease, chlamydia), endometriosis, or surgery can impair oocyte pickup and cause infertility.

Galactocele

- A milk-filled retention cyst of the breast, occurring during lactation or after weaning. Results from obstruction of a milk duct. Presents as a painless, fluctuant breast mass. Diagnosis by ultrasound showing a well-defined, hypoechoic or anechoic mass. Treatment includes aspiration. May become infected, requiring antibiotics. Recurrence is uncommon after complete drainage.

Genetic Sonogram

- A targeted ultrasound performed at 18-22 weeks that combines standard anatomic survey with specific soft markers for aneuploidy. Findings assessed: nuchal fold thickened (≥ 6 mm), echogenic intracardiac focus (EIF), echogenic bowel, renal pyelectasis (≥ 4 mm anterior-posterior), short femur/humerus, choroid plexus cyst, and sandal gap. The presence of multiple soft markers increases the risk of aneuploidy. The genetic sonogram is used for risk adjustment when combined with maternal age and serum screening (likelihood ratio for each marker). Markers are nonspecific and many are normal variants in euploid fetuses.

Genitals

- The external and internal reproductive organs. Female genitals: external (vulva — mons pubis,

labia majora, labia minora, clitoris, vaginal opening, Bartholin glands) and internal (vagina, cervix, uterus, fallopian tubes, ovaries). Male genitals: external (penis, scrotum) and internal (testes, epididymis, vas deferens, seminal vesicles, prostate, bulbourethral glands). The genitals develop from common embryological structures (genital tubercle, urogenital sinus, Wolffian and Müllerian ducts) under the influence of sex-determining genes and hormones.

Gonadotrophins

- Hormones that stimulate the gonads (ovaries and testes). In women, the pituitary gonadotrophins FSH (follicle-stimulating hormone) and LH (luteinizing hormone) regulate the menstrual cycle: FSH stimulates follicular growth and estrogen production; LH triggers ovulation and supports the corpus luteum. In men, FSH supports spermatogenesis and LH stimulates testosterone production. GnRH (gonadotropin-releasing hormone) from the hypothalamus controls pituitary gonadotrophin secretion. Exogenous gonadotrophins are used in assisted reproduction for controlled ovarian hyperstimulation (e.g., recombinant FSH, hMG, hCG).

HRT

- Hormone Replacement Therapy, the use of estrogen (with or without progesterone) to treat menopausal symptoms caused by declining ovarian hormone production. HRT is the most effective treatment for vasomotor symptoms (hot flashes, night sweats), prevents bone loss (osteoporosis), and improves urogenital atrophy. Routes: oral tablets, transdermal patches/gels, vaginal preparations. Estrogen alone is used in women after hysterectomy; combined estrogen-progestogen is used in women with an intact uterus to prevent endometrial hyperplasia/cancer. The timing hypothesis: HRT initiated within 10 years of menopause has cardiovascular benefits; late initiation increases cardiovascular and thromboembolic risks.

Hydrocele

- An accumulation of fluid within the tunica vaginalis surrounding the testicle, causing scrotal swelling.

Hysterosalpingo-Contrast-Sonography

- An ultrasound-based technique for evaluating the uterine cavity and fallopian tube patency. Sterile

saline or contrast medium is injected through the cervix while transvaginal ultrasound is performed. Advantages over HSG: no ionizing radiation, can be performed in clinic, assesses the uterine cavity (polyps, fibroids, adhesions) and tubal patency simultaneously. Disadvantages: less detailed tubal assessment than X-ray HSG, operator-dependent. Used in infertility workup to screen for tubal occlusion before proceeding to IVF.

Hysterosalpingogram (HSG)

– An X-ray procedure used to evaluate the uterine cavity and fallopian tube patency. A radiopaque contrast medium is injected through the cervix, and serial X-ray images are taken as the contrast fills the uterine cavity and spills from the fallopian tubes. Indications: infertility workup (tubal factor), recurrent miscarriage (uterine cavity assessment), and evaluation after tubal sterilization or tubal surgery. Findings: normal (smooth uterine cavity, free spill from both tubes), tubal occlusion (proximal or distal), hydrosalpinx (dilated, blocked tube), uterine filling defects (polyps, fibroids, adhesions, septate uterus).

Infertility

– Inability to conceive after 12 months of regular unprotected intercourse (6 months if woman >35). Affects 15% of couples. Female causes: ovulation disorders (PCOS, hypothalamic amenorrhea), tubal factor (blockage, PID, endometriosis), uterine (fibroids, polyps, adhesions), and diminished ovarian reserve. Male causes: low sperm count/motility, varicocele, and hormonal dysfunction. Evaluation: ovarian reserve testing, semen analysis, hysterosalpingogram, and hormonal profiling. Treatment: ovulation induction, IUI, IVF, and donor gametes/embryos.

Leiomyoma (Fibroid)

– A benign smooth muscle tumor of the uterus, arising from the myometrium. See Fibroids (Uterine Leiomyomas).

LLETZ

– Large Loop Excision of the Transformation Zone, also called LEEP (Loop Electrosurgical Excision Procedure). A common outpatient procedure used to diagnose and treat cervical intraepithelial neoplasia (CIN). A thin wire loop carrying an electrical current is used to remove the transformation zone of the cervix (where cell changes typically occur).

The procedure takes approximately 5-10 minutes under local anesthesia. The removed tissue is sent for histology. Complications: bleeding, infection, and cervical stenosis. LLETZ does not significantly affect fertility but may slightly increase the risk of preterm birth in future pregnancies.

Menorrhagia

– Excessive or prolonged menstrual bleeding (>80 mL blood loss or >7 days duration). Causes: uterine fibroids, adenomyosis, endometrial polyps, coagulation disorders, thyroid dysfunction, and anovulation. Presents with heavy bleeding, flooding, passage of clots, and iron deficiency anemia. Diagnosis: CBC, ferritin, TSH, transvaginal ultrasound, saline infusion sonography, and endometrial biopsy if indicated. Treatment: NSAIDs, tranexamic acid, hormonal contraceptives, levonorgestrel IUD, endometrial ablation, and hysterectomy in severe cases.

Mesh

– A synthetic or biological implant used to provide structural support in pelvic organ prolapse and stress urinary incontinence surgery. Types: polypropylene (most common, mid-urethral slings for SUI, vaginal mesh for prolapse), biological (porcine, bovine, or cadaveric dermis). Controversy: transvaginal mesh for prolapse has been associated with complications including mesh erosion (exposure into vagina), chronic pain, dyspareunia, infection, and organ perforation. The NHS stopped routine use of transvaginal mesh for prolapse in 2018. Mid-urethral slings for SUI (retropubic and transobturator tapes) remain in use with careful patient selection and counseling.

Metrorrhagia

– Uterine bleeding at irregular intervals, particularly between expected menstrual periods. Causes: anovulation, endometrial polyps, submucosal fibroids, endometrial hyperplasia/cancer, cervical pathology, and breakthrough bleeding with hormonal contraceptives. Diagnosis: transvaginal ultrasound, endometrial biopsy, and hysteroscopy. Treatment depends on the underlying cause and patient age.

Newborn Metabolic Screen

– A dried blood spot test (heel stick) collected 24-48 hours after birth to screen for congenital disorders before symptoms develop. The panel varies by coun-

try/state but typically includes: phenylketonuria (PKU), congenital hypothyroidism, cystic fibrosis, sickle cell disease, medium-chain acyl-CoA dehydrogenase deficiency (MCADD), maple syrup urine disease (MSUD), galactosemia, severe combined immunodeficiency (SCID), and many others (50-80 conditions in some states). Positive results require confirmatory testing.

Oophorectomy

– Surgical removal of one (unilateral) or both (bilateral) ovaries. Indications: ovarian masses (benign or malignant), ovarian torsion, endometriosis, pelvic inflammatory disease (abscess), risk-reducing surgery (BRCA1/BRCA2 mutation carriers—risk-reducing salpingo-oophorectomy reduces ovarian cancer risk by 80–96% and breast cancer risk by 50%), and as part of treatment for hormone-sensitive cancers (breast cancer, endometrial cancer). Bilateral oophorectomy causes surgical menopause (immediate loss of oestrogen, progesterone, and testosterone production), with symptoms (hot flashes, vaginal atrophy, mood changes, decreased libido) and long-term health effects (increased cardiovascular disease, osteoporosis, cognitive decline). Hormone replacement therapy mitigates these risks in women aged <50 without contraindications. Oophorectomy is often performed with salpingectomy (salpingo-oophorectomy); bilateral salpingo-oophorectomy plus hysterectomy is common for benign indications and ovarian cancer staging.

Oral Sex (Fellatio, Cunnilingus)

– Oral stimulation of the genitals for sexual pleasure. Fellatio: oral stimulation of the penis. Cunnilingus: oral stimulation of the vulva and clitoris. Analinus (rimming): oral stimulation of the anus. Oral sex carries lower STI risk than unprotected vaginal or anal intercourse, but STIs can still be transmitted (HSV-1/2, gonorrhea (pharyngeal), chlamydia (pharyngeal), syphilis, HPV (oropharyngeal cancer risk with HPV-16), and HIV (lower risk than anal/vaginal). Pharyngeal gonorrhea and chlamydia are often asymptomatic but can be transmitted to partners. Dental dams and condoms reduce risk. Oral sex is a common cause of primary HSV-1 infection (cold sores transmitted to the genitals or vice versa).

Ovum

– The female reproductive cell (egg) after ovulation and before fertilization. The ovum is a large, non-motile cell (100 μ m diameter) surrounded by the zona pellucida (glycoprotein layer that mediates sperm binding and prevents polyspermy after fertilization) and the corona radiata (follicular cells). The ovum is arrested in metaphase II of meiosis at ovulation. Upon sperm penetration, the ovum completes meiosis II (producing a mature oocyte and a second polar body), and the male and female pronuclei fuse (syngamy) to form a diploid zygote. The ovum is viable for approximately 12–24 hours after ovulation; fertilization must occur within this window. Ovum donation is used in assisted reproduction for women with poor oocyte quality, premature ovarian insufficiency, or genetic disorders.

Pessaries

– Devices inserted into the vagina to support pelvic organs in cases of pelvic organ prolapse (cystocele, rectocele, uterine prolapse). Types: ring pessary (most common, with or without supportive membrane), shelf pessary (for severe prolapse), cube pessary (suction-based), and Gellhorn pessary (for advanced prolapse). Pessaries are fitted by a trained clinician and can be self-managed for removal, cleaning, and reinsertion. Indications: women who decline or are unsuitable for surgery, women awaiting surgery, or those who wish to conceive (pessary avoids surgical risks).

Pessary

– A removable device placed in the vagina to provide structural support for pelvic organ prolapse (uterine prolapse, cystocele, rectocele) or stress urinary incontinence. Pessaries are available in various shapes and sizes: ring pessary (most common—used for mild to moderate prolapse), Gellhorn pessary (for severe prolapse—has a knob that sits above the levator plate), cube pessary (suction-cup shaped, for advanced prolapse), and incontinence pessary (with a knob that supports the urethrovesical junction). Pessaries are fitted by a trained clinician; the correct size prevents discomfort or expulsion. Patients are taught to remove, clean, and reinsert the pessary (if they can) or return every 3–6 months for cleaning and inspection. Complications: vaginal discharge, ulceration, bleeding, and rarely fistula

formation. Oestrogen cream may reduce vaginal erosion in postmenopausal women.

Prolapse of the Uterus (Uterine Prolapse)

– Descent of the uterus into the vaginal canal due to weakening of pelvic floor supports, most commonly the uterosacral and cardinal ligaments. Graded by the POP-Q system (Pelvic Organ Prolapse Quantification): Stage 0 (no prolapse), Stage I (descent >1 cm above hymen), Stage II (descent to within 1 cm of hymen), Stage III (descent >1 cm below hymen), Stage IV (complete eversion of vagina). Risk factors: vaginal childbirth (especially multiple, prolonged, or traumatic deliveries), aging, menopause (oestrogen deficiency), obesity, chronic cough, constipation, and heavy lifting. Symptoms: vaginal bulge or pressure, sensation of something falling out, urinary incontinence or retention, incomplete bladder emptying, and difficulty with defecation. Diagnosis: clinical, confirmed on pelvic examination with Valsalva manoeuvre. Treatment: observation for asymptomatic mild prolapse; pelvic floor muscle training (Kegel exercises); vaginal pessary (ring or shelf pessary for symptomatic relief); surgery (vaginal hysterectomy with uterosacral ligament suspension, sacrospinous fixation, or sacrocolpopexy for apical prolapse). Concomitant anti-incontinence procedures may be performed.

Rectocele

– A weakening of the vaginal wall that allows the rectum to bulge into the vagina.

Sporadic

– Occurring in isolated, random, or scattered instances, without a predictable pattern or clear cause. In medicine, sporadic cases of a disease occur in individuals with no family history of the condition (as opposed to familial or hereditary cases). Sporadic cancers arise from acquired (somatic) mutations rather than inherited germline mutations. Most cases of ovarian, breast, and endometrial cancers are sporadic. Sporadic miscarriage is usually due to random chromosomal abnormalities in the embryo.

Teratoma

– A type of germ cell tumor composed of tissues derived from two or three germ layers (ectoderm, endoderm, mesoderm), reflecting pluripotent differentiation. Teratomas are classified as mature

(benign—well-differentiated tissues, most common in children and young adults) or immature (malignant—primitive/embryonal tissues, higher risk of recurrence and metastasis). Sites: ovaries (most common—dermoid cyst/mature cystic teratoma, usually benign), testes (prepubertal boys—benign; postpubertal men—may contain malignant germ cell elements), sacrococcygeal region (most common congenital tumor in neonates, 1 in 35,000 births), mediastinum (anterior mediastinal germ cell tumor), and intracranial (pineal region, suprasellar). Ovarian dermoid cyst: contains hair, teeth, sebum, bone, and thyroid tissue, often discovered incidentally on ultrasound. Treatment: surgical resection (ovarian cystectomy or oophorectomy for ovarian teratoma). Mature teratoma has an excellent prognosis; immature teratoma requires staging, chemotherapy (BEP: bleomycin, etoposide, cisplatin), and surveillance. Sacrococcygeal teratoma in neonates requires early resection (risk of malignant transformation and bleeding).

Urethracele

– A herniation or prolapse of the urethra into the anterior vaginal wall, often occurring together with a cystocele (bladder prolapse). Urethracele is caused by weakening of the pubocervical fascia, often from childbirth, aging, or increased intra-abdominal pressure. Symptoms: stress urinary incontinence (leakage with cough, sneeze, exercise), urinary urgency, and a vaginal bulge. Diagnosis: clinical (pelvic examination). Treatment: pelvic floor physiotherapy, pessary, or surgical repair (anterior colporrhaphy).

Urodynamics

– A set of tests that assess the function of the lower urinary tract (bladder and urethra). Urodynamic studies include: uroflowmetry (flow rate), filling cystometry (bladder pressure during filling, assesses detrusor overactivity and compliance), pressure-flow study (voiding phase, assesses obstruction), and leak point pressure (stress incontinence). Indicated when surgery is planned for stress incontinence, when the diagnosis is unclear, or when mixed incontinence is suspected. Urodynamics helps distinguish genuine stress incontinence from detrusor overactivity.

Uterine Fibroid (Leiomyoma)

– Benign smooth muscle tumors of the uterus, very common (70-80% of women by age 50). Submu-

cosal: most symptomatic, cause heavy bleeding. Intramural: most common. Subserosal: cause pressure symptoms. Symptoms: menorrhagia, pelvic pain/pressure, urinary frequency, and reproductive dysfunction (infertility, miscarriage). Diagnosis: ultrasound, MRI. Treatment: symptomatic management (NSAIDs, tranexamic acid), hormonal contraceptives, levonorgestrel IUD, GnRH agonists, myomectomy, uterine artery embolization, and hysterectomy.

Uterine Fibroids

– See Uterine Fibroid (Leiomyoma).

Vaginal Dryness and Atrophy (Genitourinary Syndrome of Menopause)

– Vaginal dryness and atrophy, collectively termed genitourinary syndrome of menopause, result from declining estrogen levels that cause thinning, drying, and loss of elasticity of the vaginal tissues. Symptoms include vaginal dryness, irritation, burning, dyspareunia, and urinary symptoms such as frequency and recurrent infections. Treatment options include over-the-counter vaginal lubricants and moisturizers, prescription topical estrogen therapy in various formulations, and nonhormonal options such as ospemifene or vaginal laser therapy.

Vaginismus

– Involuntary spasms of the vaginal muscles.

Vaginitis

– Inflammation of the vaginal mucosa, one of the most common gynecologic complaints. Types: bacterial vaginosis (BV: thin, fishy-odor discharge, clue cells, pH >4.5), vulvovaginal candidiasis (thick, white, cottage-cheese discharge, pruritus, pH normal), and trichomoniasis (frothy, green-yellow discharge, strawberry cervix, pH >4.5, motile trichomonads). Atrophic vaginitis: postmenopausal, due to estrogen deficiency, thin vaginal mucosa, and dyspareunia. Diagnosis: vaginal pH, wet mount microscopy, KOH preparation, and NAAT for trichomonas. Treatment: metronidazole or clindamycin for BV; topical azoles or oral fluconazole for candidiasis; metronidazole or tinidazole for trichomoniasis; topical estrogen for atrophic vaginitis.

Vulvar vestibulitis

– Pain and inflammation of the vulvar vestibule.

Vulvitis

– Inflammation of the vulva (external female genitalia), often presenting with pruritus, burning, irritation, erythema, edema, and discharge. Vulvitis is rarely isolated and is most commonly part of vulvovaginitis (inflammation of both vulva and vagina). Causes: infections (*Candida albicans* — most common, *Trichomonas vaginalis*, bacterial vaginosis, herpes simplex, human papillomavirus), irritants (soaps, detergents, douches, perfumed hygiene products, sanitary pads, synthetic underwear, chlorinated water), allergens (latex condoms, spermicides, topical medications), dermatologic conditions (lichen sclerosus, lichen planus, psoriasis, atopic dermatitis, contact dermatitis), and systemic conditions (diabetes mellitus, immunosuppression, oestrogen deficiency in menopause causing atrophic vulvovaginitis). Diagnosis: history (symptom onset, triggers, sexual history), examination (vulvar erythema, fissures, discharge, atrophy, excoriations, lichenification), swabs for culture, pH testing, and KOH preparation. Management: treat underlying cause (antifungals for *Candida*, antibiotics for bacterial infection, topical corticosteroids for inflammatory dermatoses, oestrogen cream for atrophic vulvitis). General measures: avoidance of irritants, sitz baths, loose cotton underwear, and good vulvar hygiene.

25.3 Reproductive Endocrinology & Infertility

Abnormal Uterine Bleeding

– Uterine bleeding that is abnormal in frequency, regularity, duration, or volume, occurring outside of normal menstruation or in women who are not pregnant. The PALM-COEIN classification system categorizes causes into structural (PALM: polyps, adenomyosis, leiomyomas, malignancy/hyperplasia) and non-structural (COEIN: coagulopathy, ovulatory dysfunction, endometrial, iatrogenic, not otherwise classified). Ovulatory dysfunction is the most common cause in reproductive-age women, resulting from anovulation due to polycystic ovary syndrome, thyroid disorders, hyperprolactinemia, hypothalamic dysfunction, or perimenopause. Structural causes include endometrial polyps (benign overgrowths of endometrial glands and stroma),

uterine leiomyomas (fibroids, benign smooth muscle tumors), adenomyosis (endometrial tissue within the myometrium), and endometrial hyperplasia or carcinoma (particularly in postmenopausal women).

Bladder Exstrophy

– A rare congenital abdominal wall defect where the bladder is exposed on the outside of the body due to failure of the lower abdominal wall and bladder to close during embryonic development. Part of the exstrophy-epispadias complex. Associated with pubic bone diastasis, external genital anomalies, and potential bladder dysfunction. Treatment involves staged surgical repair beginning in the neonatal period, followed by long-term urologic and orthopedic follow-up.

Breast Abscess

– A localized collection of pus within the breast tissue, most commonly a complication of lactational mastitis. Presents as a fluctuant, painful mass with overlying erythema and systemic symptoms. Diagnosis by ultrasound. Treatment requires incision and drainage plus antibiotics. Non-lactational breast abscesses may be associated with smoking or duct ectasia and may require biopsy to rule out underlying malignancy.

Childbirth

– See Parturition (Childbirth).

Chromosomes

– The thread-like structures within the cell nucleus that carry genetic information in the form of DNA. Humans have 46 chromosomes arranged in 23 pairs: 22 pairs of autosomes and 1 pair of sex chromosomes (XX in females, XY in males). Each parent contributes one chromosome to each pair. Chromosomes are visible under a light microscope during cell division and are arranged in a standardized format called a karyotype (ordered by size, centromere position, and banding pattern). Chromosomal abnormalities can involve number (aneuploidy) or structure (deletions, duplications, translocations, inversions).

Clitoris

– A small, sensitive erectile organ located at the anterior junction of the labia minora, beneath the clitoral hood (prepuce). The clitoris is the primary source of female sexual pleasure and is homologous to the male penis. It consists of the external glans

(visible, about the size of a pea), the body (corpus), and the internal crura (two elongated erectile structures that extend along the pubic rami). The clitoris contains approximately 8,000 nerve endings and becomes engorged with blood during sexual arousal. The only known function of the clitoris is sexual pleasure.

Dyspareunia

– Painful sexual intercourse.

Endometrium

– The lining of the uterus.

Erythromycin Ophthalmic Prophylaxis

– Erythromycin 0.5% ophthalmic ointment administered to all newborns within 1 hour of birth to prevent ophthalmia neonatorum (neonatal conjunctivitis) from *Neisseria gonorrhoeae* and *Chlamydia trachomatis*. Instilled into both conjunctival sacs. Silver nitrate (Credé's method) was used historically but is less effective for chlamydia. The prophylaxis is required by law in most US states. Does not prevent nasopharyngeal colonization.

Fertilisation

– The union of a sperm and an egg (oocyte) to form a zygote, the first cell of a new individual. Fertilization occurs in the ampulla of the fallopian tube and involves: capacitation of sperm, binding of sperm to the zona pellucida, acrosome reaction, fusion of sperm and oocyte plasma membranes, cortical reaction (prevents polyspermy), completion of the second meiotic division of the oocyte, formation of the male and female pronuclei, and syngamy (fusion of pronuclei). The resulting zygote then begins cell division (cleavage) as it travels down the fallopian tube to implant in the uterus.

Galactagogue

– A substance that promotes breast milk production.

Gaskin Maneuver (All-Fours Position)

– A maneuver for shoulder dystocia resolution: the mother is rolled onto her hands and knees (all-fours position). Gravity and the change in pelvic dimensions (increased anteroposterior diameter of the pelvic outlet) may dislodge the impacted shoulder. The posterior arm may also be delivered more easily. Success rate: 25-50% after failed McRoberts. If the posterior shoulder delivers, the anterior shoulder

usually follows.

gynecology

- The medical specialty concerned with the health of the female reproductive system (uterus, ovaries, fallopian tubes, cervix, vagina, and vulva).

Haemolytic Disease of the Newborn

- See blood-related entries in hematology.

Hepatitis B Vaccine (Birth Dose)

- The first dose of the hepatitis B vaccine is recommended within 24 hours of birth for all medically stable infants. Administered IM in the vastus lateralis. Prevents perinatal transmission of HBV. For infants born to HBsAg-positive mothers: HBIG (0.5 mL IM) is given within 12 hours of birth along with the vaccine. The three-dose series (0, 1-2, and 6-18 months) provides >95% protection. Universal vaccination has dramatically reduced childhood HBV infection.

Hysterectomy and Surgical Menopause

- Hysterectomy is the surgical removal of the uterus, and when the ovaries are also removed (oophorectomy), it induces surgical menopause regardless of age. Surgical menopause causes an abrupt drop in estrogen levels, leading to more severe menopausal symptoms than natural menopause, including hot flashes, bone loss, and increased cardiovascular risk. Hormone replacement therapy is often recommended for younger women to mitigate these effects.

Infant Sleep Position

- The supine sleep position (back to sleep) is recommended by the AAP to reduce the risk of sudden infant death syndrome (SIDS). The Back to Sleep campaign (1994) reduced SIDS rates by >50%. Always place the baby on the back for sleep (naps and nighttime). Use a firm sleep surface with no soft bedding, pillows, bumpers, or stuffed animals. Room-sharing (same room, separate bed) is recommended for the first 6-12 months. Prone and side positions increase SIDS risk. Tummy time when awake promotes motor development and prevents positional plagiocephaly.

Kegel

- An exercise that helps prevent and treat incontinence by strengthening pelvic floor muscles.

Lactation

- The physiological process of milk production and secretion from the mammary glands, occurring after childbirth (puerperium). See Lactation (Breastfeeding).

Lanugo

- Fine, soft hair that grows all over the body of a fetus and is typically shed before birth.

Levator Ani

- The primary pelvic floor muscle complex supporting the pelvic organs, forming a hammock from the pubic symphysis to the coccyx. Composed of the pubococcygeus, puborectalis, and iliococcygeus muscles. Innervated by the pudendal nerve (S2-S4).

Male Infertility

- Male infertility—the inability to conceive after 12 months of unprotected intercourse—contributes to approximately 50% of couple infertility cases. Causes include varicocele (most common correctable cause, 40%), obstructive azoospermia (congenital bilateral absence of the vas deferens from CFTR mutations, vasectomy, infection), hormonal disorders (hypogonadotropic hypogonadism, hyperprolactinemia), spermatogenic failure (Y-chromosome microdeletions, Klinefelter syndrome, chemotherapy, cryptorchidism), and idiopathic oligoasthenoteratozoospermia. Evaluation: semen analysis per WHO criteria (volume ≥ 1.4 mL, concentration ≥ 16 million/mL, motility $\geq 30\%$, morphology $\geq 4\%$), hormonal profile (FSH, LH, testosterone), genetic testing (karyotype, Y-deletion, CFTR), and scrotal ultrasound. Treatment: varicocelectomy, hormonal therapy (hCG, clomiphene), surgical sperm extraction (TESE, micro-TESE) for IVF/ICSI, and lifestyle optimization (weight loss, smoking cessation, reducing scrotal heat).

McRoberts Maneuver

- A positioning maneuver for managing shoulder dystocia where the mother's legs are hyperflexed onto her abdomen, with thighs against the abdomen. This flattens the sacrum, increases the anteroposterior diameter of the pelvis, and rotates the symphysis pubis superiorly. Often combined with suprapubic pressure. First-line maneuver for shoulder dystocia resolution, with a reported success rate of approximately 40%.

Menopause

- The point marking the end of menstruation, officially designated as one year after a woman's final period.

Newborn Hearing Screen

- Universal screening for hearing loss in newborns before hospital discharge. Two methods: otoacoustic emissions (OAE, measures cochlear outer hair cell function) and automated auditory brainstem response (AABR, measures the auditory nerve pathway). Both are noninvasive and take 5-10 minutes. Infants who fail the screen are referred for diagnostic audiology before 3 months of age. Early detection and intervention (before 6 months) significantly improve language outcomes.

Oocyte

- The female gamete (egg cell) produced in the ovary through oogenesis. Oocytes develop from primordial germ cells, which undergo mitosis to form oogonia, then enter meiosis I before birth and arrest in prophase I until puberty. Each menstrual cycle, a cohort of follicles is recruited; one dominant follicle matures and releases its oocyte at ovulation (meiosis I completed, arrested in metaphase II). The oocyte is arrested in metaphase II until fertilization, which triggers completion of meiosis II. The oocyte is the largest cell in the human body (100–120 μm diameter) and contains maternal mRNA, proteins, organelles, and nutrients (yolk) necessary for early embryonic development until the embryonic genome activates (8-cell stage). Oocyte quality declines with maternal age (increased aneuploidy risk, reduced mitochondrial function). Oocyte cryopreservation (egg freezing) and in vitro fertilization (IVF) are key assisted reproductive technologies.

Ovariectomy

- Surgical removal of one or both ovaries.

Ovulation

- The release of a mature egg from the ovary, at which time it is available to be fertilized by sperm.

Perimenopause

- The transition time in a woman's life that begins when ovaries produce less estrogen and menstruation becomes less frequent, and ends when the ovaries no longer produce eggs and menstruation stops.

Physiologic Jaundice of Newborn

- A common, benign condition characterized by unconjugated hyperbilirubinemia appearing after 24

hours of age (peak at 3-5 days) in healthy term newborns. Caused by increased bilirubin production (high RBC turnover, short RBC lifespan) and immature hepatic conjugation (low UDP-glucuronyl transferase activity). Total bilirubin typically <12-15 mg/dL. Resolves spontaneously within 1-2 weeks. Management: monitor bilirubin, assess risk factors, and treat with phototherapy if bilirubin exceeds thresholds on the Bhutani nomogram.

Postmenopausal osteoporosis

- Bone loss caused by lower estrogen levels associated with menopause. Sometimes called type I osteoporosis.

Postmenopause

- The period in a woman's life lasting from the end of perimenopause until the end of life.

Premenstrual Syndrome

- A recurrent pattern of physical, emotional, and behavioral symptoms during the luteal phase of the menstrual cycle that resolve with menses. Affects up to 50% of reproductive-age women. Symptoms: irritability, mood swings, depression, anxiety, bloating, breast tenderness, fatigue, and appetite changes. Premenstrual dysphoric disorder (PMDD) is a severe form with marked mood symptoms and functional impairment. Treatment: lifestyle modification, SSRIs (continuous or luteal-phase), oral contraceptives, spironolactone, and CBT.

Rhesus (Rh) Factor

- See Rhesus (Rh) Factor in Hematology.

Semen

- The fluid ejaculated from the male reproductive tract, containing sperm (produced in the testes) suspended in seminal plasma (produced by the seminal vesicles, prostate, and bulbourethral glands). Semen provides nutrients (fructose, amino acids), protective agents (zinc, antioxidants), and a medium for sperm transport. Normal semen parameters (WHO 2021): volume ≥ 1.4 mL, sperm concentration ≥ 16 million/mL, total sperm count ≥ 39 million, progressive motility $\geq 30\%$, normal morphology $\geq 4\%$.

Special Care Baby Unit

- A ward within a hospital that provides specialist care for newborn babies who need additional support but not intensive care. SCBU provides: monitoring of premature babies (usually born at 32-36 weeks), phototherapy for jaundice, treatment of

hypoglycemia, intravenous fluids or nasogastric tube feeding, and treatment of mild respiratory distress. SCBU differs from a Neonatal Intensive Care Unit (NICU), which provides full intensive care including mechanical ventilation for the sickest or most premature infants.

Sperm

- The male gamete (reproductive cell), produced in the seminiferous tubules of the testis through spermatogenesis. Sperm consists of: head (contains the haploid nucleus and acrosome containing enzymes for egg penetration), midpiece (contains mitochondria for energy), and tail (flagellum for motility). Approximately 1,500 sperm are produced per second. Sperm travel from the testis through the epididymis (maturation), vas deferens, seminal vesicles, and urethra during ejaculation.

Vulvodynia

- Pain in the vulva that may or may not be brought on by touch or pressure.

Woods Screw Maneuver

- See Woods Corkscrew Maneuver in the main section above.

Chapter 26

Oncology

Acute Myeloid Leukemia

– A heterogeneous clonal disorder of hematopoietic stem cells characterized by the accumulation of immature myeloid blasts in the bone marrow and peripheral blood. Diagnostic criteria require 20 percent or more marrow or blood blasts (or blasts with AML-defining genetic abnormalities regardless of blast count). The WHO 2022 classification integrates morphologic (FAB subtypes M0-M7), immunophenotypic (flow cytometry for myeloid markers: CD13, CD33, CD34, CD117, MPO), and cytogenetic/molecular abnormalities (NPM1, CEBPA, FLT3-ITD, IDH1/2, RUNX1, TP53) for risk stratification and targeted therapy selection.

Adjuvant Therapy

– Treatment given after definitive surgery or radiation to eliminate micrometastatic disease and reduce the risk of recurrence. Chemotherapy: breast (anthracycline + taxane, dose-dense AC → T), colon (FOLFOX for stage III and high-risk stage II), lung (cisplatin-based for stage II-IIIa NSCLC), pancreas (FOLFIRINOX or gemcitabine + capecitabine), ovarian (carboplatin + paclitaxel). Radiation: post-mastectomy chest wall RT (for T3-4 or node-positive breast cancer), post-operative RT for head and neck cancer with high-risk features. Hormonal therapy: tamoxifen or aromatase inhibitor for ER+ breast cancer for 5-10 years. Targeted therapy: trastuzumab + pertuzumab for HER2+ breast cancer for 1 year. Duration: based on the natural history of the disease and drug tolerance. Timing: typically starts within 4-8 weeks of surgery.

Anthracyclines

– A class of potent chemotherapy drugs derived from the bacterium *Streptomyces*, used to treat a wide range of cancers including breast cancer (doxorubicin, epirubicin), leukemias (daunorubicin, idarubicin), lymphomas (doxorubicin), sarcomas (doxorubicin), and many others. Mechanism: intercalation into DNA (disrupts replication and transcription), inhibition of topoisomerase II (prevents DNA repair), and generation of free radicals (oxidative damage). A major dose-limiting side effect is dose-dependent cardiotoxicity: acute (arrhythmias, pericarditis) and chronic (dilated cardiomyopathy, heart failure). Cumulative lifetime dose limits: doxorubicin 450-550 mg/m², epirubicin 900 mg/m². Cardioprotection: dexrazoxane (iron chelator, reduces free radical formation). Other toxicities: myelosuppression, mucositis, alopecia, nausea/vomiting, and extravasation (tissue necrosis). Extravasation from IV administration is a medical emergency requiring immediate cold packs, dexrazoxane, and surgical consultation.

Benign Tumor

– Neoplasm exhibiting localised growth without invasion or metastatic potential, composed of well-differentiated cells resembling the tissue of origin. Typically slow-growing, encapsulated, and cured by complete excision. Location may prove dangerous despite favourable biology, and some lesions carry premalignant potential. Examples include lipoma, leiomyoma, osteochondroma, and meningioma. See Tumor and Malignant Tumor.

Biotherapy

– Treatment of cancer with biologics—substances derived from living organisms or biotechnology—that modulate the immune system or target molecular pathways. Encompasses immune checkpoint inhibitors, CAR T-cell therapy, monoclonal antibodies, cytokines, and oncolytic viruses. Distinguished from cytotoxic chemotherapy, hormonal therapy,

and small-molecule targeted therapy. Immune-related adverse events are its hallmark toxicity. See Immunotherapy (Cancer).

Bladder Cancer

- The most common malignancy of the urinary tract, ranking as the ninth most common cancer worldwide, with a male-to-female ratio of 4:1 and peak incidence in the seventh decade of life. The most significant risk factor is cigarette smoking (accounting for 50-65 percent of cases in men and 20-30 percent in women, with a 2-4 fold increased risk). Occupational exposures to aromatic amines (aniline dyes, in rubber, leather, and textile industries) are also important. The overwhelming majority (90-95 percent) are urothelial carcinoma (transitional cell carcinoma), with squamous cell carcinoma (3-5 percent, more common in regions with schistosomiasis) and adenocarcinoma (1-2 percent) comprising the remainder.

Bone Marrow Transplantation

- Hematopoietic stem cell transplantation (HSCT) replaces diseased or ablated bone marrow with healthy donor or autologous stem cells, used to treat hematologic malignancies, bone marrow failure syndromes, hemoglobinopathies, and immune deficiencies. Autologous HSCT uses the patient's own stem cells collected after mobilization (G-CSF with or without plerixafor), providing hematopoietic rescue after high-dose chemotherapy without graft-versus-host disease risk; indications include relapsed lymphoma and multiple myeloma.

Bone Tumor

- A neoplasm arising from bone tissue or its supporting structures, classified as primary (originating from bone, cartilage, or other connective tissue cells) or secondary/metastatic (spread from a distant primary cancer, which is the most common type). Primary bone tumors are rare, accounting for less than 1 percent of all cancers, while metastatic bone disease is common, particularly from primary cancers of the breast, prostate, lung, kidney, and thyroid. Primary bone tumors are classified by the type of matrix produced (osteoid, cartilage, or collagen) and the degree of cellular atypia and malignancy.

Brachytherapy

- A form of radiation therapy where a radioactive source is placed inside or immediately adjacent to

the tumor. Low-dose-rate (LDR): seeds (I-125, Pd-103, Cs-131) implanted permanently (prostate cancer, delivers radiation over months). High-dose-rate (HDR): a single source (Ir-192) is moved through catheters into the tumor for brief periods (minutes), then removed (for cervical, endometrial, breast, and prostate cancer). Pulsed-dose-rate (PDR): a source delivers radiation in pulses, mimicking LDR radiobiology with HDR equipment. Applications: cervical cancer (tandem and ovoid, intracavitary; interstitial needles for advanced), prostate cancer (LDR permanent seeds monotherapy for low-risk; HDR as boost for intermediate/high-risk), endometrial cancer (vaginal cylinder HDR), breast cancer (accelerated partial breast irradiation with balloon or multicatheter), and head and neck (interstitial HDR). Advantages: high radiation dose to the tumor with rapid fall-off, sparing surrounding normal tissues. Disadvantages: invasive placement under anesthesia, radiation exposure to staff (mitigated by afterloading techniques), and limited to accessible tumor sites.

Breast Cancer

- The most common cancer in women worldwide, arising from breast tissue (ductal or lobular epithelium). Risk factors: female sex, age, BRCA1/BRCA2 mutations, family history, early menarche, late menopause, nulliparity, and hormone therapy. Presents with a breast mass, skin changes (peau d'orange), nipple retraction, or axillary lymphadenopathy. Diagnosis: mammography, ultrasound, biopsy with hormone receptor and HER2 testing. Treatment: surgery, radiation, chemotherapy, endocrine therapy, and targeted therapy (trastuzumab for HER2+).

Cachexia

- A complex metabolic syndrome characterized by weight loss, muscle wasting, and systemic inflammation, occurring in chronic diseases such as cancer (most common), heart failure, COPD, chronic kidney disease, and AIDS. Diagnostic criteria: >5% weight loss over 6 months in the absence of simple starvation, or >2% weight loss with BMI <20 or sarcopenia. Pathophysiology: pro-inflammatory cytokines (TNF-alpha, IL-6), tumor-derived factors, hypermetabolism, and catabolic state. Unlike starvation, cachexia cannot be fully reversed by nutri-

tional supplementation alone. Management: treat underlying disease, multimodal approach (nutritional support, exercise, anti-inflammatory agents, progestins like megestrol acetate, corticosteroids for short-term appetite stimulation). Prognosis: poor; cachexia is an independent predictor of mortality.

Cancer

– A group of diseases characterized by uncontrolled cell growth and spread to nearby tissues or distant organs through the bloodstream or lymphatic system. It results from genetic mutations that disrupt normal cell cycle regulation, often influenced by environmental exposures, lifestyle factors, and inherited predisposition. Treatment modalities include surgery, radiation, chemotherapy, immunotherapy, targeted therapy, and hormone therapy.

Cancer Genetics

– The study of inherited and acquired genetic alterations that contribute to cancer development, progression, and treatment response. Hereditary cancer syndromes: hereditary breast and ovarian cancer (BRCA1, BRCA2), Lynch syndrome (MLH1, MSH2, MSH6, PMS2, EPCAM — colorectal, endometrial, ovarian, gastric), familial adenomatous polyposis (APC), Li-Fraumeni syndrome (TP53), MEN1/MEN2 (RET, MEN1), von Hippel-Lindau (VHL), neurofibromatosis (NF1, NF2), and retinoblastoma (RB1). Indications for genetic testing: early-onset cancer (<50), multiple primaries, bilateral disease, multiple family members with the same or related cancer, and specific tumor types (triple-negative breast, serous ovarian, medullary thyroid, male breast cancer). Testing: germline (blood or saliva — inherited mutations) and somatic (tumor tissue — acquired mutations for targeted therapy). Multigene panel testing (NGS) is now standard. Management of mutation carriers: enhanced screening, risk-reducing surgery (prophylactic bilateral mastectomy for BRCA, colectomy for FAP), chemoprevention (tamoxifen for BRCA), and targeted therapy (PARP inhibitors for BRCA-mutated cancers, PD-1 inhibitors for MSI-high).

Cancer Pain

– Cancer pain can arise from the tumor itself compressing nerves or organs, from metastases, or as a side effect of treatments like surgery, chemotherapy, or radiation. It may be acute or chronic and

is managed with a multimodal approach including analgesics, nerve blocks, palliative radiation, and integrative therapies. Effective pain control is a core component of cancer care and improves quality of life.

Cancer Prevention

– Cancer prevention involves strategies to reduce the risk of developing cancer, including lifestyle modifications such as avoiding tobacco, limiting alcohol, maintaining a healthy weight, exercising, and protecting against carcinogens like UV radiation. Vaccination against hepatitis B and HPV prevents infection-related cancers, and regular screenings catch precancerous changes early. Genetic testing and prophylactic surgery are options for high-risk individuals.

Cancer Screening

– Systematic testing of asymptomatic individuals to detect cancer at an early, curable stage. Principles of screening (WHO Wilson-Jungner): the disease should be an important health problem, an acceptable treatment should be available, facilities for diagnosis and treatment should be available, a recognizable latent or early symptomatic stage should exist, a suitable screening test should exist (safe, acceptable, high sensitivity/specificity, low cost), and the natural history should be understood. Recommended screenings: breast (mammography q2 years ages 50-74, ages 40-49 shared decision), cervical (Pap and HPV co-testing q5 years ages 25-65, or Pap alone q3 years), colorectal (colonoscopy q10 years, FIT q1 year, CT colonography q5 years, starting age 45), lung (low-dose CT annually ages 50-80 with 20 pack-year smoking history), and prostate (PSA, shared decision for ages 55-69). Overdiagnosis: detection of cancers that would never have caused symptoms (a risk of screening). False positives: require additional testing (imaging, biopsy) with associated anxiety and complications.

Cancer Staging

– The classification of cancer extent using the TNM system (Tumor, Node, Metastasis) from the AJCC (American Joint Committee on Cancer). T: size and local invasion of the primary tumor (Tx-T4). N: regional lymph node involvement (N0-N3). M: distant metastasis (M0-M1). Stage grouping: Stage 0 (carcinoma in situ), Stage I (localized, smaller tumors),

Stage II-III (locally advanced, nodal involvement), Stage IV (metastatic). Clinical staging (cTNM): based on physical exam, imaging, and biopsy. Pathological staging (pTNM): based on surgical pathology, more precise. Other staging systems: FIGO (gynecologic cancers), BCLC (HCC), Ann Arbor (lymphoma), Dukes (colorectal cancer, historical), Breslow thickness and Clark level (melanoma), Gleason score (prostate cancer). Staging determines prognosis, guides treatment selection (surgery, radiation, systemic therapy), and standardizes clinical trial eligibility. Stage migration: improved imaging shifts patients to higher stages (Will Rogers phenomenon).

Cancer Survivorship

– Cancer survivorship encompasses the physical, psychosocial, and economic effects of cancer diagnosis and treatment from the point of diagnosis through the balance of life. Over 18 million cancer survivors live in the United States, with prevalence increasing due to improved treatments and earlier detection. Survivorship care addresses treatment-related late effects and long-term complications: cardiovascular disease (anthracyclines causing cardiomyopathy, radiation causing coronary artery disease), second malignancies, endocrine dysfunction (hypothyroidism, gonadal failure, osteoporosis), cognitive impairment (chemo brain), chronic fatigue, peripheral neuropathy, and psychosocial issues (depression, anxiety, fear of recurrence, financial toxicity).

Cancer Treatment

– Cancer treatment encompasses surgery, radiation therapy, systemic therapies (chemotherapy, targeted therapy, immunotherapy, hormone therapy), and emerging modalities like CAR-T cell therapy. The choice depends on cancer type, stage, biomarkers, and patient health, with many patients receiving multimodal regimens. Advances in precision medicine tailor treatments to the genetic profile of individual tumors.

Carcinogen

– Any agent (chemical substance, physical radiation, or biological pathogen) directly capable of causing cancer by damaging cellular DNA or disrupting cellular metabolic/epigenetic processes. Examples: Chemical (tobacco smoke, benzene, asbestos, aflatoxin B1); Physical (ultraviolet light, ionizing

radiation); Biological (HPV, HBV, HCV, Epstein-Barr Virus, *Helicobacter pylori*). classified by IARC (Group 1: carcinogenic to humans).

Carcinoma

– A malignant neoplasm originating from epithelial cells, constituting approximately 85-90% of all human cancers. Subtypes: Adenocarcinoma (originating from glandular epithelium: breast, prostate, colon, lung adenocarcinoma) and Squamous Cell Carcinoma (originating from squamous epithelium: skin, esophagus, cervix, lung squamous cell carcinoma). Disseminates primarily via lymphatic system to regional lymph nodes.

Cervical Cancer

– The fourth most common cancer in women worldwide, with approximately 600,000 new cases annually, caused by persistent infection with high-risk human papillomavirus (HPV) types, most commonly HPV 16 and 18 (accounting for approximately 70 percent of all cervical cancers). Squamous cell carcinoma accounts for approximately 80 percent of cervical cancers, followed by adenocarcinoma (15-20 percent) and adenosquamous carcinoma. Risk factors include early sexual debut, multiple sexual partners, smoking, immunosuppression (HIV), long-term oral contraceptive use, and multiparity.

Chemoradiation (Chemoradiotherapy)

– Concurrent or sequential administration of chemotherapy and radiation therapy for synergistic anti-tumor effect. Chemotherapy acts as a radiosensitizer (increases radiation damage to DNA, inhibits repair, synchronizes cells in radiosensitive phases of the cell cycle). Indications: locally advanced cervical cancer (cisplatin + RT), head and neck squamous cell carcinoma (cisplatin + RT — definitive or adjuvant), anal cancer (5-FU + mitomycin + RT — definitive), NSCLC stage III (platinum doublet + RT — definitive), esophageal cancer (carboplatin + paclitaxel + RT — definitive; or FLOT + RT — perioperative), glioblastoma (temozolomide + RT — Stupp protocol), and rectal cancer (5-FU/capecitabine + RT — neoadjuvant). Sequential: chemotherapy first, then radiation. Concurrent: both given simultaneously (more effective, more toxic). Toxicity: enhanced acute effects (mucositis, esophagitis, enteritis, dermatitis, myelosuppression),

less effect on late toxicity if doses are appropriate.

Chemotherapy

– The use of cytotoxic drugs to kill rapidly dividing cancer cells. Classes: alkylating agents (cyclophosphamide, cisplatin, oxaliplatin — crosslink DNA), antimetabolites (5-FU, capecitabine, gemcitabine, methotrexate — interfere with DNA/RNA synthesis), antitumor antibiotics (doxorubicin, daunorubicin, bleomycin — intercalate DNA, generate free radicals), plant alkaloids (paclitaxel, docetaxel — microtubule stabilizers; vincristine, vinblastine — microtubule inhibitors), topoisomerase inhibitors (irinotecan, etoposide, topotecan), and miscellaneous (L-asparaginase, procarbazine). Administered IV (push, infusion), oral, intrathecal, intraperitoneal, or intra-arterial. Dosing: body surface area (mg/m^2), dose-limiting toxicity varies by drug (myelosuppression, cardiotoxicity, neurotoxicity, nephrotoxicity). Combination regimens are standard (e.g., CHOP, R-CHOP, FOLFOX, ABVD). Response assessment: RECIST 1.1 criteria (complete response, partial response, stable disease, progressive disease). Side effects: myelosuppression (neutropenia, thrombocytopenia, anemia), alopecia, nausea/vomiting, mucositis, and organ-specific toxicity.

Chemotherapy Extravasation

– Accidental leakage of chemotherapy drugs from the vein into the surrounding tissues, a potential medical emergency. Classification: vesicants (cause blisters, tissue necrosis — doxorubicin, daunorubicin, epirubicin, vincristine, vinblastine, paclitaxel, docetaxel, dactinomycin, mitomycin C, mechlorethamine), irritants (cause inflammation/pain — carboplatin, cisplatin, etoposide, topotecan, ifosfamide), and non-vesicants (benign — bleomycin, cyclophosphamide, 5-FU, methotrexate). Signs: immediate pain, burning, erythema, swelling at the site; later blistering, ulceration, necrosis. Management: STOP infusion immediately, leave the IV needle in place (aspirate residual drug), apply cold (anthracyclines, paclitaxel) or warm compresses (vinca alkaloids, etoposide). Specific antidotes: dexrazoxane (for anthracycline extravasation, IV over days 1-3), hyaluronidase (for vinca alkaloids and taxanes, subcutaneous injection), DMSO topical (for anthracyclines), and sodium thiosulfate (for mechlorethamine and cis-

platin). Surgical debridement may be required for severe necrosis.

Chemotherapy-Induced Nausea and Vomiting (CINV)

– A common and feared side effect of chemotherapy, classified by timing: acute (<24 hours after chemo), delayed (>24 hours), anticipatory (conditioned response before treatment), and breakthrough (occurs despite prophylaxis). High emetic risk ($>90\%$): cisplatin, cyclophosphamide >1500 mg/m^2 , dacarbazine, carmustine. Moderate (30-90%): carboplatin, oxaliplatin, doxorubicin, irinotecan. Low (10-30%): paclitaxel, docetaxel, 5-FU, gemcitabine. Minimal ($<10\%$): vincristine, bleomycin, bevacizumab. Antiemetic agents: NK1 receptor antagonists (aprepitant, fosaprepitant, netupitant), 5-HT₃ receptor antagonists (ondansetron, granisetron, palonosetron), corticosteroids (dexamethasone), and dopamine antagonists (metoclopramide, prochlorperazine). Guidelines (ASCO, NCCN): high risk — NK1 RA + 5-HT₃ RA + dexamethasone (day 1), then dexamethasone $\pm$ NK1 RA (days 2-4). Moderate risk — 5-HT₃ RA + dexamethasone. Anticipatory: behavioral therapy and optimal acute/delayed control. Breakthrough: add a different class antiemetic.

Chronic Lymphocytic Leukemia

– The most common leukemia in Western countries, characterized by the accumulation of mature but immunologically incompetent monoclonal B lymphocytes in the blood, bone marrow, lymph nodes, and spleen. Diagnosis requires a peripheral blood monoclonal B-lymphocyte count greater than or equal to 5000 per microliter with a characteristic immunophenotype (CD5+, CD19+, CD23+, CD200+, weak surface immunoglobulin, weak CD20). CLL has a highly variable clinical course, with some patients remaining asymptomatic for years while others progress rapidly.

Chronic Myeloid Leukemia

– A myeloproliferative neoplasm characterized by the Philadelphia chromosome [$t(9;22)(q34;q11.2)$], which creates the BCR-ABL1 fusion gene encoding a constitutively active tyrosine kinase. CML has three phases: chronic phase (most common at diagnosis, 85-90 percent, characterized by low blast count less than 10 percent, thrombocytosis, and basophilia),

accelerated phase (increasing blasts 10-19 percent, basophilia greater than 20 percent, or additional cytogenetic abnormalities), and blast phase (more than 20 percent blasts, resembling acute leukemia).

Colon Cancer / Colorectal Cancer

– Malignancy of the colon or rectum, typically arising from adenomatous polyps. Third most common cancer worldwide. Risk factors: age >50, family history, IBD, Lynch syndrome, smoking, obesity, and red meat consumption. Presents with change in bowel habits, hematochezia, abdominal pain, weight loss, and iron deficiency anemia. Screening: colonoscopy (starting at age 45), FIT, CT colonography. Treatment: surgical resection, chemotherapy (FOLFOX, FOLFIRI), radiation for rectal cancer, and targeted therapy.

Colorectal Cancer

– The third most common cancer worldwide, arising from abnormal growths called polyps in the colon or rectum that become malignant over time. Risk factors include age, family history, inflammatory bowel disease, diet high in red and processed meats, obesity, and smoking. Regular screening through colonoscopy can detect and remove precancerous polyps, dramatically reducing incidence and mortality.

Disseminated Intravascular Coagulation

– A pathological state of simultaneous systemic activation of coagulation and fibrinolysis, leading to widespread microvascular thrombosis that causes organ ischemia and dysfunction, paradoxically accompanied by consumptive coagulopathy and increased bleeding risk. DIC is triggered by conditions that expose tissue factor to the circulation: sepsis (most common trigger, especially gram-negative and fungal), trauma (tissue factor release), malignancy (especially acute promyelocytic leukemia and pancreatic cancer), and obstetric complications (placental abruption, amniotic fluid embolism, pre-eclampsia).

Electrochemotherapy

– A local cancer treatment that combines chemotherapy (bleomycin or cisplatin) with electroporation — brief, high-voltage electrical pulses applied to the tumor that create transient pores in cell membranes, dramatically increasing the intracellular concentration of chemotherapeutic drugs. Indications: cu-

taneous and subcutaneous metastases (melanoma, breast cancer, head and neck cancer), basal cell carcinoma, squamous cell carcinoma, and Kaposi sarcoma. The drug is injected IV or intratumorally, then electrical pulses are delivered through needle electrodes placed around the tumor under ultrasound guidance. Response rates: 70-85% for cutaneous lesions. Advantages: minimally invasive, treats irregularly shaped tumors, spares surrounding normal tissue. Limitations: requires specialized equipment, general anesthesia for larger treatments, limited to accessible lesions.

Esophageal Cancer

– Malignancy of the esophagus with two main histologic types: squamous cell carcinoma (upper/mid esophagus, associated with smoking and alcohol) and adenocarcinoma (lower esophagus, associated with GERD and Barrett esophagus). Presents with progressive dysphagia, weight loss, odynophagia, and regurgitation. Diagnosis: upper endoscopy with biopsy, EUS for staging. Treatment depends on stage: endoscopic resection for early, neoadjuvant chemoradiation followed by esophagectomy for locally advanced, and palliative chemo/palliation for metastatic.

Febrile Neutropenia

– An oncologic emergency defined as a single oral temperature $\geq 38.3^{\circ}\text{C}$ (101°F) or $\geq 38.0^{\circ}\text{C}$ (100.4°F) for ≥ 1 hour, with an absolute neutrophil count (ANC) $< 500/\mu\text{L}$ or expected to fall $< 500/\mu\text{L}$ within 48 hours. Most common dose-limiting toxicity of chemotherapy. Highest risk: after cytotoxic chemotherapy (especially anthracyclines, platinum, taxanes), typically 7-14 days after treatment. Common pathogens: gram-positive (coagulase-negative staphylococci, viridans group streptococci, *Staph aureus*) and gram-negative (*E. coli*, *Klebsiella*, *Pseudomonas aeruginosa*). MASCC risk index: low risk (≥ 21 , safe for outpatient oral antibiotics), high risk (< 21 , inpatient IV antibiotics). Empiric antibiotics: anti-pseudomonal beta-lactam (cefepime, meropenem, piperacillin-tazobactam) monotherapy. Add vancomycin for suspected line infection, skin/soft tissue infection, or MRSA colonization. Duration: treat until ANC $> 500/\mu\text{L}$ and afebrile for 48 hours. G-CSF (filgrastim, pegfilgrastim) for primary prophylaxis (risk $> 20\%$) or secondary after

febrile neutropenia episode.

Gastric Cancer

– Malignancy of the stomach, with intestinal (gland-forming, more common in high-risk regions) and diffuse (limits plastica, associated with CDH1 mutations) types. Risk factors: *H. pylori* infection, smoking, diet (pickled/smoked foods), and family history. Presents with dyspepsia, early satiety, weight loss, and epigastric pain. Often diagnosed at advanced stage. Diagnosis: upper endoscopy with biopsy, EUS, and CT for staging. Treatment: surgical resection, perioperative chemotherapy, and trastuzumab for HER2+ metastatic disease.

Glioma

– A tumor arising from glial cells (the supportive cells of the central nervous system). Gliomas account for approximately 25% of primary brain tumors and 80% of malignant brain tumors. WHO classification (2021, integrates histology and molecular markers): (1) Adult-type diffuse gliomas: astrocytoma, IDH-mutant (CNS WHO grade 2-4); oligodendroglioma, IDH-mutant and 1p/19q-codeleted (grade 2-3); glioblastoma, IDH-wildtype (grade 4). (2) Paediatric-type diffuse low-grade and high-grade gliomas. (3) Circumscribed astrocytic gliomas (pilocytic astrocytoma, grade 1, most common childhood glioma). Clinical features: headaches worse in morning, seizures, focal neurological deficits (weakness, sensory loss, speech difficulty, visual changes), cognitive changes, personality changes, signs of raised ICP (nausea, papilloedema). Diagnosis: MRI brain with contrast (T1 post-gadolinium, T2/FLAIR, diffusion, perfusion, spectroscopy). Treatment: maximal safe surgical resection, followed by radiotherapy and chemotherapy (temozolomide for glioblastoma–Stupp protocol, 60 Gy + 6 weeks temozolomide, then 6 cycles maintenance). Median survival: glioblastoma 12-15 months; anaplastic astrocytoma (grade 3) 2-5 years; low-grade glioma (grade 2) 5-15 years depending on IDH and 1p/19q status.

Gynecologic Cancers

– Cancers that originate in the female reproductive organs, including ovarian, cervical, uterine (endometrial), vulvar, and vaginal cancers. Risk factors vary by type but may include HPV infection, genetic mutations, hormonal factors, and age. Screening,

such as Pap smears and HPV testing, is essential for early detection, and treatment often involves surgery, chemotherapy, and radiation.

Head and Neck Cancer

– Group of malignancies arising from the mucosal surfaces of the upper aerodigestive tract—oral cavity, oropharynx, hypopharynx, larynx, nasopharynx, nasal cavity, paranasal sinuses—and salivary glands; approximately ninety percent are squamous cell carcinoma. Principal risk factors are tobacco, alcohol, betel quid, HPV, and Epstein-Barr virus. Multimodal treatment includes surgery, radiotherapy, chemoradiotherapy, and checkpoint inhibitors.

Hemophilia

– Hemophilia A (factor VIII deficiency, X-linked, 1 in 5000 males) and hemophilia B (factor IX deficiency, X-linked, 1 in 25,000 males) are inherited bleeding disorders caused by deficiency of intrinsic pathway coagulation factors, resulting in impaired thrombin generation and delayed clot formation. Severity correlates with factor activity level: severe (less than 1 percent, spontaneous hemarthrosis and soft tissue bleeding), moderate (1-5 percent, bleeding with minor trauma), and mild (5-40 percent, bleeding after surgery or significant injury).

Hepatocellular Carcinoma

– The most common primary liver malignancy, arising predominantly in the setting of chronic liver disease and cirrhosis. Risk factors include hepatitis B virus (HBV, the leading cause worldwide, especially in Asia and sub-Saharan Africa), hepatitis C virus (HCV, most common in developed countries), alcohol-related liver disease, non-alcoholic steatohepatitis (NASH), and hereditary hemochromatosis. Diagnosis in cirrhotic patients can be made non-invasively on imaging (CT or MRI) showing arterial hyperenhancement with venous washout.

Hodgkin Lymphoma

– A B-cell lymphoma characterized by the presence of Reed-Sternberg cells (large, binucleate or multinucleate cells with owl-eye nucleoli) in a background of reactive inflammatory cells. Classical HL (cHL) accounts for 95 percent of cases and is subdivided into nodular sclerosis (most common, mediastinal predominance, young adults), mixed cellularity, lymphocyte-rich, and lymphocyte-depleted subtypes. Nodular

lymphocyte-predominant HL (NLPHL, 5 percent) features lymphocyte-predominant cells (popcorn cells) with a nodular growth pattern and a more indolent clinical course.

Hormonal Therapy (Endocrine Therapy)

– Cancer treatments that block hormone signaling to inhibit growth of hormone-sensitive tumors. Breast cancer: selective estrogen receptor modulators (tamoxifen, raloxifene — block ER in breast, agonize in bone/uterus), aromatase inhibitors (anastrozole, letrozole, exemestane — block estrogen synthesis in postmenopausal women), selective estrogen receptor degraders (fulvestrant — downregulates ER), and ovarian suppression (GnRH agonists: leuprolide, goserelin — for premenopausal women). Prostate cancer: androgen deprivation therapy (GnRH agonists: leuprolide, goserelin — chemical castration; GnRH antagonist: degarelix), antiandrogens (bicalutamide, flutamide, nilutamide), and next-generation androgen receptor inhibitors (enzalutamide, apalutamide, darolutamide). Androgen synthesis inhibitor: abiraterone (inhibits CYP17, blocks adrenal and intratumoral androgen synthesis). Duration: adjuvant tamoxifen for 5-10 years, ADT for months to years depending on risk. Side effects: tamoxifen (hot flashes, VTE, endometrial cancer risk), aromatase inhibitors (arthralgias, osteoporosis, fractures), ADT (hot flashes, fatigue, loss of libido, erectile dysfunction, osteoporosis, metabolic syndrome, cardiovascular risk).

Immunotherapy Adverse Events

– Immune-related adverse events (irAEs) are inflammatory complications arising from checkpoint inhibitor-mediated immune activation against normal tissues, occurring in 60-80 percent of patients on combination therapy and 20-40 percent on monotherapy. The pathophysiology involves loss of immune tolerance to self-antigens due to blockade of inhibitory checkpoints that normally maintain peripheral tolerance. irAEs can affect virtually any organ system and occur at any time during treatment (median onset of 2-16 weeks after treatment initiation, depending on the agent and organ system involved).

Immunotherapy (Cancer)

– Cancer treatments that harness the immune sys-

tem to recognize and destroy tumor cells. Checkpoint inhibitors (most impactful): anti-PD-1 (pembrolizumab, nivolumab, cemiplimab), anti-PD-L1 (atezolizumab, durvalumab, avelumab), anti-CTLA-4 (ipilimumab). Indications: melanoma, NSCLC, RCC, bladder, head and neck, Hodgkin lymphoma, MSI-high colorectal, and many others. Combination: PD-1 + CTLA-4 (nivolumab + ipilimumab) in melanoma, RCC, mesothelioma. Chimeric antigen receptor T-cell therapy (CAR-T): autologous T cells engineered to express a synthetic receptor targeting a tumor antigen (CD19 for ALL, DLBCL; BCMA for multiple myeloma). Approved products: tisagenlecleucel (Kymriah), axicabtagene ciloleucel (Yescarta), brexucabtagene autoleucel (Tecartus), lisocabtagene maraleucel (Breyanzi), idecabtagene vicleucel (Abecma). Cytokine therapy: IL-2 (high-dose for metastatic RCC, melanoma) and interferon-alpha (melanoma, RCC, CML). Oncolytic virus therapy: talimogene laherparepvec (T-VEC, modified herpes simplex virus injected into melanoma lesions). Bispecific T-cell engagers (BiTEs): blinatumomab (CD3-CD19 for ALL). Immune-related adverse events (irAEs): colitis, pneumonitis, hepatitis, dermatitis, endocrinopathies (thyroiditis, hypophysitis), and myocarditis (rare but fatal). Response patterns: pseudoprogression (transient enlargement before regression), durable responses, and hyperprogression (uncommon).

Kidney Cancer (Renal Cell Carcinoma)

– The most common type of kidney cancer, arising from renal tubular epithelium. Subtypes: clear cell (75%), papillary (15%), and chromophobe (5%). Risk factors: smoking, obesity, hypertension, and genetic syndromes (VHL, Birt-Hogg-Dube, hereditary papillary RCC). Classic triad: hematuria, flank pain, and palpable mass (now less common with incidental detection on imaging). Diagnosis: CT or MRI with contrast. Treatment: partial or radical nephrectomy; targeted therapy and immunotherapy for advanced disease.

Laryngeal Cancer

– Malignancy of the larynx, most commonly squamous cell carcinoma. Risk factors: smoking, alcohol, HPV infection. Presents with hoarseness (glottic tumors), dysphagia, stridor, and referred ear pain.

Diagnosis: laryngoscopy with biopsy, CT/MRI for staging. Treatment: early stage (radiation or transoral laser surgery), advanced stage (total laryngectomy with chemoradiation, voice rehabilitation). Prognosis depends on stage and location.

Liver Cancer

– Malignant tumors originating in the liver (primary liver cancer). The most common type is hepatocellular carcinoma (HCC), accounting for 85-90% of primary liver cancers. See Hepatocellular Carcinoma.

Liver Cancer (Hepatocellular Carcinoma)

– The most common primary liver malignancy, typically arising in the setting of cirrhosis (hepatitis B/C, alcohol, NAFLD/NASH). Presents with right upper quadrant pain, hepatomegaly, ascites, and elevated alpha-fetoprotein (AFP). Diagnosis: multiphasic CT or MRI shows arterial hyperenhancement with washout. Treatment: surgical resection, liver transplantation, ablation (RFA, MWA), TACE, and systemic therapy (atezolizumab-bevacizumab, sorafenib, lenvatinib).

Living with Cancer

– Living with cancer encompasses the continuum from diagnosis through active treatment to survivorship or advanced illness, addressing physical, emotional, social, and practical challenges. Active treatment involves surgery, chemotherapy, radiation, immunotherapy, targeted therapy, or combinations thereof, tailored to cancer type, stage, and biomarkers. Common treatment side effects include fatigue, pain, nausea, myelosuppression, neuropathy, and immunotoxicity requiring proactive supportive care (antiemetics, growth factors, pain management). Survivorship care focuses on monitoring for recurrence, managing late effects (cardiotoxicity, secondary malignancies, cognitive impairment), and promoting health behaviors. For advanced/metastatic disease, palliative care integrated early improves quality of life, symptom control, and survival; goals-of-care discussions and advance care planning are essential.

Lung Cancer

– The leading cause of cancer death worldwide. Non-small cell lung cancer (NSCLC, 85%) includes adenocarcinoma, squamous cell carcinoma, and large

cell carcinoma. Small cell lung cancer (SCLC, 15%) is highly aggressive. Risk factor: tobacco smoking (85% of cases). Presents with cough, hemoptysis, dyspnea, chest pain, and weight loss. Diagnosis: CT chest, biopsy (bronchoscopy, needle aspiration), molecular testing (EGFR, ALK, ROS1, PD-L1). Treatment: surgical resection, chemotherapy, radiation, targeted therapy (osimertinib, alectinib), and immunotherapy (pembrolizumab, nivolumab).

Malignant Tumor

– Neoplasm with uncontrolled proliferation, local tissue invasion, and distant metastasis, hallmarked by cellular atypia, mitotic activity, and loss of differentiation. Classified by embryologic lineage as carcinoma, sarcoma, leukemia, lymphoma, melanoma, germ cell tumors, and blastomas; graded histologically and staged by the TNM system. Untreated, death follows local destruction, metastatic replacement, paraneoplastic syndromes, and cachexia. See Tumor and Benign Tumor.

Metastasis

– The multi-step cascade by which malignant cancer cells spread from a primary tumor site to distant non-adjacent tissues or organs. Steps: local invasion, intravasation into blood or lymphatic vessels, survival in circulation, extravasation into parenchyma of distant organs, microcolonization, and angiogenesis. Common metastatic sites: bone, liver, lung, brain (the "seed and soil" hypothesis). Primary determinant of cancer mortality.

Mutagenesis

– Process by which heritable changes arise in DNA sequence, structure, or copy number, generating the genetic diversity on which oncogenesis operates. Mutagens are physical, chemical, or biological, with mechanisms including base substitutions, frameshifts, chromosomal rearrangements, aneuploidy, and epigenetic alterations. Endogenous sources include replication errors and oxidative damage. Assayed by the Ames test. See Carcinogenesis.

Myelodysplastic Syndromes

– Clonal hematopoietic stem cell disorders characterized by ineffective hematopoiesis, peripheral blood cytopenias, dysplastic morphology, and risk of transformation to acute myeloid leukemia. The WHO classification categorizes MDS by percentage of blasts (MDS with single lineage dysplasia,

MDS with multilineage dysplasia, MDS with ring sideroblasts, MDS with excess blasts-1 [5-9 percent], MDS with excess blasts-2 [10-19 percent], and MDS/AML [20-29 percent]) and cytogenetic abnormalities (deleted 5q, -7, deleted 7q, +8, deleted 20q, complex karyotype) for risk stratification using the Revised International Prognostic Scoring System (IPSS-R).

Neoadjuvant Therapy

– Treatment given before definitive surgery to downstage tumors, convert unresectable to resectable, and assess response. Chemotherapy: breast (doxorubicin + cyclophosphamide → paclitaxel, or TCHP for HER2+), esophageal/gastric (FLOT), rectal (5-FU/capecitabine + RT), bladder (MVAC or gemcitabine + cisplatin), and pancreatic (FOLFIRINOX or gemcitabine + nab-paclitaxel for borderline resectable). Hormonal therapy: aromatase inhibitor for 3-6 months in postmenopausal ER+ breast cancer. Targeted/immunotherapy: checkpoint inhibitors in melanoma, NSCLC. Benefits: allows in vivo assessment of response (pathologic complete response pCR strongly predicts survival), facilitates breast-conserving surgery, treats micrometastases early. Disadvantages: initial treatment delay if the diagnosis is uncertain, treatment-related toxicity before surgery.

Neuroblastoma

– The most common extracranial solid tumor in children, arising from neural crest cells of the sympathetic nervous system. Median age at diagnosis: 17 months. Most common site: adrenal medulla (40%). Presents with abdominal mass, bone pain (from metastases), proptosis (periorbital metastases), and Horner syndrome. Favorable prognosis: age <18 months, localized disease, MYCN amplification absent. Unfavorable: MYCN amplification, older age, metastatic disease. Urine catecholamines (VMA/HVA) elevated in 90%. Treatment: risk-stratified: surgery alone for low-risk, chemotherapy + surgery ± radiation for intermediate-risk, intensive chemotherapy + stem cell transplant + immunotherapy + isotretinoin for high-risk.

Non-Hodgkin Lymphoma

– A diverse group of lymphoproliferative malignancies originating from B cells (85%), T cells, or NK cells. Common subtypes: diffuse large B-cell lymphoma (DLBCL), follicular lymphoma, marginal zone lymphoma, mantle cell lymphoma, and peripheral T-cell lymphoma. Presents with painless lymphadenopathy, fever, night sweats, and weight loss (B symptoms). Diagnosis: lymph node biopsy with flow cytometry, cytogenetics, and FISH. Treatment: chemoimmunotherapy (R-CHOP for DLBCL), targeted therapy, radiation, and stem cell transplantation for relapsed/refractory disease.

Oncogene

– A mutated or overexpressed form of a normal cellular gene (proto-oncogene) that promotes autonomous cell growth, proliferation, and survival. Activation occurs via point mutation (e.g., *KRAS*), gene amplification (e.g., *HER2/neu*), or chromosomal translocation (e.g., *BCR – ABL1* fusion gene in CML, *MYC* in Burkitt lymphoma). Acts in a dominant gain-of-function fashion (one mutated allele is sufficient).

Operable

– A term describing a tumor or condition that is amenable to surgical removal or treatment, typically implying that the disease is localised (no distant metastases) and that the patient's general health and fitness (performance status, cardiopulmonary reserve, comorbidities) are adequate to tolerate the planned surgical procedure and anesthesia. In oncology, 'operable' vs 'inoperable' is a critical distinction: operable cancers are treated with curative-intent resection, whereas inoperable cancers (locally advanced or metastatic) are managed with non-surgical modalities (chemotherapy, radiotherapy, immunotherapy, palliative care). Resectability criteria vary by tumor type—e.g., pancreatic cancer is considered borderline resectable if there is abutment of the superior mesenteric artery or celiac axis; liver metastases are resectable if adequate functional liver remnant remains after resection. Assessment includes staging investigations (CT, PET-CT, MRI), multidisciplinary team discussion, and preoperative risk assessment (cardiopulmonary exercise testing, ASA grade).

Oral Cancer

– Malignancy of the oral cavity, most commonly squamous cell carcinoma. Risk factors: tobacco (smoking, chewing), alcohol, betel nut, and HPV infection. Presents with non-healing ulcer, erythro-

plakia, leukoplakia, or mass in the mouth. Diagnosis: biopsy. Treatment: surgical resection with or without radiation and chemotherapy. Early detection significantly improves prognosis. Prevention: tobacco cessation, alcohol moderation, and HPV vaccination.

Other Cancers

– malignancies beyond the most common types (breast, lung, prostate, colorectal), including pancreatic (high lethality, 5-year survival 12%), liver/hepatocellular (rising incidence, linked to HBV/HCV, MASLD, alcohol), ovarian ("silent killer," often diagnosed at late stage), gastric, esophageal, bladder, kidney (renal cell carcinoma), thyroid (generally favorable prognosis), head and neck (squamous cell, linked to HPV and tobacco/alcohol), brain (glioblastoma, meningioma), sarcoma (bone and soft tissue), lymphoma (Hodgkin and non-Hodgkin), leukemia, multiple myeloma, and melanoma. Each has distinct biology, risk factors, screening modalities (where applicable), and treatment paradigms. General principles: staging (TNM classification) dictates treatment—surgery, radiation, systemic therapy (chemotherapy, molecular targeted therapy, immunotherapy, hormonal therapy)—and prognosis. Emerging approaches: tumor molecular profiling (next-generation sequencing, liquid biopsy), cancer immunotherapy (immune checkpoint inhibitors, CAR-T cells), and personalized medicine based on biomarkers.

Ovarian Cancer

– Epithelial ovarian cancer is the leading cause of death from gynecologic malignancies, with 70-80 percent of patients diagnosed at advanced stage due to the absence of reliable screening tests. High-grade serous carcinoma (the most common subtype, 70 percent) originates from the fallopian tube epithelium (serous tubal intraepithelial carcinoma, STIC, is the precursor lesion), not the ovary as previously thought. BRCA1/2 germline mutations are found in 15-20 percent of ovarian cancers, conferring sensitivity to platinum-based chemotherapy and PARP inhibitors.

Paget Disease of the Nipple

– A rare presentation of breast cancer involving the nipple-areola complex, accounting for 1-4% of all breast cancers. Paget disease of the nipple is char-

acterized by infiltration of the nipple epidermis by malignant glandular cells (Paget cells—large, pale, vacuolated cells with prominent nucleoli, positive for CK7, HER2/neu, and GATA3). Clinical presentation: an erythematous, eczematous, scaling, or crusted lesion of the nipple and areola, often associated with itching, burning, or tenderness. The lesion may be mistaken for eczema or dermatitis; failure to resolve with topical corticosteroids should prompt biopsy. Underlying breast cancer is present in >90% of cases: either an in situ component (ductal carcinoma in situ—DCIS) or invasive ductal carcinoma, which may be palpable or detected on imaging. Diagnosis: full-thickness skin punch biopsy of the nipple-areola lesion, mammogram and ultrasound of the ipsilateral breast, and MRI if indicated. Treatment: total mastectomy (with or without sentinel lymph node biopsy) is standard; breast-conserving surgery (central lumpectomy with nipple-areola complex excision and whole-breast radiotherapy) is an option for localized disease without palpable mass. Prognosis depends on the stage of the underlying breast cancer; Paget disease without associated invasive cancer has an excellent prognosis.

Palliative Care in Oncology

– An interdisciplinary approach to improving quality of life for patients with serious illness, focused on symptom management, communication about goals of care, and caregiver support. Not limited to end-of-life; early concurrent palliative care (alongside active treatment) improves symptom burden, quality of life, and survival in metastatic NSCLC (Temel 2010). Symptom management: pain (WHO analgesic ladder, opioids, neuropathic agents, palliative radiation), nausea, dyspnea, fatigue, cachexia, depression, and anxiety. Advance care planning: goals of care discussions, code status (DNR/DNI, DNR-CC), living will, and healthcare proxy. Hospice: palliative care for patients with a life expectancy of ≤ 6 months; focuses on comfort rather than disease-modifying therapy. Referral to palliative care: recommended for all patients with advanced cancer, regardless of prognosis.

Pancreatic Ductal Adenocarcinoma

– One of the most lethal solid organ malignancies, with 5-year overall survival rates of approxi-

mately 12 percent overall and less than 3 percent for metastatic disease, due to late diagnosis and chemoresistance. Risk factors include smoking (2-3 fold increased risk), obesity, chronic pancreatitis, hereditary pancreatitis, family history, BRCA1/2 and PALB2 germline mutations, Lynch syndrome, and Peutz-Jeghers syndrome. The majority (85 percent) are located in the pancreatic head, causing early obstructive jaundice, while body and tail tumors present at a more advanced stage.

Paraneoplastic Syndromes

– Systemic manifestations of cancer that occur distant from the primary tumor or metastases, mediated by hormones, cytokines, antibodies, or immune cross-reactivity between tumor and normal tissue antigens. Endocrine paraneoplastic syndromes include ectopic ACTH production (small cell lung cancer causing Cushing syndrome with hypokalemia, metabolic alkalosis), syndrome of inappropriate antidiuretic hormone secretion (SIADH, small cell lung cancer causing hyponatraemia), hypercalcaemia (squamous cell lung cancer producing PTHrP), and hypoglycaemia (insulinoma or IGF-2-producing sarcomas).

Paroxysmal Nocturnal Hemoglobinuria

– An acquired clonal hematopoietic stem cell disorder caused by somatic mutations in the PIGA gene (phosphatidylinositol glycan class A), which encodes an enzyme essential for the biosynthesis of glycosylphosphatidylinositol (GPI) anchors that attach complement regulatory proteins (CD55 and CD59) to the cell surface. Loss of CD55 (accelerator of C3 convertase decay) and CD59 (inhibitor of membrane attack complex formation) renders red blood cells, white blood cells, and platelets susceptible to complement-mediated destruction, resulting in intravascular haemolysis, thrombosis, and bone marrow failure.

Pediatric Solid Tumors

– Pediatric solid tumors differ from adult cancers in histology, biology, treatment response, and long-term survivorship considerations. Wilms tumor (nephroblastoma) is the most common renal malignancy in children (peak age 2-4 years), presenting as a large, smooth, flank mass with staging by National Wilms Tumor Study (NWTs) criteria; treatment in-

cludes nephrectomy and chemotherapy (vincristine, dactinomycin, doxorubicin for unfavorable histology). Neuroblastoma arises from neural crest cells (most commonly adrenal), presenting with an abdominal mass, bone pain, proptosis, Horner syndrome, and elevated urinary catecholamines.

Photodynamic Therapy (PDT)

– A treatment that combines a photosensitizing agent with light to produce reactive oxygen species that destroy cancer cells. Mechanism: the photosensitizer (porfimer sodium Photofrin, aminolevulinic acid ALA) is administered IV or topically and accumulates preferentially in tumor tissue. A laser or LED light of a specific wavelength activates the photosensitizer, generating singlet oxygen that causes direct tumor cell kill, vascular damage, and immune activation. Indications: actinic keratosis and superficial BCC (topical ALA-PDT), Barrett esophagus with high-grade dysplasia (porfimer sodium — Photofrin PDT), early-stage endobronchial NSCLC, and malignant pleural mesothelioma (intraoperative PDT). Side effects: photosensitivity (skin and eye sensitivity for 4-6 weeks), local pain, edema, and scarring. Limited depth of penetration (<1 cm for most photosensitizers) restricts PDT to superficial tumors.

Precision Oncology (Molecular Oncology)

– The tailoring of cancer treatment based on the unique molecular, genomic, and immunologic characteristics of each patient's tumor. Approaches: next-generation sequencing (NGS) of tumor tissue or liquid biopsy (ctDNA from blood) to identify actionable mutations. Biomarker-driven therapy: EGFR mutations (osimertinib in NSCLC), ALK fusions (alectinib), BRAF V600E (vemurafenib, dabrafenib + trametinib in melanoma), HER2 amplification (trastuzumab, T-DXd in breast, gastric, lung), MSI-high/dMMR (pembrolizumab in any solid tumor — tissue-agnostic approval), NTRK fusions (larotrectinib, entrectinib — tissue-agnostic), and BRCA mutations (olaparib, talazoparib). Tumor mutational burden (TMB): high TMB (≥ 10 mut/Mb) predicts immunotherapy response. Homologous recombination deficiency (HRD): predicts PARP inhibitor and platinum sensitivity. Minimal residual disease (MRD): ctDNA detection after curative-

intent treatment predicts recurrence. Challenges: tumor heterogeneity, acquired resistance, access to testing, and cost.

Prostate Cancer

– The most common cancer in men, typically adenocarcinoma arising from the peripheral zone of the prostate. Risk factors: age, family history, African American race, and BRCA2 mutations. Often asymptomatic early; advanced disease causes urinary symptoms, hematuria, and bone pain (from metastases). Screening: PSA blood test and digital rectal exam. Diagnosis: transrectal ultrasound-guided biopsy with Gleason scoring. Treatment: active surveillance for low-risk, prostatectomy, radiation, androgen deprivation therapy, and novel hormonal agents for advanced disease.

Radiation Sickness

– A constellation of symptoms resulting from exposure to high doses of ionizing radiation, typically >1 gray (Gy) whole-body or significant partial-body exposure. Acute radiation syndrome (ARS) follows a predictable dose-dependent course: prodromal phase (within minutes to hours—nausea, vomiting, diarrhea, anorexia, fatigue), latent phase (hours to days—apparent recovery), manifest illness phase (days to weeks—depending on the dose and organ system affected), and recovery or death. Three main ARS subsyndromes: (1) hematopoietic (2–6 Gy)—pancytopenia from bone marrow destruction, leading to infection, bleeding, and anemia; mortality without supportive care is high. (2) Gastrointestinal (6–10 Gy)—destruction of intestinal crypt cells, leading to severe diarrhea, dehydration, electrolyte imbalance, and sepsis from gut barrier breakdown. (3) Neurovascular (>10 Gy)—rapid onset of confusion, ataxia, seizures, coma, and cardiovascular collapse; universally fatal within hours to days. Chronic radiation effects: carcinogenesis (leukemia, solid tumors), cataracts, fibrosis, and hypothyroidism. Cutaneous radiation syndrome: erythema, desquamation, ulceration, necrosis. Management of ARS: remove from source, decontaminate, supportive care (transfusions, growth factors—G-CSF, GM-CSF, antibiotics, antiemetics), and potentially bone marrow transplant for severe hematopoietic syndrome. Potassium iodide for radioactive iodine exposure. Radiation sickness is rare and most

commonly associated with nuclear accidents (Chernobyl, Fukushima), radiation therapy accidents, and potential nuclear events.

Radiation Therapy (Radiotherapy)

– The use of ionizing radiation to kill cancer cells by inducing DNA damage (double-strand breaks). External beam radiation therapy (EBRT): linear accelerator delivers photons (X-rays) or electrons from outside the body. Techniques: 3D conformal (3D-CRT), intensity-modulated (IMRT), volumetric modulated arc (VMAT), stereotactic radiosurgery (SRS, for brain lesions — Gamma Knife, CyberKnife), and stereotactic body RT (SBRT, for lung, liver, spine, pancreas — high-dose, 1-5 fractions). Brachytherapy: radioactive source placed inside or near the tumor (prostate I-125 seeds, cervical cancer tandem and ovoid, breast accelerated partial breast irradiation). Proton therapy: protons deposit most energy at a specific depth (Bragg peak), sparing deeper tissues; used for pediatric, skull base, ocular, and prostate cancers. Fractionation: total dose divided into daily fractions (1.8-2.0 Gy) to allow normal tissue repair. Standard total doses: 45-50.4 Gy for microscopic disease, 60-70 Gy for gross disease. SBRT: 24-60 Gy in 1-5 fractions. Side effects: acute (skin erythema, mucositis, diarrhea, fatigue — during treatment) and late (fibrosis, xerostomia, secondary malignancy, cardiac toxicity, pulmonary fibrosis — months to years after). Radioprotectors (amifostine) and radiosensitizers (cisplatin, 5-FU) modulate radiation effects.

Radioembolization (Y-90 Selective Internal Radiation Therapy SIRT)

– A liver-directed therapy where yttrium-90 (Y-90) microspheres (glass: TheraSphere; resin: SIR-Spheres) are infused into the hepatic artery and lodge in tumor microvasculature, delivering high-dose beta radiation (30-60 Gy average, up to 200 Gy to tumor) while sparing normal liver tissue. Indications: HCC (BCLC B, C with PVT), colorectal liver metastases (chemoresistant), and other liver-dominant tumors. Pre-treatment: mesenteric angiography with Tc-99m MAA scan to calculate lung shunt fraction (<20%) and identify extrahepatic flow. Lung shunt >20%: contraindicated (risk of radiation pneumonitis). Advantages over TACE: less post-embolization syndrome, applicable with portal

vein thrombosis. Complications: radiation-induced liver disease (RILD, rare with proper dosimetry), radiation pneumonitis, gastric/duodenal ulceration (from non-target embolization), and biliary toxicity.

Radioisotope

– A radioactive isotope of an element that emits radiation (alpha particles, beta particles, gamma rays) as it decays to a stable form. Radioisotopes are used extensively in medicine for diagnostic imaging, therapeutic procedures, and research. Diagnostic radioisotopes: technetium-99m (most common, used in SPECT imaging—bone scans, myocardial perfusion, renal scans, lung ventilation/perfusion scans), iodine-123 (thyroid imaging), thallium-201 (myocardial perfusion), gallium-67 (infection/inflammation imaging), indium-111 (white blood cell scanning), and fluorine-18 (FDG-PET—most common PET tracer, glucose analogue for oncology, neurology, cardiology). Therapeutic radioisotopes: iodine-131 (hyperthyroidism, thyroid cancer), yttrium-90 (selective internal radiation therapy—SIRT for liver tumors, radioembolisation), lutetium-177 (PRRT for neuroendocrine tumors), radium-223 (bone metastases in castration-resistant prostate cancer), strontium-89 and samarium-153 (palliative therapy for painful bone metastases). Production: nuclear reactors (neutron activation) or cyclotrons (proton bombardment). Half-life: time for 50% of atoms to decay—ranges from minutes (technetium-99m: 6 hours) to years (cobalt-60: 5.3 years). Safety: radioisotopes require careful handling, shielding, and disposal; ALARA principle (as low as reasonably achievable).

Recurrence

– Reappearance of malignant disease after a period of complete clinical, radiographic, and biochemical remission, indicating residual microscopic disease below detection threshold. Classified as local, regional, or distant, and monitored by surveillance imaging, endoscopy, tumour markers, and clinical review. Management—salvage surgery, re-irradiation, systemic therapy, or palliation—depends on site, timing, prior therapy, and performance status. Distinguished from progression and refractory disease.

Remission

– A period during which the signs and symptoms of a chronic disease are reduced or absent. In

cancer, remission is classified as: complete remission (CR)—disappearance of all detectable tumor (clinical, radiographic, and laboratory evidence of disease) for at least 1 month; partial remission (PR)— $\geq 50\%$ reduction in tumor size and/or extent of disease; and stable disease (SD)—no significant change. Remission is not synonymous with cure, as microscopic residual disease may persist and lead to relapse. In autoimmune diseases (rheumatoid arthritis, systemic lupus erythematosus, inflammatory bowel disease), remission is defined by clinical (absence of symptoms), biochemical (normal inflammatory markers), and/or endoscopic (mucosal healing in IBD) criteria. In psychiatric disorders (depression—remission is defined as a Hamilton Depression Rating Scale score ≤ 7 ; schizophrenia—remission is defined by sustained improvement in core symptoms for ≥ 6 months). The goal of treatment is to achieve and maintain remission. Monitoring during remission includes regular follow-up, surveillance imaging, and laboratory tests to detect early relapse.

Retinoblastoma

– The most common intraocular malignancy in children, arising from retinal precursor cells. Presents with leukocoria (white pupillary reflex, most common), strabismus, and vision loss. Bilateral in 40% (associated with germline RB1 mutation). Unilateral: median age 24 months; bilateral: 12 months. Diagnosis: fundoscopic examination under anesthesia, ultrasound, MRI. Treatment: enucleation for large unilateral tumors; chemoreduction (vincristine, carboplatin, etoposide) plus focal therapy (cryotherapy, laser photocoagulation) for bilateral and globe-sparing approaches. External beam radiation reserved due to second malignancy risk.

Sarcoma

– A rare malignant neoplasm derived from mesenchymal (connective tissue) origin, including bone, cartilage, fat, muscle, and blood vessels. Examples: Osteosarcoma (bone), Chondrosarcoma (cartilage), Leiomyosarcoma (smooth muscle), Rhabdomyosarcoma (skeletal muscle), Liposarcoma (fat), Ewing Sarcoma. Tends to metastasize hematogenously (primarily to lungs) rather than via lymphatics.

Skin Cancer

– The most common cancer overall, including basal cell carcinoma (BCC, most common), squamous

cell carcinoma (SCC), and melanoma (most dangerous). BCC: pearly papule with telangiectasias, rarely metastasizes. SCC: scaly, hyperkeratotic lesion, can metastasize. Risk factors: UV radiation exposure, fair skin, immunosuppression, and genetic disorders. Prevention: sun protection, avoiding tanning beds. Treatment: surgical excision, Mohs surgery for cosmetically sensitive areas, and topical therapies for superficial lesions.

Soft Tissue Sarcoma

– Rare malignant neoplasm arising from mesenchymal derivatives—adipose, muscle, nerve sheath, vessels, fibrohistiocytic tissue—with over seventy subtypes. Patients present with a painless enlarging mass greater than five centimeters, deep to fascia, often in a thigh or retroperitoneum. Diagnosis requires MRI and core-needle biopsy with histology, grade, immunohistochemistry, and molecular testing. Management is by specialist sarcoma teams.

Stem Cell Transplantation (Hematopoietic)

– See Bone Marrow Transplantation.

Survival Rate

– Proportion of patients in a defined cohort alive at a specified time after diagnosis or treatment, used as a primary oncology outcome. Overall survival counts all deaths; disease-specific survival counts cancer-attributable deaths; relative survival corrects for competing risks. The five-year figure is most reported. Estimated by Kaplan-Meier and Cox methods, and influenced by stage, biology, comorbidity, treatment, and screening bias.

Targeted Therapy

– Drugs that interfere with specific molecules required for tumor growth and progression, as opposed to non-specific cytotoxic chemotherapy. Tyrosine kinase inhibitors (TKIs): imatinib (BCR-ABL in CML, KIT in GIST), erlotinib and osimertinib (EGFR in NSCLC), crizotinib and alectinib (ALK in NSCLC), sorafenib and lenvatinib (VEGFR in HCC, RCC), sunitinib (VEGFR, PDGFR in RCC, GIST), and ibrutinib (BTK in CLL, MCL). Monoclonal antibodies: trastuzumab (HER2 in breast/gastric cancer), cetuximab (EGFR in colorectal/head and neck), bevacizumab (VEGF in colorectal, NSCLC, RCC — antiangiogenic), and rituximab (CD20 in B-cell lymphomas). Small

molecule inhibitors: vemurafenib and dabrafenib (BRAF V600E in melanoma), palbociclib (CDK4/6 in breast cancer), enzalutamide (androgen receptor in prostate cancer), and olaparib (PARP inhibitor in BRCA-mutated breast, ovarian, pancreatic, prostate cancer). Mechanism: TKIs bind the ATP-binding pocket of the kinase domain, inhibiting phosphorylation and downstream signaling. Resistance mechanisms: secondary mutations (T790M for first-generation EGFR inhibitors, T315I for imatinib), bypass pathway activation, and drug efflux. Side effects: fatigue, diarrhea, rash (EGFR inhibitors), hand-foot syndrome (sorafenib, sunitinib), hypertension (VEGF inhibitors), and pneumonitis (mTOR inhibitors, EGFR inhibitors).

Teratoma

– See Teratoma in Obstetrics and Gynecology.

Testicular Cancer

– The most common solid tumor in young men (age 15-35), with an excellent prognosis with cure rates exceeding 95 percent even for advanced disease. Risk factors include cryptorchidism, history of contralateral testicular cancer, and germ cell neoplasia in situ (GCNIS, formerly intratubular germ cell neoplasia). Pathology classification includes seminoma (50 percent, excellent prognosis, sensitive to radiation and chemotherapy) and non-seminomatous germ cell tumors (NSGCT, 50 percent including embryonal carcinoma, yolk sac tumor, choriocarcinoma, and teratoma).

Thrombotic Thrombocytopenic Purpura

– A life-threatening thrombotic microangiopathy caused by severe deficiency of ADAMTS13 (a disintegrin and metalloproteinase with thrombospondin type 1 motif member 13), a von Willebrand factor-cleaving protease. ADAMTS13 deficiency (activity less than 10 percent) leads to accumulation of ultra-large von Willebrand factor multimers that cause spontaneous platelet adhesion and aggregation in the microcirculation, forming platelet-rich thrombi that consume platelets and cause microangiopathic hemolytic anemia with characteristic schistocytes on peripheral blood smear.

Thyroid Cancer

– Malignancy of the thyroid gland, with subtypes:

papillary (80%, best prognosis), follicular, medullary (associated with MEN2), and anaplastic (most aggressive). Usually presents as a thyroid nodule. Diagnosis: thyroid ultrasound and fine-needle aspiration biopsy (Bethesda classification). Treatment: thyroidectomy, radioactive iodine ablation for differentiated types, and TSH suppression with levothyroxine. Prognosis is excellent for papillary and follicular, poor for anaplastic.

TNM Staging System

– An internationally accepted anatomical staging system established by the AJCC/UICC to describe the extent of cancer spread. Components: T (Primary Tumor size and local extent, T0-T4), N (Regional Lymph Node involvement, N0-N3), M (Distant Metastasis presence, M0 or M1). Grouped into overall clinical stages (Stage 0 to Stage IV). Guides prognosis, treatment planning, and clinical trial stratifications.

Transarterial Chemoembolization (TACE)

– A liver-directed therapy for hepatocellular carcinoma (HCC) that delivers chemotherapy directly to the tumor through its hepatic artery blood supply while blocking blood flow. Procedure: a catheter is advanced through the femoral artery into the hepatic artery, then selectively into tumor-feeding vessels. Chemotherapy (doxorubicin, cisplatin, or mitomycin C, often emulsified in Lipiodol) is infused, followed by embolic agents (gelatin sponge particles, microspheres, or drug-eluting beads DEB-TACE). Indications: BCLC stage B (intermediate) HCC, also used as bridging therapy to transplant, downstaging, or palliation. Contraindications: decompensated cirrhosis (Child-Pugh C), main portal vein thrombosis, extensive extrahepatic disease, and poor performance status. Response: assessed by mRECIST (modified RECIST) — viability based on arterial enhancement. Side effects: post-embolization syndrome (fever, pain, nausea — 80%, self-limited), liver abscess, biliary injury, and tumor lysis. Repeat: every 6-12 weeks as needed.

Trousseau Syndrome (Migratory Thrombophlebitis)

– A paraneoplastic hypercoagulable state characterized by recurrent, migratory venous thrombosis and superficial thrombophlebitis appearing in multiple

atypical venous locations (arms, torso). Caused by tumor cell secretion of tissue factor, mucins, and procoagulants. Most strongly associated with Pancreatic Adenocarcinoma (particularly body and tail of pancreas), as well as gastric, lung, and ovarian cancers. Indicates advanced malignancy.

Tumor

– An abnormal mass of tissue resulting from uncontrolled, excessive cell proliferation. tumors are classified as benign or malignant. Benign tumors: well-circumscribed, slow-growing, non-invasive, do not metastasise, composed of well-differentiated cells resembling the tissue of origin. Often cured by surgical excision. Examples: lipoma (adipose tissue), leiomyoma/fibroid (smooth muscle—uterus), adenoma (glandular epithelium—colon, pituitary, thyroid), papilloma (epithelial—skin, breast ducts), meningioma (meninges), fibroadenoma (breast), osteochondroma (bone). Malignant tumors (cancer): invasive, rapid growth, poorly differentiated (anaplasia), can metastasise via lymphatics or blood vessels, can recur after treatment. Named by tissue of origin: carcinoma (epithelial—most common, 80%: adenocarcinoma, squamous cell carcinoma), sarcoma (mesenchymal—bone, muscle, fat, connective tissue), leukemia (hematopoietic—bone marrow), lymphoma (lymphoid tissue—nodes, spleen, mucosa-associated lymphoid tissue), melanoma (melanocytes), and germ cell tumors (testis, ovary). Grading: histological degree of differentiation (well, moderate, poorly, undifferentiated). Staging: TNM system (tumor size/extent, nodal involvement, metastases). Cachexia: weight loss, muscle wasting, anorexia in advanced malignancy. Paraneoplastic syndromes: remote effects of cancer not due to direct invasion (e.g., hypercalcaemia in squamous cell lung cancer, SIADH in small cell lung cancer, myasthenia gravis in thymoma).

Tumor Ablation

– Minimally invasive techniques that destroy tumors using extreme temperatures or chemicals. Radiofrequency ablation (RFA): an electrode delivers alternating current, generating heat ($>60^{\circ}\text{C}$) that causes coagulative necrosis. Microwave ablation (MWA): electromagnetic waves produce rapid heating with larger and more uniform ablation zones; advantages

over RFA: faster, less heat-sink effect, no grounding pads needed. Cryoablation: argon gas-based freezing (to -40°C) with freeze-thaw cycles, creating an ice ball that destroys cells by membrane rupture and ischemia. Ethanol ablation: 95% ethanol injection causes cellular dehydration and protein denaturation. Irreversible electroporation (IRE): non-thermal, high-voltage electrical pulses create nanopores in cell membranes, inducing apoptosis; preserves extracellular matrix (safe near bile ducts, ureters). Indications: HCC (RFA/MWA for early-stage, BCLC 0-A), colorectal liver metastases (small, $<3\text{ cm}$), RCC (cryoablation for T1a tumors, $<4\text{ cm}$), small lung tumors, bone metastases (cryoablation for pain palliation). Guidance: ultrasound, CT, or MRI. Efficacy: local control 80-95% for small tumors ($<3\text{ cm}$). Advantages: less invasive than surgery, shorter recovery, preserves parenchyma. Limitations: size dependent ($<3\text{ cm}$ ideal), proximity to vessels (heat-sink effect), proximity to critical structures.

Tumor Lysis Syndrome (TLS)

– An oncologic emergency caused by the rapid release of intracellular contents from lysing cancer cells, occurring most commonly after initiation of chemotherapy for highly proliferative tumors (ALL, Burkitt lymphoma, AML, DLBCL). Laboratory TLS: ≥ 2 of hyperuricemia, hyperkalemia, hyperphosphatemia, and hypocalcemia (corrected calcium, from calcium-phosphate precipitation). Clinical TLS: lab TLS + acute kidney injury, cardiac arrhythmia (hyperkalemia), seizure, or death. Risk stratification: high-risk (ALL with WBC $>100\text{K}$, Burkitt lymphoma), intermediate (DLBCL, AML with WBC $>25\text{K}$), low-risk (CLL, solid tumors). Prevention: aggressive IV hydration, rasburicase (recombinant urate oxidase, rapidly lowers uric acid) or allopurinol (prevents new uric acid formation — not for established TLS). Management: cardiac monitoring, treat hyperkalemia (calcium gluconate, insulin + glucose, albuterol, kayexalate, dialysis), correct hypocalcemia only if symptomatic, and hemodialysis for refractory hyperkalemia/azotemia. Cairo-Bishop grading: Grade 0 (no TLS), Grade I (lab TLS), Grade II (lab + mild Cr elevation), Grade III (lab + Cr $>3\text{x ULN}$, arrhythmia, seizure), Grade IV (life-threatening), Grade V (death).

Tumor Markers

– Substances produced by cancer cells or the body in response to cancer, measured in blood, urine, or tissue to aid diagnosis, prognosis, monitoring treatment response, and detecting recurrence. Common tumor markers: AFP (HCC, nonseminomatous germ cell tumors), CA-125 (ovarian cancer), CA 19-9 (pancreatic cancer), CA 15-3 and CA 27.29 (breast cancer), CEA (colorectal, pancreatic, lung, gastric cancer), hCG (choriocarcinoma, germ cell tumors), PSA (prostate cancer), thyroglobulin (thyroid cancer — post-thyroidectomy), LDH (germ cell tumors, lymphoma — prognostic), beta-2 microglobulin (CLL, multiple myeloma), and calcitonin (medullary thyroid carcinoma). Limitations: not diagnostic alone (false positives from benign conditions), not sufficiently sensitive for screening (except PSA), and many cancers lack specific markers. Role: monitoring response to treatment (declining levels indicate response, rising levels suggest recurrence) and surveillance after definitive therapy.

Tumor Suppressor Gene

– A gene that normally functions to inhibit cell proliferation, repair DNA errors, or promote apoptosis when DNA damage is irreparable. Loss-of-function mutations or epigenetic silencing of both alleles (Knudson's two-hit hypothesis) drive oncogenesis. Examples: *TP53* (p53, "guardian of the genome," mutated in $>50\%$ of cancers), *RB1* (retinoblastoma), *APC* (colorectal cancer), *BRCA1/BRCA2* (hereditary breast/ovarian cancer).

Uterine Cancer (Endometrial Cancer)

– The most common gynecologic cancer in developed countries, arising from the endometrium. Risk factors: unopposed estrogen exposure, obesity, nulliparity, late menopause, tamoxifen use, and Lynch syndrome. Presents with postmenopausal bleeding. Diagnosis: endometrial biopsy. Treatment: total abdominal hysterectomy with bilateral salpingo-oophorectomy; adjuvant radiation and/or chemotherapy for high-risk features (high grade, deep myometrial invasion, advanced stage).

Vitamin B12 Deficiency

– Vitamin B12 (cobalamin) deficiency causes megaloblastic anemia and neurologic dysfunction through impaired DNA synthesis and abnormal fatty acid

metabolism in myelin. Dietary sources include animal products (meat, fish, dairy), with daily requirement of 2-3 mcg. Absorption requires adequate gastric acid and pepsin to release B12 from food proteins, binding to intrinsic factor (IF) produced by gastric parietal cells, and absorption in the terminal ileum via the cubilin-amnionless receptor complex in the terminal ileum. Causes of deficiency include pernicious anemia (autoimmune destruction of parietal cells), gastric surgery, ileal resection or disease (Crohn disease), pancreatic insufficiency, dietary deficiency (vegans), and malabsorption syndromes.

Chapter 27

Ophthalmology

Age-Related Macular Degeneration

– The leading cause of irreversible central vision loss in individuals over 50 in developed countries, affecting approximately 200 million people worldwide with prevalence increasing with age (10 percent over age 65, 30 percent over age 75). Pathogenesis involves progressive degeneration of the macula with accumulation of drusen (extracellular deposits of lipids, proteins, and complement factors between the retinal pigment epithelium and Bruch membrane) and loss of retinal pigment epithelium cells, leading to accumulation of lipofuscin and reactive oxygen species that damage photoreceptors and RPE. AMD is classified into early (medium drusen greater than 63 micrometres without pigmentary changes), intermediate (large drusen greater than 125 micrometres with pigmentary abnormalities), and advanced AMD, which is subdivided into dry AMD (geographic atrophy, accounting for 85 to 90 percent of advanced AMD cases) and wet AMD (neovascular or exudative AMD, accounting for 10 to 15 percent of advanced AMD but responsible for 80 to 90 percent of severe vision loss, characterized by the growth of abnormal new blood vessels from the choroid through Bruch membrane into the sub-RPE or subretinal space, which leak fluid, lipid, and blood). Risk factors include increasing age, smoking (the strongest modifiable risk factor, increasing risk 2- to 4-fold), family history, Caucasian race, and genetic susceptibility variants in complement factor H (CFH), ARMS2, and HTRA1 genes.

Allergic Conjunctivitis

– An inflammatory condition of the conjunctiva mediated by IgE-dependent mast cell degranulation in response to environmental allergens, characterized by bilateral ocular itching, tearing, conjunctival injection, and eyelid edema. The condition is classified

into two main forms: seasonal allergic conjunctivitis, which occurs during specific pollen seasons and presents with acute symptoms of itching, tearing, and conjunctival injection; and perennial allergic conjunctivitis, which may be less symptomatic but persistent throughout the year, with indoor allergens such as dust mites, mould, and animal dander as common triggers. The ocular surface reaction is characterized by vasodilation of conjunctival blood vessels (causing injection), increased vascular permeability (leading to chemosis), and stimulation of the trigeminal nerve (causing intense itching). Diagnosis is primarily clinical, and treatment consists of topical antihistamine-mast cell stabiliser combination drops (olopatadine, ketotifen, azelastine, epinastine, bepotastine), systemic antihistamines for associated allergic rhinitis, artificial tears, and cold compresses.

Alpha-Agonists

– Alpha-adrenergic agonists are a class of topical medications used in the treatment of glaucoma that lower intraocular pressure through a dual mechanism: reduction of aqueous humor production by the ciliary body through alpha-2 adrenergic receptor stimulation and enhancement of uveoscleral outflow through remodeling of the extracellular matrix. Available agents include brimonidine, apraclonidine, and dipivefrin, with brimonidine being the most commonly used due to its superior tolerability profile. Brimonidine is the most widely prescribed topical alpha-2 agonist for chronic glaucoma therapy, reducing intraocular pressure by 20 to 30 percent. Brimonidine is often used as adjunctive therapy in patients inadequately controlled on prostaglandin analogs and beta-blockers. Common side effects include ocular allergy and conjunctival folliculosis (allergic conjunctivitis develops in up to 10 to 15

percent of patients within 9 to 12 months of initiation), dry mouth, ocular burning and stinging, blurred vision, and fatigue. Apraclonidine is primarily used for acute short-term control of intraocular pressure spikes, such as before, during, and after laser procedures.

Amblyopia

– Amblyopia, commonly known as lazy eye, is a neurodevelopmental disorder of visual acuity that results from abnormal visual experience during the critical period of visual development (birth to approximately eight years of age), leading to reduced best-corrected visual acuity that cannot be attributed to structural ocular pathology. The condition is classified based on the underlying cause: strabismic amblyopia from ocular misalignment, anisometropic amblyopia from unequal refractive errors between the two eyes, and deprivation amblyopia from obstruction of the visual axis by cataract, ptosis, or corneal opacity. The pathophysiology involves abnormal development of the visual cortex, particularly the lateral geniculate nucleus and primary visual cortex (V1), where the input from the amblyopic eye is suppressed by the cortical dominance of the normal eye. The critical period of susceptibility to amblyopia spans from birth to approximately 8 years of age. The diagnosis is made by detecting a 2-line or greater difference in best-corrected visual acuity between the two eyes. Management consists of correction of any underlying refractive error (the first and most important step), occlusion therapy (patching of the non-amblyopic eye for 2 to 6 hours per day), and pharmacological penalisation (atropine 1 percent drops in the non-amblyopic eye once daily as an alternative to patching).

Anisocoria

– Unequal pupillary diameter exceeding 0.4 mm, physiological in about 20 percent of the population. Pathological causes are localized by which pupil is abnormal and whether asymmetry worsens in bright light (iris sphincter damage, Adie pupil) or dim light (Horner syndrome). Association with ptosis, ophthalmoplegia, headache, or altered mental status demands urgent evaluation for third nerve palsy from intracranial aneurysm.

Anterior Chamber Angle

– The anterior chamber angle is the anatomical region where the cornea and iris meet, and it contains the trabecular meshwork, the primary drainage structure for aqueous humor from the eye. The angle is bounded anteriorly by Schwalbe line (the termination of Descemet membrane), posteriorly by the anterior surface of the iris root, and laterally by the scleral spur and ciliary body band. The trabecular meshwork consists of three regions: the uveal meshwork adjacent to the iris, the corneoscleral meshwork, which is the outermost layer and the primary site of aqueous humor outflow resistance in primary open-angle glaucoma, and the juxtacanalicular meshwork adjacent to Schlemm canal. The trabecular meshwork is drained by Schlemm canal, a circular, lymphatic-like channel lined by endothelial cells, and from there aqueous humor drains through 25 to 30 collector channels into the episcleral and conjunctival venous system. The anterior chamber angle is evaluated clinically using gonioscopy, which allows direct visualisation of the angle structures and determination of whether the angle is open, narrow, or closed.

Anterior Uveitis

– Anterior uveitis, also known as iritis or iridocyclitis when the ciliary body is involved, is inflammation of the anterior segment of the eye involving the iris and/or ciliary body, and it is the most common form of uveitis. Patients typically present with acute onset of unilateral eye pain, photophobia, blurred vision, and conjunctival injection, and slit-lamp examination reveals cells and flare in the anterior chamber, which represent inflammatory cells and leaked protein from inflamed blood vessels. The etiology of anterior uveitis can be classified as idiopathic (the most common, accounting for 50 to 60 percent of cases), HLA-B27-associated (20 to 30 percent, including patients with ankylosing spondylitis, reactive arthritis, psoriatic arthritis, and inflammatory bowel disease), sarcoidosis (5 to 10 percent, typically with a chronic, bilateral, granulomatous course), and herpes simplex or herpes zoster virus (5 to 10 percent). Treatment consists of topical corticosteroids (prednisolone acetate 1 percent or difluprednate 0.05 percent, with hourly dosing during the acute phase, tapering slowly over weeks to months), cycloplegic agents (homatropine

2 or 5 percent or cyclopentolate 1 percent, to dilate the pupil, relieve ciliary spasm pain, and reduce the risk of posterior synechiae), and systemic therapy for refractory or severe cases.

Aqueous Humor

– A clear, watery fluid that fills the anterior and posterior chambers of the eye, maintaining intraocular pressure and providing nutrients and oxygen to the avascular cornea and lens while removing metabolic waste products. The fluid is produced by the non-pigmented epithelium of the ciliary processes at a rate of approximately 2.5 microliters per minute, through a combination of active secretion (involving carbonic anhydrase and sodium-potassium ATPase), ultrafiltration, and difand diffusion of fluid and electrolytes across the ciliary epithelium, and it drains from the eye through the trabecular meshwork and Schlemm canal into the venous system (conventional outflow pathway, responsible for 80 to 90 percent of outflow resistance and the site of pathology in primary open-angle glaucoma) and through the uveoscleral pathway (unconventional outflow, responsible for 10 to 20 percent of outflow, which is enhanced by prostaglandin analogs).

Arcus Senilis (Corneal Arcus)

– A white, gray, or bluish opaque ring in the peripheral corneal stroma separated from the limbus by a clear zone (lucid interval of Vogt). Caused by lipid (cholesterol) deposition in the peripheral cornea. Common and benign in elderly individuals (>60 years). When present in young patients (< 40 years, arcus juvenilis), it strongly suggests severe familial hypercholesterolemia or familial combined hyperlipidemia and warrants a lipid panel workup.

Astigmatism

– A refractive error caused by an irregular curvature of the cornea or lens, resulting in light rays being focused at multiple points rather than a single point on the retina, leading to blurred or distorted vision at all distances. The most common form is regular astigmatism, in which the cornea has two principal meridians with different curvatures at right angles to each other, creating a shape similar to a football rather than a basketball. The steepest meridian is called the agaagain or the flattest meridian, and light rays are refracted unequally in the two principal meridians. The diagnosis is made by refraction,

keratometry, corneal topography, and autorefractation. Correction is achieved with toric spectacle or contact lenses (which have different powers in the two principal meridians), or refractive surgery including LASIK, PRK, and SMILE, which can reshape the cornea to reduce or eliminate the irregular curvature.

Bacterial Conjunctivitis

– An infection of the conjunctival mucous membrane caused by various bacterial pathogens, presenting with a purulent or mucopurulent discharge that causes the eyelids to become matted together, particularly upon waking, conjunctival injection, and a gritty or foreign body sensation. Acute bacterial conjunctivitis is most commonly caused by *Staphylococcus aureus*, *Streptococcus pneumoniae*, and *Haemophilus influenzae*, and it is usually self-limited but may be treated with topical antibiotics, most commonly a fluoroquinolone (ciprofloxacin, ofloxacin, levofloxacin, moxifloxacin, or gatifloxacin) or polymyxin B-trimethoprim combination, instilled 4 to 6 times daily for 5 to 7 days. Gonorrhoeal conjunctivitis, caused by *Neisseria gonorrhoeae*, is a sight-threatening emergency presenting with a profuse, purulent discharge, marked chemosis, eyelid edema, and preauricular lymphadenopathy, requiring systemic antibiotic treatment with intramuscular or intravenous ceftriaxone. Chlamydial conjunctivitis, caused by *Chlamydia trachomatis* serotypes D to K, presents with a chronic, mucopurulent discharge, conjunctival follicles, and keratitis, and requires systemic therapy with azithromycin or doxycycline.

Beta-Blockers

– Beta-adrenergic blocking agents, commonly known as beta-blockers, are topical medications used in the treatment of glaucoma that lower intraocular pressure by reducing the production of aqueous humor by the ciliary body, primarily through blockade of beta-2 adrenergic receptors. Available agents include timolol, levobunolol, metipranolol, and carteolol, typically administered once or twice daily, and they reduce intraocular pressure by approximately twenty to twenty-five percent. Beta-blockers are contraindicated in patients with asthma (due to the risk of bronchospasm), chronic obstructive pulmonary disease, heart block, bradycardia, and congestive heart failure, and they should be used with caution

in patients with diabetes mellitus and depression. The alpha-2 agonist brimonidine and the carbonic anhydrase inhibitors dorzolamide and brinzolamide are often used as second-line agents or as adjunctive therapy.

Bevacizumab

– A full-length recombinant humanized monoclonal antibody that binds to all isoforms of vascular endothelial growth factor A, originally developed and approved for the treatment of various cancers including colorectal cancer, non-small cell lung cancer, and glioblastoma, but widely used off-label in ophthalmology for the treatment of wet age-related macular degeneration, diabetic macular edema, and retinal vein occlusion through intravitreal injection. The CATT trial demonstrated that bevacizumab is non-inferior to ranibizumab (the first FDA-approved anti-VEGF agent) for the treatment of wet age-related macular degeneration at one year, leading to widespread off-label use due to its significantly lower cost (approximately 1/40th the cost of ranibizumab per dose). The drug is administered by intravitreal injection at a typical dose of 1.25 mg in 0.05 mL, originally every 4 weeks. The risk of serious ocular adverse events, including endophthalmitis (0.05 to 0.1 percent per injection), retinal detachment, and traumatic cataract, is low but requires sterile technique and careful patient monitoring.

Blepharitis

– Chronic inflammation of the eyelid margins, one of the most common ophthalmic conditions, classified into anterior blepharitis (affecting the eyelash follicle and base) and posterior blepharitis (affecting the meibomian glands). Anterior blepharitis is further subdivided into staphylococcal blepharitis (caused by *Staphylococcus aureus* colonization, presenting with collarettes and crusting at the base of lashes) and seborrheic blepharitis (associated with seborrheic dermatitis, presenting with greasy scales and crusts along the eyelid margin with associated seborrheic dermatitis of the scalp, eyebrows, and nasolabial folds). The pathophysiology involves bacterial colonisation (particularly *Staphylococcus epidermidis* and *Staphylococcus aureus*, which produce exotoxins and enzymes that destabilise the tear film), meibomian gland dysfunction (with al-

tered meibum composition, thickened and turbid meibum that obstructs the gland orifices, leading to reduced tear film lipid layer, increased tear evaporation, and tear hyperosmolarity), and ocular surface inflammation. Diagnosis is clinical, based on slit lamp examination of the lid margins, and treatment includes eyelid hygiene (warm compresses for 5 to 10 minutes twice daily followed by lid margin massage and scrubbing), topical antibiotics (bacitracin or erythromycin ointment applied to the lid margins at bedtime, or azithromycin 1 percent solution twice daily), and artificial tears for dry eye symptoms.

Bulbar Conjunctiva

– The bulbar conjunctiva is the portion of the conjunctival membrane that covers the anterior surface of the sclera, extending from the limbus (the junction of the cornea and sclera) to the fornices where it reflects onto the inner surface of the eyelids. It is a thin, transparent, loosely attached membrane through which the underlying white sclera is visible, and it contains blood vessels, lymphatics, and sensory nerve fibers. The bulbar conjunctiva is normally smooth and moist, and its vessels can become dilated and tortuous in conditions such as conjunctivitis and uveitis, providing important diagnostic information on slit-lamp examination. The bulbar conjunctiva is freely movable over the underlying sclera, to which it is only loosely attached by a thin layer of connective tissue, and this mobility allows for the formation of conjunctival folds or chemosis (edema of the conjunctiva) in inflammatory and allergic conditions. The blood supply to the bulbar conjunctiva arises from two main sources: the anterior ciliary arteries, which are branches off the muscular arteries supplying the extraocular muscles, and the posterior conjunctival arteries from the palpebral arcades.

Carbonic Anhydrase Inhibitors

– A class of medications used in the treatment of glaucoma that lower intraocular pressure by reducing the production of aqueous humor through inhibition of the enzyme carbonic anhydrase, which catalyzes the conversion of carbon dioxide and water to bicarbonate and hydrogen ions, a process essential for the active secretion of bicarbonate into the aqueous humor by the ciliary epithelium. Available topical agents include dorzolamide and brinzolamide, ad-

ministered three times daily. Systemic carbonic anhydrase inhibitors, including acetazolamide and methazolamide, are reserved for acute pressure elevation in angle-closure glaucoma, uveitic glaucoma, and as a temporising measure before surgery, due to the systemic side effects of paresthesias, metallic taste, fatigue, depression, weight loss, and the risk of nephrolithiasis with prolonged use.

Cataract

– A cataract is an opacity or clouding of the crystalline lens that impairs the transmission of light to the retina, resulting in blurred vision, glare, decreased contrast sensitivity, and progressive vision loss, and it is the leading cause of preventable blindness worldwide. The most common form is age-related cataract, which is classified by the location of the opacity within the lens: nuclear sclerosis, characterized by yellowing and hardening of the lens nucleus; cortical cataract, characterized by radial, spoke-like opacities that extend from the periphery toward the center of the lens; and posterior subcapsular cataract, characterized by granular, plaque-like opacities located at the posterior pole of the lens, just anterior to the posterior capsule, which are particularly visually disabling due to their location in the visual axis and are strongly associated with corticosteroid use, diabetes, trauma, and radiation exposure.

Cataracts

– A clouding of the eye's natural lens that develops gradually with aging, causing blurred vision, glare sensitivity, faded colors, and difficulty seeing at night. They are the leading cause of vision loss worldwide but are treatable with surgical removal of the cloudy lens and replacement with an artificial intraocular lens. Surgery is safe and highly effective, restoring vision in the vast majority of cases.

Chalazion

– A chronic, non-infectious granulomatous inflammation of a meibomian gland caused by duct obstruction. Presents as a firm, painless, well-circumscribed nodule in the eyelid, usually away from the lid margin. Different from a sty (which is acute and tender). Most resolve spontaneously over weeks to months. Treatment: warm compresses, lid massage. For persistent chalazia: intralesional corticosteroid injection or incision and curettage (I&C).

Cherry-Red Spot

– A striking fundoscopic finding in which the macula appears bright red against a pale, ischemic, or lipid-laden surrounding retina. Mechanism: the fovea centralis lacks inner retinal layers and receives blood supply from the underlying choroid, preserving its natural red color while adjacent edematous retina turns opaque white. Classic causes: Central Retinal Artery Occlusion (CRAO — sudden painless monocular vision loss), Tay-Sachs Disease (hexosaminidase A deficiency), Niemann-Pick Disease (sphingomyelinase deficiency), and Gaucher Disease.

Choroidal Neovascularization

– The pathological growth of new, fragile blood vessels from the choroid through Bruch membrane into the subretinal or sub-retinal pigment epithelium space, and it is the hallmark of wet age-related macular degeneration and the primary cause of severe central vision loss in this condition. The neovascular vessels are stimulated by vascular endothelial growth factor, which is produced in response to hypoxia, inflammation, and oxidative stress in the aging retina, and they are fragile and prone to leakage and bleeding, leading to sudden central vision loss from hemorrhage as well as gradual vision loss from exudation and fibrosis. The diagnosis of choroidal neovascularization is confirmed by fluorescein angiography (which shows the classic lacy, petaloid hyperfluorescence in the subretinal space with early leakage and late staining in the classic type) and optical coherence tomography (which shows subretinal or sub-RPE fluid, intraretinal cystic spaces, and a hyperreflective lesion above or below the RPE).

Color Blindness

– Inability or decreased ability to perceive color differences under normal lighting conditions. Most commonly X-linked recessive, affecting 8% of males and 0.5% of females. Types: deuteranopia (green deficiency, most common), protanopia (red deficiency), tritanopia (blue-yellow deficiency, rare), and achromatopsia (complete color blindness, very rare). Most congenital color blindness is non-progressive and does not affect visual acuity. Diagnosis: Ishihara color plates. No treatment available; patients adapt with compensatory strategies.

Color Vision Deficiency

– Color vision deficiency, commonly known as color

blindness, is a condition in which the ability to perceive and discriminate certain colors is reduced or absent, most commonly affecting the perception of red and green hues, and it is caused by abnormalities in the cone photoreceptors responsible for color vision. The most common form is red-green color deficiency, which is an X-linked recessive condition affecting approximately eight percent of males and 0.5 percent of females, caused by mutations in the opsin genes (OPN1LW and OPN1MW on the X chromosome encoding the long-wavelength and middle-wavelength cone photopigments, respectively, which cause the common red-green color deficiencies through deletions, fusions, or point mutations). Blue-yellow color deficiency (tritanopia) is much rarer and is caused by mutations in the OPN1SW gene on chromosome 7 encoding the short-wavelength cone photopigment, and it is inherited as an autosomal dominant condition. Complete color blindness (achromatopsia) is a rare autosomal recessive condition characterized by the absence of all three types of cone function, resulting in severe photophobia, nystagmus, and poor visual acuity.

Congenital Cataract

– Opacification of the crystalline lens present at birth, a leading cause of treatable childhood blindness worldwide. Causes: genetic (autosomal dominant most common, mutations in crystallin genes or PAX6), infectious (congenital rubella syndrome, toxoplasmosis, CMV, syphilis, HSV), metabolic (galactosemia, hypoglycemia, Wilson disease), and syndromic (Down syndrome, Lowe syndrome, Marfan syndrome). Bilateral cataracts are more commonly genetic or metabolic; unilateral cataracts suggest structural eye anomalies or asymmetric intrauterine infection. Presents with leukocoria (white pupillary reflex), nystagmus, strabismus, or poor visual tracking. Screening: red reflex examination (absent or abnormal). Diagnosis: slit-lamp examination after dilation. Treatment: early surgical extraction (within 4-6 weeks for dense bilateral cataracts to prevent deprivation amblyopia), primary or secondary intraocular lens implantation (depending on age), and immediate postoperative aphakic correction with contact lenses or glasses. Lifelong monitoring for glaucoma, strabismus, and amblyopia.

Congenital Glaucoma

– A rare form of glaucoma (1 in 10,000-20,000 births) caused by developmental anomalies of the trabecular meshwork and anterior chamber angle, impairing aqueous humor outflow. Most cases are sporadic; familial forms are autosomal recessive (CYP1B1 gene mutations). Presents in the first year of life with the classic triad: epiphora (excessive tearing, often the earliest sign), photophobia, and blepharospasm. Corneal edema causes corneal enlargement (buphthalmos, or ox eye, from elevated IOP stretching the immature collagen), Haab striae (linear breaks in Descemet membrane), and corneal clouding. Increased axial length leads to progressive myopia. Diagnosis: examination under anesthesia — elevated intraocular pressure, increased corneal diameter (>12 mm by 1 year), and optic nerve cupping (reversible in early stages). Treatment: surgical angle surgery (goniotomy or trabeculotomy) is first-line (success rate 80-90% if performed early). Trabeculectomy or drainage implants for failed angle surgery. Lifelong IOP monitoring is essential.

Conjunctiva

– The conjunctiva is a thin, transparent, mucous membrane that lines the inner surface of the eyelids (palpebral conjunctiva) and covers the anterior surface of the sclera (bulbar conjunctiva), forming a continuous sheet that protects the eye and facilitates smooth eyelid movement. The palpebral conjunctiva is further divided into the tarsal conjunctiva, which is firmly adherent to the tarsal plates of the eyelids, and the forniceal conjunctiva, which forms loose folds at the junction between the tarsal and forniceal conjunctiva. The conjunctiva is composed of a non-keratinising stratified columnar epithelium with goblet cells that secrete mucin, a critical component of the tear film that stabilises the tear film by lowering its surface tension, and an underlying substantia propria, a layer of loose connective tissue containing blood vessels, lymphatics, nerves, and immune cells. The conjunctiva is a highly vascularised, immunologically active tissue that protects the eye from pathogens and environmental insults.

Conjunctivitis

– Inflammation of the conjunctiva, the thin, transparent mucous membrane lining the inner surface of the eyelids and the anterior surface of the sclera. Conjunctivitis is the most common cause of red eye and

is classified by etiology. Infectious conjunctivitis: viral (most common overall, caused by adenovirus serotypes 3, 4, 7, 8, 19, 37, presenting with watery discharge, preauricular lymphadenopathy, and highly contagious, often involving both eyes with one eye affected first), bacterial (purulent/purulent discharge, often unilateral, treated with topical antibiotics), and chlamydial (inclusion conjunctivitis, with a chronic course, mucopurulent discharge, and follicles, requiring systemic antibiotics). Infectious conjunctivitis is distinguished from non-infectious causes: allergic conjunctivitis (intense itching, bilateral, seasonal or perennial, with diffuse conjunctival injection and chemosis, treated with antihistamine-mast cell stabiliser drops) and chemical or irritant conjunctivitis (acute exposure to chemicals or irritants, with immediate onset of redness, tearing, and pain, treated with copious irrigation and lubrication).

Corneal Cross-Linking

– Corneal collagen cross-linking is a minimally invasive therapeutic procedure that strengthens the corneal stroma by creating additional chemical bonds between collagen fibrils, thereby stiffening the cornea and halting or slowing the progression of corneal ectatic disorders, particularly keratoconus and post-refractive surgery ectasia. The procedure involves debriding the central corneal epithelium, applying riboflavin (vitamin B2) drops to the cornea for approximately thirty minutes to saturate the corneal stroma with riboflavin, and then exposing the cornea to ultraviolet A light (365 nm, 3 mW/cm²) for 30 minutes, which causes the riboflavin to undergo a photochemical reaction that generates reactive oxygen species that induce new covalent cross-links between collagen molecules, increasing the biomechanical rigidity of the cornea by 3 to 4 times. The epithelium-on (epi-on) and epithelium-off (epi-off) techniques exist, with epi-off being the traditional Dresden protocol and still considered the gold standard.

Corneal Ulcer

– A corneal ulcer is a defect in the corneal epithelium with associated stromal inflammation and necrosis, typically caused by infectious or non-infectious mechanisms, and it is a sight-threatening condition that requires prompt diagnosis and treatment. Bac-

terial corneal ulcers, the most common infectious type, are associated with contact lens wear, ocular surface disease, and corneal trauma, and common causative organisms include *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Streptococcus pneumoniae*. Fungal corneal ulcers, more common in tropical regions and associated with agricultural trauma, contact lens wear, and topical corticosteroid use, are caused by filamentous fungi (*Fusarium*, *Aspergillus*) and yeasts (*Candida*), and they present with a dry, elevated infiltrate with a feathery border and satellite lesions. Viral corneal ulcers, most commonly caused by herpes simplex virus and varicella-zoster virus, present with a characteristic dendritic epithelial defect on fluorescein staining, and they are treated with topical or oral antivirals (acyclovir, ganciclovir, valacyclovir) and cycloplegia.

Cortical Cataract

– A type of age-related lens opacity that begins in the peripheral lens cortex as wedge-shaped or spoke-like opacities that extend centripetally toward the visual axis, caused by disruption of the normally orderly arrangement of lens fibers and the accumulation of fluid between them. The opacities appear as white, wedge-shaped streaks in the lens cortex on slit-lamp examination, with the narrow end of the wedge pointing toward the lens center, and they may progress centrally toward the visual axis, eventually involving the central visual axis and causing significant visual impairment. The cortical spokes may form a wedge-shaped opacity with a clear center (cuneiform cataract) or may extend centrally to create a radial, star-shaped pattern. Patients with cortical cataract often complain of glare and difficulty with night vision.

Cup-to-Disc Ratio

– The cup-to-disc ratio is a clinical measurement used to assess the severity of glaucomatous optic nerve damage, comparing the diameter of the optic cup (the central depression within the optic nerve head where neural tissue is absent) to the diameter of the optic disc (the entire optic nerve head). A normal cup-to-disc ratio ranges from 0.1 to 0.3, while progressive enlargement of the cup, known as cupping, indicates loss of retinal ganglion cell axons and is a hallmark of glaucomatous optic neuneu-

ropathy. The cup-to-disc ratio is assessed during fundoscopic examination of the optic nerve head, and its measurement is essential for the diagnosis and monitoring of glaucoma, with a focal or diffuse enlargement of the cup (increased cup-to-disc ratio), asymmetry of cup-to-disc ratio between the two eyes (a difference of greater than 0.2 is suspicious for glaucoma), and notching or thinning of the neuroretinal rim being characteristic of glaucomatous optic nerve damage.

Dacryoadenitis

– Inflammation of the lacrimal gland, presenting as tender swelling in the superolateral aspect of the upper eyelid with characteristic S-shaped ptosis. It can be acute or chronic in presentation. Acute dacryoadenitis is most commonly caused by viral infection (Epstein-Barr virus, mumps, adenovirus, herpes zoster, enterovirus), with bacterial causes (Staphylococcus aureus, Streptococcus, Haemophilus influenzae, gonococcus) less common but more severe. Chronic dacryoadenitis is associated with autoimmune conditions including sarcoidosis, rheumatoid arthritis, Sjogren syndrome, granulomatosis with polyangiitis, systemic lupus erythematosus, IgG4-related disease, and thyroid eye disease. Diagnosis is clinical, with slit-lamp examination showing an enlarged, erythematous lacrimal gland. Imaging with CT or MRI may be needed to confirm the diagnosis and rule out orbital mass lesions. Treatment of acute viral dacryoadenitis is supportive, while bacterial dacryoadenitis requires systemic antibiotics. Chronic dacryoadenitis requires treatment of the underlying systemic condition.

Dacryocystitis

– Inflammation of the lacrimal sac, most commonly caused by obstruction of the nasolacrimal duct leading to stagnation of tears and secondary bacterial infection (Staphylococcus aureus, Streptococcus pneumoniae, Haemophilus influenzae). Presents with pain, swelling, erythema, and tenderness over the medial canthus, with epiphora (excessive tearing) and purulent discharge expressed from the punctum. Acute dacryocystitis requires systemic antibiotics and warm compresses; chronic cases may require dacryocystorhinostomy (DCR) to bypass the obstruction.

Dendritic Ulcer

– A characteristic branching (dendritic) epithelial ulcer of the cornea caused by herpes simplex virus (HSV) infection. It is the most common infectious cause of corneal blindness in developed countries. Presents with unilateral red eye, photophobia, tearing, foreign body sensation, and decreased vision. Slit-lamp examination with fluorescein staining shows a branching linear ulcer with terminal bulbs (dendrite). Treatment: topical antivirals (trifluridine drops, ganciclovir gel) or oral antivirals (acyclovir, valacyclovir). Topical corticosteroids are contraindicated in active epithelial disease.

Detached Retina

– Separation of the neurosensory retina from the underlying retinal pigment epithelium (RPE), a medical emergency requiring prompt surgical repair to prevent permanent vision loss. Types: rhegmatogenous (most common—a tear or hole in the retina allows vitreous fluid to accumulate in the subretinal space, associated with posterior vitreous detachment, high myopia, trauma, and aphakia), tractional (vitreoretinal adhesions from proliferative diabetic retinopathy, retinopathy of prematurity, or penetrating trauma pull the retina away), and exudative (fluid accumulation beneath the retina without a tear, from inflammation, tumors, or choroidal disorders). Presents with sudden onset of flashes (photopsia), floaters, and a curtain-like or shadowy visual field defect. Treatment: pneumatic retinopexy, scleral buckle, or pars plana vitrectomy with gas or silicone oil tamponade.

Diabetic Macular Edema

– The accumulation of fluid within the macula due to breakdown of the blood-retinal barrier in diabetic retinopathy, resulting in thickening of the macula and central vision loss, and it can occur at any stage of diabetic retinopathy, from mild non-proliferative to proliferative disease. The pathogenesis involves hyperglycemia-induced damage to retinal vascular endothelial cells and pericytes, leading to increased vascular permeability, leakage of plasma components into the retinal tissue, and thickening of the macula. The severity of DME is graded on clinical examination based on the distance of the retinal thickening from the fovea. The diagnosis of DME is confirmed and quantified by optical coherence tomography. The treatment of

center-involving DME is primarily with intravitreal anti-VEGF agents (ranibizumab, aflibercept, bevacizumab, and faricimab), which have revolutionised the management of DME.

Diplopia (Double Vision)

– The perception of two images of a single object, classified by onset, duration, and whether it resolves with covering one eye. Monocular diplopia (persists with one eye covered): caused by ocular surface abnormalities (dry eye, irregular astigmatism, cataract, corneal scar, lens dislocation)—usually benign. Binocular diplopia (resolves with either eye covered): results from misalignment of the visual axes due to cranial nerve palsy (CN III, IV, VI), neuromuscular junction disease (myasthenia gravis), restrictive orbital disease (thyroid eye disease), or strabismus. Evaluation: cover test in nine gaze positions, forced duction testing, and neuroimaging if nerve palsy suspected.

Drusen

– Yellowish-white deposits of extracellular material that accumulate beneath the retinal pigment epithelium between the retinal pigment epithelium basement membrane and Bruch membrane, and they are the hallmark clinical finding in dry age-related macular degeneration. Drusen are composed of lipids, complement components, inflammatory mediators, and other proteins, and they represent localized abnormalities of the retinal pigment epithelium basement membrane. Small hard drusen (less than 63 micrometres in diameter) are common in the aging retina and are not associated with an increased risk of progression to advanced AMD, while medium (63 to 125 micrometres) and large (greater than 125 micrometres) drusen, particularly when associated with pigmentary abnormalities, are the hallmark of early and intermediate AMD and are associated with a significantly increased risk of progression to advanced AMD.

Dry Eye Disease

– Dry eye disease, also known as keratoconjunctivitis sicca, is a multifactorial disorder of the ocular surface characterized by loss of homeostasis of the tear film, resulting in symptoms of ocular discomfort, visual disturbance, and tear film instability, with potential damage to the ocular surface. The disease is classified into two major subtypes: aqueous-deficient

dry eye, caused by decreased lacrimal gland production of the aqueous layer of the tear film, as seen in Sjogren syndrome and aging in non-Sjogren dry eye), and evaporative dry eye, caused by meibomian gland dysfunction (the most common cause of evaporative dry eye, accounting for 80 percent of dry eye cases in some series), where a reduction in the quantity or quality of the lipid layer of the tear film leads to increased tear evaporation and tear hyperosmolarity. The diagnosis of dry eye disease is made by a combination of patient symptom assessment using validated questionnaires and objective clinical tests including the Schirmer test, tear film breakup time, corneal and conjunctival staining, and evaluation of the meibomian glands.

Dry Eye Syndrome

– A multifactorial disease of the ocular surface characterized by tear film instability, hyperosmolarity, and inflammation. Aqueous-deficient dry eye: Sjogren syndrome (autoimmune), non-Sjogren (lacrimal gland dysfunction, age). Evaporative dry eye: meibomian gland dysfunction (most common), incomplete blink, environmental factors. Symptoms: dryness, grittiness, burning, photophobia, blurred vision that improves with blinking. Diagnosis: Schirmer test, tear breakup time, corneal fluorescein staining, meibomian gland evaluation. Treatment: artificial tears (preservative-free), warm compresses, lid hygiene, topical cyclosporine, punctal plugs, and omega-3 supplements.

Endophthalmitis

– A severe, sight-threatening intraocular inflammation involving the vitreous cavity, aqueous humor, and adjacent structures, representing an ophthalmologic emergency. It is classified as exogenous (most common, caused by direct inoculation from intraocular surgery particularly cataract extraction, intravitreal injections, penetrating trauma, or corneal infection) or endogenous (metastatic seeding from a distant infection source, more common in immunocompromised patients, endocarditis, intravenous/intravenous drug use, indwelling catheters, and septicemia, with the most common causative organisms being *Streptococcus* species, *Staphylococcus aureus*, and gram-negative bacilli). The condition presents with rapid onset of severe, progressive eye pain, decreased visual acuity, conjunctival injection,

chemosis, corneal edema, hypopyon (the hallmark of endophthalmitis, present in 80 to 90 percent of cases), and vitreous inflammation. The Endophthalmitis Vitrectomy Study established the management protocol: immediate intravitreal injection of antibiotics (vancomycin 1 mg/0.1 mL for gram-positive coverage and ceftazidime 2.25 mg/0.1 mL for gram-negative coverage), with vitreous tap for culture, and vitrectomy for patients with light perception vision only.

Entropion

– An eyelid malposition in which the eyelid margin rolls inward, causing the eyelashes and skin to rub against the ocular surface, resulting in corneal irritation, conjunctival injection, tearing, photophobia, and a foreign body sensation. The condition most commonly affects the lower eyelid and is classified into four types. Involutional entropion (most common, age-related, due to horizontal laxity from canthal tendon weakening, dehiscence or attenuation of the lower eyelid retractors, and overridding of the preseptal orbicularis oculi muscle, allowing the lower eyelid to roll inward), cicatricial entropion (caused by scarring and contraction of the posterior lamella, most commonly following chemical burns, Stevens-Johnson syndrome, ocular cicatricial pemphigoid, or chronic trachoma), congenital entropion (rare, due to hypertrophic marginal bundle of the orbicularis oculi muscle), and spastic entropion (temporary, due to sustained orbicularis oculi contraction). The diagnosis is clinical, based on slit-lamp examination.

Epiphora

– Excessive tearing caused by impaired tear drainage or reflex hypersecretion. Causes: nasolacrimal duct obstruction (most common in infants and elderly), punctal stenosis, eyelid malposition (ectropion, entropion), and reflex tearing from dry eye or ocular surface irritation. Congenital NLDO: presents with tearing and mucoid discharge in infants; most resolve spontaneously by 12 months. Diagnosis: dye disappearance test, lacrimal irrigation, dacryocystography. Treatment: lacrimal massage for infants; probing and irrigation; dacryocystorhinostomy (DCR) for adults with structural obstruction.

Episcleritis

– A benign, self-limited inflammatory condition of

the episclera, the thin layer of connective tissue between the sclera and conjunctiva. It is most common in young to middle-aged women and is typically idiopathic, though it is associated with systemic inflammatory conditions in approximately 30 percent of cases (rheumatoid arthritis, systemic lupus erythematosus, Sjogren syndrome, granulomatosis with polyangiitis, inflammatory bowel disease, psoriatic arthritis, and ankylosing spondylitis). The patient presents with acute or subacute onset of unilateral or bilateral eye redness, a dull ache or irritation, and sectoral injection of the episcleral vessels (which appear as bright red, radially oriented, tortuous engorged vessels that blanch with topical phenylephrine 2.5 percent, distinguishing episcleritis from scleritis). The diagnosis is clinical. The condition is self-limited and resolves spontaneously within 2 to 3 weeks in most cases.

Esotropia

– A type of strabismus in which one eye deviates inward (toward the nose). Congenital/infantile esotropia: large-angle, constant, onset before 6 months; requires early surgical correction. Accommodative esotropia: associated with hyperopia, onset age 2-3 years; treatment with corrective glasses improves alignment. Intermittent esotropia can be controlled with fusion. Complications: amblyopia (lazy eye) and loss of binocular vision. Diagnosis: cover-uncover test, alternate cover test, cycloplegic refraction. Management: glasses, patching, prism therapy, and strabismus surgery.

Exophthalmos

– Abnormal protrusion of the eyeball (globe) from the orbit, most commonly caused by thyroid eye disease (Graves ophthalmopathy—an autoimmune condition associated with hyperthyroidism). The proptosis results from inflammation, edema, and fibrosis of the extraocular muscles and proliferation of orbital fat within the fixed bony orbit. Bilateral exophthalmos is classic for Graves disease. Unilateral exophthalmos suggests orbital tumor (hemangioma, meningioma, optic nerve glioma, lymphoma), orbital pseudotumor, cellulitis, or carotid-cavernous fistula. Measurement: Hertel exophthalmometry (normal <20 mm, or asymmetry >2 mm). Symptoms: proptosis, lid retraction, lid lag (lagophthalmos), exposure keratopathy, diplopia, and optic

nerve compression. Treatment: glucocorticoids, orbital decompression surgery, and management of the underlying thyroid disease.

Exotropia

- A type of strabismus in which one eye deviates outward (toward the temple). Intermittent exotropia: most common type, often noticed when tired or daydreaming, can be controlled with fusion. Constant exotropia: requires treatment to prevent amblyopia. Congenital exotropia: rare, requires early evaluation. Diagnosis: cover test, angle measurement. Treatment: part-time patching, orthoptic exercises (convergence exercises), prism glasses, and surgical correction for persistent deviations.

Eye Disorders

- See Vision.

Eye Health

- The maintenance of optimal vision and prevention of ocular disease through regular eye examinations, protective measures, and timely treatment. Common conditions affecting eye health include refractive errors, cataracts, glaucoma, diabetic retinopathy, and age-related macular degeneration. Protective strategies include wearing UV-blocking sunglasses, managing systemic health conditions, and avoiding eye strain.

Flashes

- Perception of flickering light or lightning-like streaks from mechanoelectrical stimulation of the retina rather than an external source. The leading cause is posterior vitreous detachment, often with floaters; retinal tears and detachment, migraine aura, and optic neuritis also produce flashes. New flashes with floaters or a curtain-like field defect require urgent examination to exclude retinal break or detachment.

Floaters

- Mobile spots, threads, cobwebs, or rings in the visual field caused by vitreous opacities casting shadows on the retina. Most arise from posterior vitreous detachment, an age-related separation of the vitreous gel from the retina; hemorrhage, vitritis, and asteroid hyalosis are other causes. Sudden new floaters with flashes or field loss require prompt retinal evaluation to exclude tear or detachment.

Fluorescein Angiography

- An ophthalmological diagnostic procedure that in-

volves intravenous injection of sodium fluorescein dye and sequential photography of the retinal vasculature using a specialized fundus camera fitted with excitation and barrier filters, providing detailed information about retinal blood flow, vascular permeability, and retinal pigment epithelium integrity. The dye is excited by blue light at approximately 490 nanometers and emits yellow-green fluorescence at approximately 520 to 530 nanometers. The procedure involves a series of timed images captured in rapid succession following the injection: the early arterial phase (10 to 15 seconds), the arteriovenous phase (15 to 20 seconds), the venous phase (20 to 30 seconds), and the late phase (5 to 10 minutes). The normal fluorescein angiogram shows the retinal vessels fluoresce brightly against the dark background of the choroidal fluorescence.

Fornix

- The conjunctival fornix is the redundant, dome-shaped fold of conjunctiva where the palpebral conjunctiva transitions to the bulbar conjunctiva, forming a deep recess superiorly (superior fornix), inferiorly (inferior fornix), and medially and laterally (medial and lateral fornices). The fornices are important anatomical landmarks for contact lens fitting, conjunctival sampling for diagnosis of chlamydial and viral infections, and as reservoirs for topical medications applied to the eye. The superior fornix is the deepest, extending approximately 8 to 10 mm above the superior corneal limbus, while the inferior fornix is approximately 6 to 8 mm deep. The fornices are also the site of lymphatic drainage of the conjunctiva, which drains to the preauricular and submandibular lymph nodes, and they contain accessory lacrimal glands (the glands of Krause and Wolfring) that contribute to the basal secretion of the aqueous component of the tear film.

Fovea Centralis

- The fovea centralis is the small, central depression within the macula of the retina that represents the area of highest visual acuity, containing the highest concentration of cone photoreceptors and no rod photoreceptors. The unique anatomy of the fovea, where the inner retinal layers are displaced laterally in a process called foveal pit formation, allows light to reach the photoreceptors with minimal scattering, resulting in the sharpest possible image formation.

The foveola, the central 0.3535 mm in diameter, contains only cone photoreceptors (no rod photoreceptors), with the highest concentration of cones in the entire retina, providing the highest possible spatial resolution for central, sharp vision (visual acuity of 20/20 or better). The central 0.5 mm of the fovea, the foveola, is avascular and has no inner retinal layers, ensuring that light reaches the cone outer segments with minimal scattering.

Fundus Photography

– The documentation of the appearance of the retina, optic nerve, and retinal vasculature using a specialized camera that illuminates and photographs the posterior segment of the eye, providing a permanent, objective record of retinal findings that can be used for comparison over time, patient education, and telemedicine consultations. Standard fundus photography captures images of the optic disc, macula, and major retinal vessels, and widefield fundus photography can image up to 200 degrees of the retina in a single image. Fundus photography can be performed with or without pupillary dilation. The images are taken in color, red-free (using green light to enhance the visibility of retinal vessels and haemorrhages), and autofluorescence (using blue light to excite lipofuscin in the RPE).

Geographic Atrophy

– The advanced form of dry age-related macular degeneration, characterized by well-demarcated, progressively enlarging areas of complete loss of the retinal pigment epithelium, choriocapillaris, and overlying photoreceptors in the macula, resulting in irreversible central vision loss. The atrophic areas appear as well-defined, depigmented regions on fundus examination, with visible underlying choroidal vessels, and they typically begin in the parafoveal region and expand centrically over time, leading to a progressive, bilateral, irreversible, and painless loss of central vision, with the preservation of peripheral vision until late in the disease process. The diagnosis of geographic atrophy is based on fundoscopic examination (showing well-demarcated, depigmented areas with visible choroidal vessels), fundus autofluorescence (showing areas of absent autofluorescence), and optical coherence tomography (showing the loss of the RPE and outer retinal layers).

Glaucoma

– A group of progressive optic neuropathies characterized by the degeneration of retinal ganglion cells and their axons, resulting in characteristic optic nerve head changes and visual field loss, with elevated intraocular pressure being the most important modifiable risk factor. Primary open-angle glaucoma, the most common form, involves gradual obstruction of the trabecular meshwork with chronically elevated intraocular pressure, progressive cupping of the optic nerve head, and characteristic visual field defects (paracentral scotomas, arcuate scotomas, and nasal steps in the early stages, progressing to central vision loss and tunnel vision in advanced disease). Other forms of glaucoma include normal-tension glaucoma (glaucomatous optic neuropathy and visual field loss with intraocular pressure consistently within the normal range), primary angle-closure glaucoma (caused by pupillary block, leading to an acute, painful, red eye with fixed, mid-dilated pupil, corneal edema, and elevated IOP), and secondary glaucomas resulting from other ocular or systemic disease.

Gleeta

– A thick, tenacious, mucopurulent discharge from the eye. An older term for the viscous crusting and discharge seen in purulent conjunctivitis, especially gonococcal ophthalmia neonatorum. The term gummous gleet referred to a urethral discharge in gonorrhea. Modern usage: the medical term is purulent discharge or mucopurulent discharge.

Goldmann Tonometry

– Goldmann applanation tonometry is the gold standard method for measuring intraocular pressure, the most important modifiable risk factor for glaucoma, and it involves applanating (flattening) a fixed area of the cornea using a biprism attached to a slit lamp, measuring the force required to achieve this applanation. The principle is based on the Imbert-Fick law, which states that the pressure inside a sphere is equal to the force needed to flatten a given area of its surface, and the Goldmann tonometer is calibrated to measure the intraocular pressure based on the force required to applanate a 3.06 mm diameter area of the central cornea. The Goldmann tonometer is mounted on a slit lamp, topical anesthesia is applied to the cornea, and flu-

orescein dye is added to the tear film to stain the tear meniscus.

Gonioscopy

– An ophthalmological examination technique that allows direct visualization of the anterior chamber angle, the anatomical region where the cornea and iris meet and where the trabecular meshwork is located, and it is essential for distinguishing between open-angle and angle-closure forms of glaucoma. The procedure uses a specialized gonioscope placed on the surface of the eye that overcomes total internal reflection at the corneal-air interface, allowing light to enter and illuminate the angle structures for gonioscopic evaluation. Gonioscopy is performed using either a direct gonioscope (such as the Koeppe lens, providing a direct view of the angle) or an indirect gonioscope (such as the Goldmann three-mirror lens or the Zeiss four-mirror lens, providing an indirect, mirrored view of the angle using mirrors at various angles).

Hemianopia

– Loss of vision in half the visual field of one or both eyes. Homonymous hemianopia affects the same side in both eyes and localizes to a contralateral lesion posterior to the optic chiasm, most often stroke or tumor. Bitemporal hemianopia affects both temporal fields and localizes to the chiasm, classically from pituitary adenoma or craniopharyngioma.

Hordeolum (Stye)

– See Stye.

Hyperopia

– Hyperopia, commonly known as farsightedness, is a refractive error in which parallel light rays from distant objects are focused posterior to the retina rather than directly on it, resulting in blurred near vision that may be accompanied by blurred distance vision in moderate to high degrees. The condition is caused by an insufficient axial length of the globe relative to the refractive power of the cornea and lens, or by a flat corneal curvature, and it is corrected with convex (plus-powered) or concave (minus-powered) converging lenses (spectacles or contact lenses) that move the focal point of light from behind the retina back onto the retina. Hyperopia is quantified by the refractive error in dioptres, with the degree classified as low (less than +2.00 D), moderate (+2.00 D to +5.00 D), and high (greater than +5.00 D).

Hypertensive Retinopathy

– Retinal changes caused by chronic or acute hypertension. Grading (Keith-Wagener-Barker): Grade I: generalized arteriolar narrowing; Grade II: arteriovenous nicking; Grade III: cotton-wool spots, flame hemorrhages, hard exudates; Grade IV: papilledema (malignant hypertension). Severe hypertension can cause retinal artery occlusion, vitreous hemorrhage, and vision loss. Management: blood pressure control; ophthalmology referral for advanced grades.

Hyphema

– Bleeding into the anterior chamber of the eye, between the cornea and iris, typically resulting from blunt ocular trauma that tears the blood vessels of the iris or ciliary body. Less common causes include spontaneous hyphema (from iris neovascularization in diabetes, retinal vein occlusion, or ocular ischemic syndrome), intraocular surgery (post-cataract or glaucoma surgery), and coagulopathy (anticoagulant or antiplatelet therapy, hemophilia, von Willebrand disease, thrombocytopenia). The blood in the anterior chamber layers dependently due to gravity, forming a visible level (the hyphema) that is graded based on the height of the blood level relative to the total anterior chamber height. The immediate management includes strict bed rest with the head elevated at 30 to 45 degrees, shielding the eye with a protective patch, and cycloplegia with atropine 1 percent or homatropine 5 percent.

Hypopyon

– A layering of inflammatory cells (purulent exudate/leukocytes) in the anterior chamber of the eye, forming a visible white-to-yellow fluid level in the lower portion of the cornea. Caused by severe anterior uveitis (HLA-B27 spondyloarthropathies, Behçet disease), infectious keratitis (bacterial/fungal corneal ulcers), or endophthalmitis. Ophthalmic emergency requiring immediate ophthalmology consultation, slit-lamp examination, and targeted antimicrobial or immunosuppressive therapy.

Intermediate Uveitis

– Inflammation primarily affecting the vitreous body, peripheral retina, and ciliary body, with the classic presentation being pars planitis, which is characterized by the presence of snowbanking (a white, inflammatory exudate on the inferior pars plana) and snowballs (vitreous inflammatory aggregates).

Patients typically present with floaters and blurred vision, often with minimal pain or redness, and slit-lamp examination reveals vitreous cells and haze, with a quiet antequiet anterior chamber. The main differential diagnosis includes multiple sclerosis, sarcoidosis, tuberculosis, Lyme disease, and cat-scratch disease, as well as the masquerade syndrome (vitreoretinal lymphoma). The diagnosis is made by slit-lamp examination showing vitreous cells and haze, with OCT used to detect cystoid macular edema, the most common cause of vision loss in intermediate uveitis.

Intraocular Lens

– An intraocular lens is an artificial, biocompatible, transparent lens implanted during cataract surgery to replace the natural crystalline lens that has been removed, restoring the eye's refractive power and enabling clear vision. Intraocular lenses are typically made of polymethylmethacrylate, silicone, or acrylic materials, and they are available in various designs including monofocal (correcting vision at a single distance), multifocal (providing vision at multiple distances), and toric (correcting astigmatism). The power of the IOL is calculated using biometric measurements of the eye, including axial length, corneal curvature, and anterior chamber depth, with formulas such as the SRK/T, Holladay, and Haigis formulas. The most common IOL implantation technique is in-the-bag placement within the intact capsular bag.

Intravitreal Injection

– An ophthalmological procedure in which medication is injected directly into the vitreous cavity of the eye through the pars plana, a safe entry zone located approximately 3.5 to 4 millimeters posterior to the limbus, to deliver therapeutic agents directly to the retina and vitreous for the treatment of various retinal diseases. The most commonly injected medications are anti-vascular endothelial growth factor agents for wet age-related macular degeneration, diabetic macular edema secondary to retinal vein occlusion. The procedure is performed in the clinic under sterile conditions using a topical anesthetic, and the eye is prepared with 5 percent povidone-iodine. The injection is performed through the pars plana, located 3.5 to 4 mm posterior to the limbus, using a 30-gauge or 31-gauge needle.

Iridotomy

– Laser peripheral iridotomy is a minimally invasive laser procedure used to treat or prevent angle-closure glaucoma by creating a small full-thickness hole in the peripheral iris, allowing aqueous humor to flow directly from the posterior chamber to the anterior chamber, bypassing the pupil and equalizing the pressure between the two chambers. The procedure is indicated for acute angle-closure glaucoma, where it is performed as an emergency to relieve pupillary block and lower intraocular pressure within minutes, and for eyes with occludable angles at high risk of angle closure. The iridotomy is created at the 10 or 2 o'clock position to avoid the visual axis and is typically 100 to 200 micrometres in diameter.

Iritis

– Inflammation of the iris, the most common form of anterior uveitis. Presents with acute onset eye pain, photophobia, blurred vision, and redness (ciliary flush). Signs: cells and flare in the anterior chamber, keratic precipitates (KP), synechiae (adhesions between iris and lens). Causes: idiopathic, trauma, HLA-B27-associated (ankylosing spondylitis, reactive arthritis, inflammatory bowel disease), sarcoidosis, herpes simplex/zoster. Diagnosis: slit lamp examination. Treatment: topical corticosteroids (prednisolone acetate) and cycloplegics (homatropine, atropine) to reduce inflammation and prevent synechiae.

Juvenile angiofibroma

– A rare, benign but locally aggressive vascular tumor of the nasopharynx, accounting for 0.05-0.5 percent of all head and neck tumors, occurring almost exclusively in adolescent males (mean age 14 years, 80-90 percent male predominance). The tumor originates from the posterolateral wall of the nasal cavity at the sphenopalatine foramen and is composed of vascular channels (irregular, thin-walled vessels lacking smooth muscle and elastic fibers) embedded in a fibrous stroma. Although histologically benign, the tumor is locally aggressive, eroding bone and extending into the paranasal sinuses, orbit, and cranial cavity. Clinical presentation is with progressive, recurrent, typically unilateral epistaxis (the most common presenting symptom), followed by

nasal obstruction, facial swelling, proptosis, and anosmia. Diagnosis is by nasal endoscopy, CT, and angiography.

Keratitis

– Inflammation of the cornea. Infectious keratitis: bacterial (contact lens wear, trauma: *Pseudomonas*, *Staph aureus*), viral (HSV, VZV, adenovirus), fungal (*Candida*, *Fusarium*, *Aspergillus*), and *Acanthamoeba* (contact lens-related). Presents with eye pain, photophobia, tearing, conjunctival injection, and corneal opacity/ulcer. Diagnosis: slit lamp exam with fluorescein staining reveals corneal epithelial defect. Treatment: topical antibiotics (fluoroquinolones, fortified aminoglycosides) for bacterial; antivirals (acyclovir, gancyclovir) for herpetic; antifungals for fungal. Corneal perforation requires urgent ophthalmology referral and possible penetrating keratoplasty.

Keratoconus

– A progressive, non-inflammatory ectatic corneal disorder characterized by bilateral (90 percent of cases) thinning and cone-like protrusion of the cornea, leading to irregular astigmatism, myopia, and decreased visual acuity. The condition typically presents in adolescence or early adulthood (peak incidence at age 15-25) and progresses until the 4th-5th decade of life, when it usually stabilizes. The prevalence is approximately 1 in 2000 in the general population. The pathophysiology involves weakening of the corneal stroma due to reduced structural integrity of the collagen framework, with a genetic predisposition (association with Down syndrome, Ehlers-Danlos syndrome, Marfan syndrome, and mutations in the *VSX1* and *LOX* genes). The diagnosis is made by slit-lamp examination (showing corneal thinning, Vogt striae, Fleischer ring, and apical scarring), corneal topography, and pachymetry.

Lacrimal Apparatus

– The anatomical structures responsible for tear production, distribution, and drainage. Components: (1) Lacrimal gland—situated in the superolateral orbit (frontal bone lacrimal fossa); produces the aqueous layer of the tear film. Divided into orbital and palpebral parts; innervated by parasympathetic fibers from CN VII (via pterygopalatine ganglion). Accessory lacrimal glands (Krause, Wolfring) contribute to basal tear secre-

tion. (2) Tear film—three layers: outer lipid layer (meibomian glands—reduces evaporation), middle aqueous layer (lacrimal gland—nutrients, antimicrobials—lysozyme, IgA), inner mucin layer (goblet cells—spreads tears evenly over the cornea). (3) Lacrimal drainage: tears flow from the lateral eye across the cornea to the puncta (upper and lower, medial eyelid margins), through the canaliculi, lacrimal sac, and nasolacrimal duct, draining into the inferior meatus of the nose. Blinking spreads tears and pumps them through the drainage system. Disorders: dry eye disease/keratoconjunctivitis sicca (aqueous deficiency—Sjögren syndrome, or evaporative—meibomian gland dysfunction, MGD), epiphora (excessive tearing—blocked nasolacrimal duct, punctal stenosis, ectropion, reflex tearing from dry eye), dacryocystitis (infection of the lacrimal sac—pain, swelling at the medial canthus, purulent discharge, treated with warm compresses, massage, antibiotics, and dacryocystorhinostomy).

Laser Trabeculoplasty

– A minimally invasive laser procedure used in the treatment of open-angle glaucoma that lowers intraocular pressure by improving the outflow of aqueous humor through the trabecular meshwork. Selective laser trabeculoplasty, the current standard technique, uses a frequency-doubled Q-switched Nd:YAG laser to deliver non-thermal laser burns to the pigmented trabecular meshwork cells, stimulating biological changes that enhance aqueous humor outflow through the conventional outflow pathway, enhancing the outflow of aqueous humor through the trabecular meshwork without damaging adjacent tissues. SLT is most effective in primary open-angle glaucoma, pseudoexfoliation glaucoma, and pigmentary glaucoma, with minimal post-operative pain and inflammation.

LASIK

– LASIK, or laser-assisted in situ keratomileusis, is a refractive surgical procedure that corrects myopia, hyperopia, and astigmatism by reshaping the corneal stroma using an excimer laser, after creating a thin corneal flap with either a microkeratome (a mechanical blade) or a femtosecond laser. The procedure begins with the creation of a hinged corneal flap approximately 100 to 160 micrometers thick, which is folded back to expose the underlying corneal

stroma, and the excimer laser then ablateablates the stromal tissue according to a pre-programmed treatment profile that reshapes the corneal curvature to correct the refractive error, with sub-micron precision in the removal of stromal tissue, with the depth and pattern determined by the refractive error, the optical zone, and the transition zone.

LASIK (Laser-Assisted In Situ Keratomileusis)

– A refractive surgical procedure that reshapes the cornea using an excimer laser to correct myopia, hyperopia, and astigmatism, thereby reducing dependence on glasses or contact lenses. A corneal flap is created with a femtosecond laser or microkeratome, the underlying stroma is ablated per pre-operative topography, and the flap is repositioned. Ideal candidates are adults aged >21 with stable refraction for ≥ 1 year, adequate corneal thickness, and no active ocular disease (keratoconus, severe dry eye, autoimmune disorders). Most patients achieve 20/20 or better vision; temporary side effects include dry eye, glare, halos, and fluctuating vision. Serious complications (flap striae, infection, ectasia, epithelial ingrowth) are rare with appropriate screening and technique.

Leber Congenital Amaurosis

– The most severe inherited retinal dystrophy, presenting at birth or within the first few months of life with profound visual impairment, nystagmus, and pupillary light-near dissociation. Caused by mutations in over 20 genes (most commonly GUCY2D, CEP290, CRB1, RPE65, and AIPL1), encoding proteins critical for phototransduction, retinal development, or ciliary function. Inheritance is autosomal recessive. Presents with poor visual behavior (inability to fix and follow), roving nystagmus, oculodigital sign (eye poking, rubbing), and photophobia or night blindness. Fundus examination may appear normal initially, but electroretinography (ERG) is the diagnostic gold standard — shows markedly reduced or absent rod and cone responses. Treatment: gene therapy (voretigene neparvovec, Luxturna) for RPE65-associated LCA — the first FDA-approved gene therapy for a retinal disease. Low-vision rehabilitation, orientation and mobility training, and genetic counseling. Most patients have severe visual impairment from birth.

Lisch Nodules

– Pathognomonic ocular finding of Neurofibromatosis Type 1 (NF1, von Recklinghausen disease). Consists of clear, yellow-brown, dome-shaped melanocytic hamartomas located on the surface of the iris. Asymptomatic and do not affect vision. Present in $> 90\%$ of adult NF1 patients. Part of official diagnostic criteria alongside ≥ 6 café-au-lait macules, neurofibromas, optic pathway glioma, and axillary/inguinal freckling (Crowe sign).

Macula

– The macula is a specialized region of the central retina approximately five and a half millimeters in diameter that is responsible for high-acuity central vision, color perception, and fine detail discrimination, and it contains the highest density of cone photoreceptors in the eye. The central-most region of the macula is the fovea centralis, a depression approximately one and a half millimeters in diameter where the inner retinal layers are displaced laterally, allowing light to strike the photoreceptors directly, maximising the efficiency of photon capture. The fovea is surrounded by the parafovea and perifovea, where the retinal layers transition to the normal architecture of the peripheral retina.

Macular degeneration

– Also known as age-related macular degeneration (AMD), a progressive degenerative disease of the central retina (macula) and the leading cause of irreversible vision loss in individuals over age 50 in developed countries, affecting approximately 10 percent of those over 65 and 30 percent over 80. The pathophysiology involves oxidative stress, chronic inflammation, and complement system dysregulation at the interface between the retinal pigment epithelium (RPE) and Bruch membrane, resulting in accumulation of drusen, lipofuscin, and inflammatory debris that trigger a chronic, complement-mediated immune response and progressive RPE and photoreceptor atrophy. The dry form accounts for 85-90 percent of AMD, with no effective treatment to reverse or slow the atrophy. The wet form accounts for 10-15 percent but causes the majority of severe vision loss, treated with anti-VEGF intravitreal injections.

Miosis

– Constriction of the pupil of the eye (< 2 mm diam-

eter). Controlled by parasympathetic nerve fibers via the oculomotor nerve (CN III) acting on the sphincter pupillae muscle. Causes: Opioid toxicity (pathognomonic pinpoint pupils), organophosphate/nerve agent poisoning (cholinergic excess), Horner syndrome (loss of sympathetic input: ptosis, miosis, anhidrosis), pontine hemorrhage, and miotic eye drops (pilocarpine).

Mydriasis

– Dilation of the pupil of the eye (> 5 mm diameter). Controlled by sympathetic nerve fibers acting on the dilator pupillae muscle. Causes: Anticholinergic toxicity (atropine, scopolamine, diphenhydramine — "blind as a bat, mad as a hatter"), sympathomimetic agents (cocaine, amphetamines), third cranial nerve (CN III) palsy (uncal herniation causing "blown pupil"), and traumatic iridoplegia.

Myopia

– Myopia, commonly known as nearsightedness, is a refractive error in which parallel light rays from distant objects are focused anterior to the retina rather than directly on it, resulting in blurred distance vision while near vision remains relatively clear. The condition is caused by an excessive axial length of the globe relative to the refractive power of the cornea and lens, or by excessive corneal curvature, and it is corrected with concave (minus-powered) diverging lenses that move the focofocal point of light from in front of the retina back onto the retina, enabling clear distance vision. The degree of myopia is quantified in dioptres (D), with low (less than -3.00 D), moderate (-3.00 D to -6.00 D), and high (greater than -6.00 D) categories, with high myopia being associated with increased risk of retinal detachment, choroidal neovascularization, macular atrophy, glaucoma, and cataract.

Night Blindness

– Impaired vision in dim light (nyctalopia). Causes: vitamin A deficiency (most common cause worldwide, leading to retinol deficiency and rod dysfunction), retinitis pigmentosa (progressive rod-cone degeneration, genetic), congenital stationary night blindness, advanced glaucoma, and cataract. Vitamin A deficiency: also causes xerophthalmia (dry cornea) and Bitot spots (foamy conjunctival deposits); treat with vitamin A supplementation. Retinitis pigmentosa: no cure; vitamin A, lutein sup-

plementation, and low-vision aids.

Non-Contact Tonometry

– Non-contact tonometry, commonly known as the air puff test, is a method of measuring intraocular pressure that uses a calibrated air pulse to appanate the cornea, with the force of the air pulse determined by a sensor that detects the moment of appanation, providing a rapid, non-invasive measurement without requiring direct corneal contact. The technique eliminates the need for topical anesthesia and reduces the risk of cross-infection between patients, making it particularly useful for screenscreening in high-volume settings and for patients unable to tolerate contact tonometry. The device measures the force of the air puff at the moment of corneal appanation, but it is generally less accurate than Goldmann appanation tonometry, especially in patients with irregular corneas.

Non-Proliferative Retinopathy

Diabetic

– The early stage of diabetic retinopathy, characterized by structural abnormalities of the retinal vasculature resulting from chronic hyperglycemia-induced damage to the endothelial cells and pericytes of retinal capillaries, without neovascularization. The clinical features include microaneurysms, which are the earliest clinically visible sign and appear as small, red dots on fundus examination; dot and blot hemorrhages, representing deeper retinal hemorrhages; hard exudates, which are lipid deposits in the outer plexiform layer; cotton-wool spots, representing nerve fibre layer infarcts; and retinal vascular changes, including venous beading, arteriolar narrowing, and intraretinal microvascular abnormalities.

Nuclear Sclerosis

– The most common type of age-related cataract, characterized by progressive yellowing and hardening of the lens nucleus due to the accumulation and aggregation of insoluble crystallin proteins, resulting in a gradual decrease in vision that is often noticed as increased difficulty with distance vision and a phenomenon called second-sight vision, where temporarily improved near vision occurs as the lens becomes more myopic from its increased refractive index. The lens nucleus becomes progres-

sively harder and more yellow, and the resulting increase in the refractive index of the nucleus causes the lens power to increase, leading to a shift toward myopia. The diagnosis is made by slit-lamp examination after dilation, showing the yellowing and increased density of the lens nucleus, graded from 1+ to 4+.

Nystagmus

– A rhythmic, involuntary oscillation of the eyes that can be horizontal, vertical, rotational, or mixed in pattern, and it is classified based on the underlying cause as infantile (developing in the first six months of life), acquired (developing later in life), or periodic alternating. Infantile nystagmus is the most common form, often associated with albinism, congenital cataracts, or other conditions that impair visual development, and it typically has a null point (a position of the specific direction of gaze, or a head turn or tilt that reduces the intensity of the nystagmus). In acquired nystagmus, the onset is typically subacute and oscillopsia is prominent, and neurological evaluation with imaging is essential to rule out an underlying structural or metabolic cause, including vestibular disorders, brainstem or cerebellar lesions, and drug-induced causes.

Opacity

– Lack of transparency of a normally transparent ocular structure (cornea, lens, vitreous, or aqueous humour). Corneal opacity results from scarring (trauma, infection—herpes simplex keratitis, trachoma), dystrophies (Fuchs endothelial dystrophy, granular/lattice/macular dystrophies), or edema. Lenticular opacity is cataract—age-related, congenital, traumatic, or metabolic (diabetes). Vitreous opacity arises from hemorrhage (diabetic retinopathy, retinal tear), inflammation (vitritis, posterior uveitis), or asteroid hyalosis (calcium-lipid deposits in the vitreous, benign). Assessment: slit-lamp examination, visual acuity, and optical coherence tomography. Opacity causes decreased visual acuity, glare, and contrast sensitivity loss. Management depends on cause: corneal transplant (penetrating keratoplasty, DSEK) for irreversible corneal opacity; cataract surgery (phacoemulsification with intraocular lens implantation) for visually significant cataract; vitrectomy for non-clearing vitreous hemorrhage.

Optical Coherence Tomography

– A non-invasive imaging technique that uses low-coherence interferometry to produce high-resolution, cross-sectional images of the retina and other ocular structures, providing quantitative measurements of retinal layer thickness and detecting structural abnormalities with micrometer-level resolution. In ophthalmology, OCT is the gold standard for diagnosing and monitoring macular diseases including age-related macular degeneration, diabetic macular edema, and macular hole, epiretinal membrane, and central serous chorioretinopathy, and for measuring retinal nerve fibre layer thickness in glaucoma. The principle of OCT is analogous to ultrasound imaging but using light rather than sound, achieving an axial resolution of 2 to 7 micrometres.

Optic Atrophy

– End-stage degeneration of the optic nerve fibers resulting from any optic neuropathy. Causes: glaucoma, ischemic optic neuropathy, multiple sclerosis, compressive lesions (pituitary tumor, aneurysm), toxins (methanol, ethambutol), and hereditary (Leber hereditary optic neuropathy). Fundoscopic findings: pale optic disc with sharp margins (primary atrophy) or blurred margins (secondary atrophy). Presents with visual acuity loss, color vision deficits, and visual field defects. Irreversible; treatment addresses underlying cause.

Optic Neuritis

– An inflammatory demyelinating condition of the optic nerve that typically presents with acute or subacute unilateral vision loss, pain with eye movement, and a relative afferent pupillary defect, and it is most commonly associated with multiple sclerosis, occurring in approximately fifty percent of patients at some point during their disease course. The pathophysiology involves autoimmune-mediated demyelination of the optic nerve, with T lymphocyte infiltration and antibody-mediated demyelination. The afferent visual dysfunction is characterized by reduced best-corrected visual acuity, decreased contrast sensitivity, dyschromatopsia (impaired color vision, particularly red color desaturation), and a relative afferent pupillary defect. A central or paracentral scotoma is found on formal visual field testing.

Optometry

– A healthcare profession concerned with examining the eyes and visual system for defects and abnormalities, prescribing corrective lenses (spectacles, contact lenses), diagnosing eye disease, and providing pre- and post-operative care for surgical eye treatments. Optometrists (in the UK) perform sight tests (refraction, visual field assessment, tonometry, retinal examination), detect ocular disease (glaucoma, diabetic retinopathy, macular degeneration, cataracts), and refer to ophthalmologists when medical or surgical intervention is required. They also manage low vision, binocular vision disorders (strabismus, amblyopia), and provide advice on visual ergonomics. In the UK, optometrists train for 4 years (BSc Optometry) followed by a pre-registration year and professional qualifying examinations.

Orbital Cellulitis

– A serious infection of the orbital tissues posterior to the orbital septum, potentially sight-threatening and life-threatening due to the risk of optic nerve compression, cavernous sinus thrombosis, and intracranial extension. The condition is classified by the Chandler system into five stages: preseptal cellulitis (infection confined to the eyelid and tissues anterior to the orbital septum), orbital cellulitis (infection of the orbital fat and muscles without abscess formation), and postseptal cellulitis (the true orbital cellulitis, involving the orbital fat, muscles, optic nerve, and neurovascular structures). Preseptal cellulitis presents with eyelid erythema, edema, warmth, and tenderness, with no proptosis, no limitation of extraocular movements, no relative afferent pupillary defect, and no visual loss, and it is managed with oral antibiotics.

Palpebral Conjunctiva

– The palpebral conjunctiva is the portion of the conjunctival membrane that lines the inner surface of the upper and lower eyelids, and it is subdivided into the tarsal conjunctiva, which is firmly adherent to the tarsal plates and appears smooth and pink, and the forniceal conjunctiva, which forms loose, redundant folds at the superior and inferior fornices where the palpebral conjunctiva reflects to become the bulbar conjunctiva. The palpebral conjunctiva contains meibomian glands (sebaceous glands) that produce the lipid layer of the tear film. The tarsal conjunctiva is normally pink and smooth,

and abnormalities such as follicles (characteristically seen in viral and chlamydial conjunctivitis), papillae (characteristically seen in allergic conjunctivitis), and membranes provide important diagnostic clues.

Panretinal Photocoagulation

– A laser treatment for proliferative diabetic retinopathy that involves applying laser burns to the peripheral retina (typically 1,200 to 2,000 burns over three to four sessions) to ablate ischemic retinal tissue, reducing the production of vascular endothelial growth factor and other angiogenic factors that drive pathological neovascularization. The laser burns destroy the oxygen-consuming photoreceptor cells in the peripheral retina, improving oxygenation of the remaining retina, reducing the VEGF drive for neovascularization, thereby causing regression of existing new vessels and preventing the growth of new abnormal vessels. The specific indications for PRP are high-risk proliferative diabetic retinopathy.

Panuveitis

– Inflammation involving all segments of the uveal tract, including the anterior chamber, vitreous cavity, and choroid, resulting in a severe, potentially sight-threatening condition that requires aggressive systemic immunosuppressive therapy. The clinical presentation combines features of anterior, intermediate, and posterior uveitis, with patients experiencing significant eye pain, photophobia, blurred vision, and decreased vision, and examination revealing cells and flare in the anterior chamber, vitreous haze and cells, and active choroiditis or chorioretinitis, often with exudative retinal detachment, cystoid macular edema, and papillitis. The etiology includes infectious causes (toxoplasmosis, tuberculosis, syphilis, cytomegalovirus), non-infectious causes (sarcoidosis, Behcet disease, Vogt-Koyanagi-Harada syndrome, birdshot chorioretinopathy), and masquerade syndrome (intraocular lymphoma).

Papilledema

– Swelling of the optic disc caused by elevated intracranial pressure, and it is a critical clinical sign that requires urgent investigation to identify the underlying cause, which may be life-threatening. The pathophysiology involves transmission of elevated cerebrospinal fluid pressure through the optic nerve sheath to the optic nerve head, causing axoplasmic stasis, disc edema, and potentially progressive

optic nerve damage. Clinical findings include disc blurring, elevation, venous congestion, retinal venous pulsation loss, and peripapillary haemorrhages. The urgency mandates immediate neuroimaging (CT head without contrast) to rule out a space-occupying lesion or hydrocephalus, followed by lumbar puncture with opening pressure measurement if CT is negative.

Phacoemulsification

– The most commonly performed modern cataract surgery technique, involving the use of an ultrasonic handpiece with a titanium tip that vibrates at high frequency to fragment and emulsify the opaque lens nucleus while simultaneously irrigating and aspirating the lens material through a coaxial or bimanual system, leaving the posterior lens capsule intact for implantation of an artificial intraocular lens. The procedure is performed through a small self-sealing incision, typically 2.2 to 3.2 mm in width, through the clear cornea near the limbus. Phacoemulsification has a low rate of wound leak, post-operative inflammation, and induced astigmatism, with rapid visual recovery and a return to full activity within days to weeks.

Pinguecula

– A yellowish-white, slightly elevated benign degenerative lesion of the bulbar conjunctiva near the limbus, from elastotic degeneration of the substantia propria. Chronic ultraviolet exposure, dust, wind, and dryness are the principal risk factors. Most are asymptomatic but may cause irritation, foreign body sensation, cosmetic concern, or inflammation (pingueculitis). Management is conservative with lubrication and UV protection; excision is rarely required.

Pink Eye

– Inflammation of the conjunctiva producing a pink or red appearance of the eye, most often indicating conjunctivitis. Causes are infectious (viral, bacterial, chlamydial) or noninfectious (allergic, irritant), with viral the most common overall. Typical features include conjunctival injection, discharge, tearing, and foreign body sensation. Most cases are self-limited or managed with targeted therapy and hygiene to limit spread.

Posterior Subcapsular Cataract

– A type of lens opacity located at the posterior

aspect of the lens, just anterior to the posterior lens capsule, in the visual axis, and it is particularly visually disabling because of its central location. The opacity appears as a granular, plaque-like whitish area on the posterior lens surface on slit-lamp examination, and it may have a flower-petal or vacuolar pattern. This form of cataract is more common in younger patients and is strongly associated with corticosteroid use (both topical, inhaled, and systemic, which is the strongest modifiable risk factor, with risk increasing with dose and duration of use), diabetes mellitus, trauma, intraocular inflammation, and radiation exposure. The treatment is surgical removal with phacoemulsification and IOL implantation.

Posterior Uveitis

– Inflammation primarily affecting the choroid (choroiditis), retina (retinitis), or both (chorioretinitis), and it can be caused by infectious agents including *Toxoplasma gondii*, cytomegalovirus, herpes simplex virus, tuberculosis, and syphilis, as well as non-infectious causes including sarcoidosis, Behcet disease, and Vogt-Koyanagi-Harada syndrome. The clinical presentation depends on the underlying cause and may include floaters, blurred vision, scotomas, and decreased vision with a relative afferent pupillary defect in severe or unilateral cases. The diagnosis is based on fundoscopic examination showing active choroidal or retinal lesions, with ancillary testing to characterise the disease and laboratory evaluation to identify the underlying cause.

Preseptal Cellulitis

– Preseptal cellulitis, also known as periorbital cellulitis, is an infection of the eyelid and periorbital tissues anterior to the orbital septum, without involvement of the orbital contents, and it is the most common orbital infection, particularly in children. The condition typically results from contiguous spread from adjacent skin infections, insect bites, or trauma, and common causative organisms include *Staphylococcus aureus* and *Streptococcus pyogenes* in community-acquired cases, and *Haemophilus influenzae* in children and *Staphylococcus aureus* and *Streptococcus pyogenes* in adults. Preseptal cellulitis presents with eyelid edema, erythema, warmth, and tenderness, with no

proptosis, no limitation of extraocular movements, no relative afferent pupillary defect, and no visual loss. Management is with oral antibiotics covering the common pathogens.

PRK

– Photorefractive keratectomy, commonly known as PRK, is a refractive surgical procedure that corrects myopia, hyperopia, and astigmatism by reshaping the corneal stroma using an excimer laser after mechanical removal of the corneal epithelium, without creating a corneal flap. The procedure begins with the removal of the corneal epithelium using an alcohol solution, mechanical debridement, or the excimer laser itself, and the excimer laser then ablates the exposed stromal surface according to a customized laser treatment profile, removing the Bowman layer and anterior stroma without creating a flap. After ablation, a bandage contact lens is placed to promote epithelial healing. The epithelial defect typically heals over 3 to 5 days, and visual recovery is more gradual than LASIK.

Proliferative Diabetic Retinopathy

– The advanced stage of diabetic retinopathy, characterized by the growth of new, fragile blood vessels (neovascularization) on the retinal surface, optic disc, or iris in response to severe retinal ischemia and the release of vascular endothelial growth factor. These new vessels are abnormal in structure, lacking tight junctions and pericyte support, making them prone to hemorrhage into the vitreous cavity, which can cause sudden, painless, severe vision loss due to vitreous hemorrhage. The neovascular vessels also grow on the iris (rubeosis iridis) and in the anterior chamber angle, leading to neovascular glaucoma, a severe, refractory form of glaucoma requiring prompt panretinal photocoagulation to induce regression of the new vessels.

Prostaglandin Analogs

– A class of topical medications used in the treatment of open-angle glaucoma and ocular hypertension that lower intraocular pressure by increasing the uveoscleral outflow of aqueous humor, reducing intraocular pressure by approximately twenty-five to thirty-five percent. The mechanism involves binding to prostaglandin F₂-alpha receptors in the ciliary muscle and ciliary body, which activates matrix metalloproteinases that remodel the extracellular ma-

trix of the uveoscleral pathway through enhanced matrix metalloproteinase activity, reducing the outflow resistance. Available agents include latanoprost (the most commonly prescribed), travoprost, tafluprost, and bimatoprost, and they are generally safe and well tolerated, with the most common side effect being conjunctival hyperaemia.

Pterygium

– A triangular, fibrovascular proliferation of bulbar conjunctiva extending onto the cornea, usually nasal, associated with chronic ultraviolet exposure, dust, and dry climates. Most are asymptomatic or cause mild irritation, but growth toward the visual axis can induce astigmatism and obstruct vision. Excision with conjunctival autograft is reserved for threat to the visual axis or significant astigmatism.

Ptosis

– The drooping of the upper eyelid, which can be congenital or acquired, and can range from mild drooping that is primarily a cosmetic concern to severe drooping that obstructs the visual axis and causes amblyopia in children or visual impairment in adults. Congenital ptosis is most commonly caused by developmental abnormalities of the levator palpebrae superioris muscle, including myogenic dysgenesis, and is typically present at birth with poor levator function and an absent lid crease. Congenital ptosis is most commonly caused by developmental abnormalities of the levator palpebrae superioris muscle, including myogenic dysgenesis, and is typically present at birth with poor levator function and an absent lid crease. Acquired ptosis is further classified by etiology into aponeurotic (most common in older adults, caused by dehiscence of the levator aponeurosis), myogenic, neurogenic, and mechanical ptosis.

Pupil

– The central aperture of the iris that regulates the amount of light entering the eye. Pupil size is controlled by two smooth muscles: the sphincter pupillae (circular fibers, innervated by parasympathetic fibers from CN III—oculomotor nerve, via the ciliary ganglion, muscarinic M₃ receptors) causes constriction (miosis); the dilator pupillae (radial fibers, innervated by sympathetic fibers from the superior cervical ganglion, α_1 receptors) causes dilation (mydriasis). Normal pupil diameter: 2–4

mm in bright light, 4–8 mm in dim light. Pupillary light reflex: light in one eye causes direct (same eye) and consensual (opposite eye) constriction (afferent: CN II—optic nerve; efferent: CN III—oculomotor nerve). Near reflex: convergence, accommodation, and pupillary constriction. Abnormal pupils: anisocoria (unequal size—physiological in 20%, Horner syndrome, CN III palsy, Adie tonic pupil), afferent pupillary defect (relative afferent pupillary defect—Marcus Gunn pupil, in optic nerve disease—optic neuritis, ischemic optic neuropathy, compression), and Argyll Robertson pupils (bilateral small irregular pupils that accommodate but do not react to light—classically in neurosyphilis).

Ranibizumab

– A recombinant humanized monoclonal antibody Fab fragment that binds to and neutralizes all isoforms of vascular endothelial growth factor A, inhibiting the growth of pathological choroidal neovascular blood vessels and reducing vascular permeability in wet age-related macular degeneration. The drug is administered by intravitreal injection, typically monthly initially with the possibility of extending intervals based on treatment response, and it was the first anti-vascular endothelial growth factor agent approved for wet AMD, receiving FDA approval in 2006 based on the MARINA and ANCHOR clinical trials, which demonstrated that monthly intravitreal injections led to a mean improvement in visual acuity of 7 to 10 letters at 12 months.

Refraction

– The bending of light rays as they pass through the eye’s optical system (cornea, aqueous humour, crystalline lens, vitreous humour) to focus a sharp image on the retina. The refractive power of the eye is measured in dioptres (D). Emmetropia: normal refractive state—parallel light rays focus exactly on the retina without accommodation. Ametropia (refractive error): (1) Myopia (short-sightedness)—light focuses in front of the retina, corrected by concave (negative) lenses; axial myopia (elongated eyeball) is most common. (2) Hypermetropia (long-sightedness)—light focuses behind the retina, corrected by convex (positive) lenses; young hypermetropes may compensate by accommodation. (3) Astigmatism—unequal curvature of the cornea or

lens causes light to focus on multiple points, corrected by cylindrical lenses. (4) Presbyopia—age-related loss of accommodation (lens hardening), typically becomes symptomatic after age 40, corrected by reading glasses or bifocals. Refraction is measured objectively (retinoscopy, autorefractor) and subjectively (the patient’s response to lens choices during a sight test). Refractive surgery (LASIK, PRK, SMILE) reshapes the cornea to correct refractive errors.

Refractive Errors and Astigmatism

– Refractive errors are vision disorders caused by the eye’s inability to properly focus light onto the retina, resulting in blurred vision. Common types include myopia (nearsightedness), hyperopia (farsightedness), presbyopia (age-related loss of near vision), and astigmatism, which occurs when the cornea or lens has an irregular curvature that causes distorted vision at all distances. These conditions are typically diagnosed through a comprehensive eye examination and are correctable with eyeglasses, contact lenses, or refractive surgery such as LASIK.

Refractive Surgery

– Surgical procedures that reshape the cornea or alter the eye to correct refractive errors and reduce dependence on eyeglasses or contact lenses. Laser techniques include LASIK (corneal flap with excimer ablation), photorefractive keratectomy (surface ablation), and small-incision lenticule extraction (SMILE). Phakic intraocular lens implantation suits patients unsuited to corneal laser surgery. Careful candidate selection avoids ectasia, infection, and dry eye.

Retinal Detachment

– A separation of the neurosensory retina from the underlying retinal pigment epithelium, creating a potential space that fills with fluid and resulting in progressive vision loss in the affected area, and it is classified into three main types based on the underlying mechanism. Rhegmatogenous retinal detachment, the most common type, is caused by a full-thickness break or tear in the retina that allows liquefied vitreous to enter the subretinal space, separating the retina from the underlying RPE. Tractional retinal detachment is caused by the contraction of fibrovascular membranes on the retinal surface, most commonly in proliferative diabetic

retinopathy. Exudative retinal detachment occurs when subretinal fluid accumulates due to leakage from blood vessels, without a retinal break, most commonly associated with inflammatory conditions.

Retinal Layers

– The retina consists of ten distinct layers that process visual information through a complex neural circuit. From innermost to outermost, these layers include the internal limiting membrane (the boundary between retina and vitreous), nerve fiber layer (containing retinal ganglion cell axons), ganglion cell layer (containing retinal ganglion cell bodies), inner plexiform layer (synapses between bipolar and ganglion cells), inner nuclear layer (cell bodies of bipolar, horizontal, amacrine, and Müller cells), outer plexiform layer (synapses between photoreceptors and bipolar cells), outer nuclear layer (cell bodies of rod and cone photoreceptors), external limiting membrane, and the photoreceptor layer. The retinal pigment epithelium (RPE) is a single layer of pigmented cells beneath the photoreceptors that is essential for photoreceptor health and function.

Retinitis Pigmentosa

– A group of inherited retinal dystrophies characterized by progressive degeneration of rod and cone photoreceptors, leading to visual field loss and eventual blindness. Prevalence: 1 in 4,000. Genetics: autosomal dominant, autosomal recessive, X-linked, and mitochondrial inheritance; >60 genes implicated (RHO, RPGR, RP2, USH2A, PDE6B, ABCA4). Pathophysiology: rod photoreceptors degenerate first, followed by cones. Characteristic fundus findings: 'bone-spicule' pigmentary deposits in the mid-peripheral retina (perivascular), waxy pallor of the optic disc, and attenuated retinal arterioles. Clinical: night blindness (nyctalopia—earliest symptom, often in childhood), progressive constriction of the visual field (tubular vision—preserves central vision until late stages), and eventually loss of central vision (legal blindness by age 40–60). Associated systemic conditions: Usher syndrome (RP plus congenital sensorineural hearing loss), Bardet–Biedl syndrome (RP, obesity, polydactyly, intellectual disability, renal abnormalities). Diagnosis: electroretinography (ERG—reduced or extinguished rod and cone responses), visual field testing (Goldmann

perimetry—constricted fields), optical coherence tomography (OCT—thinning of outer retinal layers), and genetic testing. Treatment: no cure. Management: low vision aids, vitamin A palmitate (15,000 IU/day—may slow progression in some forms, controversial), and avoidance of bright light. Gene therapy: voretigene neparvovec (Luxturna) approved for RPE65-related RP (restores visual function). Retinal prostheses (Argus II—epiretinal implant) for end-stage disease. Research: stem cell therapy, optogenetics. Prognosis: progressive, most patients are legally blind by age 60.

Rhegmatogenous Retinal Detachment

– The most common type of retinal detachment, caused by a full-thickness break or tear in the retina that allows liquefied vitreous humor to enter the subretinal space, separating the neurosensory retina from the underlying retinal pigment epithelium. The condition typically occurs in association with posterior vitreous detachment, where vitreoretinal traction at sites of abnormal adhesion causes retinal tears, most commonly at the equator of the eye. Patients typically present with sudden onset of unilateral, painless, progressive visual field loss, often described as a curtain or shade over their vision, with or without preceding photopsias and floaters. On examination, there is a relative afferent pupillary defect, decreased visual acuity if the macula is detached, and the neurosensory retina is seen to be elevated and billowing on fundoscopy.

Scotoma

– A focal area of diminished or absent vision within an otherwise intact visual field, classified by location and morphology. Central scotomas involving fixation are characteristic of macular disease and optic neuropathies; paracentral and arcuate scotomas are typical of glaucoma; peripheral scotomas result from retinal detachment, chorioretinitis, or visual pathway lesions. Perimetry localizes the site of damage.

Slit Lamp Biomicroscopy

– A fundamental ophthalmological examination technique that uses a high-intensity, adjustable slit beam of light combined with a binocular microscope to provide a magnified, stereoscopic view of the anterior segment and, with the use of auxiliary lenses,

the posterior segment of the eye. The slit beam can be adjusted in width, height, and angle, allowing the examiner to create an optical section through the transparent ocular media and visualize individual corneal layers and structures in fine detail, including the corneal epithelium, Bowman layer, stroma, Descemet membrane, and endothelium, as well as allowing the detection of cells and flare in the anterior chamber, cataract in the lens, and vitreous cells. The slit lamp is also used for Goldmann applanation tonometry and for performing diagnostic and therapeutic procedures.

SMILE

- Small incision lenticule extraction, commonly known as SMILE, is a minimally invasive refractive surgical procedure that corrects myopia and myopic astigmatism by creating and removing a thin, disc-shaped piece of corneal stroma called a lenticule through a small incision, without creating a corneal flap. The procedure uses a femtosecond laser to create two intrastromal cuts: the posterior surface of the lenticule and the anterior cap, and a small peripheral incision approximately 2 to 4 millimetres in length creating a side-entry channel for extraction of the lenticule. SMILE offers advantages over LASIK, including the absence of a corneal flap, preservation of corneal biomechanical stability, and a lower risk of dry eye syndrome.

Squint

- See Strabismus.

Strabismus

- A misalignment of the visual axes of the two eyes, where one eye is deviated inward (esotropia), outward (exotropia), upward (hypertropia), or downward (hypotropia) relative to the other, disrupting binocular vision and potentially leading to amblyopia in children. The condition can be constant or intermittent, unilateral or alternating, and it may be comitant (the angle of deviation is the same in all directions of gaze) or incomitant (the angle varies depending on the direction of gaze, indicating a paretic or restrictive cause). The diagnosis is made by the cover-uncover test and the alternate cover test, which detect manifest or latent strabismus and measure the angle of deviation in prism dioptres. Additional tests include measurement of visual acuity, evaluation of ductions and versions,

and the Hess chart.

Stye

- A common infection of the eyelid. External hordeolum: acute bacterial infection of the Zeis or Moll glands at the eyelash follicle, typically caused by *Staphylococcus aureus*. Presents as a tender, red, well-localized swelling at the lid margin. Internal hordeolum: infection of the meibomian gland, larger and more painful than external. Treatment: warm compresses 3-4 times daily, lid hygiene. Incision and drainage for persistent cases. Avoid squeezing to prevent spread of infection.

Trabeculectomy

- A conventional glaucoma filtration surgery that creates a new drainage pathway for aqueous humor by removing a small piece of the trabecular meshwork and creating a partial-thickness scleral flap under which aqueous humor filters from the anterior chamber into the subconjunctival space, forming a filtering bleb. The procedure is indicated for glaucoma that is uncontrolled with maximal medical and laser therapy, and it achieves intraocular pressure reduction to target levels in target levels in up to 80 to 90 percent of patients at 2 years. The procedure involves creating a conjunctival flap, a partial-thickness scleral flap, excising a trabecular and deep scleral block, and creating a peripheral iridectomy. The scleral flap is then sutured to control the rate of aqueous filtration.

Uvea

- The middle vascular coat of the eye, consisting of three parts from anterior to posterior: the iris (the coloured part of the eye, controlling pupil size), the ciliary body (producing aqueous humour and controlling lens shape via the zonular fibers), and the choroid (the vascular layer supplying the outer retina, between the sclera and the retinal pigment epithelium). The uvea is the site of inflammation in uveitis. Uveal melanoma is the most common primary intraocular malignancy in adults, arising from melanocytes in the choroid, ciliary body, or iris. Benign uveal tumors include naevi.

Uveitis

- An inflammatory condition of the uveal tract, which includes the iris, ciliary body, and choroid, and it is classified anatomically based on the location of the inflammation: anterior uveitis (iritis

and iridocyclitis), intermediate uveitis (pars planitis and periphlebitis), posterior uveitis (choroiditis and chorioretinitis), and panuveitis (involvement of all three segments). Anterior uveitis is the most common form, presenting with eye pain, photophobia, blurred vision, and redness/redness with ciliary flush. The diagnosis is confirmed by slit-lamp examination revealing cells and flare in the anterior chamber, keratic precipitates, and synechiae. Treatment depends on location and severity, with topical corticosteroids for anterior uveitis and systemic immunosuppression for posterior and panuveitis.

Viral Conjunctivitis

– The most common form of infectious conjunctivitis, caused predominantly by adenoviruses (serotypes 3, 4, 7, 8, 19, and 37), and it is highly contagious, spreading through direct contact with infected ocular secretions or contaminated surfaces. The condition typically begins unilaterally and spreads to the contralateral eye within one to two days, presenting with watery discharge, foreign body sensation, tearing, and conjunctival injection, often accompanied by preauricular/preauricular lymphadenopathy in 30 to 50 percent of cases. The diagnosis is clinical, and treatment is largely supportive (cool compresses, lubricating drops, and careful hand hygiene to prevent spread), as the disease is self-limited and resolves within 2 to 3 weeks.

Vision

– The sensory ability to perceive light and interpret visual information processed by the eyes and brain, enabling recognition of shapes, colors, depth, and motion. Normal vision depends on the proper function of the cornea, lens, retina, and optic nerve, as well as intact neural pathways to the visual cortex. Age-related changes such as presbyopia and cataracts commonly affect vision, while conditions like glaucoma, macular degeneration, and diabetic retinopathy can cause permanent vision loss if not detected and treated early.

Vision and Hearing

– The two primary sensory modalities through which humans perceive and interact with their environment. Age-related declines in both senses are common, with presbyopia and cataracts affecting vision and presbycusis affecting hearing, often beginning as early as the fourth decade of life. Regular sen-

sory screening is important for early detection of impairments, and corrective measures including eyeglasses, contact lenses, hearing aids, and cochlear implants can substantially improve quality of life and reduce the risk of falls, social isolation, and cognitive decline.

Vision Loss

– A decrease in the ability to see that cannot be fully corrected with eyeglasses, contact lenses, or medical treatment. It ranges from partial impairment to complete blindness and can result from conditions such as macular degeneration, glaucoma, diabetic retinopathy, cataracts, and traumatic injury. Low vision rehabilitation services, assistive technologies including magnifiers and screen readers, and environmental modifications help individuals with vision loss maintain independence and quality of life.

Visual Acuity

– The resolving power of the eye, defined as the ability to distinguish two points as distinct, and the most common clinical measure of visual function. It is quantified using the Snellen chart (e.g., 20/20), in which the numerator is the testing distance and the denominator the distance a normal eye could read the same line; smaller denominators indicate better acuity.

Visual Field Defects

– Areas of reduced or absent vision within the visual field that correspond to damage at specific points along the visual pathway, and their pattern provides crucial localizing information for diagnosis. A scotoma is an area of diminished or absent vision surrounded by normal vision, with the most common types being central scotomas (from macular disease or optic neuropathy) and paracentral scotomas (from glaucoma or retinal disease). Homonymous hemianopia is loss of the same side of the visual field in both eyes, which localizes to the optic tract or optic radiation contralateral to the side of the field loss, most commonly caused by stroke. Bitemporal hemianopia is loss of the temporal half of the visual field in both eyes, which localizes to the optic chiasm, most commonly caused by a pituitary adenoma.

Visual Field Perimetry

– A systematic method of measuring the sensitivity of the retina across the entire visual field using

standardized light stimuli, providing a quantitative map of visual function that can detect, characterize, and monitor visual field loss caused by diseases of the retina, optic nerve, and visual pathways. Automated static perimetry, most commonly performed using the Humphrey Field Analyzer, presents points of light at varying intensities throughout the visual field and rereports the threshold sensitivity at each tested point. The Humphrey 24-2 and 30-2 protocols are the most commonly used. The results are displayed as a gray-scale map, a total deviation probability map, and a pattern deviation probability map.

Vitrectomy

- Surgical removal of the vitreous gel, typically via the pars plana approach, using a cutting probe under microscopic visualization. Indications include vitreous hemorrhage, complicated retinal detachment, macular holes, epiretinal membranes, intraocular foreign bodies, and endophthalmitis. The three-port trocar technique often employs endolaser and gas or silicone oil tamponade. Complications include retinal tears, cataract, and elevated intraocular pressure.

Vitreous Body

- See Vitreous Humor.

Vitreous Humor

- The vitreous humor, or vitreous body, is a transparent, gel-like substance that fills the space between the lens and the retina, occupying approximately eighty percent of the volume of the eye, and it consists primarily of water (approximately ninety-nine percent) with a network of collagen fibrils and hyaluronic acid that give it its gel-like consistency. The vitreous is attached to the retina at several sites, including the vitreous base anteriorly (the strongest attachment), the optic disc margin (the ring of attachment around the optic disc). The vitreous is subject to age-related changes, with liquefaction (synchysis senilis) and posterior vitreous detachment, which can be asymptomatic or cause flashes and floaters.

Xerophthalmia

- A medical condition of progressive drying of the conjunctiva and cornea caused by vitamin A deficiency, one of the leading causes of preventable blindness worldwide, particularly in developing countries

where vitamin A deficiency is endemic. Xerophthalmia encompasses a spectrum of ocular manifestations: night blindness (nyctalopia, earliest symptom, due to impaired rhodopsin regeneration in rod photoreceptors), conjunctival xerosis (dry, lustreless, thickened conjunctiva with loss of transparency and wrinkling on movement), Bitot spots (superficial, foamy, white, cheesy patches on the bulbar conjunctiva, typically temporal, composed of desquamated epithelial cells and keratin debris, pathognomonic but not always present), corneal xerosis (dry, hazy, dull cornea with loss of corneal lustre), corneal ulceration and keratomalacia (liquefactive necrosis of the cornea, the most severe form, leading to corneal perforation, prolapse of intraocular contents, and permanent blindness). Diagnosis: clinical (WHO classification: XN = night blindness, X1A = conjunctival xerosis, X1B = Bitot spots, X2 = corneal xerosis, X3A = corneal ulceration $<1/3$ corneal surface, X3B = keratomalacia), serum retinol <0.35 micromol/L. Treatment: high-dose vitamin A supplementation (WHO regimen: 200,000 IU vitamin A orally immediately, repeated the next day and at least 2 weeks later for severe xerophthalmia; children under 12 months: 50,000 IU; 12-36 months: 100,000 IU). Prevention: vitamin A supplementation (in measles-endemic areas, postpartum women), dietary diversification, and food fortification.

YAG Capsulotomy

- YAG laser posterior capsulotomy is a minimally invasive laser procedure used to treat posterior capsule opacification, the most common late complication of cataract surgery, in which the posterior lens capsule becomes opacified by proliferation of residual lens epithelial cells, causing decreased vision. The procedure uses a neodymium:yttrium-aluminum-garnet laser to create a central opening in the opacified posterior capsule, allowing light to pass unobstructed to the retina and restoring clear vision, often within 24 to 48 hours. The procedure is performed on an outpatient basis at the slit lamp, with the pupil dilated and topical anesthetic applied. The laser creates an opening in the posterior capsule typically measuring 3 to 5 mm in diameter, with a total of 20 to 50 laser applications of 1 to 5 mJ each.

Chapter 28

Orthopedics

Achilles Tendonitis

– Inflammation and degeneration of the Achilles tendon, most common in runners and middle-aged athletes. Insertional: at the calcaneal insertion, associated with bone spurs and Haglund deformity. Non-insertional (mid-portion): 2-6 cm above insertion, due to repetitive microtrauma and tendinosis. Presents with posterior heel pain and morning stiffness, improving with activity and worsening with activity (later stages). Diagnosis: clinical; ultrasound/MRI for confirmation. Treatment: eccentric calf stretching (most effective), activity modification, heel lifts, NSAIDs, and shockwave therapy. Refractory cases: PRP, tenotomy, or surgical debridement.

Achilles Tendon Rupture

– Complete tear of the Achilles tendon, most common in middle-aged men during recreational sports (weekend warrior). Mechanism: sudden push-off with knee extended. Presents with hearing/feeling a pop, acute posterior ankle pain, inability to stand on tiptoes, and palpable gap in the tendon. Positive Thompson test (no plantarflexion with calf squeeze). Diagnosis: clinical; MRI/ultrasound for confirmation. Treatment: non-operative (functional bracing in equinus with early weight-bearing, complication: rerupture 5-10%) vs. operative repair (open vs. percutaneous, complication: wound healing, infection 2-5%). Both have similar long-term outcomes.

ACL Injuries

– Anterior cruciate ligament (ACL) tears: non-contact (pivot, deceleration) > contact. Clinical: Lachman (most sensitive), pivot shift (most specific), anterior drawer. MRI confirms (bone bruise lateral femoral condyle + lateral tibial plateau, ACL discontinuity). Treatment: nonoperative (rehab, bracing)

for sedentary, low-demand; ACL reconstruction (autograft: BTB - gold standard, hamstring, quadriceps tendon; allograft: higher failure in young active) for active, instability. Timing: acute (<3 weeks): nonoperative vs operative (controversial, no difference in outcomes); subacute to chronic: reconstruction. Post-op: brace locked 0-90, NWB 6 weeks, WBAT 6-12 weeks, return to sports 6-9 months.

ACL Reconstruction

– Surgical reconstruction of the anterior cruciate ligament (ACL) following rupture, one of the most common knee ligament injuries. The ACL is a primary restraint to anterior tibial translation and rotatory instability, and its rupture frequently occurs during non-contact pivoting sports activities (skiing, soccer, basketball). Risk factors include female sex (2-8 times higher incidence than males, attributed to hormonal, anatomic, and neuromuscular factors), family history, participation in high-risk sports with cutting, pivoting, and jumping. The surgical technique involves harvesting an autograft (bone-patellar tendon-bone or hamstring tendon graft are the most common) or using an allograft for multiligament knee injuries.

Acromioclavicular Joint Injuries

– AC joint injuries: Rockwood classification: I (sprain AC ligaments), II (AC ligaments torn, CC intact), III (AC+CC torn, 25-100% displacement), IV (posterior displacement into trapezius), V (superior displacement >100%), VI (inferior displacement subcoracoid/subacromial). Treatment: I/II: nonoperative (sling, PT); III: controversial (nonoperative for most, surgical for high-demand overhead athletes, laborers); IV-VI: surgical (anatomic CC reconstruction: allograft/autograft, synthetic tape,

sutures, cerclage wires). Complications: AC joint arthritis, distal clavicle osteolysis, coracoclavicular ossification, fixation failure, and infection.

Adhesive Capsulitis

– A condition of progressive shoulder stiffness and pain caused by inflammation and fibrosis of the glenohumeral joint capsule. Common name: frozen shoulder. Stages: freezing (painful, 2-9 months), frozen (stiff, 4-12 months), thawing (gradual improvement, 5-24 months). Most common ages 40-60. Risk factors: diabetes (strongest), thyroid disease, female sex, and prior shoulder trauma/surgery. Bilateral in up to 40% of diabetics. Diagnosis: clinical (restricted active and passive ROM in all planes, especially external rotation). Treatment: physical therapy, NSAIDs, intra-articular corticosteroid injection, hydrodilatation (capsular distension), and arthroscopic capsular release for refractory cases.

Adult Spinal Deformity

– Adult spinal deformity (ASD): scoliosis (coronal Cobb >10 deg), kyphosis (sagittal), sagittal imbalance. SRS-Schwab classification: PI-LL mismatch, SVA (sagittal vertical axis), PT (pelvic tilt). Clinical: back pain, radiculopathy, neurogenic claudication, disability (ODI, SRS-22). Imaging: full-length standing AP/lateral, bending, CT for bone quality. Treatment: nonoperative (PT, core, epidural injections); operative: decompression + fusion (PSF, ALIF, TLIF, XLIF, OLIF, anterior column realignment, three-column osteotomy, PSO). Complications: pseudarthrosis, implant failure, proximal junctional kyphosis (PJK), infection, neurologic deficit. Outcomes: reliable pain relief, functional improvement, but high complication rates (30-40 percent).

Amelia

– A rare congenital anomaly characterized by complete absence of one or more limbs. Unilateral upper limb amelia is the most common form. Causes include vascular disruption, amnion rupture sequence, and teratogens. May be isolated or syndromic (Roberts syndrome, ADAM sequence, amniotic band syndrome). Diagnosis by prenatal ultrasound. Management: prosthetic fitting as early as 6 months of age to promote functional adaptation and normal development. Multidisciplinary care includes physical and occupational therapy. Children with

amelia can achieve high levels of independence with adaptive technology.

Ankle Arthroplasty

– Total ankle arthroplasty (TAA): indications: end-stage ankle OA (post-traumatic, primary, inflammatory), preserved hindfoot alignment (<10-15 deg varus/valgus), no severe osteoporosis, no active infection. Contraindications: severe deformity, Charcot, prior infection, young high-demand. Implants: 3-component (mobile bearing: STAR, Salto, Hinge) vs 2-component (fixed bearing: Infinity, Vantage). Approaches: anterior (standard), anterolateral. Alignment: neutral mechanical axis. Complications: infection, wound healing problems, deep vein thrombosis, aseptic loosening, impingement, gutter pain, subsidence, and polyethylene wear.

Ankle Fractures

– Ankle fractures: Weber classification (fibular fracture relative to syndesmosis): A (below syndesmosis, stable), B (at syndesmosis, variable stability), C (above syndesmosis, unstable). Lauge-Hansen: supination-external rotation (SER, most common), supination-adduction, pronation-external rotation, pronation-abduction. Treatment: stable (Weber A, SER stage I/II): closed reduction, short leg cast/boot, NWB 6 weeks; unstable (Weber B/C, SER III/IV): ORIF (lateral plate for fibula, medial screws/medial screws/tension band for medial malleolus), syndesmotic screw fixation (if unstable, 3.5-4.5 mm quadricortical screw 2-3 cm above tibiotalar joint, weightbearing at 8 weeks with screw removal at 3-4 months; alternatively, suture button fixation). Post-op: splint, NWB 6-8 weeks, then progressive weightbearing. Complications: wound breakdown, infection, malunion (most common), nonunion, post-traumatic osteoarthritis (most common late complication).

Ankle Sprain

– An injury to the ligaments surrounding the ankle joint, most commonly involving the lateral ligament complex (anterior talofibular ligament [ATFL, most commonly injured], calcaneofibular ligament [CFL], and posterior talofibular ligament [PTFL]) from an inversion mechanism. Medial (deltoid) ligament sprains occur less commonly from eversion injuries and syndesmotic (high ankle) sprains from external

rotation. Classification: Grade I (mild, microscopic ligament fibers, minimal swelling and ecchymosis with a stable ankle joint), Grade II (moderate, partial tearing of ligament fibers, with moderate swelling, ecchymosis, and joint laxity with a firm end point), and Grade III (severe, complete ligament rupture, with profound swelling, ecchymosis, and joint instability with no firm end point).

Ankylosing Spondylitis

– A chronic, progressive inflammatory disease primarily affecting the axial skeleton (sacroiliac joints and spine), characterized by inflammation at entheses (where tendons, ligaments, and joint capsules insert into bone), leading to new bone formation, syndesmophyte development, and eventual vertebral fusion (bamboo spine). It is the prototype of the spondyloarthritis family of diseases and is strongly associated with HLA-B27 (present in 80-90 percent of patients, though HLA-B27 is present in 6-8-8 percent of the general population, with the risk of developing AS in HLA-B27-positive individuals being 1 to 2 percent per year. The disease typically begins in early adulthood with insidious onset of low back pain and stiffness that is worse in the morning and with rest, relieved by activity.

Anterior Cruciate Ligament Injury

– Tear of the ACL, a common sports injury (non-contact deceleration, pivoting, or hyperextension). Presents with a pop, immediate swelling (hemarthrosis), and giving way of the knee. Positive Lachman test (most sensitive), anterior drawer test, and pivot shift test. Associated injuries: MCL (O'Donoghue triad: ACL, MCL, medial meniscus), meniscal tears. Diagnosis: MRI. Treatment: functional rehab for low-demand patients; ACL reconstruction (hamstring autograft, patellar tendon autograft, quadriceps tendon, or allograft) for high-demand athletes or those with persistent instability.

Arthrogryposis

– A group of congenital disorders characterized by multiple joint contractures present at birth, caused by decreased fetal movement (fetal akinesia) during development. Etiology includes neuropathic (most common, spinal anterior horn cell degeneration), myopathic (congenital muscular dystrophies), and mechanical (oligohydramnios, uterine abnormalities). Amyoplasia is the most common type (1 in 3,000

births): symmetric limb involvement, no internal organ involvement, and normal cognition. Physical exam shows fixed joint contractures (clubfeet, flexed wrists, extended knees), smooth, shiny skin over affected joints, and decreased muscle bulk. Joints are typically rigid with no skin creases. Treatment: aggressive physical therapy, serial casting, and orthopedic surgery (tendon releases, osteotomies) to improve function. Most children achieve ambulation with assistive devices. Intelligence is typically normal.

Articular Cartilage Injuries

– Chondral/osteochondral lesions: Outerbridge grading (I: softening, II: fibrillation <50%, III: fibrillation >50%, IV: subchondral bone exposed). OCD (osteochondritis dissecans): subchondral bone necrosis, fragment separation (knee: lateral femoral condyle, elbow: capitellum, ankle: talar dome). Treatment: microfracture (marrow stimulation, fibrocartilage, <2-3cm²), OATS (osteochondral autograft transfer, mosaicplasty), allograft transplantation (large defects), MACI (matrix-induced autologous chondrocyte implantation). Treatment: repair if possible (young, active, large fragment) vs excision (small, loose).

Backache

– Pain or discomfort located anywhere in the posterior trunk from neck to buttocks, a symptom rather than a disease. Causes include musculoskeletal strain (most common), disc herniation, spinal stenosis, facet arthropathy, sacroiliac joint dysfunction, and referred pain from renal, pancreatic, or vascular sources. Acute backache often resolves with conservative care; chronic backache benefits from exercise, physical therapy, and multidisciplinary pain management.

Back Pain

– One of the most common medical complaints, affecting up to 80 percent of the population at some point in life, and the leading cause of disability worldwide. Back pain is classified by duration: acute (less than 4 weeks), subacute (4-12 weeks), and chronic (greater than 12 weeks). It is further divided into mechanical (non-specific) back pain (90 percent of cases, caused by muscle strain, ligament sprain, degenerative disc disease, facet joint arthropathy), radicular pain (from nerve root compression (from her-

niated disc, spinal stenosis, or foraminal stenosis), and referred pain (from conditions such as pancreatitis, renal colic, aortic aneurysm). The diagnosis is clinical, based on history and physical examination. Imaging is indicated when red flags are present.

Baker Cyst

– A fluid-filled cyst in the popliteal fossa, resulting from herniation of the synovial membrane through the posterior knee joint capsule or from a communication between the knee joint and the gastrocnemius-semimembranosus bursa. A Baker cyst is not a true cyst but rather an effusion of the gastrocnemius-semimembranosus bursa that communicates with the knee joint, containing synovial fluid. It occurs in association with knee joint effusion from any underlying cause, most commonly osteoarthritis, rheumatoid arthritis, or trauma, and it presents as a palpable, firm, mildly tender mass in the popliteal fossa that is more prominent with knee extension (Foucher sign). Diagnosis is confirmed by ultrasound or MRI.

Bone Metastases

– Bone metastases: most common from breast, prostate, lung, kidney, thyroid. Solitary vs multiple. Clinical: pain (worse at night), pathologic fracture, hypercalcemia, spinal cord compression. Mirels score for impending pathologic fracture: site (upper limb 1, lower limb 2, peritrochanteric 3), pain (mild 1, moderate 2, functional 3), lesion (blastic 1, mixed 2, lytic 3), size ($<1/3$ 1, $1/3$ - $2/3$ 2, $>2/3$ 3). Score ≥ 9 : prophylactic fixation. Spinal metastases: Bilsky epidural spinal cord compression (Bilsky grade 0-3). Grade 1: external beam radiotherapy + bisphosphonates/denosumab; grade 2/3: surgical decompression plus stabilization followed by radiotherapy. Pathologic fracture: surgical fixation or arthroplasty.

Bones and Joints

– Bones and joints form the skeletal system, providing structural support, protection of organs, and enabling movement through articulations between bones. Joints are classified as fibrous, cartilaginous, or synovial, with synovial joints offering the greatest range of motion. Common conditions include osteoarthritis, rheumatoid arthritis, fractures, and osteoporosis.

Brachial Plexus Injuries

– Brachial plexus injuries: traction (motorcycle accidents, sports), compression (crutches, thoracic outlet). Classification: supraclavicular (roots/trunks), infraclavicular (divisions/cords). Narakas classification: I (proximal C5-C6, Erb's palsy: waiter's tip), II (C5-C7), III (C5-T1), IV (complete C5-T1), V (complete + root avulsions). Root avulsion: pseudomeningocele on MRI myelography, Horner syndrome (T1 avulsion), SER test (sensory evoked potentials). Treatment: early (3-6 months): neurolysis/neurolysis vs reconstruction (sural nerve graft, nerve transfer). Late (>6 months): tendon transfer, free muscle transfer, arthrodesis. Prognosis: better for lower trunk/infraclavicular, worse for upper trunk/supraclavicular.

Bunion

– A bony prominence (exostosis) at the medial aspect of the first metatarsal head, causing lateral deviation of the great toe (hallux valgus). The deformity is characterized by a structural abnormality at the first metatarsophalangeal joint, with the first metatarsal deviating medially and the proximal phalanx deviating laterally. The bunion itself is the medial eminence of the first metatarsal head, which becomes prominent and painful due to chronic pressure from footwear. Risk factors include narrow-toed shoes, high heels, female sex (10:1), family history, and inflammatory arthritis. Diagnosis is made on physical examination with weight-bearing radiographs confirming the hallux valgus angle and intermetatarsal angle.

Bursitis

– Inflammation of a bursa, a fluid-filled sac that reduces friction between tendons, muscles, bones, and skin. Bursae are lined by synovial cells and normally contain a thin layer of lubricating synovial fluid. Bursitis most commonly affects the subacromial (shoulder), olecranon (elbow), trochanteric (hip), prepatellar (knee), infrapatellar, and retrocalcaneal (ankle) bursae. Causes include repetitive micro-trauma or overuse (the most common mechanism), acute trauma, infection (septic bursitis, most commonly *Staphylococcus aureus* (80 to 90 percent of cases), which may complicate superficial skin infections, rheumatoid arthritis, and sporting injuries, with the olecranon and prepatellar bursae being the most common sites.

Carpal Tunnel Syndrome

– Carpal tunnel syndrome: median nerve compression at wrist (carpal tunnel: transverse carpal ligament roof, carpal bones floor). Clinical: nocturnal paresthesias (thumb, index, middle, radial ring), thenar wasting late, Tinel wrist, Phalen (60 sec wrist flexion), Durkan (carpal compression). NCS/EMG: prolonged DML, DSL, CMAP amplitude. Treatment: mild/mod: night splinting (neutral), corticosteroid injection (diagnostic/therapeutic), PT; severe/failed nonop: carpal tunnel release (open, endoscopic/endoscopic). Prognosis: excellent, recovery 90 percent plus.

Cervical Spine Trauma

– Cervical spine trauma: Subaxial (C3-C7) injury classification (SLIC - Subaxial Cervical Spine Injury Classification): morphology (1-4), discoligamentous complex (0-2), neurologic (0-3). Total <4 nonop, >4 op, =4 surgeon discretion. Upper cervical: occiput-C1 (occipital condyle fracture, occipitocervical dissociation), C1 (Jefferson burst fracture: lateral mass displacement >6.9mm on CT), C2 (odontoid fracture: Type I tip, Type II base - most common, nonunion risk >5mm displacement/age >70/smoking/diabetes); Type III (odontoid body/synchondrosis, less than 3 percent, surgical). Treatment: nonoperative (collar, Halo vest) for stable; C1 lateral mass screws (Harms), C1-2 transarticular screws (Magerl), occipitocervical fusion for unstable.

Chondrosarcoma

– The second most common primary malignant bone tumor (after osteosarcoma) and the most common primary malignant bone tumor in adults (peak age 40-70 years). It arises from cartilage-forming cells and is classified by grade (Grade 1: low-grade/conventional; Grade 2: intermediate; Grade 3: high-grade) and by location (central/intramedullary, surface/peripheral, or secondary). Conventional chondrosarcoma typically arises in the proximal femur, pelvis, and proximal humerus. Secondary chondrosarcoma may arise from a pre-existing osteochondroma (in multiple hereditary exostosis when the cartilage cap thickness exceeds 1.5 to 2 cm, the risk of malignant transformation is approximately 2 to 5 percent) or from Paget disease of bone. The clinical presentation is with localized pain, a palpa-

ble mass, and pathological fracture in approximately 10 to 15 percent of cases.

Clavicle Fractures

– Clavicle fractures: 80% midshaft (Group I), 15% lateral (Group II: Neer I nondisplaced, II displaced with CC ligament disruption, III intra-articular), 5% medial (Group III). Midshaft: nondisplaced/shortening <2cm: sling, figure-8; displaced/comminuted/shortening >2cm/skin tenting: ORIF (superior plate, anteroinferior plate). Lateral: Neer I: nonoperative; Neer II: ORIF (hook plate, anatomic plate, CC screw + plate); Neer III: ORIF. Medial: rare, check for mediastinal injury. Complications: nonunion (5-15 percent), malunion, hardware irritation, shoulder stiffness.

Clubfoot (Talipes Equinovarus)

– A congenital foot deformity with an incidence of approximately 1 in 1,000 live births, characterized by four components: equinus (ankle plantarflexion), varus (hindfoot inversion), adductus (forefoot adduction), and cavus (high arch). Clubfoot is classified as idiopathic (most common, no identifiable cause), postural (positional, passively correctable), or syndromic (associated with neuromuscular conditions like myelomeningocele, arthrogryposis, or chromosomal abnormalities). The male-to-female male-to-female ratio is 2:1. The Ponseti method is the gold standard for treatment, involving serial casting, Achilles tenotomy, and bracing.

Codman Triangle

– A characteristic periosteal reaction seen on plain radiographs, formed when an aggressive bone lesion elevates the periosteum away from the bone cortex, creating a triangular area of new reactive bone at the angle between the raised periosteum and underlying cortex. Highly suggestive of malignant bone tumors (most commonly Osteosarcoma and Ewing Sarcoma) or severe osteomyelitis.

Compartment Syndrome

– A surgical emergency caused by increased pressure within a closed osteofascial compartment, leading to tissue ischemia, necrosis, and permanent functional loss. The lower leg (anterior, lateral, deep posterior, and superficial posterior compartments) and forearm (flexor and extensor compartments) are the most commonly affected sites. Causes include tibial fractures (most common cause of lower leg compart-

ment syndrome), forearm fractures (Colles, Smith, radial neck), crushcrush injuries, vascular injuries, burns, limb compression, and reperfusion injury after revascularisation. The earliest and most important symptom is severe, unremitting pain out of proportion to the injury, worse with passive stretching. Diagnosis is clinical, with compartment pressure measurement confirming the diagnosis.

Congenital Scoliosis

– A lateral curvature of the spine caused by congenital vertebral anomalies that arise during embryogenesis (failure of formation or segmentation). Failure of formation: hemivertebra (wedge-shaped vertebra causing progressive curvature). Failure of segmentation: unilateral unsegmented bar (block of bone on one side). Mixed: combination of hemivertebra and unsegmented bar (most progressive). Presents with a progressive spinal curvature noted in infancy or early childhood. Associated with intraspinal anomalies (tethered cord, syringomyelia, diastematomyelia in 20-30%), renal anomalies (10-20%), and cardiac defects (10-15%). Diagnosis: spine X-ray and MRI (to evaluate intraspinal anatomy) and renal ultrasound. Treatment: observation for mild curves; bracing is generally ineffective for congenital scoliosis. Surgical correction: in situ fusion, hemivertebra excision, or growth-friendly techniques (growing rods, VEPTR) for young children with progressive curves.

Cubital Tunnel Syndrome

– Cubital tunnel syndrome: ulnar nerve compression at elbow (cubital tunnel: Osborne's ligament, FCU aponeurosis, medial epicondyle, olecranon). Clinical: paresthesias ulnar 1.5 digits, nocturnal, Tinel at elbow, Froment sign (IP flexion of thumb with key pinch), Wartenberg sign (abduction of small finger), thenar/hypothenar wasting late. McGowan classification: I (intermittent), II (constant sensory, no motor), III (motor weakness). NCS/EMG: slowing across elbow. Treatment: I/II: nonoperative (night orthosis (elbow splint at 45-60 degrees of flexion), activity modification, ergonomics; Grade III or failed nonop: cubital tunnel release (in situ decompression, medial epicondylectomy, or transposition).

Degenerative Spine Disease

– Lumbar spinal stenosis: central (neurogenic claudi-

cation: bilateral leg pain with walking, relieved by sitting/flexion), lateral recess, foraminal. Imaging: MRI (central canal AP diameter <10mm, cross-sectional area <70mm²). Treatment: nonoperative (PT, epidural steroid, prostaglandin); operative: laminectomy (open, minimally invasive, tubular), decompression + fusion if instability (spondylolisthesis, scoliosis). Herniated nucleus pulposus: posterolateral (radiculopathy), central (cauda equina: cauda equina syndrome: surgical emergency; treated with urgent decompression).

De Quervain Tenosynovitis

– De Quervain tenosynovitis: first dorsal compartment (APL, EPB) stenosis. Clinical: radial wrist pain, Finkelstein test (thumb in palm, ulnar deviation), swelling over radial styloid. Treatment: splint (thumb spica), NSAIDs, corticosteroid injection (80-90% cure); surgical: first dorsal compartment release (identify radial sensory nerve branches, watch for subcompartments).

Developmental Dysplasia of the Hip

– A spectrum of hip abnormalities in infants and children, ranging from mild acetabular dysplasia to complete hip dislocation. The femoral head is partially or completely displaced from the acetabulum due to capsular laxity and acetabular underdevelopment. Risk factors: female sex (4:1), breech presentation, family history, first-born, and oligohydramnios. Screening: clinical examination at every well-child visit (Ortolani test for reduction, Barlow test for dislocation, Galeazzi sign, asymmetric thigh/gluteal folds). Imaging: hip ultrasound for infants <4-6 months (dynamic and static views); X-ray for older infants and children (Hilgenreiner line, Perkin line, acetabular index). Treatment: Pavlik harness for infants <6 months (success rate 85-95%); closed reduction and spica casting for harness failure or older infants; open reduction and pelvic/femoral osteotomy for children >18 months or failed closed reduction. Complications: avascular necrosis of the femoral head, redislocation, and early osteoarthritis.

Discectomy

– The surgical removal of herniated intervertebral disk material that compresses nerve roots or the spinal cord, causing radiculopathy or myelopathy. Indicated in severe disk herniation causing unremit-

ting pain, progressive motor weakness, or cauda equina syndrome.

Dislocation

– Complete displacement of the articular surfaces of a joint, resulting in loss of normal bony alignment and often associated with ligamentous, capsular, and neurovascular injury. The most commonly dislocated joints are the glenohumeral shoulder joint (accounting for 50 percent of all dislocations, anterior in 95 percent of cases), followed by the interphalangeal joints of the fingers, patellofemoral joint, elbow, and hip. The mechanism typically involves traumatic force applied to the joint beyond the normal range of motion, usually with significant force, causing capsular and ligamentous tearing, and often associated fractures, nerve injuries (axillary nerve in anterior shoulder dislocation, radial nerve in posterior shoulder dislocation), vascular injuries, and soft tissue injuries. Treatment involves urgent reduction followed by immobilization and rehabilitation.

Distal Radius Fractures

– The most common upper extremity fracture. Classification: AO/OTA: A (extra-articular), B (partial articular), C (complete articular); Frykman. Colles fracture: dorsal angulation/displacement (fall on outstretched hand). Smith fracture: volar angulation (fall on flexed wrist). Barton fracture: intra-articular fracture-dislocation (dorsal or volar). Chauffeur fracture: radial styloid. Treatment: nondisplaced/extra-articular: closed reduction + cast/splint; displaced intra-articular: ORIF (volar locking plate, dorsal plate, external fixation, fragment-specific fixation). Post-op: splint, early motion (for ORIF). Complications: malunion, nonunion (rare), carpal tunnel syndrome, post-traumatic arthritis, EPL rupture (3-5 percent), and complex regional pain syndrome (CRPS type I).

Dupuytren contracture

– A benign, progressive fibroproliferative disorder of the palmar fascia causing nodules, cords, and contractures of the fingers, most commonly affecting the ring and small fingers. The condition is caused by proliferation of myofibroblasts and deposition of type III collagen in the palmar aponeurosis, leading to formation of pathologic cords that contract and flex the metacarpophalangeal (MCP) and proximal

interphalangeal (PIP) joints. Prevalence is highest in individuals of Northern European descent (up to 30 percent in some Scandinavian populations), with men affected 3 to 4 times more than women. The condition is associated with diabetes mellitus, epilepsy, alcoholism, and manual labour. The diagnosis is clinical.

Ectrodactyly

– A congenital limb malformation characterized by a deep median cleft of the hand or foot with missing central digits, resulting in a claw-like or lobster-claw appearance. Also known as split hand/foot malformation (SHFM). Most cases are autosomal dominant with incomplete penetrance, linked to mutations in TP63, DLX5, or WNT10B genes. May be isolated or syndromic (EEC syndrome — ectrodactyly, ectodermal dysplasia, cleft lip/palate; Split hand/foot malformation with long bone deficiency). Physical exam shows variable absence of the central rays (second, third, and/or fourth digits), ranging from a mild cleft to complete absence of central structures. Treatment: surgical reconstruction to improve pinch and grip function; prosthetics for severe cases. Genetic counseling is recommended.

Ewing Sarcoma

– A highly malignant small round blue cell tumor of bone and soft tissue, representing the second most common primary bone malignancy in children and adolescents (peak age 10-20 years), with a strong predilection for males and Caucasian populations. It arises from the EWSR1-FLI1 fusion gene (t(11;22)(q24;q12)) present in approximately 85 percent of cases, with other EWSR1 translocations (EWSR1-ERG, EWSR1-WT1) in the remainder. Unlike osteosarcoma, Ewing sarcoma most commonly involves the diaphysis of long bones (femur, tibia, humerus) and the pelvis, with a predilection for the femur (25 percent), pelvis (20 percent), and tibia (15 percent). The typical presentation is painful swelling, often with fever, warmth, and erythema. Diagnosis is by biopsy and molecular genetics showing the EWSR1-FLI1 fusion transcript.

Femoral Shaft Fractures

– Femoral shaft fractures: high energy (MVC, fall from height) or low energy (elderly, pathologic). Winquist-Hansen classification of comminution: I (none), II (butterfly <50% width), III (butterfly

>50%), IV (segmental). Treatment: antegrade intramedullary nailing (gold standard, reamed, statically locked), retrograde nailing (pregnant, bilateral, ipsilateral tibia fracture, morbid obesity), plate fixation (distal metaphyseal, nonunion). Early fixation (<24h) reduces ARDS, MODS, mortality (EPIC). (EPIC, early versus delayed stabilisation of the femur in multiply injured patients, with damage control orthopedics involving initial temporary external fixation followed by delayed definitive nailing at 48 to 72 hours, being the current standard of care for the polytrauma patient).

Fracture

– A break in the continuity of bone, classified by location, pattern (transverse, oblique, spiral, comminuted), displacement, and whether the fracture communicates with the external environment (open vs. closed). Fracture healing occurs through inflammatory, reparative, and remodeling phases. Management: reduction, immobilization (cast, splint, or surgical fixation with plates/screws/intramedullary nails), and rehabilitation. Open fractures require urgent debridement and antibiotics. Complications: nonunion, malunion, infection, compartment syndrome, and avascular necrosis.

Ganglion Cysts

– Ganglion cysts: mucin-filled cysts from joint capsule/tendon sheath. Dorsal wrist (60-70%, scapholunate interval), volar wrist (radial artery), flexor tendon sheath (volar retinaculum, "seed ganglion"), DIP (mucous cyst, Heberden node association). Clinical: fluctuant mass, transilluminates, may cause nerve compression (volar: median/ulnar). Treatment: observation (spontaneous resolution 30-50%), aspiration (high recurrence), surgical excision (capsule stalk removal, recurrence 5-10%). Mucous cyst (ganglion at DIP joint): associated with Heberden node, risk of nail deformity. Treatment: decompression, excision, pinning of DIP joint.

Golfer Elbow

– Medial epicondylitis, a tendinopathy of the common flexor/pronator tendon at the medial epicondyle. Less common than tennis elbow. Caused by repetitive wrist flexion and forearm pronation. Presents with medial elbow pain worsened by wrist flexion and gripping. Tenderness over the medial epicondyle. Positive Golfer elbow test. Risk of ulnar

nerve compression. Diagnosis: clinical. Treatment: rest, ice, activity modification, NSAIDs, physical therapy (eccentric exercises), and corticosteroid injection (avoid ulnar nerve). Refractory cases: surgical release.

Hallux Valgus

– Lateral deviation of the great toe (hallux) with medial prominence of the first metatarsal head (bunion). More common in women, associated with narrow-toed shoes, high heels, and genetic predisposition. Presents with pain over the medial eminence, difficulty with shoe wear, and progressive deformity. Second toe can become hammer toe from crowding. Diagnosis: weight-bearing foot X-ray (hallux valgus angle >15°, intermetatarsal angle >9°). Treatment: wide-toed shoes, orthotics, toe spacers, and NSAIDs. Surgery (osteotomy, arthrodesis, or arthroplasty) for severe deformity or failed conservative treatment.

Hallux Valgus (Bunion)

– A progressive deformity of the first metatarsophalangeal (MTP) joint, characterized by lateral deviation of the great toe (hallux valgus) and medial deviation of the first metatarsal head (metatarsus primus varus), resulting in a bony prominence on the medial side of the forefoot (the bunion). Epidemiology: 3 times more common in women, prevalence increases with age (up to 35% in adults >65). Risk factors: narrow-toed shoes with high heels (most significant modifiable risk factor), family history, heredity, pes planus (flatfoot), hypermobile first ray, ligamentous laxity, and inflammatory arthritis (rheumatoid arthritis, gout). Pathophysiology: the proximal phalanx rotates and drifts laterally, the first metatarsal head drifts medially, the sesamoids sublux laterally, and the MTP joint capsule stretches medially. Symptoms: pain over the medial eminence (bursitis), difficulty fitting shoes, cosmetic concern, and progression of deformity. May be associated with hammer toe of the second toe and transfer metatarsalgia. Treatment: (1) Conservative: footwear modification (wide-toed shoes, soft uppers, bunion pads/orthoses/splints; NSAIDs for acute pain). (2) Surgical: over 150 described techniques - distal chevron osteotomy (mild-moderate), Scarf osteotomy (moderate-severe), Lapidus arthrodesis (severe with first TMT instability), Akin osteotomy (proximal phalanx). Post-op: 6 weeks non-weight-

bearing in a postoperative shoe or boot, gradual return to normal footwear.

Hammer Toe

– A deformity of the second, third, or fourth toe characterized by flexion at the PIP joint and extension at the MTP and DIP joints. Caused by muscle imbalance (intrinsic foot muscle weakness) and narrow-toed shoes. Presents with pain over the dorsal PIP joint (corn/callus) and the tip of the toe. Flexible hammer toe: correctable passively. Rigid: fixed deformity. Diagnosis: clinical. Treatment: conservative: wide toe box shoes, toe crests/pads, and stretching exercises. Surgical: flexor tenotomy (flexible) or PIP arthroplasty/arthrodesis (rigid).

Hamstring

– One of three muscles forming the posterior compartment of the thigh: semitendinosus, semimembranosus, and biceps femoris (long and short heads). Common origin: ischial tuberosity (except short head of biceps femoris which originates from the linea aspera of the femur). Insertion: semitendinosus and semimembranosus to the medial tibial condyle (pes anserinus area); biceps femoris to the fibular head. Actions: hip extension, knee flexion, and (with knee flexed) tibial rotation (medial by semitendinosus/semimembranosus, lateral by biceps femoris). Innervation: tibial branch of sciatic nerve (L5-S2) for all except short head of biceps femoris (common peroneal nerve, L5-S2). Hamstring strain is the most common muscle injury in athletes (especially sprinters, football, rugby), typically involving the proximal musculotendinous junction of biceps femoris. Grades: grade 1 (mild, microscopic tears), grade 2 (partial tear), grade 3 (complete rupture). Risk factors: eccentric overload, fatigue, poor flexibility, previous hamstring injury, muscle imbalance (quadriceps dominance). Management: RICE (rest, ice, compression, elevation) in acute phase, followed by progressive rehabilitation (eccentric strengthening, Nordic hamstring curl for prevention, core stability, sport-specific training). Return to sport when full range of motion, strength >90% of unaffected side, and sport-specific movements are pain-free.

Herniated Disc

– Protrusion of the nucleus pulposus through a tear in the annulus fibrosus of the intervertebral disc, causing compression or inflammation of adjacent

nerve roots. Most common at L4-L5 and L5-S1 (lumbar) and C5-C6, C6-C7 (cervical). Lumbar: sciatica (radiating leg pain), paresthesias, sensory loss, and motor weakness (foot drop). Cervical: neck pain radiating to arm with sensory/motor deficits. Cauda equina syndrome: surgical emergency with saddle anesthesia, bowel/bladder dysfunction, and bilateral leg weakness. Diagnosis: MRI. Treatment: conservative first (NSAIDs, PT, activity modification, epidural steroid injections). Surgical: microdiscectomy for refractory pain, progressive weakness, or cauda equina syndrome.

Herniated disk

– Also known as intervertebral disc herniation, displacement of nucleus pulposus material through a tear in the annulus fibrosus, most commonly occurring in the lumbar spine (L4-L5 and L5-S1 account for 95 percent of lumbar herniations) and cervical spine (C5-C6 and C6-C7). The pathophysiology involves age-related degenerative changes in the intervertebral disc: desiccation of the nucleus pulposus, fissuring of the annulus fibrosus, and eventual extrusion of nuclear material into the spinal canal or neural foramen, where the herniated disc material can compress the spinal cord (central herniation) or the nerve roots (posterolateral herniation, the most common), causing the characteristic radicular pain, sensory and motor deficits, and reflex changes in a dermatomal and myotomal distribution.

Hip Disorders

– The hip joints are ball-and-socket joints connecting the femur to the pelvis, providing stability and a wide range of motion for walking, running, and weight-bearing activities. Common hip conditions include osteoarthritis, fractures, bursitis, and labral tears. Management involves physical therapy, pain management, and joint replacement surgery for advanced degenerative disease.

Hip Fractures

– Common in elderly (osteoporosis, falls), classified by location: femoral neck (intracapsular), intertrochanteric (extracapsular), subtrochanteric. Garden classification for femoral neck: I (incomplete/impacted), II (complete nondisplaced), III (complete partially displaced), IV (complete displaced). Treatment: Garden I/II: cannulated screws; Garden III/IV in elderly: hemiarthroplasty

(bipolar preferred) or total hip arthroplasty (if active, pre-existing arthritis); young patients (<65, good bone): ORIF (cannulated screws or sliding hip screw, blade plate, or cephalomedullary nail depending on fracture pattern). Subtrochanteric fractures: high nonunion rate, IM nail (long, statically locked, reamed) versus plate fixation.

Hip Replacement

– A surgical procedure in which the diseased hip joint is replaced with a prosthetic implant (arthroplasty). Total hip replacement (THR) replaces both the femoral head and the acetabulum. Indications: osteoarthritis (most common, 60%), rheumatoid arthritis, avascular necrosis (AVN) of the femoral head, femoral neck fracture (especially displaced in elderly), hip dysplasia, ankylosing spondylitis, Paget disease, and failed previous hip surgery. Components: acetabular component (metal shell with polyethylene or ceramic liner), femoral component (metal stem with modular head—cobalt-chrome or ceramic). Fixation: cemented (using polymethylmethacrylate bone cement, preferred in elderly with osteoporotic bone) or cementless (press-fit, with porous coating for bone ingrowth, preferred in younger patients with good bone quality). Surgical approaches: posterior (most common, risk of dislocation 2-5% in first 3 months, repairs capsule/external rotators), lateral (Hardinge, gluteus medius split, lower dislocation risk), anterolateral (Watson-Jones), and direct anterior (muscle-sparing, faster recovery, less postoperative pain). Outcomes: excellent pain relief and functional improvement in 90-95% at 10 years, 80-85% implant survival at 20 years. Complications: dislocation (2-5%, highest in first 3 months), periprosthetic fracture, infection (1-2%, devastating, requires two-stage revision: removal of implant + antibiotic cement spacer + 6 weeks IV antibiotics + reimplantation), aseptic loosening (most common cause of late failure, due to wear debris-induced osteolysis, polyethylene wear particles stimulate macrophage activation and RANKL-mediated osteoclastic bone resorption), leg length discrepancy (subjective or objective), DVT/PE (routine thromboprophylaxis), nerve injury (sciatic, femoral).

Joint Diseases

– A broad category of pathological conditions affect-

ing the structure and function of joints. Classification by etiology: (1) Degenerative: osteoarthritis (most common, non-inflammatory, affects load-bearing joints—knee, hip, spine). (2) Inflammatory: rheumatoid arthritis (autoimmune, symmetric small-joint synovitis), psoriatic arthritis, ankylosing spondylitis, reactive arthritis, gout (crystal arthropathy, uric acid, podagra), pseudogout (CPPD). (3) Infectious: septic arthritis (bacterial, urgent, joint destruction within 24 hours), Lyme arthritis, tuberculosis arthritis, viral arthritis (parvovirus, rubella, hepatitis B/C). (4) Metabolic: gout, pseudogout, haemochromatosis (chondrocalcinosis, calcium pyrophosphate), ochronosis (alkaptonuria, homogentisic acid accumulation, pigmented cartilage, spondylosis). (5) Trauma: intra-articular fracture, dislocation, ligament tear, meniscal tear, haemarthrosis. (6) Neoplastic: synovial sarcoma, pigmented villonodular synovitis (benign, recurrent haemarthrosis). (7) Childhood: juvenile idiopathic arthritis (JIA). Diagnosis: history (mechanical vs inflammatory pain, stiffness, swelling), examination (warmth, effusion, crepitus, range of motion, instability), imaging (X-ray, ultrasound, MRI), synovial fluid analysis (cell count, crystals, Gram stain, culture). Diagnosis: medical history, physical examination, imaging (X-ray, ultrasound, MRI), and synovial fluid analysis. Treatment directed at the underlying cause.

Joint Pain

– Discomfort arising from articular structures including cartilage, synovium, ligaments, and periarticular soft tissues due to inflammation, degeneration, injury, or infection. Common causes: osteoarthritis (degenerative, most prevalent), rheumatoid arthritis (autoimmune inflammatory), gout (crystal arthropathy), septic arthritis (bacterial infection requiring urgent intervention), and trauma. Clinical features include pain worsened by movement, stiffness, swelling, warmth, and decreased range of motion. Diagnosis requires history, physical exam, imaging (X-ray, MRI), and laboratory studies (inflammatory markers, autoantibodies, uric acid, synovial fluid analysis). Treatment targets the underlying cause: NSAIDs or corticosteroids for inflammation, disease-modifying antirheumatic drugs (DMARDs) for inflammatory arthritis, analgesics, physical ther-

apy, and joint replacement for advanced disease.

Joint Replacement (Arthroplasty)

– A surgical procedure in which a damaged or arthritic joint surface is removed and replaced with a prosthetic implant, most commonly performed for the hip (total hip arthroplasty) and knee (total knee arthroplasty). Indications include end-stage osteoarthritis, rheumatoid arthritis, avascular necrosis, and severe joint trauma causing debilitating pain and functional limitation refractory to conservative therapy. The procedure involves resurfacing the articular ends of bone with metal, polyethylene, or ceramic components fixated with cement or press-fit technique. Postoperative management includes early mobilization, physical therapy, thromboprophylaxis, and activity restrictions to prevent dislocation. Complications: infection, loosening, fracture, nerve injury, venous thromboembolism, and prosthetic wear requiring revision.

Joints

– The sites where two or more bones meet, providing structural support and enabling movement. Classification by structure and function: (1) Fibrous joints (synarthroses, immovable): sutures of the skull, gomphoses (tooth in socket), syndesmoses (tibia-fibula). (2) Cartilaginous joints (amphiarthroses, slightly movable): synchondroses (costochondral, growth plates), symphyses (pubic symphysis, intervertebral discs). (3) Synovial joints (diarthroses, freely movable): characterized by a joint cavity lined by synovial membrane containing synovial fluid, articular cartilage (hyaline), and a fibrous joint capsule. Further classified by shape: hinge (elbow, knee), ball-and-socket (hip, shoulder), pivot (atlantoaxial, proximal radioulnar), condylar (temporomandibular, knee–also hinge), saddle (first carpometacarpal-thumb), gliding (intercarpal, intertarsal), and ellipsoid (wrist). Synovial fluid: plasma dialysate with hyaluronic acid (lubrication, shock absorption, nutrition for avascular articular cartilage). Joint health is maintained by low-impact exercise, weight-bearing activity, and avoidance of excessive repetitive loading. Joint pathology: osteoarthritis, rheumatoid arthritis, gout, septic arthritis, trauma (dislocation, fracture), and haemarthrosis.

Kienbock Disease

– Kienbock disease (lunatomalacia): AVN of lu-

nate. Lichtman classification: I (normal XR, MRI edema), II (lunate sclerosis), IIIA (lunate collapse, no scaphoid rotation), IIIB (lunate collapse, fixed scaphoid rotation, DISI), IV (perilunate arthritis). Etiology: negative ulnar variance, trauma, vascular variation. Treatment: I/II: radial shortening (negative ulnar variance), capitate shortening, vascularized bone graft (4,5-extensor compartments artery); IIIA: radial shortening, capitoulunate fusion, lunatocapitolunate fusion, capitate-lunate-triquetrum fusion, lunate core decompression; IIIB-IV: salvage (proximal row carpectomy, scaphoidectomy plus 4-corner fusion, total wrist arthrodesis).

Klippel-Feil Syndrome

– A congenital condition characterized by fusion of two or more cervical vertebrae, resulting from failure of normal segmentation of the cervical somites during weeks 3-8 of gestation. Classic triad: short neck, low posterior hairline, and limited cervical range of motion (present in <50% of cases). Patients are at risk for atlantoaxial instability, cervical stenosis, and the CRUS sequence (Cervical fusion, Renal anomalies, Uterine anomalies, and Sensorineural hearing loss). Associated anomalies: Sprengel deformity (30%), scoliosis (60%), renal agenesis/ectopia, congenital heart disease (VSD, ASD), hearing loss, and synkinesia (mirror movements). Diagnosis: cervical spine X-ray or CT shows fused vertebral bodies and posterior elements; MRI for spinal cord and brainstem assessment; renal ultrasound and audiometry for associated anomalies. Treatment: activity restriction to prevent cervical injury; surgical stabilization for instability or neurologic compromise.

Kneecap

– See Patella (Kneecap).

Knee Disorders

– The knee is a complex hinge-type synovial joint connecting the femur, tibia, and patella, stabilized by ligaments (ACL, PCL, MCL, LCL), menisci (medial and lateral), and surrounding muscles/tendons. Common knee disorders include osteoarthritis (degenerative cartilage loss most prevalent in older adults), anterior cruciate ligament (ACL) tears (sports-related pivot injury), meniscal tears (twisting injury with mechanical locking or clicking), patellofemoral pain syndrome (anterior knee pain in active young adults), and Baker's cyst (popliteal

swelling from fluid extrusion). Diagnosis relies on history, physical examination (Lachman test, McMurray test, joint line tenderness), and imaging (weight-bearing X-rays, MRI for soft-tissue pathology). Treatment ranges from conservative (activity modification, physical therapy, bracing, NSAIDs) to surgical (arthroscopic meniscectomy/repair, ligament reconstruction, partial or total knee arthroplasty).

Kyphosis

– An excessive anterior-posterior curvature of the thoracic spine, measured by the Cobb angle on lateral spine x-ray (normal thoracic kyphosis is 20-40 degrees). Types: postural kyphosis (most common, flexible, correctable with hyperextension, in adolescents, benign, not progressive, no structural vertebral abnormalities), Scheuermann kyphosis (rigid, structural kyphosis in adolescents, caused by anterior wedging of greater than 5 degrees in three or more consecutive thoracic vertebrae, with endplate irregularities, Schmorl nodes, and decreased disc height), and congenital kyphosis (rare, due to failure of formation or segmentation of vertebral bodies). The diagnosis is made by standing lateral x-ray with the Cobb angle measured from the superior endplate of one vertebra to the inferior endplate of the lowest involved vertebra.

Lateral Collateral Ligament Injury

– Tear of the LCL, less common than MCL injury but more significant. Mechanism: varus stress to the knee (direct blow to medial knee). Presents with lateral knee pain, swelling, and varus laxity. Part of the posterolateral corner (PLC) — when injured, causes significant rotational instability. Grade III LCL injury is often associated with PCL injury and peroneal nerve injury. Diagnosis: varus stress test at 0° and 30°; MRI. Treatment: Grade I-II: bracing. Grade III or multiligament: surgical repair or reconstruction.

Lordosis

– The normal inward curvature of the cervical and lumbar spine. Excessive lumbar lordosis (hyperlordosis): increased pelvic tilt, commonly due to hip flexor tightness, weak abdominals, or pregnancy. Presents with low back pain and forward protrusion of the abdomen and buttocks. Causes: postural, congenital (achondroplasia), neuromuscular (cere-

bral palsy), and compensatory (kyphosis). Diagnosis: clinical, standing lateral X-ray. Treatment: postural exercises, core strengthening, hamstring/hip flexor stretching. Surgery rarely needed.

Lumbago

– A non-specific term for low back pain, typically referring to acute or chronic pain in the lumbar region (between the lower ribs and the gluteal folds). Lumbago is a symptom, not a diagnosis. Causes: mechanical low back pain (most common, 90%, includes lumbar strain/sprain, discogenic pain, facet joint pain, sacroiliac joint dysfunction), disc herniation with radiculopathy (sciatica, 5%), spinal stenosis, spondylolisthesis, vertebral compression fracture (osteoporotic or traumatic), infection (discitis, osteomyelitis, epidural abscess), malignancy (bone metastases, multiple myeloma, primary bone tumor), inflammatory (ankylosing spondylitis, psoriatic arthritis), and visceral referred pain (pancreatitis, nephrolithiasis, AAA, endometriosis). Red flags (cauda equina syndrome, infection, malignancy, fracture): saddle anesthesia, bowel/bladder incontinence, bilateral sciatica, progressive neurological deficit, fever, night pain, weight loss, age >50, history of cancer, IV drug use, immunosuppression. Yellow flags (psychosocial risk factors for chronicity): fear-avoidance beliefs, catastrophizing, depression, job dissatisfaction, pending litigation. Most acute lumbago resolves within 4-6 weeks. Management: conservative—analgesics (paracetamol, NSAIDs—ibuprofen, naproxen, diclofenac), muscle relaxants (short-term, diazepam, cyclobenzaprine), heat/ice, activity modification (avoid bed rest, stay active), physiotherapy (core stability, McKenzie exercises, manual therapy). For radicular pain: epidural corticosteroid injections. Surgery: discectomy for refractory sciatica, decompression for spinal stenosis, fusion for instability.

Medial Collateral Ligament Injury

– Tear of the MCL, the most common knee ligament injury. Mechanism: valgus stress to the knee (direct blow to lateral knee). Presents with medial knee pain, swelling, and valgus laxity. Grading: I (pain, no laxity), II (partial tear, some laxity), III (complete tear, significant laxity). Diagnosis: valgus stress test at 0° and 30° of flexion; MRI. Treatment: almost always conservative — functional bracing

with early motion. Grade III injuries with associated ACL/PCL/PLC injuries may require surgical repair.

Meniscal Injuries

– Meniscal tears: traumatic (vertical longitudinal, bucket handle, radial, horizontal cleavage, flap) vs degenerative (complex, horizontal). Clinical: joint line tenderness, McMurray, Apley, Thessaly test. MRI: sensitivity 90%+. Treatment: repairable (vertical longitudinal, peripheral 100–3mm, red-red/red-white zone, young): inside-out, all-inside, outside-in; irreparable (degenerative, white-white, complex): partial meniscectomy (preserve rim). Root tears: radial tears at posterior horn attachment site (medial meniscus). Treatment: repair (transtibial pull-out, suture anchor) vs meniscectomy.

Meniscal Tear

– Tear of the C-shaped fibrocartilage (medial or lateral meniscus) that provides shock absorption and stability in the knee. Medial meniscus tears more common (attached to capsule). Mechanism: twisting injury with weight-bearing. Presents with joint line tenderness, pain with deep squatting, catching, locking, and giving way. Positive McMurray test. Diagnosis: MRI. Treatment: conservative for small, peripheral (red zone) tears; arthroscopic partial meniscectomy for large, complex tears that cannot be repaired; meniscal repair for peripheral tears in young patients.

Muscle Pain (Myalgia)

– Myalgia—muscle pain—is a common symptom arising from skeletal muscle injury, inflammation, overuse, infection, or systemic disease. Acute myalgia is often due to trauma (muscle strain/tear, contusion), eccentric exercise (delayed-onset muscle soreness peaking 24–72 hours post-exertion), or viral infections (influenza, COVID-19, enterovirus). Chronic diffuse myalgia characterizes fibromyalgia (widespread pain with tender points, fatigue, sleep disturbance, cognitive fog—affecting 2–4% of population, 80% female) and polymyalgia rheumatica (morning stiffness and aching in shoulder/pelvic girdles in adults >50, ESR/CRP markedly elevated). Diagnosis: CK, ESR, CRP, TSH, vitamin D, autoimmune serologies, EMG, and muscle biopsy when indicated. Treatment: symptomatic (acetaminophen, NSAIDs, heat/ice, massage), treatment of under-

lying cause (antibiotics for infectious myositis, corticosteroids for polymyalgia rheumatica/idiopathic inflammatory myopathies, exercise and tricyclic antidepressants/gabapentinoids for fibromyalgia).

Nonunion and Malunion

– Nonunion is failure of a fractured bone to heal after an adequate period (generally 6–9 months for long bones) without clinical or radiographic evidence of progression toward union for 3 months. Classification: hypertrophic (viable ends, inadequate stability), atrophic (devitalized ends, poor biology), oligotrophic (intermediate). Risk factors: open fractures, severe comminution, inadequate fixation, infection, smoking, NSAIDs, steroids, diabetes, vascular disease, radiation. Diagnosis: persistent pain, implant failure. Treatment: hypertrophic (increase stability with compression plating, exchange nailing, dynamization); atrophic (improve biology with bone graft, vascularized bone graft).

Open Fractures

– Fractures with communication between the fracture site and the external environment, classified by Gustilo-Anderson: Grade I (<1 cm wound, clean), Grade II (1–10 cm wound, moderate soft tissue injury), Grade IIIA (>10 cm wound, adequate soft tissue coverage), Grade IIIB (>10 cm wound, extensive soft tissue loss requiring flap coverage), Grade IIIC (any open fracture with arterial injury requiring repair). Management: ATLS protocol, antibiotics within 1 hour (Grade I: cefazolin/cefazolin 1–2g IV q8h; Grade II/III: cefazolin plus gentamicin; Grade III: penicillin for farm injuries, tetanus prophylaxis, thorough irrigation and debridement within 6 hours, fracture stabilization (external fixation for severe contamination), wound closure by 7 days.

Orthopedic Biologics

– Bone graft substitutes: autograft (iliac crest gold standard, osteogenic/osteoinductive/osteoconductive, donor site morbidity), allograft (osteoconductive, some osteoinductive if DBM, disease transmission risk), DBM (demineralized bone matrix, osteoinductive), synthetic (calcium phosphate, calcium sulfate, bioactive glass - osteoconductive), BMPs (rhBMP-2, rhBMP-7, potent osteoinductive, swelling/ectopic bone cost), stem cells (BMAC, MSCs, adipose-derived), PRP (platelet-rich plasma, growth

factgrowth factors, cytokines). Complications: infection, graft resorption, nonunion, heterotopic ossification. Applications: nonunion, delayed union, spinal fusion, osteochondral defects.

Orthopedic Infections

– Septic arthritis: see Infectious Disease. Osteomyelitis: see Infectious Disease. Prosthetic joint infection: see Periprosthetic Joint Infection. Diabetic foot infection: Wagner classification (0-5), University of Texas (grade + ischemia + infection). Treatment: offloading (total contact cast), debridement, vascular assessment (ABI, TBI, TcPO₂), revascularization (endovascular, bypass), antibiotics (mild: oral; moderate/severe: IV), amputation (toe, ray, transmetatarsal, BKA, AKA). Charcot neuroosteoarthropathy (Charcot foot): midfoot collapse (rocker bottom), neuropathic, treated with Charcot reconstruction (superconstruct fixation, intramedullary beam, exostectomy, TCC, and AFO).

orthopedics

– The branch of surgery concerned with the musculoskeletal system, including bones, joints, ligaments, tendons, muscles, and nerves. Orthopaedic surgeons diagnose and treat conditions such as fractures and dislocations, arthritis (osteoarthritis, inflammatory arthritis), spinal disorders (disc herniation, spinal stenosis, scoliosis), sports injuries (ACL tear, rotator cuff tear, meniscal injury), paediatric orthopaedic conditions (developmental dysplasia of the hip, clubfoot, Perthes disease), bone tumors, and infections (osteomyelitis, septic arthritis). Treatment modalities: conservative (cast/splint, physiotherapy, medications), minimally invasive (arthroscopy, percutaneous fixation) and open surgery (joint replacement—hip, knee, shoulder; spinal fusion; osteotomy; limb reconstruction). Subspecialties include trauma, arthroplasty, hand surgery, foot and ankle, spine, paediatric orthopedics, sports medicine, and orthopaedic oncology.

Osgood-Schlatter Disease

– A traction apophysitis of the tibial tuberosity at the insertion of the patellar tendon, caused by repetitive microtrauma during periods of rapid growth. It is a common cause of anterior knee pain in adolescents aged 10–15 years, more common in boys (ratio 3:1) and in active/sporty children (running, jumping sports—basketball, football, volleyball).

Presentation: gradual onset of unilateral (30% bilateral) anterior knee pain just below the kneecap, worsened by activity (running, jumping, kneeling, climbing stairs), improved by rest. Physical exam: tenderness and swelling over the tibial tuberosity, pain on resisted knee extension or squatting. X-ray may show irregularity or fragmentation of the tibial tuberosity apophysis, but diagnosis is clinical. Management: activity modification (reduce high-impact sports, not complete rest), ice after activity, NSAIDs, quadriceps and hamstring stretching/strengthening, patellar tendon strap, and reassurance (self-limiting condition that resolves with skeletal maturity—apophyseal closure at age 14–18). Surgery (ossicle excision, tibial tuberosity reduction) is rarely needed for persistent symptoms.

Osteochondritis Dissecans

– A condition characterized by separation of a fragment of articular cartilage and subchondral bone from the joint surface, most commonly in the knee (lateral aspect of the medial femoral condyle). Most common in adolescents and young adults. Etiology: repetitive microtrauma, ischemia, or genetic predisposition. Presents with vague joint pain, swelling, catching, locking, and giving way. Diagnosis: X-ray (lucent crater with loose fragment), MRI (fragment stability and viability). Treatment: stable lesions in skeletally immature: activity modification, immobilization, or drilling. Unstable or loose bodies: arthroscopic fixation or fragment excision.

Osteochondroma

– The most common benign bone tumor, accounting for approximately 20-35 percent of all benign bone tumors. It is characterized by a bony projection with a cartilage cap arising from the surface of a bone, continuous with the underlying cortex and medullary cavity. Solitary osteochondromas typically present in the second decade of life (ages 10-20 years) as a painless, firm, immobile mass near the knee (distal femur or proximal tibia, most common), proximal humerus, or the proximal tibia or humerus. The characteristic radiographic appearance is a pedunculated or sessile bony excrescence arising from the metaphysis, pointing away from the adjacent joint, with a cartilage cap continuous with the host bone. Malignant transformation to secondary chondrosarcoma occurs in approximately

1 to 2 percent of solitary osteochondromas but in 2 to 5 percent of patients with multiple hereditary exostosis.

Osteoid Osteoma

– A benign bone-forming tumor that accounts for approximately 10-12 percent of all benign bone tumors, predominantly affecting adolescents and young adults (ages 5-25 years, male-to-female ratio 2:1). It is characterized by a small (< 1.5 -2 cm) radiolucent nidus surrounded by reactive sclerotic bone. The nidus contains osteoblasts, osteoid, and woven bone with prominent vascular channels. Osteoid osteomas produce high levels of prostaglandin E₂, which causes the characteristic severe, localised, deep, boring pain that is worse at night and dramatically relieved by NSAIDs, which inhibit COX-2 and reduce the production of prostaglandin E₂, the key mediator of pain in this tumor.

Osteopathy

– A system of manual medicine and healthcare founded by Andrew Taylor Still (1828–1917) based on the principle that the body's structure (musculoskeletal system) and function are interrelated, and that the body has inherent self-regulatory and healing mechanisms. Osteopathic practitioners (osteopaths in the UK; Doctors of Osteopathic Medicine, DOs, in the US) use hands-on techniques including soft tissue massage, joint articulation, myofascial release, high-velocity low-amplitude thrust, muscle energy technique, and cranial osteopathy to diagnose and treat musculoskeletal pain, dysfunction, and associated conditions. In the UK, osteopathy is regulated by the General Osteopathic Council (GOsC) and is a statutory regulated profession; osteopaths complete a 4-year integrated Master's degree (MOst). Osteopathy is distinct from orthopaedic surgery but often works alongside it in managing back pain, neck pain, and sports injuries. Evidence supports osteopathic manipulative treatment for chronic low back pain, although the evidence base for cranial osteopathy is limited.

Osteopenia

– Bone mineral density (BMD) that is lower than normal but not low enough to be classified as osteoporosis. T-score between -1.0 and -2.5 on DXA scan. A risk factor for osteoporosis and fractures. Management: lifestyle modifications (weight-bearing ex-

ercise, adequate calcium [1200 mg/day] and vitamin D [800-1000 IU/day]), smoking cessation, fall prevention, and reassess BMD every 1-2 years. Pharmacotherapy considered if FRAX score indicates high fracture risk.

Osteopetrosis

– A rare inherited bone disease characterized by defective osteoclast function, leading to impaired bone resorption and abnormally dense, sclerotic bones. The bone is structurally abnormal—brittle despite increased density—and prone to fracture. Two main forms: (1) Autosomal recessive ('malignant'): presents in infancy with failure to thrive, anemia, thrombocytopenia (bone marrow failure from marrow space obliteration), hepatosplenomegaly (extramedullary haematopoiesis), cranial nerve palsies (optic atrophy, deafness, facial palsy due to nerve compression), and recurrent infections. Life expectancy is poor without treatment. (2) Autosomal dominant ('benign'): milder, presents in adolescence or adulthood with fractures, osteomyelitis of the mandible, and sometimes asymptomatic (incidental finding on X-ray). Diagnosis: X-ray shows generalised osteosclerosis ('sandwich vertebrae', 'bone-within-bone' appearance, Erlenmeyer flask deformity of femurs). Treatment: hematopoietic stem cell transplantation (HSCT) for the malignant form (restores osteoclast function, improves survival), supportive care for fractures and anemia, and interferon gamma-1b. Gene therapy is experimental.

Osteoporosis

– A systemic skeletal disease of low bone mass and microarchitectural deterioration of bone tissue, leading to increased bone fragility and fracture risk. It is most common in postmenopausal women (due to estrogen deficiency accelerating bone resorption) and older adults; peak bone mass is achieved by age 30 and declines with age. Fragility fractures—vertebral compression fractures (often asymptomatic or causing height loss, kyphosis), hip fracture (associated with 20–30% 1-year mortality), and distal radius (Colles') fracture—are hallmark clinical events. Screening: DXA (dual-energy X-ray absorptiometry) at hip and lumbar spine; T-score ≤ -2.5 defines osteoporosis, -1.0 to -2.5 defines osteopenia. FRAX tool estimates 10-year fracture risk to guide treatment decisions. Pharmacotherapy:

first-line bisphosphonates (alendronate, risedronate, zoledronic acid), anabolic agents (teriparatide, romosozumab) for high-risk or severe disease, denosumab (RANKL inhibitor), and raloxifene (SERM). Nonpharmacologic: adequate calcium (1000–1200 mg/day from diet or supplements), vitamin D (800–1000 IU/day), weight-bearing and resistance exercise, fall prevention, and smoking cessation.

Osteosarcoma

– The most common primary malignant bone tumor in children and adolescents (excluding leukemia), with a peak incidence during the adolescent growth spurt (ages 10–20 years), and a second smaller peak in older adults (usually secondary to Paget disease or prior radiation). It most commonly arises in the metaphysis of long bones, particularly the distal femur (most common, 30–40 percent), proximal tibia, and proximal humerus. Histologically, it is characterized by malignant osteoid production (malignant osteoid) by malignant tumor cells. Clinical presentation is with localised pain (the most common symptom, worse at night), swelling, a palpable mass, and pathological fracture in 10 to 15 percent of cases.

Osteotomy

– A surgical procedure involving cutting and repositioning of bone to correct deformity, realign joint surfaces, alter weight-bearing forces, or change limb length. Indications: (1) Lower limb—high tibial osteotomy (HTO) for medial compartment knee osteoarthritis in young, active patients (realigns the mechanical axis, delaying arthroplasty), distal femoral osteotomy for lateral compartment or valgus deformity, and femoral/tibial osteotomy for congenital deformities (blount disease, leg length discrepancy). (2) Hip—pelvic osteotomy (periacetabular osteotomy—Ganz procedure) for developmental dysplasia of the hip in young adults, and femoral varus/valgus osteotomy for Perthes disease or hip dysplasia. (3) Spine—spinal osteotomy (Smith-Petersen, pedicle subtraction osteotomy, vertebral column resection) for sagittal imbalance (kyphosis, flatback syndrome). (4) Foot—calcaneal osteotomy for hindfoot deformity, first metatarsal osteotomy for hallux valgus. Osteotomy is also used in orthognathic surgery (jaw osteotomy for malocclusion). Fixation: plates, screws, external fixators.

Recovery involves non-weight-bearing or protected weight-bearing for 6–12 weeks post-operatively.

Paget Disease of Bone

– A chronic bone disorder characterized by excessive, disorganized bone remodeling with increased osteoclastic bone resorption followed by compensatory osteoblastic bone formation, producing structurally abnormal bone that is enlarged, weak, and prone to fracture. Often asymptomatic; can present with bone pain, deformity (bowing of tibia, skull enlargement), fractures, and arthritis. Diagnosis: elevated serum alkaline phosphatase with normal calcium, phosphate, and PTH; X-ray findings (lytic lesions, bone enlargement). Treatment: bisphosphonates (alendronate, risedronate, zoledronic acid).

Paget's Disease

– See Paget Disease of Bone.

Patella (Kneecap)

– The largest sesamoid bone in the human body, embedded within the quadriceps tendon anterior to the knee joint. The patella increases the lever arm of the quadriceps muscle (improving mechanical advantage for knee extension by 30%), protects the anterior knee joint, and distributes compressive forces across the femoral trochlea. Articular surface: the posterior patella has a V-shaped ridge that articulates with the femoral trochlear groove (medial and lateral facets). Patellofemoral joint: transmits up to 3–5 times body weight during stair climbing and 7–8 times during squatting. Patellar dislocation: typically lateral (vastus medialis obliquus disruption, trochlear dysplasia, patella alta, increased Q-angle), reduced by extending the knee. Patellar fracture: caused by direct trauma or forceful quadriceps contraction (transverse fracture most common); non-displaced: cast immobilisation; displaced/disrupted extensor mechanism: tension band wiring. Patellofemoral pain syndrome (anterior knee pain): common in young active individuals and runners, treated with quadriceps strengthening, activity modification, and patellar taping.

Patellofemoral Instability

– Patellar dislocation: lateral dislocation (95%), often reduces spontaneously. Risk factors: trochlear dysplasia (Dejour classification), patella alta (Caton-Deschamps >1.2), increased TT-TG distance (>20mm), MPFL insufficiency, femoral anteversion,

genu valgum. First-time: nonoperative (brace, PT, MPFL healing) if no loose body; recurrent: MPFL reconstruction (gold standard), tibial tubercle osteotomy (Fulkerson anteromedialization) for patella alta/TT-TG >20mm, trochleoplasty (deepening) for severe trochlear dysplasia (Dejour type B/D).

Patellofemoral Pain Syndrome

– Anterior knee pain related to the patellofemoral joint, common in adolescents and young adults (especially runners). Etiology: multifactorial (malalignment, quadriceps imbalance, overuse, tight lateral structures, weak VMO, and patellar instability). Presents with retropatellar or peripatellar pain with activities (squatting, running, stair climbing, prolonged sitting with knees bent — theater sign). Diagnosis: clinical; X-ray and MRI to rule out other pathology. Treatment: quadriceps and VMO strengthening, IT band and hamstring stretching, patellar taping/bracing, and activity modification. Most improve with non-operative management.

PCL Injuries

– Posterior cruciate ligament (PCL) tears: dashboard injury (posterior tibial force), hyperflexion. Clinical: posterior drawer (most sensitive), quadriceps active test, posterior sag sign. Grade I (1-5mm), II (6-10mm), III (>10mm). Isolated PCL: nonoperative (brace, rehab) for Grade I/II; surgical for Grade III or combined. PCL reconstruction: transtibial or tibial inlay (open posterior approach), single or double bundle. Combined with PLC/ACL/MCL for multi-ligament.

Peripheral Nerve Injuries

– Peripheral nerve injury classification (Sunderland): 1st degree (neuropraxia, conduction block, full recovery), 2nd degree (axonotmesis, Wallerian degeneration, endoneurium intact, recovery), 3rd degree (endoneurium disrupted, perineurium intact, partial recovery), 4th degree (perineurium disrupted, neuroma-in-continuity, no recovery without surgery), 5th degree (neurotmesis, complete transection). Management: acute sharp transection: primary epineurial repair (9-0/10-0 nylon); blunt/crush: wait 3-6 weeks, then repair; chronic (>6-12 months): nerve transfer, tendon transfer, free functional muscle transfer. Prognosis: better for distal, sharp, clean injuries; worse for proximal, blunt, contaminated.

Phocomelia

– A severe congenital limb deficiency where the proximal portion of a limb (humerus/femur, radius/tibia) is absent or severely hypoplastic, and the hand or foot attaches directly to the trunk. Most famously associated with thalidomide exposure during the first trimester of pregnancy (days 20-36 after conception). Can also occur in Roberts syndrome, Holt-Oram syndrome, and TAR syndrome. Complete phocomelia: hand/foot directly attached to the trunk. Proximal phocomelia: absent humerus/femur with forearm/leg present. Distal phocomelia: absent radius/ulna with humerus present. Treatment: prosthetics and adaptive devices to optimize function; reconstructive surgery for selected cases. Genetic counseling and prenatal diagnosis are important.

Plantar Fasciitis

– The most common cause of heel pain, caused by degeneration and microtears of the plantar fascia at its calcaneal origin. Presents with sharp, stabbing heel pain with the first steps in the morning (post-static dyskinesia), improving after a few minutes but worsening with prolonged standing or activity. Risk factors: tight Achilles/gastrocnemius, obesity, prolonged standing, and high-impact activities. Diagnosis: clinical. Treatment: calf and plantar fascia stretching (first-line), orthotics (arch support, heel cup), night splints, NSAIDs, and corticosteroid injection. Refractory: shockwave therapy, PRP, or fasciotomy.

Polydactyly

– A congenital anomaly characterized by supernumerary digits on the hands or feet. Postaxial polydactyly (ulnar/fibular side, most common): more frequent in African American and Native American populations, often isolated and autosomal dominant. Preaxial polydactyly (radial/tibial side): more common in Asian populations, may be associated with syndromes (Holt-Oram, Fanconi anemia, VACTERL, TAR syndrome). Central polydactyly: rare, often syndromic. Classification: Type A (well-formed, articulating digit) vs. Type B (rudimentary, pedunculated skin tag). Physical exam and X-ray to assess for bony connection, joint articulation, and functional impact. Treatment: surgical excision for aesthetic and functional concerns; Type B can be

ligated in the nursery. Preaxial polydactyly may require more complex reconstruction.

Posterior Cruciate Ligament Injury

- Tear of the PCL, less common than ACL injury. Mechanism: dashboard injury (tibia striking dashboard), hyperflexion, or fall on a flexed knee with foot plantarflexed. Presents with posterior knee pain, mild swelling, and posterior sag of the tibia. Positive posterior drawer test (most sensitive), posterior sag sign (Godfrey test). Often associated with PLC injury (posterolateral corner: popliteus, popliteofibular ligament, LCL). Diagnosis: MRI. Treatment: Grade I-II: conservative with quadriceps strengthening. Grade III or combined injuries: PCL reconstruction.

Proximal Humerus Fractures

- Proximal humerus fractures: Neer classification (4 parts: articular surface, greater tuberosity, lesser tuberosity, shaft; displaced >1 cm or angulated >45 degrees = part). 1-part (nondisplaced): sling, early motion. 2-part: surgical neck (ORIF plate, IM nail) or greater tuberosity (if displaced >5mm or rotator cuff involvement). 3-part: ORIF (locking plate) or hemiarthroplasty (elderly, osteoporotic). 4-part: high risk of AVN; hemiarthroplasty or reverse total shoulder arthroplasty (RSA, preferred, particularly for elderly patients with 4-part fractures). Post-op: sling, early passive ROM, active assist at 6 weeks, strengthening at 12 weeks. Complications: AVN (up to 30 percent for 4-part), malunion, nonunion, stiffness, hardware failure, infection.

Radial Club Hand

- A congenital longitudinal deficiency of the radial ray, ranging from thumb hypoplasia to complete absence of the radius. The hand is radially deviated due to the absent radial support, with the carpus displaced proximally and radially. Associated with Holt-Oram syndrome (TBX5 mutation, with VSD or ASD), TAR syndrome (thrombocytopenia-absent radius, bilateral radial aplasia with thumbs present — key distinguishing feature), Fanconi anemia (progressive pancytopenia, radial anomalies), and VACTERL association. Physical exam shows radial deviation of the hand, short forearm, thumb anomalies (absent, hypoplastic, or triphalangeal), and limited elbow extension. X-ray confirms radius deficiency and associated skeletal anomalies.

Treatment: centralization or radialization of the wrist (surgical repositioning over the ulna), thumb reconstruction (pollicization), and splinting. Genetic testing for Fanconi anemia is essential due to associated bone marrow failure and malignancy risk.

Rickets

- A childhood disorder of bone mineralization due to vitamin D deficiency, calcium deficiency, or phosphate deficiency (see also endocrine chapter). X-ray findings: widened, irregular metaphyseal plates (cupping, fraying, splaying) at sites of rapid bone growth (wrists, knees). Clinical features: bone pain, deformities (bowing of legs, frontal bossing, rachitic rosary, Harrison groove), growth retardation, and motor delay. Treatment: high-dose vitamin D (600,000 IU total over several months), calcium supplementation, and orthopedic bracing/surgery for severe deformities.

Rotator Cuff Tears

- Rotator cuff tears: partial (articular-sided PASTA, bursal-sided, intrasubstance) vs full-thickness. Ellman classification for PASTA: Grade I (<3mm), II (3-6mm), III (>6mm). Cofield sizing: small (<1cm), medium (1-3cm), large (3-5cm), massive (>5cm). Clinical: Neer/Hawkins impingement, drop arm, lag signs (external rotation lag, internal rotation lag), weakness. MRI: tear size, retraction, fatty infiltration (Goutallier classification: 0-4), muscle atrophy. Treatment: partial tears <50%: nonoperative (PT, corticosteroid injection, NSAIDs); full-thickness: repair (arthroscopic primary repair: single-row vs double-row, suture bridge, transosseous equivalent). Massive tears: nonop vs repair vs tendon transfer (latissimus dorsi for posterosuperior, pectoralis major for subscapularis) vs RTSA (reverse total shoulder arthroplasty, for massive retracted tears with rotator cuff arthropathy).

Sacroiliac Joint

- See Sacroiliac Joint in Anatomy.

Scaphoid Fractures

- Scaphoid fractures: most common carpal fracture (young males, FOOSH). Classification: Herbert: A (incomplete), B (complete: B1 distal waist, B2 proximal waist, B3 proximal pole, B4 distal tubercle, B5 transverse). Vascularity: retrograde

from distal radius → proximal pole at risk for AVN. Clinical: snuffbox tenderness, scaphoid compression test, pain with axial thumb loading. Imaging: PA/lateral/oblique/scaphoid views; MRI/CT if occult (high suspicion, negative XR). Treatment: distal pole/waist distal pole/waist fractures: closed reduction and cast immobilization (below elbow thumb spica or scaphoid cast for 6-12 weeks). Proximal pole fractures: ORIF (headless compression screw) due to high risk of nonunion and AVN. Nonunion: bone graft with or without fixation.

Scoliosis

– A lateral spinal curvature >10 degrees on standing radiograph (Cobb angle). Idiopathic scoliosis (most common, 80%): adolescent onset (≥10 years), more common in girls. Congenital: due to vertebral anomalies. Neuromuscular: associated with cerebral palsy, muscular dystrophy. Degenerative: from asymmetric disc/facet degeneration in older adults. Screening: Adam forward bend test (rib hump). Management: observation for mild curves (<25°), bracing for moderate (25-45°) in skeletally immature, surgical correction for severe (>45-50°) or progressive curves.

Shoulder Instability

– Anterior instability (95%): Bankart lesion (anterior-inferior labral tear), Hill-Sachs lesion (posterolateral humeral head impression fracture), ALPSA (anterior labroligamentous periosteal sleeve avulsion), HAGL (humeral avulsion of glenohumeral ligament), GLAD (glenoid labral articular disruption). Recurrence: <20 years 80-90%, >40 years <20%. Treatment: first-time: immobilization (controversial, may not reduce recurrence), early PT; recurrent: arthroscopic Bankart repair (suture anchors), remplissage (Hill-Sachs remplissage), coracoid transfer (Latarjet, Bristow) for glenoid bone loss >20-25 percent, bone grafting (distal tibia allograft, iliac crest autograft).

SLAP Tears

– Superior labrum anterior-posterior (SLAP) tears: Snyder classification: I (fraying), II (detachment of biceps anchor, most common), III (bucket-handle tear of labrum, stable biceps), IV (bucket-handle extending into biceps). Clinical: O'Brien active compression test, Speed test, Yergason test, crank test. MRI arthrogram: sensitivity >90%. Treat-

ment: Type I: debridement; Type II: repair (young, overhead athletes), biceps tenodesis (older, >35-40, non-overhead); Type III: debridement; Type IV: debridement with biceps tenodesis or tenotomy; Type IV: repair plus biceps tenodesis/tenotomy.

Soft Tissue Tumors

– Lipoma: most common benign soft tissue tumor, subcutaneous, encapsulated. Liposarcoma: most common malignant STS in adults, deep, subtypes (well-differentiated/dedifferentiated, myxoid/round cell, pleomorphic). Synovial sarcoma: t(X;18), SS18-SSX, young adults, deep extremity, "triple sign" on MRI. Rhabdomyosarcoma: most common pediatric STS, embryonal (favorable), alveolar (PAX3/7-FOXO1, unfavorable). Malignant peripheral nerve sheath tumor (MPNST): NF1 association, painful, rapid growth. Desmoid tumor: locally aggressive, not metastatic, watch and wait, surgery (high recurrence), cryotherapy, NSAIDs, tyrosine kinase inhibitor. Myxoma: intramuscular, benign. Nodular fasciitis: reactive, self-limited. Elastofibroma dorsi: subscapular, benign. Imaging: MRI with contrast. Biopsy: core needle (preferred), incisional, excisional. Staging: AJCC, Enneking classification.

Spinal Cord Injury

– Spinal cord injury: ASIA impairment scale (A-E). Complete (ASIA A) vs incomplete. Syndromes: central cord (cervical hyperextension, upper > lower extremity weakness, burning hands), Brown-Sequard (hemisection: ipsilateral motor/proprioception loss, contralateral pain/temp loss), anterior cord (motor + pain/temp loss, proprioception spared), posterior cord (proprioception loss), conus medullaris (L1-L2, saddle anesthesia, bowel/bladder, mixed UMN/LMN), cauda equina (LMN, radicular pain, asymmetric neurologic involvement). Treatment: high-dose methylprednisolone (controversial), blood pressure augmentation (MAP >85 mmHg for 7 days), surgical decompression and stabilization. Timing: early (<24h) for cervical injury with incomplete deficit. Rehabilitation, bowel/bladder management, and psychosocial support.

Spinal Stenosis

– Narrowing of the spinal canal causing compression of the spinal cord or nerve roots. Lumbar stenosis (most common): neurogenic claudi-

cation (leg pain/weakness with walking, relieved by sitting/leaning forward), often bilateral. Cervical stenosis: myelopathy (hyperreflexia, Babinski, Hoffman, gait disturbance, hand clumsiness, bowel/bladder dysfunction). Risk factors: aging, degenerative disc disease, facet hypertrophy, ligamentum flavum hypertrophy, and congenital stenosis. Diagnosis: MRI. Treatment: physical therapy, NSAIDs, epidural steroid injections, and decompressive laminectomy with or without fusion for refractory or severe cases.

Spine Disorders

- The spine, or vertebral column, is a complex bony and soft-tissue structure that provides axial support, protects the spinal cord, and enables flexible movement of the trunk. It consists of 33 vertebrae divided into cervical, thoracic, lumbar, sacral, and coccygeal regions, separated by intervertebral discs that act as shock absorbers. Common spinal conditions include degenerative disc disease, herniated discs, spinal stenosis, scoliosis, and vertebral fractures, which can cause pain, neurological symptoms, and impaired mobility; management ranges from physical therapy and medications to surgical intervention.

Spondylolisthesis

- Forward slippage of one vertebral body relative to the vertebra below it. Isthmic (Type II, most common in children/adolescents): defect in pars interarticularis (spondylolysis), often L5-S1. Degenerative (Type III, most common in adults): facet joint and disc degeneration, often L4-L5. Presents with low back pain, radicular leg pain, and hamstring tightness. High-grade slips: may cause postural deformity and neurologic deficits. Diagnosis: standing lateral X-ray (Myerding grading: I-V based on percentage slip), MRI. Treatment: conservative (PT, bracing, activity modification) for low-grade. Surgical: reduction and fusion for high-grade, progressive slip, or persistent pain.

Sprain

- An injury to a ligament (connective tissue connecting bone to bone) caused by excessive stretching or tearing. Grading: Grade I (mild stretching, microscopic tears), Grade II (partial tear with laxity), Grade III (complete tear with instability). Common sites: ankle (lateral ligaments most common),

knee (ACL, MCL), wrist, and thumb (gamekeeper's thumb). Presents with pain, swelling, bruising, and joint instability (Grades II-III). Diagnosis: clinical, stress testing, MRI for confirmation. Treatment: RICE (rest, ice, compression, elevation), NSAIDs, immobilization, physical therapy. Grade III injuries may require surgical reconstruction.

Sprenkel Deformity

- A congenital elevation of the scapula due to failure of the scapula to descend from its embryonic cervical position to its normal thoracic position during weeks 9-12 of gestation. The scapula is higher, smaller, and rotated inferiorly compared to the normal side. Range of motion is limited, especially in shoulder abduction. Often associated with Klippel-Feil syndrome, scoliosis, and cervical ribs. An omovertebral bone (fibrous, cartilaginous, or bony connection between the scapula and cervical spine) is present in 30-50% of cases. Physical exam shows an elevated scapula with a webbed-appearing neck on the affected side. X-ray confirms the elevated scapula and identifies associated cervical anomalies. Treatment: observation for mild cases; surgical correction (Woodward or Green procedure) for moderate to severe cases with functional or cosmetic concerns, ideally performed at 3-8 years of age.

Strain

- An injury to a muscle or tendon (connective tissue connecting muscle to bone) caused by excessive stretching, contraction, or overload. Grading: Grade I (mild stretching with few muscle fibers torn), Grade II (moderate partial tear), Grade III (complete muscle/tendon rupture). Common sites: hamstring, quadriceps, calf (gastrocnemius), lower back, and rotator cuff. Presents with acute pain, swelling, muscle spasm, and loss of function. Diagnosis: clinical, ultrasound or MRI for Grade II-III. Treatment: RICE (rest, ice, compression, elevation), NSAIDs, gradual return to activity with physical therapy. Grade III ruptures (e.g., Achilles tendon) may require surgical repair.

Syndactyly

- A congenital anomaly where two or more digits are fused together by skin (simple syndactyly) or by both skin and bone (complex syndactyly). Most common congenital hand anomaly, often bilateral. May be isolated (autosomal dominant, incomplete

penetrance) or syndromic (Poland, Apert, Crouzon, Holt-Oram syndromes). The third web space is most commonly affected. Physical exam assesses the extent of fusion, nail involvement, and functional limitation. X-ray evaluates the degree of bony fusion and associated anomalies. Treatment: surgical separation (syndactyly release) performed at 6-18 months to prevent angular growth deformity. Z-plasties or skin grafts are used to reconstruct the web space. Separation of multiple digits requires staging to avoid vascular compromise.

Tendinitis

– Inflammation of a tendon, typically at its insertion (enthesis) or at the musculotendinous junction. Tendinitis is often caused by repetitive microtrauma/overuse but the term is increasingly replaced by 'tendinopathy' as histopathology shows tendinosis (collagen degeneration, neovascularisation, mucoid change) rather than acute inflammation. Common sites: rotator cuff (supraspinatus—shoulder impingement, subacromial pain), lateral epicondylitis (tennis elbow—extensor carpi radialis brevis origin), medial epicondylitis (golfer's elbow—common flexor origin), patellar tendinitis (jumper's knee—inferior pole of patella), Achilles tendinitis (insertional or mid-portion), de Quervain tenosynovitis (first dorsal compartment of the wrist—abductor pollicis longus, extensor pollicis brevis), and bicipital tendinitis (long head of biceps). Diagnosis: clinical (tenderness over the affected tendon, pain on resisted contraction, and passive stretch), ultrasound or MRI to confirm. Treatment: relative rest, activity modification, ice, NSAIDs, physiotherapy (eccentric exercises—proven effective for Achilles and patellar tendinopathy), corticosteroid injection (short-term relief, but may increase rupture risk—avoid for Achilles and patellar tendons), platelet-rich plasma (PRP) injection (evidence mixed), extracorporeal shock wave therapy, and surgery (tendon debridement, repair) for refractory cases.

Tennis Elbow

– Lateral epicondylitis, a tendinopathy of the common extensor tendon at the lateral epicondyle (extensor carpi radialis brevis). Caused by repetitive wrist extension and overuse, not limited to tennis. Presents with lateral elbow pain worsened by wrist

extension and grip. Tenderness over the lateral epicondyle. Positive Cozen test and Mill test. Diagnosis: clinical; MRI or ultrasound to confirm. Treatment: rest, ice, activity modification, NSAIDs, physical therapy (eccentric exercises), and corticosteroid injection. Refractory cases: PRP injection, extracorporeal shock wave therapy, or surgical release.

Thoracolumbar Spine Trauma

– Thoracolumbar trauma: T10-L2 (thoracolumbar junction), L3-L5. AO classification: A (compression), B (distraction), C (translation/rotation). TLICS (Thoracolumbar Injury Classification and Severity): morphology (1-3), PLC (0-2), neurologic (0-3). <4 nonop, >4 op. Neurologic: complete (ASIA A) vs incomplete. Treatment: nonop (TLSO brace, early mobilization); op: posterior instrumentation (pedicle screws 1 above/1 below), decompression (laminectomy if retropulsed fragment, transpedicular or costotransversectomy for anterolateral compression). Post-op: TLSO brace, early mobilisation. Complications: infection, hardware failure, pseudarthrosis, proximal junctional kyphosis.

Thumb CMC Arthritis

– Thumb carpometacarpal (CMC) arthritis: Eaton-Littler classification: I (normal), II (slight narrowing, osteophytes <2mm), III (narrowing, osteophytes >2mm, subluxation), IV (pantrapezial arthritis). Clinical: base of thumb pain, pinch weakness, thenar wasting, squaring (subluxation). Treatment: I/II: splint, NSAIDs, corticosteroid injection, PT; III/IV: surgical: trapeziectomy (LRTI - ligament reconstruction tendon interposition with FCR/APL, suture button suspension, tightrope), total joint arthroplasty with hemi or total (trapezium-sparing, resurfacing).

Tibial Shaft Fractures

– Tibial shaft fractures: most common long bone fracture. AO/OTA: 42-A (simple), 42-B (wedge), 42-C (complex). Soft tissue critical: Gustilo for open. Treatment: IM nailing (gold standard, reamed, anteromedial or medial parapatellar entry, suprapatellar), plating (medial, anterolateral - for proximal/distal metaphyseal), external fixation (severe open, damage control). Compartment syndrome risk high (4 compartments). Complications: malunion, nonunion, infection, nerve injury, vascular injury, deep vein thrombosis, pulmonary embolism.

nion (valgus/procurvatum), nonunion (exchange nail, plate + bone grafting, exchange nailing, plate + bone graft).

Torticollis (Wryneck)

– A condition in which the head is tilted to one side (ear toward the shoulder) and rotated to the opposite side (chin toward opposite shoulder), due to contraction or shortening of the sternocleidomastoid muscle. Congenital muscular torticollis (most common): presents in infancy (2–3 weeks of age), caused by fibrosis of the sternocleidomastoid (possibly from intrauterine positioning, birth trauma, or compartment syndrome). A palpable neck mass (pseudotumour of infancy) may be present. Diagnosis: clinical, ultrasound to exclude other causes. Management: passive stretching exercises (95% resolve with physiotherapy by 12 months). If persistent after 12–18 months: surgical release of the sternocleidomastoid. Acquired torticollis: causes—infection (retropharyngeal abscess, cervical lymphadenitis—Grisel syndrome, tonsillitis, mastoiditis—inflammatory torticollis), trauma (atlantoaxial rotatory subluxation/fixation—C1–C2 rotary fixation—most common in children after minor trauma or upper respiratory infection, presents with Cock Robin position), neurological (cervical dystonia/spasmodic torticollis—idiopathic, adult onset, treated with botulinum toxin injections), ocular (superior oblique palsy—head tilt to compensate for diplopia), and drug-induced (dystonic reaction to antipsychotics—acute, responsive to anticholinergics). Red flags: fever, meningism, neurological deficit, trauma, pain, or fixed deformity.

Total Hip Arthroplasty

– THA indications: end-stage OA, inflammatory arthritis, AVN, fracture, dysplasia. Approaches: posterior (most common, dislocation risk), direct anterior (DAA, muscle-sparing, fluoroscopy), anterolateral (Watson-Jones), lateral (Hardinge). Bearings: ceramic-on-poly (standard), ceramic-on-ceramic (young, squeaking risk), metal-on-poly (historical). Fixation: cemented (elderly, osteoporotic), cementless (porous coated, hydroxyapatite, young), hybrid (cemented stem + cementless cup). Complications: dislocation (posterior approach 1–3 percent, DAA <1 percent), infection (1–2 percent), periprosthetic fracture, aseptic loosening, leg length

discrepancy, nerve injury, venous thromboembolism.

Total Knee Arthroplasty

– TKA indications: end-stage OA, inflammatory arthritis, post-traumatic. Components: femoral (cobalt-chrome), tibial (titanium tray + polyethylene insert), patellar (polyethylene, resurfacing vs not). Alignment: mechanical (neutral), kinematic (patient-specific), restricted kinematic. Ligament balancing: measured resection, gap balancing. Patellar resurfacing: selective vs routine. Complications: stiffness (manipulation under anesthesia, arthroscopic lysis), instability (collateral, PCL), patellofemoral complications, aseptic loosening, periprosthetic fracture, infection (1–2 percent), venous thromboembolism, arthrofibrosis, and extensor mechanism disruption.

Trigger Finger

– Trigger finger (stenosing tenosynovitis): A1 pulley thickening, flexor tendon nodule → catching/locking. Clinical: triggering, palpable nodule at distal palmar crease, morning stiffness. Grades: I (pain only), II (catching, active extension), III (catching, passive extension), IV (locked flexed). Treatment: corticosteroid injection (60–70% cure, less in diabetics); percutaneous release (needle); open A1 pulley release (gold standard for refractory/recurrent). Thumb: MP flexion contracture risk.

Whiplash Injury

– An acceleration-deceleration injury to the cervical spine, most commonly resulting from rear-end motor vehicle collisions. Mechanism: sudden hyperextension followed by hyperflexion of the neck causes stretching or tearing of cervical muscles, ligaments, facet joint capsules, and annulus fibrosus of intervertebral discs. The S-shaped curve of the cervical spine during whiplash (initial straightening of the cervical lordosis followed by flexion at the lower segments and extension at the upper segments) produces shear stress on the facet joints. Clinical presentation: neck pain and stiffness (onset within 24 hours, may be delayed up to 72 hours), headache (typically occipital or suboccipital, cervicogenic origin), interscapular pain, upper limb pain and paraesthesiae (referred or radicular, from nerve root stretching), dizziness, fatigue, and temporomandibular joint pain. Quebec Task Force

Classification: Grade 0 (no neck complaint, no physical sign), Grade I (neck pain, stiffness, tenderness only, no neurological signs), Grade II (neck complaint AND musculoskeletal signs — decreased range of motion, point tenderness), Grade III (neck complaint AND neurological signs — decreased or absent deep tendon reflexes, weakness, sensory deficits), Grade IV (neck complaint AND fracture or dislocation on imaging). Chronic whiplash syndrome: persistent pain and disability beyond 6 months, associated with high initial pain intensity, female sex, older age, and psychological factors (catastrophizing, fear avoidance). Diagnosis: clinical; imaging (cervical spine X-ray, CT, MRI) indicated if red flags present (fracture suspicion, neurological deficit, age >65, high-energy mechanism). Management: active treatment (early mobilisation, neck exercises, NSAIDs, muscle relaxants) is superior to immobilisation (soft collar). Cervical collars should be discontinued within 72 hours. Physiotherapy, manual therapy, and acupuncture for persistent pain. Prognosis: 50% recover within 3 months, 75% by 6 months. Chronic pain develops in 25%.

Wrist Drop

– See Radial Nerve Palsy (Wrist Drop).

Chapter 29

Pathology

Acute Inflammation

– A rapid, predominantly non-specific immune response to tissue injury or infection that typically lasts hours to days and involves vascular and cellular reactions. The cardinal signs are redness, heat, swelling, pain, and loss of function, resulting from increased blood flow, vascular permeability, and cellular infiltration. The process begins with vasodilation mediated by histamine, prostaglandins, and nitric oxide, followed by increased vascular permeability allowing plasma proteins and leukocytes to exit the circulation. Neutrophils are the first leukocytes recruited, followed by monocytes that transform into tissue macrophages, working together to eliminate the inciting stimulus and initiate tissue repair.

Adrenal Cortical Carcinoma

– A rare, aggressive malignancy arising from the adrenal cortex, with an incidence of approximately one to two per million population per year. The tumor may be functional, producing excessive hormones, or non-functional. Functional tumors may produce cortisol causing Cushing syndrome, aldosterone causing Conn syndrome, or androgens causing virilization in women or feminization in men. Non-functional tumors present with abdominal pain, early satiety, or are discovered incidentally on abdominal imaging. Complete surgical resection is the treatment of choice, but prognosis is poor, with five-year survival rates under 40 percent due to advanced stage at presentation and high recurrence rates.

Adult Still's Disease

– Adult Still's disease, also known as systemic-onset juvenile idiopathic arthritis when occurring in children, is a systemic inflammatory disorder character-

ized by high-spiking daily fevers, evanescent salmon-colored rash, arthritis, and multiorgan involvement. The pathogenesis involves excessive activation of the innate immune system with overproduction of IL-1, IL-6, IL-18, and TNF. The characteristic fever pattern is quotidian, meaning it occurs once daily typically in the evening, with rapid return to baseline between spikes. The rash is typically salmon-colored, transient, and associated with fever spikes. Arthritis may be severe and destructive. Laboratory findings include markedly elevated ferritin levels, leukocytosis, and elevated inflammatory markers. Treatment involves NSAIDs, corticosteroids, and biologic agents targeting IL-1 or IL-6.

Air Embolism

– Air embolism occurs when air enters the venous or arterial circulation, potentially causing cardiovascular collapse and death. Venous air embolism is more common, typically occurring during neurosurgery in the sitting position, central venous catheterization or removal, chest trauma, or underwater diving. Approximately 100 milliliters of air introduced rapidly into the venous circulation can be fatal, as air bubbles coalesce in the right ventricle and create an air lock that obstructs pulmonary outflow, causing right heart strain and cardiovascular collapse. Treatment includes immediate placement in the left lateral decubitus position, administration of 100 percent oxygen, and aspiration of air from the right ventricle via a central venous catheter.

Amyloidosis

– A group of disorders characterized by the extracellular deposition of misfolded proteins that polymerize into insoluble fibrils with a distinctive beta-pleated sheet configuration. These fibrils bind Congo red dye and show characteristic apple-green birefrin-

gence under polarized light microscopy. AA amyloidosis results from chronic inflammatory conditions with serum amyloid A protein depositing predominantly in the kidneys, spleen, and liver. AL amyloidosis involves immunoglobulin light chain deposition from plasma cell dyscrasias, affecting the heart, kidneys, and peripheral nerves. Diagnosis requires tissue biopsy with Congo red staining showing apple-green birefringence under polarised light. Treatment targets the underlying plasma cell disorder.

Anaphylaxis

– A severe, potentially life-threatening systemic allergic reaction that occurs rapidly after exposure to an allergen, typically within minutes. The mechanism involves massive systemic mast cell and basophil degranulation, releasing histamine, leukotrienes, prostaglandins, and other mediators that cause widespread vasodilation, increased vascular permeability, bronchoconstriction, and cardiac dysfunction. Clinical features include urticaria and angioedema, wheezing and stridor from laryngeal edema, hypotension, tachycardia, and potential cardiovascular collapse. First-line treatment is intramuscular epinephrine, followed by antihistamines, corticosteroids, and intravenous fluids. Prompt recognition and treatment are essential to prevent fatal outcomes.

Anaplasia

– A lack of differentiation, describing cells that have reverted to a more primitive, embryonic phenotype with loss of the specialized structural and functional characteristics of their tissue of origin. Anaplastic cells exhibit marked pleomorphism with variation in cell size and shape, hyperchromatic nuclei with coarse irregular chromatin, prominent and irregular nucleoli, and a high nuclear-to-cytoplasmic ratio exceeding 80 percent. Mitotic figures are abundant, frequently atypical, including tripolar and quadripolar forms. Anaplasia is a hallmark of malignancy and correlates with aggressive clinical behaviour, high histological grade, and poor prognosis. The most anaplastic tumors are classified as poorly differentiated or undifferentiated (grade IV).

Angiogenesis

– The formation of new blood vessels from pre-existing vasculature, a process essential for wound healing, embryonic development, and pathological

conditions including tumor growth. It is regulated by the balance between pro-angiogenic factors, particularly vascular endothelial growth factor, and anti-angiogenic factors like thrombospondin and endostatin. During wound healing, hypoxia in the injured tissue stimulates VEGF production through HIF-1 alpha, which activates endothelial cell proliferation, migration, and tube formation. The new vessels are immature, leaky, and lack pericyte coverage, contributing to the abnormal tumor microenvironment. Anti-angiogenic therapies targeting VEGF have been developed as anti-cancer treatments, though resistance is common.

APC Tumor Suppressor

– The adenomatous polyposis coli protein is a large multidomain tumor suppressor that functions as a critical negative regulator of the canonical Wnt signaling pathway. In the absence of Wnt ligands, APC forms a destruction complex with axin, glycogen synthase kinase-3 beta, and casein kinase 1, which phosphorylates beta-catenin, targeting it for ubiquitination and proteasomal degradation. When APC is inactivated by mutation, the destruction complex cannot degrade beta-catenin, which accumulates in the nucleus and activates transcription of pro-proliferative genes including MYC and cyclin D1. Germline mutations in APC cause familial adenomatous polyposis, with hundreds of colorectal adenomas and near-100 percent risk of colorectal cancer by age 40.

Apoptosis

– A tightly regulated form of programmed cell death that serves as a critical homeostatic mechanism in multicellular organisms, removing damaged or unnecessary cells without inciting inflammation. The intrinsic pathway is initiated by intracellular stressors such as DNA damage, oxidative stress, or growth factor withdrawal, leading to mitochondrial outer membrane permeabilization through BAX and BAK pore formation. This releases cytochrome c into the cytoplasm, which binds APAF-1 to form the apoptosome, which activates caspase-9, initiating a caspase cascade leading to DNA fragmentation and cell dismantling. The extrinsic pathway is triggered by death receptor ligation. Both pathways converge on effector caspases-3 and -7, which execute the final phases of apoptosis.

Apoptosis Extrinsic Pathway

– The extrinsic pathway of apoptosis is triggered by extracellular ligands binding to death receptors belonging to the tumor necrosis factor receptor superfamily, including Fas (CD95), TNFR1, and TRAIL receptors DR4 and DR5. Upon ligand binding, these receptors trimerize and recruit intracellular adaptor proteins including FADD and TRADD through their death domains, forming the death-inducing signaling complex. FADD then recruits procaspase-8 through death effector domain interactions, leading to autocatalytic activation of caspase-8, which then cleaves and activates effector caspases-3 and -7. The extrinsic pathway can also engage the intrinsic pathway through BID cleavage, amplifying the apoptotic signal. This pathway is critical for immune surveillance and lymphocyte homeostasis.

Apoptosis Intrinsic Pathway

– The intrinsic, or mitochondrial, pathway of apoptosis is initiated by intracellular stress signals including DNA damage, growth factor withdrawal, endoplasmic reticulum stress, and hypoxia. These signals activate BH3-only proteins such as BIM, BAD, BID, and PUMA, which neutralize anti-apoptotic BCL-2 family members or directly activate the pro-apoptotic effectors BAX and BAK. Activated BAX and BAK oligomerize and form pores in the outer mitochondrial membrane, a process called mitochondrial outer membrane permeabilisation, releasing cytochrome c and other pro-apoptotic factors. Cytochrome c binds APAF-1 to form the apoptosome, activating caspase-9. This pathway is tightly regulated by the BCL-2 family and is disrupted in many cancers, contributing to chemotherapy resistance.

Atherosclerotic Plaque

– An atherosclerotic plaque is a lesion within the arterial intima composed of a necrotic lipid core covered by a fibrous cap, representing the pathological substrate of atherosclerotic cardiovascular disease. The necrotic core contains cholesterol crystals, calcium deposits, cellular debris, and foam cells derived from lipid-laden macrophages. The fibrous cap consists of smooth muscle cells, collagen, elastin, and proteoglycans that separate the thrombogenic core from the flowing blood. The plaque may be stable, with a thick fibrous cap and small lipid core, or vulnerable, with a thin cap, large

lipid core, and dense inflammation. Rupture of a vulnerable plaque exposes thrombogenic core material, triggering acute thrombosis responsible for myocardial infarction and stroke.

Autoimmune Disease

– Autoimmune diseases result from loss of immunological self-tolerance, leading to immune-mediated attack on the body's own tissues. The mechanisms include molecular mimicry, where microbial antigens share epitopes with self-antigens triggering cross-reactive immune responses; bystander activation, where tissue damage releases sequestered self-antigens; epitope spreading, where immune responses extend to additional self-epitopes; and defective regulatory T cell function. Systemic lupus erythematosus, rheumatoid arthritis, type 1 diabetes, multiple sclerosis, and inflammatory bowel disease are common examples. Treatment typically involves immunosuppressive agents including corticosteroids, disease-modifying anti-rheumatic drugs, and biologic therapies targeting specific immune pathways.

Bacterial Endocarditis Vegetations

– Vegetations in bacterial endocarditis are complex masses composed of bacteria, fibrin, and platelets that form on heart valve surfaces or endocardium. The pathogenesis begins with bacteremia seeding a site of endothelial damage or a previously abnormal valve surface. The damaged endothelium exposes subendothelial collagen and von Willebrand factor, promoting platelet adhesion and fibrin deposition, creating a non-bacterial thrombotic endocarditis nidus. Bacteria, particularly *Staphylococcus aureus*, *Streptococcus viridans*, and *Enterococcus* species, adhere to the thrombotic nidus and proliferate, embedded in layers of fibrin and platelets. The vegetations can embolise to distant organs and destroy valve tissue, leading to acute or subacute endocarditis with fever, heart murmur, and peripheral stigmata.

Behcet Disease

– A chronic, relapsing systemic vasculitis characterized by recurrent oral ulcers, genital ulcers, and ocular inflammation, with a distribution along the ancient Silk Road from the Mediterranean to East Asia. The pathogenesis involves inappropriate neutrophil and T-cell mediated vascular inflammation,

with genetic susceptibility associated with HLA-B51. The hallmark oral aphthous ulcers are painful, recurrent, and heal without scarring. Genital ulcers typically affect the scrotum and vulva, healing with scarring. Ocular involvement manifests as anterior or posterior uveitis and retinal vasculitis, potentially causing blindness. Neurological and large-vessel involvement carries the highest morbidity. Diagnosis is clinical. Treatment includes corticosteroids, immunosuppressants, and biologic agents.

Benign Neoplasm

– Benign neoplasms are proliferations of cells that remain confined to their site of origin, grow by expansion rather than invasion, and do not metastasize to distant sites. They typically grow slowly, pushing aside adjacent normal tissue and often becoming enclosed by a fibrous pseudocapsule formed from compressed connective tissue. Histologically, benign neoplasms show well-differentiated cells with regular nuclear morphology, low mitotic activity, no atypical mitotic figures, and growth pattern that preserves normal tissue architecture. They are usually encapsulated or well-circumscribed. Clinical effects result from local compression, hormone production, or obstruction of adjacent structures. Complete surgical excision is generally curative with an excellent prognosis.

Bilirubin Metabolism

– Bilirubin is the breakdown product of heme from senescent red blood cells, metabolized primarily by the liver through a series of enzymatic steps. Heme is converted to biliverdin by heme oxygenase, then to unconjugated bilirubin by biliverdin reductase. Unconjugated bilirubin is lipophilic and transported bound to albumin to the liver. In hepatocytes, unconjugated bilirubin is conjugated with glucuronic acid by UDP-glucuronosyltransferase, forming water-soluble conjugated bilirubin that is excreted into bile. In the intestine, conjugated bilirubin is deconjugated by bacterial enzymes and reduced to urobilinogen. Most urobilinogen is excreted in feces, but a portion undergoes enterohepatic circulation and is excreted in urine. Elevation of unconjugated or conjugated bilirubin causes clinical jaundice.

Biopsy

– A medical procedure involving the removal of a

small sample of tissue from the body for microscopic examination to establish a diagnosis, most commonly to differentiate benign from malignant pathology and to characterize disease processes. Biopsies are classified by technique: excisional biopsy (the entire lesion is removed, providing the most complete specimen), incisional biopsy (a portion of a larger lesion is sampled, often used for large tumors), needle biopsy (core needle using a hollow needle to obtain a core of tissue for histological analysis), fine needle aspiration (extracting cells for cytological examination), and endoscopic biopsy (during colonoscopy or bronchoscopy). Proper tissue handling, fixation, and orientation are essential for accurate pathological diagnosis.

Carcinoid Tumor

– Carcinoid tumors are well-differentiated neuroendocrine neoplasms that arise from enterochromaffin cells throughout the gastrointestinal tract and bronchial system. The most common primary sites are the appendix, small intestine, and rectum. The tumors produce biogenic amines and peptides, but clinically significant hormone secretion occurs mainly with hepatic metastases, which allow vasoactive substances to bypass hepatic first-pass metabolism. Carcinoid syndrome occurs in approximately 10 percent of patients, presenting with flushing, diarrhea, wheezing, and right-sided valvular heart disease from serotonin and other vasoactive substances. Diagnosis involves urinary 5-HIAA measurement. Surgical resection is curative for localized disease; somatostatin analogues control symptoms in metastatic disease.

Carcinoma

– A malignant neoplasm arising from epithelial cells, representing the most common class of cancer. Carcinomas originate from any epithelial tissue and are classified based on cell type, architectural pattern, and anatomical location. Squamous cell carcinoma arises from stratified squamous epithelium and commonly affects the skin, lung, esophagus, cervix, and head and neck regions. Adenocarcinoma develops from glandular epithelium and commonly affects the colon, breast, prostate, stomach, and lung. Subtypes include small cell carcinoma, large cell carcinoma, transitional cell carcinoma, and basal cell carcinoma. Carcinomas are graded by differentiation

and staged by tumor size, lymph node involvement, and metastasis. Prognosis varies widely by type, stage, and grade.

Cardiomyopathy

– Diseases of the myocardium that result in cardiac dysfunction, excluding coronary artery disease, valvular disease, and congenital heart disease as primary causes. The three main types are dilated, hypertrophic, and restrictive cardiomyopathy. Dilated cardiomyopathy is characterized by ventricular dilation and impaired systolic function with reduced ejection fraction. It may be idiopathic, familial with mutations in genes encoding cytoskeletal and sarcomeric proteins, or secondary to causes such as alcoholic cardiomyopathy, chemotherapy-induced cardiotoxicity, or viral myocarditis. Hypertrophic cardiomyopathy is characterized by left ventricular hypertrophy without dilation, typically due to sarcomeric protein mutations. Restrictive cardiomyopathy involves impaired diastolic filling with preserved systolic function.

Caseous Necrosis

– A distinctive form of cell death that characteristically occurs in granulomatous infections, most notably tuberculosis. The term derives from the cheese-like, friable, whitish-yellow appearance of the necrotic tissue on gross examination. Histologically, caseous necrosis appears as amorphous, granular, eosinophilic debris without recognizable cellular outlines or tissue architecture, distinct from the structural preservation seen in coagulative necrosis. The process results from the combination of macrophage activation, T-cell mediated immunity, and bacterial products creating a hypoxic microenvironment. The necrotic material contains dead immune cells and bacterial debris. It may undergo liquefaction and cavitation, facilitating spread of infection to other sites.

Cellular Adaptation

– Cellular adaptations are reversible changes in cell morphology and function that occur in response to altered physiological demands or mild pathological conditions. Hypertrophy involves an increase in cell size through increased protein synthesis and organelle production, resulting in increased organ size, as seen in cardiac hypertrophy from chronic hypertension or skeletal muscle growth with resis-

tance exercise. Hyperplasia involves an increase in cell number through mitotic division, as seen in the breast and endometrium in response to hormonal stimulation. Atrophy involves decreased cell size and organ mass due to reduced functional demand, inadequate blood supply, or ageing. Metaplasia is a reversible change where one differentiated cell type is replaced by another more resilient to environmental stress.

Cerebral Edema

– The accumulation of excess fluid within the brain parenchyma, leading to increased intracranial pressure and potentially fatal brain herniation. There are three main types with different pathophysiological mechanisms. Vasogenic edema results from disruption of the blood-brain barrier, allowing protein-rich fluid to enter the extracellular space; it is seen in brain tumors, abscesses, hypertensive encephalopathy, and posterior reversible encephalopathy syndrome. Cytotoxic edema results from energy failure and impaired ion pumps, causing intracellular swelling; it is seen in cerebral ischemia, hypoxia, and metabolic disorders. Interstitial edema occurs in obstructive hydrocephalus from transependymal CSF flow. Management focuses on reducing intracranial pressure through osmotic therapy, corticosteroids, or surgical decompression.

Cerebral Infarction

– Cerebral infarction, or ischemic stroke, results from occlusion of a cerebral artery causing irreversible neuronal damage. The most common cause is thromboembolism from atherosclerotic carotid or intracranial arteries, or cardioembolism from atrial fibrillation or cardiac thrombus. The brain is particularly vulnerable to ischemia due to its high metabolic rate and limited energy reserves, with neurons dying within minutes of complete ischemia. The ischemic core is surrounded by a penumbra of potentially salvageable tissue where blood flow is reduced but above the threshold for cell death. Clinical presentation depends on the affected vascular territory. Treatment includes thrombolysis within the therapeutic window, endovascular thrombectomy, and secondary prevention with antiplatelet agents and risk factor modification.

Cholangiocarcinoma

– A malignant tumor arising from the biliary ep-

ithelium, classified based on anatomical location as intrahepatic, perihilar, or distal extrahepatic. Risk factors include primary sclerosing cholangitis, particularly in association with inflammatory bowel disease, parasitic liver fluke infections, hepatolithiasis, and congenital biliary anomalies including choledochal cysts. Intrahepatic cholangiocarcinoma presents as a liver mass with abdominal pain and weight loss. Perihilar (Klatskin) tumors are the most common type and present with obstructive jaundice. Distal extrahepatic tumors have the best resectability rate. Overall prognosis is poor, with five-year survival under 20 percent. Surgical resection with negative margins offers the only chance of cure; liver transplantation may be considered in selected cases.

Cholecystitis

– Inflammation of the gallbladder, most commonly caused by obstruction of the cystic duct by a gallstone, which occurs in approximately 95 percent of cases. The obstruction leads to bile stasis, increased intraluminal pressure, and ischemia of the gallbladder wall, which may progress to bacterial infection. Acute cholecystitis presents with right upper quadrant pain, fever, nausea, and vomiting, with physical findings including Murphy's sign, arrest of inspiration during palpation of the right upper quadrant. Ultrasound findings include gallbladder wall thickening, distension, pericholecystic fluid, and a positive sonographic Murphy sign. Treatment involves intravenous antibiotics and cholecystectomy, typically performed laparoscopically either early or delayed depending on clinical severity.

Chronic Granulomatous Disease

– A primary immunodeficiency disorder caused by defects in the NADPH oxidase enzyme complex of phagocytes, resulting in inability to generate the respiratory burst needed for intracellular killing of microorganisms. The disease is most commonly X-linked, caused by mutations in the CYBB gene encoding gp91phox, or autosomal recessive, involving mutations in other components of the NADPH oxidase complex. Without the respiratory burst, phagocytes can ingest but cannot effectively kill catalase-positive organisms, particularly *Staphylococcus aureus*, *Aspergillus* species, and gram-negative enteric bacteria. Patients present with

recurrent infections and granuloma formation in the lungs, skin, and lymph nodes. Management includes prophylactic antibiotics, antifungals, and interferon-gamma. hematopoietic stem cell transplantation may be curative.

Chronic Inflammation

– A prolonged inflammatory response characterized by simultaneous tissue destruction and attempts at repair, lasting weeks to years. Unlike acute inflammation, it is predominantly mononuclear, involving macrophages, lymphocytes, and plasma cells rather than neutrophils. The process is driven by persistent infections such as tuberculosis, autoimmune reactions as in rheumatoid arthritis, prolonged exposure to toxic agents including silica, or non-degradable foreign bodies. Chronic inflammation is characterized by mononuclear cell infiltration, tissue destruction, and fibrosis. Granuloma formation represents a specialized pattern seen in tuberculosis, sarcoidosis, and foreign body reactions. Chronic inflammation underlies many common diseases including rheumatoid arthritis and atherosclerosis.

Cirrhosis

– The end stage of chronic liver disease, characterized by diffuse fibrosis with distortion of the hepatic architecture and formation of regenerative nodules. The most common causes include chronic hepatitis C infection, alcoholic liver disease, non-alcoholic steatohepatitis, chronic hepatitis B infection, and autoimmune hepatitis. The pathogenesis involves repeated cycles of hepatocyte injury, inflammation, and repair, with activation of hepatic stellate cells that produce excessive extracellular matrix. The resulting fibrosis disrupts normal blood flow and hepatocyte function, causing portal hypertension and hepatic synthetic dysfunction. Clinical features include jaundice, ascites, variceal bleeding, hepatic encephalopathy, and coagulopathy. Cirrhosis is irreversible and increases the risk of hepatocellular carcinoma.

Coagulation Cascade

– The coagulation cascade is a series of enzymatic reactions leading to fibrin clot formation, involving serine protease activation cascades. The intrinsic pathway is initiated by contact activation when factor XII binds exposed collagen, sequentially activating factors XI, IX, and the cofactor

VIII. The extrinsic pathway is initiated when tissue factor released from damaged cells binds factor VII, forming the TF-VIIa complex that activates factor X. Both pathways converge at factor X activation, forming the prothrombinase complex that converts prothrombin to thrombin. Thrombin cleaves fibrinogen to fibrin, which polymerises to form a stable clot. The cascade is regulated by natural anticoagulants including antithrombin III, protein C, and protein S. Laboratory assessment uses prothrombin time and activated partial thromboplastin time.

Coagulative Necrosis

– The most common form of necrosis, typically resulting from ischemic injury or infarction in most solid organs except the brain. The fundamental process involves denaturation of both structural proteins and enzymatic proteins, which prevents the immediate liquefaction of the dead tissue. The affected tissue maintains its basic structural outline for several days, a phenomenon known as structural preservation that allows histological identification of the original organ architecture. Over time, the necrotic tissue is removed by phagocytes and replaced by granulation tissue, which matures into a fibrous scar. Coagulative necrosis is the typical pattern in myocardial infarction, renal infarction, and splenic infarction, where the organ outline is preserved histologically for days to weeks.

Colorectal Adenocarcinoma

– The third most common cancer worldwide and the second leading cause of cancer death, arising from the colonic epithelium through the adenoma-carcinoma sequence over 10 to 15 years. The pathogenesis involves sequential accumulation of genetic mutations beginning with APC loss, followed by KRAS activation, TP53 loss, and other alterations. Approximately 15 percent of cases are associated with hereditary syndromes including Lynch syndrome with mismatch repair gene mutations, and familial adenomatous polyposis with APC mutation. Sporadic cases account for the majority. Screening via colonoscopy with polypectomy reduces both incidence and mortality. Treatment includes surgical resection, chemotherapy, and targeted therapies including anti-EGFR and anti-VEGF agents based on tumor molecular profile.

Condition

– A general term for a state of bodily health or, in medical usage, a specific deviation from normal in structure or function that may or may not constitute a disease, including complaints lacking a discrete pathologic basis and overt diagnoses. It is used when a precise disease cannot yet be identified and distinguished from a sign, symptom, or syndrome.

Congestion

– A passive vascular phenomenon of engorgement of a tissue or organ with blood from impaired venous or lymphatic drainage. Chronic venous congestion produces stasis, hypoxia, dilated vessels, edema, hemorrhage, and hemosiderin-laden macrophages, exemplified by the lungs (heart failure cells) and liver (nutmeg liver). Causes include heart failure, portal hypertension, and venous obstruction; long-standing congestion progresses to fibrosis.

Cyanosis

– A bluish discoloration of the skin and mucous membranes resulting from excessive amounts of deoxygenated hemoglobin in the capillary blood. It becomes clinically apparent when the concentration of deoxygenated hemoglobin exceeds 5 grams per deciliter, which corresponds to an oxygen saturation of approximately 85 percent. Central cyanosis affects the entire body and results from arterial hypoxemia, as seen in congenital heart disease with right-to-left shunting, severe pulmonary disease, and severe pneumonia. Peripheral cyanosis affects the extremities and results from reduced blood flow with increased oxygen extraction, as seen in cold exposure, shock, and peripheral vascular disease. Differential cyanosis, affecting only the lower body, can indicate specific congenital heart defects such as patent ductus arteriosus with Eisenmenger syndrome.

Cyst

– An abnormal closed cavity or sac lined by epithelium, containing liquid, semisolid, or gaseous material, and distinguished from an abscess (which contains pus) and a pseudocyst (which lacks an epithelial lining). Cysts occur in virtually every organ and tissue and are classified by pathogenesis: retention cysts (from obstruction of a duct, e.g., sebaceous cyst, ovarian follicular cyst, breast cyst), developmental cysts (arising from embryonic remnants, e.g., branchial cleft cyst, thyroglossal duct

cyst, bronchogenic cyst), parasitic cysts (e.g., hydatid cyst from *Echinococcus*), and neoplastic cysts (e.g., cystic teratoma). Diagnosis is by imaging. Treatment depends on the type, size, location, and symptoms, ranging from observation to complete surgical excision.

Cytology

– The microscopic study of individual cells, distinct from histology in that tissue architecture is not examined, used for screening and diagnosis of neoplastic and infectious disease. Specimens are exfoliative (cervical smears, sputum) or aspirated (fine needle aspiration, body fluids), interpreted with Papanicolaou or special stains. Applications include the Papanicolaou test, sputum for lung cancer, and urine for urothelial carcinoma.

Cytopathology

– The branch of pathology using cytologic examination of cells to diagnose disease, particularly neoplastic and infectious processes, built on standardized reporting systems that guide management. Examples include the Bethesda System for thyroid fine needle aspiration and cervical cytology, and the Paris and Yokohama systems for urinary and pancreaticobiliary cytology. It overlaps with surgical pathology through immunocytochemistry and molecular testing.

Dysplasia

– Disordered cellular growth and maturation characterized by structural abnormalities within a tissue, representing a pre-neoplastic condition that may progress to invasive carcinoma. At the cellular level, dysplasia shows nuclear enlargement, hyperchromasia with clumped chromatin, irregular nuclear contours, increased nuclear-to-cytoplasmic ratio, and prominent nucleoli. Architecturally, there is loss of normal tissue organization, with cells failing to mature properly as they migrate from the basal layer to the surface. Dysplasia is graded as mild, moderate, or severe based on the extent of cytologic and architectural abnormalities. Severe dysplasia may progress to carcinoma in situ, where abnormal cells involve the full epithelial thickness but have not breached the basement membrane.

Dystrophic Calcification

– The deposition of calcium phosphate salts in damaged, necrotic, or degenerating tissues despite nor-

mal serum calcium levels. It occurs in areas of tissue injury, inflammation, or chronic degeneration where the local tissue environment favors calcium precipitation. The mechanism involves release of calcium-binding phospholipids and matrix vesicles from damaged cell membranes, which serve as nucleation sites for hydroxyapatite crystal formation. Common sites include atherosclerotic plaques, heart valves in degenerative aortic stenosis, and areas of previous trauma or infection. Dystrophic calcification can impair organ function, for example by restricting valve leaflet motion. It is distinct from metastatic calcification, which occurs in normal tissues in the setting of hypercalcaemia.

Ecchymosis

– An ecchymosis is a flat, purple or blue discoloration of the skin larger than 10 millimeters caused by extravasation of blood from damaged blood vessels into the subcutaneous tissue. Unlike petechiae, which result from platelet disorders, ecchymoses may result from coagulopathies, trauma, or vascular fragility. They are commonly seen in the elderly due to skin thinning and increased vascular fragility, as well as in patients taking anticoagulant or antiplatelet medications. The color of an ecchymosis evolves through characteristic changes over days to weeks: initially red-purple from deoxygenated hemoglobin, then blue-black, green from biliverdin, and finally yellow-brown from haemosiderin before complete resolution. The color progression helps estimate the age of the bruise.

Edema

– The accumulation of excess fluid in the interstitial tissue spaces, resulting from disturbances in Starling forces, increased vascular permeability, or impaired lymphatic drainage. Transudates form when hydrostatic pressure increases or oncotic pressure decreases, producing fluid with low protein content and few inflammatory cells. Common causes of transudative edema include congestive heart failure, liver cirrhosis with hypoalbuminemia, and nephrotic syndrome. Exudates form when vascular permeability increases, producing fluid with high protein content and inflammatory cells, as seen in inflammation, infection, and malignancy. Lymphoedema results from impaired lymphatic drainage, commonly after lymphatic obstruction from surgery, radiation, or

filariasis. edema impairs tissue perfusion, delays wound healing, and increases infection risk.

Embolism

– An embolism is the occlusion of a blood vessel by a detached mass that has traveled through the bloodstream from its site of origin. The most common form is thromboembolism, where a fragment of a thrombus dislodges and travels to a distant site through the venous or arterial circulation. Other types of emboli include fat emboli from bone fractures, amniotic fluid emboli during pregnancy, air emboli from trauma or surgery, tumor emboli from malignancy, foreign body emboli from injected materials, and cholesterol emboli from atherosclerotic plaque rupture. Clinical consequences depend on the size, composition, and location of the embolus. Pulmonary embolism is the most common life-threatening form. Treatment includes anticoagulation, thrombolysis, or embolectomy in selected cases.

Exudate

– An exudate is an inflammatory fluid with high protein content and abundant cells, resulting from increased vascular permeability during inflammation. Exudates are typically caused by bacterial infections, autoimmune diseases, viral infections, or malignancy. The fluid is often cloudy or turbid due to the presence of inflammatory cells, particularly neutrophils in bacterial infections. Exudates have high specific gravity above 1.020 and contain more than 300 cells per microliter. They are rich in fibrin and inflammatory mediators and are distinguished from transudates by Light's criteria: pleural fluid protein-to-serum protein ratio greater than 0.5, pleural fluid LDH-to-serum LDH ratio greater than 0.6, or pleural fluid LDH greater than two-thirds the upper limit of normal for serum.

Fat Embolism

– Fat embolism occurs when fat globules enter the bloodstream, typically following long bone fractures, orthopedic surgery, or severe trauma involving adipose tissue. The fat emboli travel through the venous circulation to the lungs, where they cause mechanical obstruction of pulmonary capillaries and chemical inflammation as lipases break down neutral fat into toxic free fatty acids. The pulmonary manifestations range from mild hypoxia to acute

respiratory distress syndrome with severe hypoxemia and acute respiratory distress syndrome. Systemic embolisation causes petechial rash, neurological symptoms including confusion and focal deficits, and retinal changes. Diagnosis is clinical, supported by imaging. Treatment is supportive with oxygenation, ventilation, and hemodynamic support.

Fat Necrosis

– A specialized form of necrosis that occurs in adipose tissue, most commonly following acute pancreatitis when activated pancreatic lipases escape into the surrounding tissues and digest triglycerides in mesenteric or subcutaneous fat cells. The released fatty acids combine with calcium ions to form chalky-white deposits known as soap-stone lesions or saponification, which are visible on gross examination as firm, white, opaque areas. Histologically, fat necrosis shows shadowy outlines of necrotic adipocytes with basophilic calcium deposits. Over time, the necrotic fat is replaced by fibrosis and chronic inflammation. In the breast, fat necrosis can mimic carcinoma clinically and radiographically, often requiring biopsy for definitive diagnosis.

Fever

– An elevation of body temperature above the normal daily variation, typically defined as a core temperature exceeding 38 degrees Celsius or 100.4 degrees Fahrenheit. It results from resetting of the hypothalamic thermoregulatory set point upward, mediated by pyrogenic substances. Exogenous pyrogens include microbial products such as lipopolysaccharide, which stimulate immune cells to produce endogenous pyrogens. The major endogenous pyrogens are IL-1, IL-6, TNF, and interferon, which act on the hypothalamus to increase the thermoregulatory set point via prostaglandin E2 synthesis. Fever enhances immune function by increasing neutrophil and T-cell activity and inhibiting pathogen growth. Antipyretic treatment is reserved for patients with significant discomfort or underlying cardiovascular or neurological disease.

Fibrinoid Necrosis

– A specialized pattern of vascular necrosis characterized by the deposition of immune complexes, fibrin, and plasma proteins within the walls of blood vessels, creating an amorphous, bright pink, smudgy eosinophilic appearance on hematoxylin and eosin

staining. This pattern is characteristic of immune-mediated vascular injury, occurring in several important clinical conditions. In malignant hypertension, severely elevated blood pressure above 200/120 millimeters of mercury causes direct arterial wall damage, with plasma proteins leaking into the damaged vessel wall. In polyarteritis nodosa, immune complex deposition in small and medium arteries triggers fibrinoid necrosis. In systemic lupus erythematosus, similar immune complex-mediated vascular damage occurs. Affected vessels may thrombose, leading to tissue ischemia or rupture.

Fibrinous Pericarditis

– Inflammation of the pericardium characterized by deposition of fibrin on the pericardial surfaces, giving them a rough, shaggy appearance described as bread-and-butter pericarditis. It is the most common form of acute pericarditis, typically occurring after myocardial infarction, uremia, systemic lupus erythematosus, radiation therapy, or post-cardiac surgery syndrome. The fibrinous exudate consists of fibrin strands deposited on the visceral and parietal pericardial surfaces. The fibrin may organize into fibrous adhesions if the underlying process persists, potentially obliterating the pericardial space and causing constrictive pericarditis. Clinical presentation includes sharp retrosternal chest pain that improves with sitting forward, pericardial friction rub on auscultation, and diffuse ST-segment elevation on ECG.

Fibroadenoma

– The most common benign tumor of the female breast, a proliferation of stromal and epithelial elements presenting as a firm, rubbery, smooth, mobile, painless mass, most often in women aged fifteen to thirty. The mass slips easily under the fingers (breast mouse), and ultrasonography shows a well-defined oval hypoechoic lesion. Histologically it comprises fibrous stroma with benign epithelial-lined ducts.

Fibrosis

– The excessive deposition of extracellular matrix components, primarily collagen types I and III, in response to chronic tissue injury. It represents a pathological wound healing response that leads to organ scarring and dysfunction. The process is driven by activated fibroblasts and myofibroblasts,

which are stimulated by growth factors including TGF-beta, PDGF, and CTGF produced by inflammatory cells and injured epithelium. Fibrosis can occur in any organ, but is particularly problematic in the liver (cirrhosis), lungs (pulmonary fibrosis), heart (myocardial fibrosis), and kidneys (renal fibrosis). Unlike normal wound healing, fibrosis involves excessive extracellular matrix that distorts tissue architecture and impairs organ function. Fibrosis is often progressive and currently lacks effective treatments beyond addressing the underlying cause.

Fine Needle Aspiration (FNA)

– A percutaneous sampling technique in which a 22 to 25-gauge needle, often ultrasound- or palpation-guided, aspirates cellular material from a palpable or imaging-detected lesion for cytologic examination, with minimal trauma and lower morbidity than core or open biopsy. Widely used for thyroid nodules, breast lumps, lymph nodes, salivary glands, and soft tissue lesions; rapid on-site evaluation improves adequacy.

Fistula

– A fistula is an abnormal epithelial-lined connection between two body surfaces or organs that normally do not communicate. Fistulas may be congenital, such as tracheoesophageal fistula, or acquired, resulting from inflammation, infection, surgery, trauma, or malignancy. Common acquired types include enterocutaneous fistulas between the intestine and skin, seen after surgery or in Crohn's disease; perianal fistulas following anorectal abscesses; and arteriovenous fistulas between arteries and veins from traumatic injury or congenital malformations. Fistulas may cause continuous leakage of contents, infection, electrolyte disturbances, and malnutrition. Diagnosis involves imaging including fistulography, CT, or MRI. Treatment depends on the site and cause, ranging from medical therapy to surgical closure.

FNA

– See Fine Needle Aspiration (FNA).

Free Radical Injury

– Free radicals are highly reactive molecules with unpaired electrons that can damage cellular components through oxidative stress. Reactive oxygen species include the superoxide anion, hydrogen peroxide, and the hydroxyl radical generated through

the Fenton reaction. Sources include normal mitochondrial oxidative metabolism, the NADPH oxidase respiratory burst in neutrophils, cytochrome P450 reactions, and external sources including ionizing radiation and ultraviolet light. Free radical damage to lipids initiates lipid peroxidation of polyunsaturated fatty acids in cell membranes, disrupting membrane integrity and function. Protein damage causes enzyme inactivation and receptor dysfunction. DNA damage leads to strand breaks and base modifications. Antioxidant defences include superoxide dismutase, catalase, glutathione peroxidase, and vitamins C and E.

Frozen Section

- An intraoperative pathology consultation in which a fresh tissue specimen is rapidly frozen, sectioned on a cryostat, and stained with hematoxylin and eosin within 10 to 20 minutes to guide immediate surgical decision-making. It is used to establish benign versus malignant, assess margins, and identify lymph node metastases. Freezing artifacts make it less accurate than permanent paraffin histology.

Gangrene

- Death of tissue due to loss of blood supply, typically affecting the extremities and bowel, and represents a form of coagulative necrosis. Dry gangrene occurs in tissues with gradual arterial occlusion, where the dead tissue becomes dry, shrunken, and dark brown or black. It is commonly seen in the toes and feet of patients with diabetes mellitus and peripheral arterial disease. The black color results from hemoglobin degradation and iron sulfide deposition in the necrotic tissue. A clear line of demarcation typically separates viable from non-viable tissue. Wet gangrene results from bacterial superinfection of ischemic tissue, producing a swollen, foul-smelling, liquefied mass with systemic toxicity and a less distinct line of demarcation. Gas gangrene is a specific form caused by *Clostridium* species, particularly *C. perfringens*, producing gas within tissues and representing a surgical emergency requiring urgent debridement and antibiotics.

Gas Gangrene

- A life-threatening bacterial infection characterized by the presence of gas in tissues (subcutaneous emphysema) and rapid myonecrosis. Caused by *Clostridium perfringens* (type A, 80% of cases),

C. novyi, *C. septicum*, and *C. histolyticum*—Gram-positive, spore-forming, obligate anaerobic bacilli that produce exotoxins (alpha-toxin: phospholipase C, destroys cell membranes; theta-toxin: cytotoxin; collagenase, hyaluronidase, DNase). Predisposing factors: contaminated wounds (soil, foreign bodies), trauma (crush injuries, deep lacerations), devascularised tissue, immunosuppression, and abdominal surgery. Incubation period: 6 hours to 6 days. Clinical features: sudden onset of severe pain at wound site, discoloured (bronze or purplish) skin, bullae filled with serosanguinous fluid, crepitus (gas in tissue, palpable), foul-smelling discharge, tachycardia (out of proportion to fever), hypotension, renal failure, hemolytic anemia, sepsis, and rapidly progressive necrosis. Diagnosis: clinical (crepitus, gas on X-ray/CT, Gram stain of exudate showing Gram-positive rods with absent white cells), culture, and PCR. Treatment: emergent surgical debridement (fasciotomy and excision of all necrotic tissue, often requiring amputation), high-dose intravenous penicillin G plus clindamycin (metronidazole as alternative), hyperbaric oxygen therapy (adjunctive, suppresses toxin production by raising tissue oxygen tension). Mortality: 20-30% overall, >50% with trunk involvement or delay in treatment.

Glomerulonephritis

- An inflammatory disease of the glomeruli, typically immune-mediated. Classification by clinical presentation: nephritic syndrome (acute onset: haematuria, red cell casts, hypertension, oliguria, edema) vs nephrotic syndrome (insidious: heavy proteinuria >3.5 g/day, hypoalbuminaemia, hyperlipidaemia, generalised edema). Classification by histology (light microscopy, immunofluorescence, electron microscopy): (1) IgA nephropathy (Berger disease): most common worldwide, mesangial IgA deposits, post-infectious triggers, variable progression. (2) Post-streptococcal GN: immune complex deposition after group A streptococcal infection, subepithelial hump-like deposits. (3) Membranous GN: subepithelial IgG deposits, PLA2R antibodies, 80% cause of nephrotic syndrome in adults. (4) Minimal change disease: podocyte foot process effacement on EM, most common nephrotic syndrome in children. (5) Focal segmental glomerulosclerosis (FSGS): scarring of some glomeruli, progressive to ESRD. (6)

Membranoproliferative GN (MPGN): mesangial proliferation and basement membrane thickening. (7) Rapidly progressive GN (RPGN/crescentic GN): crescents in Bowman's space, medical emergency. (8) Lupus nephritis: immune complex deposits in SLE, WHO/ISN-RPS classification (I-VI).

Granuloma

– A granuloma is an organized collection of macrophages, often modified into epithelioid cells, typically surrounded by a cuff of lymphocytes and occasionally by fibroblasts and multinucleated giant cells. Granulomas represent a distinctive pattern of chronic inflammation that forms in response to persistent stimuli that resist elimination by ordinary phagocytosis and acute inflammation. The two main types are caseating granulomas, which have a central area of necrosis resembling cheese on gross examination (tuberculoma), and non-caseating granulomas, which lack central necrosis and are characteristic of sarcoidosis, Crohn's disease, and foreign body reactions. Granuloma formation requires T-cell mediated immunity, with interferon-gamma playing a central role in macrophage activation and epithelioid transformation.

Granulomatous Inflammation

– A distinctive pattern of chronic inflammation characterized by organized collections of activated macrophages that have undergone morphological transformation into epithelioid cells, often surrounded by a rim of lymphocytes and occasionally fibroblasts. Epithelioid cells have abundant eosinophilic cytoplasm and cell borders that blend together, resembling epithelial cells. Multinucleated giant cells, formed by fusion of macrophages under the influence of cytokines including interferon-gamma, form around persistent stimuli such as *Mycobacterium tuberculosis*, fungi, foreign bodies, and in sarcoidosis. The granuloma walls off the inciting agent and contains the infection, but the inflammatory response also causes tissue destruction and fibrosis in surrounding tissues.

Gross Examination

– The macroscopic, naked-eye inspection of a specimen in the pathology laboratory, performed before microscopic sectioning and the essential first step in pathologic diagnosis of resected tissues and organs. It records the specimen's origin, dimensions, weight,

color, shape, and lesion characteristics, and determines how it is sampled for histology. Accurate gross description underpins microscopic interpretation, staging, and margin assessment.

Hemorrhage

– Extravasation of blood from the cardiovascular system (heart, arteries, veins, capillaries). Classification by severity: class 1 (<15% blood loss, compensated, minimal symptoms), class 2 (15-30%, mild tachycardia, decreased pulse pressure), class 3 (30-40%, significant tachycardia, hypotension, pallor, oliguria, altered mental status—decompensated), class 4 (>40%, severe hypotension, anuria, loss of consciousness—immediately life-threatening). Classification by location: external (visible from wound, or body orifice—epistaxis, haemoptysis, haematemesis, melaena, haematuria, vaginal) vs internal (concealed, into body cavities—intracranial, intrathoracic/ haemothorax, intra-abdominal/ haemoperitoneum, retroperitoneal, haemarthrosis, muscle haematoma). Causes: trauma (most common cause of preventable death from exsanguination), ruptured aneurysm (AAA, cerebral berry aneurysm, splenic artery), gastrointestinal bleeding (peptic ulcer, varices, diverticulosis, angiodysplasia, cancer), obstetric hemorrhage (postpartum hemorrhage—atomic uterus, placental abruption, placenta praevia), surgery, anticoagulation, coagulopathy (hemophilia, DIC, vitamin K deficiency). Management: ABC (airway, breathing, circulation), direct pressure for external bleeding, IV access (two large-bore cannulae), fluid resuscitation (crystalloids, blood products—massive transfusion protocol: 1:1:1 ratio of PRBCs:FFP:platelets), pressure control (tourniquet for life-threatening extremity hemorrhage, pelvic binder for pelvic fracture), reversal of anticoagulation (vitamin K, fresh frozen plasma, PCC—prothrombin complex concentrate, protamine for heparin, tranexamic acid), damage control surgery (abbreviated laparotomy, packing to control hemorrhage, angioembolisation, endovascular stenting).

Hemosiderin

– A golden-brown, granular, iron-containing pigment derived from the degradation of hemoglobin and stored within macrophages as an insoluble complex. It forms when red blood cells are phagocytosed and

degraded, typically in conditions of hemorrhage, hemolysis, or excessive red blood cell destruction. The iron from hemoglobin is initially stored as soluble ferritin, but under conditions of iron overload, ferritin aggregates to form hemosiderin, which is more insoluble and visible on routine haematoxylin and eosin sections. The Prussian blue stain specifically identifies iron in hemosiderin deposits. Common sites include the lungs in chronic left heart failure (heart failure cells), the spleen and liver in chronic hemolytic anemia, and at sites of old hemorrhage.

Histology

– The microscopic study of the structure of tissues and cells. Histology involves preparing thin tissue sections (3-10 micrometres) by fixation (formalin, paraffin embedding), sectioning (microtome), staining (haematoxylin and eosin, H&E), and examination under a light or electron microscope. Basic tissue types: (1) Epithelium: lining of surfaces and cavities, glandular tissue; classified by cell shape (squamous, cuboidal, columnar) and layering (simple, stratified, pseudostratified). (2) Connective tissue: supports and connects other tissues; includes bone, cartilage, adipose, blood, and loose/dense connective tissue; consists of cells (fibroblasts, osteocytes, chondrocytes, adipocytes, macrophages, mast cells) embedded in extracellular matrix (collagen, elastin, proteoglycans). (3) Muscle tissue: skeletal (striated, voluntary), cardiac (striated, involuntary, intercalated discs), smooth (non-striated, involuntary). (4) Nervous tissue: neurons (conduct electrical impulses) and glial cells (support, myelinate, nourish, defend). Special stains: Masson trichrome (collagen), periodic acid-Schiff (PAS, glycogen/mucin), silver stains (reticulin, nerve fibers), immunohistochemistry (antigen detection using labelled antibodies). Histopathology is the histological diagnosis of disease (cancer grading/staging, identification of inflammatory or infectious processes).

Histopathology

– The laboratory-based diagnosis of disease through microscopic examination of tissue sections from biopsy, excision, or autopsy, built on fixation, paraffin embedding, sectioning, and hematoxylin and eosin staining. Interpretation integrates architecture with morphology to identify inflammatory, in-

fectious, metabolic, degenerative, and neoplastic processes and to assign tumor type, grade, and stage. Adjuncts include special stains, immunohistochemistry, and molecular assays.

Huntington's Disease

– An autosomal dominant neurodegenerative disorder caused by a CAG trinucleotide repeat expansion in the huntingtin gene on chromosome 4p16.3. The disease is characterized by the triad of progressive chorea, cognitive decline, and psychiatric manifestations. The pathogenesis involves accumulation of mutant huntingtin protein with expanded polyglutamine tract in neurons, particularly in the caudate nucleus and putamen, leading to transcriptional dysregulation, mitochondrial dysfunction, excitotoxicity, and oxidative stress. The disease typically manifests in mid-adulthood with progressive chorea, cognitive decline, and psychiatric symptoms. The number of CAG repeats correlates inversely with age of onset. There is no cure; treatment is supportive and symptom-focused, with tetrabenazine for chorea.

Hyperaldosteronism

– Hyperaldosteronism, also known as Conn syndrome when caused by an adrenal adenoma, is characterized by excessive aldosterone production causing hypertension, hypokalemia, and metabolic alkalosis. Primary hyperaldosteronism results from autonomous aldosterone production by the adrenal gland, most commonly from a unilateral aldosterone-producing adenoma or bilateral adrenal hyperplasia. The excessive aldosterone acts on the distal nephron, promoting sodium reabsorption and potassium and hydrogen ion secretion, leading to hypokalaemia and metabolic alkalosis. Hypertension results from sodium and water retention. Diagnosis involves measuring the plasma aldosterone-to-renin ratio, followed by confirmatory suppression testing. Treatment includes surgical resection for adenomas and mineralocorticoid receptor antagonists for bilateral hyperplasia.

Hypersensitivity Type I

– Type I hypersensitivity, also known as immediate hypersensitivity or allergic reactions, is mediated by IgE antibodies and mast cells, producing symptoms within minutes of allergen re-exposure. During sensitization, initial allergen exposure activates Th2

cells that secrete IL-4 and IL-13, promoting B cell class switching to IgE production. IgE antibodies bind with high affinity to Fc epsilon RI receptors on mast cells and basophils, priming these cells for re-exposure. Upon subsequent allergen exposure, IgE cross-linking on mast cells triggers degranulation, releasing histamine, tryptase, leukotrienes, and prostaglandins that cause vasodilation, bronchoconstriction, and increased vascular permeability. Clinical manifestations range from mild allergic rhinitis and urticaria to life-threatening anaphylaxis. Treatment includes antihistamines, corticosteroids, and epinephrine.

Hypersensitivity Type II

– Type II hypersensitivity, also known as cytotoxic hypersensitivity, is mediated by IgG or IgM antibodies directed against antigens on cell surfaces or the extracellular matrix, causing tissue damage through complement activation, antibody-dependent cellular cytotoxicity, and phagocytosis. When antibodies bind to cell-surface antigens, the classical complement pathway is activated, generating C3b for opsonization and the membrane attack complex for direct cell lysis. Antibody-coated cells are also killed by NK cells through antibody-dependent cellular cytotoxicity. Clinical examples include autoimmune hemolytic anemia, Goodpasture syndrome, myasthenia gravis, and immune thrombocytopenia. In drug-induced hemolytic anemia, drugs such as penicillin act as haptens, binding to red cell surfaces and triggering antibody-mediated destruction.

Hypersensitivity Type III

– Type III hypersensitivity is caused by deposition of antigen-antibody immune complexes in tissues and blood vessel walls, activating complement and recruiting neutrophils that release destructive enzymes and reactive oxygen species. This reaction occurs when there is a slight excess of antigen relative to antibody, forming small, soluble immune complexes that are not efficiently cleared by the reticuloendothelial system. The complexes deposit in vessel walls, particularly in the kidneys, joints, and skin, causing vasculitis, arthritis, and glomerulonephritis. Clinical examples include systemic lupus erythematosus (DNA-anti-DNA complexes), post-streptococcal glomerulonephritis, serum sickness, and the Arthus reaction. Chronic immune

complex deposition leads to persistent inflammation and progressive tissue damage.

Hypersensitivity Type IV

– Type IV hypersensitivity, also known as delayed-type hypersensitivity, is mediated by T lymphocytes rather than antibodies and takes 48 to 72 hours to develop after antigen exposure. The reaction involves sensitized CD4 Th1 cells that, upon re-exposure to the antigen presented by dendritic cells or macrophages, release pro-inflammatory cytokines including interferon-gamma and TNF, which activate macrophages and cause tissue damage. Contact dermatitis is the most common clinical example, occurring after contact with poison ivy, nickel, and other sensitizing chemicals. The tuberculin reaction (PPD test) is another classic example. Type IV hypersensitivity is also involved in allograft rejection and many autoimmune diseases. It is characterized by a delayed onset of 24 to 72 hours.

Hypovolemic Shock

– A life-threatening condition resulting from inadequate circulating blood volume, leading to decreased venous return, reduced cardiac output, and tissue hypoperfusion. The most common causes are hemorrhage from trauma, gastrointestinal bleeding, or ruptured aortic aneurysm, and severe dehydration from vomiting, diarrhea, burns, or third-space fluid sequestration. The pathophysiology involves activation of the sympathetic nervous system, causing tachycardia, peripheral vasoconstriction, and increased heart rate to maintain blood pressure and vital organ perfusion. As shock progresses, compensatory mechanisms fail, leading to hypotension, oliguria, altered mental status, and metabolic acidosis. Treatment involves rapid volume resuscitation with crystalloids and blood products, control of bleeding, and treatment of the underlying cause.

Increased Vascular Permeability

– A fundamental feature of acute inflammation that allows plasma proteins, fluid, and leukocytes to exit the vascular space and enter the extravascular tissue. The most common mechanism involves endothelial cell contraction caused by histamine, leukotrienes C4 and D4, and complement components C3a and C5a, creating intercellular gaps between endothelial cells that permit passage of protein-rich fluid. This response occurs predominantly in postcapillary

venules and is immediate but short-lived, lasting 15 to 30 minutes. Other mechanisms include direct endothelial damage (burns, radiation, toxins) causing immediate and prolonged leakage, leukocyte-mediated damage via toxic oxygen species, and increased transcytosis through vesicular transport.

Inflammatory Myopathies

– A group of autoimmune disorders characterized by chronic muscle inflammation and progressive proximal muscle weakness. The three main types are dermatomyositis, polymyositis, and inclusion body myositis. Dermatomyositis is characterized by perifascicular atrophy of muscle fibers, perivascular inflammation, and characteristic skin findings including heliotrope rash on the eyelids, Gottron papules over the knuckles, and mechanic hands. It is associated with complement-mediated microangiopathy with membrane attack complex deposition in endomysial capillaries. Polymyositis shows endomysial inflammation with CD8 T cells invading non-necrotic muscle fibers. Inclusion body myositis, the most common type in patients over 50, features rimmed vacuoles and protein aggregates. Diagnosis involves EMG, muscle biopsy, and elevated creatine kinase.

Inspection

– The first step of the physical examination, involving systematic visual observation of the patient's overall appearance, posture, body habitus, gait, skin color, nutritional status, respiratory effort, and specific anatomical regions. Requires adequate lighting and proper patient exposure. Provides immediate diagnostic clues prior to palpation, percussion, or auscultation.

Interstitial Nephritis

– Inflammation of the renal interstitium and tubules, which can be acute or chronic. Acute interstitial nephritis is most commonly caused by medications, particularly NSAIDs, antibiotics including penicillins and cephalosporins, and proton pump inhibitors. The pathogenesis involves immune-mediated hypersensitivity reaction to the offending drug, with T-cell and eosinophil infiltration of the renal interstitium. Clinical features include acute kidney injury occurring days to weeks after starting the offending medication, with fever, rash, eosinophilia, and sterile pyuria. Renal biopsy shows

interstitial inflammation with eosinophils. Treatment involves discontinuation of the causative drug and corticosteroids in severe cases. Most patients recover renal function fully.

Ischemia-Reperfusion Injury

– The paradoxical tissue damage that occurs when blood flow is restored to previously ischemic tissue, a phenomenon with major clinical significance in myocardial infarction treatment, stroke management, organ transplantation, and shock resuscitation. During ischemia, ATP depletion causes failure of the sodium-potassium pump leading to cellular swelling, calcium accumulation, activation of phospholipases and proteases, and anaerobic metabolism with lactic acid accumulation. Upon reperfusion, the sudden reintroduction of oxygen triggers a burst of reactive oxygen species from mitochondria and neutrophils, causing lipid peroxidation, protein damage, and DNA injury. Inflammatory mediators are released, recruiting more neutrophils and amplifying the damage. Therapeutic strategies focus on minimising this injury through controlled reperfusion.

Lesion

– A general term for any abnormal change in tissue structure due to disease or injury. Lesions can occur in any organ or tissue and can be classified by: (1) morphology: macule, papule, plaque, nodule, vesicle, bulla, pustule, ulcer, erosion, fissure, tumor; (2) location: skin, organ-specific, or systemic; (3) etiology: traumatic, infectious, inflammatory, neoplastic (benign or malignant), degenerative, congenital, vascular, metabolic; (4) imaging characteristics: radiolucent, radiopaque, contrast-enhancing, cystic, solid. A lesion is a descriptive finding, not a diagnosis; further characterisation (biopsy, imaging) is needed to determine the specific pathology.

Lipofuscin

– A yellow-brown granular pigment composed of oxidized lipids and cross-linked proteins that accumulates progressively within cells with age, particularly in post-mitotic cells such as neurons, cardiac myocytes, and hepatocytes. It represents the residues of lysosomal digestion of autophagocytosed organelles and damaged cellular components that cannot be further degraded or exocytosed. Lipofuscin accumulation is a hallmark of cellular aging and is found in increased amounts in tissues with

high oxidative stress. It is often called the 'wear and tear' pigment of ageing. Lipofuscin granules are autofluorescent and stain with periodic acid-Schiff and Sudan black. Its accumulation does not directly harm cells but serves as a marker of cumulative oxidative damage and cellular senescence.

Liquefactive Necrosis

– Characterized by the complete enzymatic digestion of dead cells, resulting in a liquid, viscous mass that eventually liquefies and forms a cystic cavity. This form of necrosis occurs most commonly in focal bacterial or fungal infections, where the inflammatory response releases abundant hydrolytic enzymes from neutrophils and macrophages that digest both dead and viable tissue. In the central nervous system, liquefactive necrosis follows ischemic stroke because the brain has abundant hydrolytic enzymes and limited connective tissue, so necrotic tissue liquefies rapidly, forming a cystic cavity. In bacterial infections, accumulated neutrophils release proteolytic enzymes that digest dead tissue, producing pus. The resulting cavity may persist as a cyst or be replaced by fibrous tissue during healing.

Liver Failure

– A life-threatening condition resulting from severe impairment of hepatic synthetic, metabolic, and detoxification functions. Acute liver failure occurs in previously healthy individuals, most commonly from acetaminophen toxicity accounting for approximately 50 percent of cases in the United States, viral hepatitis, drug-induced liver injury, or autoimmune hepatitis. The pathogenesis involves massive hepatocyte necrosis leading to loss of synthetic function with coagulopathy, impaired bilirubin clearance with jaundice, and hepatic encephalopathy from failure to detoxify ammonia and other neurotoxins. Chronic liver failure develops more slowly on a background of cirrhosis, with portal hypertension and synthetic dysfunction. Liver transplantation is the definitive treatment for end-stage liver disease.

Lupus Erythematosus

– Systemic lupus erythematosus is a chronic autoimmune disease characterized by production of autoantibodies against nuclear antigens, leading to immune complex-mediated inflammation and tissue damage in multiple organ systems. The disease predominantly affects women of childbearing age,

with a striking female predominance of 9 to 1. The pathogenesis involves loss of self-tolerance to nuclear antigens, with formation of immune complexes that deposit in tissues and activate complement, causing inflammation in the kidneys, skin, joints, and serosal surfaces. The malar butterfly rash is characteristic. Key laboratory findings include positive ANA, anti-dsDNA, and anti-Smith antibodies. Disease flares and remissions are typical. Treatment includes NSAIDs, corticosteroids, hydroxychloroquine, and immunosuppressive agents for severe organ involvement.

Malignant Neoplasm

– Malignant neoplasms, commonly called cancers, are uncontrolled proliferations of cells that invade surrounding tissues and have the capacity to metastasize to distant sites through lymphatic, hematogenous, or transcoelomic routes. They exhibit infiltrative growth, penetrating basement membranes and spreading along tissue planes, nerve sheaths, and vascular structures. Malignant cells show varying degrees of anaplasia, increased and often atypical mitotic activity, and loss of normal tissue architecture capable of invasion and metastasis. Malignant tumors grow rapidly, have poorly defined margins, and can recur after resection. They cause morbidity through local tissue destruction, obstruction, hemorrhage, and systemic effects including cachexia, paraneoplastic syndromes, and metastatic spread.

Mediators of Inflammation

– Inflammatory mediators are soluble molecules that initiate, amplify, or regulate the inflammatory response. They include lipid mediators derived from arachidonic acid such as prostaglandins and leukotrienes, vasoactive amines like histamine and serotonin, cytokines including TNF, IL-1, and IL-6, chemokines that direct leukocyte migration, complement components, and kinins like bradykinin. These mediators are produced by activated macrophages, mast cells, endothelial cells, and platelets. Many mediators have multiple overlapping functions and are tightly regulated to prevent excessive tissue damage. Understanding their roles has enabled targeted therapies including NSAIDs (inhibiting prostaglandins), leukotriene inhibitors, and biologic agents blocking TNF-alpha, IL-1, and IL-6 in chronic inflammatory diseases such as rheumatoid arthritis and inflamma-

tory bowel disease.

Metaplasia

– A reversible adaptive change in which one differentiated adult cell type is replaced by another, representing the body's attempt to better withstand a chronic stress or irritation. The process involves reprogramming of tissue stem cells to differentiate along a different lineage that is more resilient to the new environment. The most common example is squamous metaplasia in the respiratory tract of chronic smokers, where the normal ciliated pseudostratified columnar epithelium is replaced by non-ciliated stratified squamous epithelium that is more resistant to smoke damage. Another key example is Barrett's esophagus, where the normal squamous epithelium of the lower esophagus is replaced by intestinal-type columnar epithelium due to chronic gastro-esophageal reflux, increasing the risk of esophageal adenocarcinoma.

Metastatic Calcification

– The deposition of calcium salts in otherwise normal tissues due to systemic hypercalcemia, where elevated serum calcium levels exceed the tissue ability to maintain calcium homeostasis. Causes include hyperparathyroidism with excess PTH causing bone resorption, vitamin D intoxication increasing intestinal calcium absorption, milk-alkali syndrome, bone destruction from malignancy or Paget's disease, sarcoidosis through extrarenal production of 1,25-dihydroxyvitamin D, and renal failure with phosphate retention. Metastatic calcification primarily affects tissues that excrete acid or generate alkaline environments, including the gastric mucosa, kidneys, lungs, and blood vessels. The deposits are intracellular and extracellular and may impair organ function over time.

Microscopic Examination

– The pathologic evaluation of tissue or cells under the light or electron microscope, complementing the gross examination to form the complete morphologic diagnosis. Routine light microscopy uses hematoxylin and eosin sections to assess architecture, cellular morphology, mitotic activity, and relation to margins. Special stains (periodic acid-Schiff, Masson trichrome, reticulin, Grocott methenamine silver) highlight specific components; immunohistochemistry adds further detail.

Mural Thrombus

– A mural thrombus is a blood clot that forms on the wall of a heart chamber or large blood vessel, typically in areas of damaged endothelium, stasis, or turbulent flow. In the heart, mural thrombi commonly form in the left ventricle following myocardial infarction, where the akinetic or dyskinetic segment promotes stasis of blood, or in the left atrium in patients with atrial fibrillation or mitral stenosis where blood stasis favors clot formation. The thrombus is attached to the wall by a broad base. In large vessels, mural thrombi form over atherosclerotic plaques or aneurysms. They can embolise to distant sites, causing infarction. Treatment includes anticoagulation to prevent propagation and embolisation. Over time, mural thrombi may organize via fibroblast ingrowth and become incorporated into the vessel wall or recanalise.

Myocardial Infarction

– The irreversible necrosis of myocardial tissue resulting from prolonged ischemia, most commonly due to atherosclerotic plaque rupture with superimposed thrombosis in a coronary artery. The process begins with platelet adhesion to the disrupted plaque, followed by activation of the coagulation cascade and formation of an occlusive thrombus. The resulting complete cessation of blood flow causes coagulative necrosis of the supplied myocardium within 20 to 40 minutes. The infarct evolves through stages: coagulation necrosis in the first 24 hours, neutrophil infiltration at days 1 to 3, granulation tissue formation at days 7 to 14, and eventual fibrous scar formation over 4 to 6 weeks. Diagnosis relies on ECG changes, elevated cardiac troponin, and imaging. Treatment includes reperfusion, antiplatelet therapy, and risk factor modification.

Necroptosis

– A regulated, programmed form of necrosis that shares features of both classical necrosis and apoptosis, serving as a backup cell death mechanism when apoptosis is inhibited. It is particularly important during viral infections, as many viruses encode proteins that block caspase-mediated apoptosis to ensure their own replication. The process is mediated by receptor-interacting protein kinase 1 and 3, known as RIPK1 and RIPK3, which form a complex called the necrosome. When TNF binds

its receptor, RIPK1 and RIPK3 are recruited and activated. RIPK3 phosphorylates MLKL, which oligomerises and inserts into the plasma membrane, forming pores that cause cell swelling and membrane rupture, releasing damage-associated molecular patterns that trigger inflammation. Necroptosis is implicated in ischemia-reperfusion injury and neurodegenerative diseases.

Necrosis

– A pathological, unregulated form of cell death resulting from severe, irreversible injury that invariably provokes an intense inflammatory response. Unlike apoptosis, necrosis occurs when cells are exposed to extreme stresses such as profound hypoxia, toxins, trauma, burns, or extreme temperatures that overwhelm cellular repair mechanisms. The hallmark features include cellular swelling due to failure of the sodium-potassium pump, membrane disruption, organelle breakdown, and leakage of cytoplasmic contents into the extracellular space, triggering an inflammatory response. The morphologic patterns include coagulative (most common, in solid organs), liquefactive (brain and abscesses), caseous (tuberculosis), fat (adipose tissue), and fibrinoid (blood vessels).

Neurodegeneration

– The progressive loss of structure and function of neurons, culminating in their death, and represents the underlying mechanism of many devastating neurological disorders. It encompasses a heterogeneous group of diseases including Alzheimer's disease, Parkinson's disease, Huntington's disease, amyotrophic lateral sclerosis, and frontotemporal dementia. The mechanisms of neuronal death are multifactorial and include protein aggregation and misfolding, mitochondrial dysfunction, and oxidative stress. Common themes across neurodegenerative diseases include aberrant protein aggregation, mitochondrial impairment, excitotoxicity, neuroinflammation, and defective axonal transport. Despite intensive research, most neurodegenerative diseases remain incurable, with current treatments focused on symptom management.

Neurotransmitter

– Neurotransmitters are endogenous chemical messengers that transmit signals across synapses from one neuron to another or to target cells such as muscle or

gland cells. They are synthesized in the presynaptic neuron from precursor molecules through specific enzymatic pathways, stored in synaptic vesicles, and released upon arrival of an action potential and calcium influx. Major neurotransmitters include acetylcholine synthesized from choline and acetyl-CoA, dopamine synthesized from tyrosine through tyrosine hydroxylase, and serotonin from tryptophan through tryptophan hydroxylase. After release, neurotransmitters bind to specific receptors on the postsynaptic membrane, either ionotropic receptors that directly open ion channels or metabotropic G-protein-coupled receptors. Signalling is terminated by reuptake, enzymatic degradation, or diffusion.

Neutrophil Recruitment

– A multistep process essential for acute inflammation and host defense, involving sequential adhesive interactions between neutrophils and endothelial cells. The process begins with the rolling phase, where neutrophils loosely attach to endothelial cells through selectin-mediated interactions. Activated endothelial cells express P-selectin stored in Weibel-Palade bodies and newly synthesized E-selectin, which bind to sialyl-Lewis X carbohydrates on neutrophils. The next step is firm adhesion, mediated by integrins including LFA-1 and Mac-1 on neutrophils binding to ICAM-1 on activated endothelial cells. Finally, neutrophils transmigrate through the endothelium via the paracellular route between endothelial cells (diapedesis) and migrate along chemotactic gradients to reach the site of injury.

Obstructive Shock

– A form of shock caused by physical obstruction of blood flow outside the heart, reducing cardiac output despite normal cardiac function. Common causes include cardiac tamponade, where fluid accumulation in the pericardial space compresses the heart and prevents adequate diastolic filling; tension pneumothorax, where air in the pleural space causes mediastinal shift and compression of the great veins reducing venous return; and massive pulmonary embolism, where thrombus in the pulmonary arteries obstructing right ventricular outflow. In all cases, cardiac output falls and compensatory vasoconstriction may be insufficient. Treatment involves relieving the obstruction: pericardiocentesis for tamponade, needle decompression for tension pneumoth-

orax, and thrombolysis or embolectomy for massive pulmonary embolism.

Obstructive Uropathy

– Urinary tract obstruction at any level from the renal pelvis to the urethra, leading to impaired urine flow and potential renal damage. Causes include nephrolithiasis, benign prostatic hyperplasia, ureteral strictures, tumors of the bladder, prostate, or cervix, and external compression from lymphadenopathy or retroperitoneal fibrosis. The pathogenesis involves increased intratubular pressure proximal to the obstruction, leading to decreased glomerular filtration, tubular dysfunction, and ultimately irreversible renal parenchymal damage (obstructive nephropathy). Acute complete obstruction causes severe flank pain, anuria, and rapidly progressive renal failure. Chronic partial obstruction leads to hydronephrosis and gradual loss of renal function. Treatment involves relieving the obstruction.

Ochronosis

– A blue-black or brownish pigmentation of connective tissues (cartilage, skin, sclerae, tendons) caused by accumulation of homogentisic acid and its oxidation products. Ochronosis is the characteristic feature of alkaptonuria (also spelled alcaptonuria), a rare autosomal recessive disorder of tyrosine metabolism due to deficiency of homogentisate 1,2-dioxygenase (HGD gene). Homogentisic acid accumulates, polymerises, and deposits in collagen-rich tissues. Clinical: urine turns dark on standing (alkalinisation or oxidation—classic sign), ochronotic pigmentation (ear cartilage—blue-black, sclerae—triangular brown patches, skin over nose and knuckles, costochondral junctions), and ochronotic arthropathy (progressive osteoarthritis, especially of the spine and large joints—lumbar kyphosis, disc degeneration with calcification on X-ray, joint space narrowing). Other complications: aortic valve stenosis, kidney stones, and prostate stones. Onset of arthropathy in the 4th–5th decade. Treatment: nitisinone (inhibits 4-hydroxyphenylpyruvate dioxygenase upstream, reduces homogentisic acid production—licensed for alkaptonuria), low-protein diet, vitamin C (may delay polymerisation), and joint replacement for advanced arthropathy.

Oncogenes

– Mutated, amplified, or overexpressed versions of normal cellular genes called proto-oncogenes that encode proteins involved in cell growth, proliferation, and survival. Proto-oncogenes encode growth factors, growth factor receptors, signal transduction molecules, and transcription factors that normally regulate controlled cell growth. When activated by mutation, gene amplification, chromosomal translocation, or viral insertion, they become constitutively active, driving uncontrolled cell proliferation and survival. Common oncogenes include RAS (mutated in many cancers), MYC (transcription factor), HER2/ERBB2 (amplified in breast cancer), and BCR-ABL (translocation causing chronic myeloid leukemia). Targeted therapies against specific oncogenic drivers, such as tyrosine kinase inhibitors, have revolutionised cancer treatment.

Oncosis

– A form of cell death characterized by cellular swelling, derived from the Greek word *onkos* meaning swelling, representing a pre-lethal state that precedes necrosis. It is typically caused by ischemic injury leading to ATP depletion, which impairs the sodium-potassium pump and causes osmotic water influx. Unlike apoptosis, oncosis involves progressive cellular and organellar swelling, increased membrane permeability, cellular fragmentation, and eventual membrane rupture. Histologically, oncotic cells appear swollen with pale, vacuolated cytoplasm and clumped chromatin. The term is often used interchangeably with necrosis in the context of ischemic injury. Oncosis is distinct from apoptosis, which involves cell shrinkage rather than swelling, and is considered an unregulated, energy-independent form of cell death.

p53 Tumor Suppressor

– The p53 protein, encoded by the TP53 gene on chromosome 17p, is a transcription factor and the most commonly mutated gene in human cancer, with mutations found in over 50 percent of all malignancies. Known as the guardian of the genome, p53 is a short-lived protein normally kept at low levels by MDM2-mediated ubiquitination and proteasomal degradation. In response to DNA damage, oncogene activation, hypoxia, or nutrient deprivation, p53 is stabilized through phosphorylation and acetylation

that increase its half-life and transcriptional activity. Activated p53 transactivates target genes involved in cell cycle arrest (p21), DNA repair (GADD45), apoptosis (BAX, PUMA), and senescence. Mutant p53 not only loses tumor suppressor function but often gains oncogenic properties. Germline TP53 mutations cause Li-Fraumeni syndrome.

Palpation

– The second step of the physical examination, utilizing the sense of touch to evaluate body structures for size, shape, consistency, mobility, tenderness, temperature, and vibration. Technique: light palpation (1-2 cm depth) assesses superficial tenderness and muscle guarding; deep palpation (4-5 cm depth) delineates abdominal organomegaly and masses. Palmar surfaces of fingers assess texture and shape; dorsal surfaces assess temperature; ulnar borders assess tactile fremitus.

Pancreatic Adenocarcinoma

– A highly lethal malignancy arising from the pancreatic ductal epithelium, with a five-year survival rate of less than 10 percent, making it one of the deadliest cancers. The most common risk factors include smoking, obesity, chronic pancreatitis, diabetes mellitus, and hereditary syndromes including BRCA2 mutations and Lynch syndrome. The pathogenesis involves sequential genetic mutations including KRAS activation, TP53 loss, SMAD4 loss, and CDKN2A inactivation. The majority of tumors arise in the head of the pancreas, presenting with painless obstructive jaundice. CA 19-9 is a useful serum tumor marker, though not specific for screening. Surgical resection (pancreaticoduodenectomy, Whipple procedure) offers the only chance of cure, but less than 20 percent of patients are resectable at presentation.

Pancreatic Pseudocyst

– A pancreatic pseudocyst is a localized collection of pancreatic fluid surrounded by a wall of granulation tissue without an epithelial lining, typically occurring as a complication of acute or chronic pancreatitis. Unlike true cysts, pseudocysts lack an epithelial lining, which is why they are called pseudocysts. The pathogenesis involves disruption of the pancreatic duct with leakage of pancreatic enzymes, causing enzymatic digestion of surrounding tissues and formation of a fluid collection that

may reach large sizes. Pseudocysts present with epigastric pain, fullness, and tenderness. Complications include infection, rupture, and hemorrhage. Diagnosis is confirmed by CT or MRI showing a thick-walled fluid collection. Treatment options include observation, endoscopic drainage, or surgical cystogastrostomy.

Parkinson's Disease

– A progressive neurodegenerative disorder caused by selective loss of dopaminergic neurons in the substantia nigra pars compacta, leading to dopamine depletion in the striatum. The pathological hallmark is the presence of Lewy bodies, intracellular inclusions composed of aggregated alpha-synuclein protein, within surviving neurons. The disease typically manifests after age 60 with a male predominance. Clinical features include the cardinal motor symptoms of resting tremor, typically a pill-rolling tremor, bradykinesia, rigidity, and postural instability, as well as non-motor symptoms including depression, dementia, and autonomic dysfunction. Treatment is based on dopamine replacement with levodopa-carbidopa, dopamine agonists, and deep brain stimulation for advanced disease with motor fluctuations.

Pathologic Hypertrophy

– The enlargement of an organ resulting from an increase in the size of its constituent cells without an increase in cell number, typically occurring as a response to chronically increased workload or hormonal stimulation. Unlike physiologic hypertrophy, pathologic hypertrophy occurs under abnormal conditions and may eventually decompensate. The most important example is cardiac hypertrophy in response to chronic pressure overload from systemic hypertension or aortic stenosis. Initially compensatory and beneficial, sustained pathologic hypertrophy leads to maladaptive changes including myocardial fibrosis, diastolic dysfunction, and eventual systolic failure. The transition from compensated hypertrophy to heart failure involves altered calcium handling, energy metabolism, and apoptosis of cardiomyocytes.

Petechiae

– Small, pinpoint, non-blanching red or purple spots on the skin or mucous membranes caused by extravasation of red blood cells from capillaries into

the surrounding tissue. They are typically less than 2 millimeters in diameter and result from decreased platelet count, platelet dysfunction, or increased vascular fragility. The most common cause is thrombocytopenia, where platelet counts fall below 20,000 to 30,000 per microliter, impeding primary hemostasis. Other causes include vascular fragility from vasculitis, connective tissue disorders, or corticosteroid use. Petechiae are non-blanching and extremely small. Their distribution provides diagnostic clues: dependent areas suggest thrombocytopenia, while distribution above the nipple line suggests superior vena cava syndrome. Diagnosis involves evaluating platelet count and coagulation studies.

Platelet Plug Formation

– The initial hemostatic response to vascular injury, involving platelet adhesion, activation, and aggregation. When the endothelium is disrupted, subendothelial von Willebrand factor and collagen are exposed to flowing blood. Platelet glycoprotein Ib-IX-V complex binds to vWF under high shear stress, tethering and decelerating platelets on the damaged surface. Collagen binding to glycoprotein VI and integrin α -2- β -1 triggers intracellular signaling cascades through activation of phospholipase C and increased cytosolic calcium, leading to conformational change of integrin α -IIb- β -3 which binds fibrinogen, cross-linking platelets into an aggregated plug. The plug is stabilised by the coagulation cascade generating a fibrin mesh. This primary hemostatic response is critical for stopping bleeding but can contribute to pathological thrombosis.

Pressure Atrophy

– The gradual wasting of tissue resulting from sustained external compression that impairs blood supply and causes cellular shrinkage and eventual death. The mechanism involves compression of blood vessels, which reduces perfusion and causes ischemia of the dependent tissue. Prolonged ischemia leads to cellular atrophy with reduced cell size and organ function, and if compression continues, progresses to necrosis. Clinical examples include decubitus ulcers that develop over bony prominences in bedridden patients, and atrophy of normal tissue adjacent to an expanding tumor. Affected cells show reduced size, decreased protein synthesis, and increased au-

tophagic vacuoles. Unlike necrosis, pressure atrophy is a reversible adaptive change if the compressive force is removed before irreversible cell damage occurs.

Prion Disease

– Prion diseases, also known as transmissible spongiform encephalopathies, are a group of invariably fatal neurodegenerative disorders caused by misfolding of the normal cellular prion protein PrPC into the abnormal scrapie form PrPSc. The misfolded protein acts as an infectious agent by inducing normal PrPC to adopt the pathological conformation, propagating the misfolding process through an autocatalytic mechanism. PrPSc accumulates in the brain, causing neuronal death and characteristic spongiform change in the brain. The most common human prion disease is sporadic Creutzfeldt-Jakob disease, presenting with rapidly progressive dementia, myoclonus, and ataxia. Variant CJD is linked to bovine spongiform encephalopathy. Diagnosis is based on clinical features, MRI, EEG, and detection of 14-3-3 protein in CSF. All prion diseases are uniformly fatal.

Prostate Adenocarcinoma

– The most common non-cutaneous malignancy in men and the second leading cause of cancer death in men after lung cancer. The disease typically arises in the peripheral zone of the prostate and is hormone-dependent, requiring androgens for growth. Risk factors include age, family history, and race, with African American men having higher incidence and mortality. Most tumors are slow-growing and may never cause symptoms, while a subset are aggressive and metastasize. The Gleason grading system, based on histological glandular architecture, is the most important prognostic factor, with scores ranging from 6 to 10. PSA screening has improved early detection but remains controversial due to overdiagnosis of indolent disease. Treatment options include active surveillance, radical prostatectomy, radiation therapy, and androgen deprivation therapy.

Purpura

– Purple discoloration of the skin or mucous membranes caused by extravasation of red blood cells from blood vessels into the surrounding tissue. Purpura can be classified by size: petechiae are less than 2 millimeters, purpura are 2 to 10 millimeters, and

ecchymoses are greater than 10 millimeters. Causes include thrombocytopenia from decreased production or increased destruction, platelet dysfunction from medications or uremia, vascular fragility from aging or vitamin C deficiency (scurvy), and Henoch-Schönlein purpura with IgA immune complex deposition. Palpable purpura suggests underlying vasculitis. Diagnosis involves complete blood count, coagulation studies, and skin biopsy if vasculitis is suspected. Treatment targets the underlying cause; corticosteroids are used in vasculitic causes.

Pyelonephritis

– An infection of the renal parenchyma and pelvicalyceal system, typically resulting from ascending urinary tract infection. Acute pyelonephritis most commonly affects women and is caused by gram-negative enteric organisms, particularly *Escherichia coli*, which account for approximately 80 percent of cases. The pathogenesis involves bacterial ascent from the bladder to the kidneys, facilitated by vesicoureteral reflux, urinary obstruction, and bacterial virulence factors including adhesins and toxins. Acute pyelonephritis presents with fever, chills, flank pain, nausea, and vomiting, with pyuria and bacteriuria on urinalysis. Treatment involves antibiotics guided by culture sensitivity. Complications include renal abscess, emphysematous pyelonephritis, sepsis, and chronic pyelonephritis leading to renal scarring and hypertension.

Red Infarction

– Red infarction, also known as hemorrhagic infarction, occurs in tissues with dual blood supply, loose tissue architecture, or venous obstruction, allowing blood to accumulate in the necrotic area and produce a dark red appearance. The hemorrhagic appearance results from extravasation of red blood cells from congested vessels into the necrotic tissue. Red infarcts characteristically occur in the lung, where the dual pulmonary arterial and bronchial arterial circulation provides collateral flow, allowing blood to seep into the necrotic area from adjacent patent vessels. In the liver and small intestine, red infarction can also occur due to dual blood supply. The affected tissue is dark red, wedge-shaped, and poorly demarcated. Organisation and scar formation follow, with functional impact depending on the size and location of the infarct.

Renal Infarction

– Renal infarction results from occlusion of the renal artery or its branches, causing coagulative necrosis of the renal parenchyma. The kidney has end-arterial supply with limited collateral circulation, making it susceptible to ischemic injury even from small vessel occlusion. Common causes include thromboembolism from the heart, aortic dissection extending into the renal arteries, atherosclerotic disease, and fibromuscular dysplasia. Clinical features include sudden onset severe flank pain, haematuria, nausea, and vomiting. Hypertension may develop due to renin release from the ischemic kidney. Diagnosis is confirmed by CT angiography or renal scintigraphy. Treatment depends on the cause and may include anticoagulation, revascularisation, or conservative management with analgesics and blood pressure control.

Sarcoma

– A malignant neoplasm arising from mesenchymal cells, including bone, cartilage, fat, muscle, blood vessels, and fibrous tissue. Sarcomas are rare, accounting for approximately one percent of all adult cancers but are more common in children and adolescents, where they represent approximately 15 percent of pediatric malignancies. They are classified based on the tissue of origin: osteosarcoma from bone, chondrosarcoma from cartilage, liposarcoma from adipose tissue, leiomyosarcoma from smooth muscle, and rhabdomyosarcoma from skeletal muscle. Histological grading and staging are critical for prognosis. Wide surgical resection with negative margins is the primary treatment. Sarcomas are relatively resistant to chemotherapy, though specific subtypes show variable sensitivity to radiation and cytotoxic agents.

Septic Embolism

– Septic embolism occurs when infected material, typically thrombi containing bacteria, embolizes through the bloodstream to distant sites, causing metastatic infection. The most common source is infective endocarditis, where infected vegetations on heart valves break off and lodge in peripheral vessels. Other sources include infected central venous catheters, septic pelvic thrombophlebitis, and infected arterial thrombi. Septic emboli typically lodge in the lungs, causing multiple bilateral wedge-

shaped pulmonary infarcts with cavitation, presenting with chest pain, haemoptysis, and fever. Systemic embolisation can cause abscesses in the brain, spleen, kidneys, and skin. Diagnosis involves blood cultures and imaging. Treatment requires prolonged antibiotics and often surgical intervention for source control.

Septic Shock

– A form of distributive shock caused by overwhelming infection and the host dysregulated immune response, leading to systemic vasodilation, increased vascular permeability, myocardial depression, and multiorgan dysfunction. It is the most common cause of death in intensive care units worldwide. The pathogenesis involves recognition of microbial products including lipopolysaccharide and peptidoglycan by pattern recognition receptors on immune cells, triggering massive release of pro-inflammatory cytokines including TNF- α , IL-1, and IL-6, causing widespread vasodilation, increased capillary permeability, and myocardial depression. This results in refractory hypotension, tissue hypoperfusion, and multiorgan failure. Management includes early broad-spectrum antibiotics, fluid resuscitation, vasopressors, and source control of infection.

Shock

– A state of generalized tissue hypoperfusion resulting from inadequate cardiac output or effective circulating blood volume, leading to cellular hypoxia, metabolic acidosis, and potentially irreversible organ damage if not promptly treated. The four main categories are hypovolemic, cardiogenic, distributive, and obstructive shock, each with distinct pathophysiological mechanisms but sharing the common endpoint of inadequate oxygen delivery to meet metabolic demands. Compensatory mechanisms include activation of the sympathetic nervous system, the renin-angiotensin-aldosterone axis, and release of vasopressin, all attempting to maintain perfusion to vital organs. However, prolonged shock leads to irreversible cellular damage, multiorgan failure, and death. Early recognition and treatment targeted at the specific type of shock are critical to survival.

Splenic Infarction

– Splenic infarction occurs when the splenic artery or its branches are occluded, typically by emboli from the heart. The spleen has end-arterial supply

with limited collateral circulation, making it vulnerable to infarction even with small vessel occlusion. The most common cause is cardioembolism, particularly in patients with atrial fibrillation, infective endocarditis, or left ventricular thrombus. Other causes include hematologic disorders like sickle cell disease and myeloproliferative disorders such as polycythaemia vera. Splenic infarction presents with left upper quadrant pain, often pleuritic, sometimes radiating to the left shoulder. Fever and splenomegaly may be present. Most cases are managed conservatively with analgesics and treatment of the underlying cause, though complications include abscess formation and splenic rupture.

Starling Forces

– Starling forces describe the balance of hydrostatic and oncotic pressures that govern fluid movement across capillary walls, determining the distribution of fluid between the intravascular and extravascular compartments. The Starling equation states that net filtration equals the filtration coefficient times the difference between capillary and interstitial hydrostatic pressures minus the difference between capillary and interstitial oncotic pressures. Capillary hydrostatic pressure, generated by arterial blood pressure, pushes fluid out of the capillary at the arteriolar end. Plasma oncotic pressure, generated primarily by albumin, pulls fluid back into the capillary at the venular end. The net result is that approximately 90 percent of filtered fluid is reabsorbed; the remainder drains via the lymphatic system as lymph.

Storage Diseases

– A group of inherited metabolic disorders characterized by accumulation of substrates within cells due to specific enzyme deficiencies. Lysosomal storage diseases result from defects in lysosomal hydrolytic enzymes, leading to accumulation of undigested macromolecules within lysosomes. Gaucher disease results from glucocerebrosidase deficiency, causing glucocerebroside accumulation in macrophages that become enlarged Gaucher cells with characteristic wrinkled tissue paper cytoplasm. Niemann-Pick disease results from sphingomyelinase deficiency causing sphingomyelin accumulation in macrophages. Tay-Sachs disease results from hexosaminidase A deficiency causing GM2 ganglioside accumulation

in neurons, leading to neurodegeneration. Mucopolysaccharidoses result from deficiencies of enzymes degrading glycosaminoglycans.

Synaptic Transmission

– The fundamental process by which neurons communicate with each other through specialized junctions called synapses. At chemical synapses, an action potential arriving at the presynaptic terminal opens voltage-gated calcium channels, allowing calcium influx that triggers fusion of synaptic vesicles with the presynaptic membrane through SNARE protein complexes. Neurotransmitters are released into the synaptic cleft by exocytosis and bind to specific receptors on the postsynaptic membrane, generating either excitatory postsynaptic potentials (EPSPs) or inhibitory postsynaptic potentials (IPSPs). Signal termination occurs via neurotransmitter reuptake by specific transporters, enzymatic degradation in the synaptic cleft, or diffusion away from the synapse. This process forms the basis of all neural communication and information processing.

Systemic Sclerosis

– Systemic sclerosis, also known as scleroderma, is a chronic autoimmune disease characterized by progressive fibrosis of the skin and internal organs, vasculopathy, and immune dysfunction. The pathogenesis involves an aberrant wound healing response with excessive collagen production by activated fibroblasts, triggered by endothelial injury and immune activation. The disease exists in two main forms: limited cutaneous systemic sclerosis, formerly called CREST syndrome, with skin involvement distal to the elbows and knees, and diffuse cutaneous systemic sclerosis with widespread skin thickening and early internal organ involvement including interstitial lung disease, pulmonary hypertension, and renal crisis. Anti-centromere antibodies are associated with limited disease; anti-Scl-70 (anti-topoisomerase I) is associated with diffuse disease.

Takayasu Arteritis

– A chronic granulomatous vasculitis primarily affecting the aorta and its major branches, most commonly diagnosed in women under 50 years of age, particularly in Asian populations. The disease involves transmural inflammation of the aortic wall and its branches, leading to intimal fibrosis, luminal narrowing, and sometimes aneurysmal dilation.

The pathogenesis involves inappropriate immune-mediated vascular inflammation with CD4 T cell and macrophage infiltration. Clinical features include absent or diminished pulses, blood pressure discrepancies between arms, vascular bruits, claudication, and syncope. Diagnosis is based on imaging showing vascular wall thickening, stenosis, or aneurysm. Treatment includes high-dose corticosteroids and other immunosuppressive agents to control inflammation and prevent disease progression.

Temporal Arteritis

– A vasculitic disorder affecting medium and large arteries, particularly the temporal artery, predominantly occurring in adults over 50 years of age. The disease is characterized by granulomatous inflammation of the arterial wall with fragmentation of the internal elastic lamina, intimal proliferation, and luminal narrowing that can lead to ischemia of affected tissues. The most feared complication is anterior ischemic optic neuropathy, which can cause sudden, irreversible vision loss. Other symptoms include headache, jaw claudication, scalp tenderness, and constitutional symptoms such as fever and weight loss. ESR and CRP are typically markedly elevated. Temporal artery biopsy shows granulomatous inflammation with giant cells and elastic lamina fragmentation. Prompt high-dose corticosteroid therapy protects against vision loss.

Teratoma

– See Teratoma in Obstetrics and Gynecology.

Thrombosis

– The formation of a blood clot within the cardiovascular system during life, potentially obstructing blood flow and causing tissue ischemia or infarction. Arterial thrombi typically form on ruptured atherosclerotic plaques, are composed primarily of platelets and fibrin, and appear pale and grossly attached to the vessel wall. Venous thrombi form in areas of stasis, are rich in fibrin and trapped red blood cells, and appear red with a characteristic Lines of Zahn layering pattern. Venous thrombi commonly cause deep vein thrombosis with leg swelling and pain, and may embolise to the lungs causing pulmonary embolism. Arterial thrombosis leads to myocardial infarction, stroke, or peripheral arterial occlusion. Risk factors are described by Virchow's triad. Treatment involves anticoagulants, throm-

bolytics, or mechanical thrombectomy.

Thrombus Organization

– The process by which a thrombus is gradually replaced by granulation tissue and eventually fibrous scar tissue. The process begins when inflammatory cells, particularly macrophages, infiltrate the thrombus and begin digesting the fibrin and dead cells through fibrinolysis. Fibroblasts then migrate into the thrombus and begin producing collagen and other extracellular matrix components, gradually replacing the original clot. New blood vessels grow into the thrombus through the process of angiogenesis, a phenomenon called recanalisation. The organized thrombus becomes a fibrous scar that may contract and narrow the vessel lumen or, in the case of recanalisation, restore partial blood flow. This process is part of the natural healing response to thrombosis.

Thyroid Follicular Carcinoma

– approximately 10 to 15 percent of thyroid cancers and is the second most common differentiated thyroid malignancy. Unlike papillary carcinoma, follicular carcinoma typically spreads hematogenously to distant sites including bone, lung, and liver, rather than to regional lymph nodes. The diagnosis requires demonstration of capsular invasion or vascular invasion on histological examination, distinguishing it from follicular adenoma which lacks these features. Prognosis is generally good, with ten-year survival exceeding 85 percent, though worse in the presence of distant metastasis. Treatment includes total thyroidectomy followed by radioactive iodine ablation and TSH suppression therapy.

Thyroid Papillary Carcinoma

– The most common type of thyroid cancer, accounting for approximately 80 percent of all thyroid malignancies, and has an excellent prognosis with over 95 percent 10-year survival. The tumor arises from follicular thyroid cells and is characterized by papillary architectural growth pattern and characteristic nuclear features including nuclear grooves, intranuclear inclusions, and orphan eye nuclei. Risk factors include childhood radiation exposure, particularly from therapeutic radiation to the head and neck in childhood. The tumor has a propensity for lymphatic spread, with cervical lymph node metastases present in up to 50 percent of cases at diagnosis.

However, the prognosis remains excellent. Treatment involves thyroidectomy with or without radioactive iodine ablation and TSH suppression.

TNF Alpha

– Tumor necrosis factor alpha is a potent pro-inflammatory cytokine produced primarily by activated macrophages, as well as by T cells, NK cells, mast cells, and endothelial cells. TNF-alpha exists as a 26-kilodalton transmembrane protein that is cleaved by the metalloprotease TACE to release a soluble 17-kilodalton active form. It acts through two receptors: TNFR1, which contains a death domain and can activate both NF-kappaB survival signaling and caspase-8-mediated apoptosis, and TNFR2, which lacks a death domain and preferentially activates NF-kappaB, promoting cell survival and inflammation. TNF-alpha is a key therapeutic target in chronic inflammatory diseases including rheumatoid arthritis, psoriasis, and inflammatory bowel disease, where monoclonal antibodies (infliximab, adalimumab) and fusion proteins (etanercept) are used.

Transudate

– A transudate is a type of edema fluid with low protein content and few cells, resulting from imbalances in hydrostatic and oncotic pressures across capillary walls rather than from inflammation or increased vascular permeability. Transudates are typically caused by conditions that increase capillary hydrostatic pressure, such as congestive heart failure causing pulmonary edema, or decrease plasma oncotic pressure, such as hypoalbuminemia from liver cirrhosis or nephrotic syndrome. The fluid is clear, straw-coloured, and has low cellularity. Laboratory criteria for transudate include pleural fluid protein-to-serum protein ratio less than 0.5, pleural fluid LDH-to-serum LDH ratio less than 0.6, and pleural fluid LDH less than two-thirds the upper limit of normal for serum.

Tumor Differentiation

– The degree to which neoplastic cells morphologically and functionally resemble their normal counterparts of origin. Well-differentiated tumors retain many structural features of the original tissue, including organized architectural patterns, specialized cellular structures, and sometimes functional capabilities such as hormone production or mucin

secretion. Poorly differentiated or anaplastic tumors show minimal resemblance to the normal tissue and often require immunohistochemistry and molecular profiling for accurate classification. tumor grade, a measure of differentiation, is a powerful independent prognostic factor in most cancers. Well-differentiated tumors generally have a better prognosis than poorly differentiated ones, though notable exceptions exist.

Tumor Embolism

– Tumor embolism occurs when malignant cells, tumor fragments, or tumor thrombi enter the venous circulation and travel to distant sites. The pulmonary vasculature is the most common site of embolization, as venous blood from most organs drains to the lungs through the pulmonary arteries. Tumor emboli can also reach the arterial circulation through pulmonary capillary shunts or a patent foramen ovale, causing systemic embolization to the brain, kidneys, or other organs. The clinical presentation ranges from asymptomatic pulmonary emboli to acute respiratory failure and cor pulmonale. tumor embolism is an under-recognised complication of malignancy and may mimic thromboembolic disease. Diagnosis requires a high index of suspicion and histopathological confirmation.

Tumor Suppressor Genes

– Tumor suppressor genes encode proteins that normally inhibit cell proliferation, promote DNA repair, or induce programmed cell death in response to cellular damage. They function as brakes on the cell cycle, and loss of their function removes critical checkpoints that normally prevent uncontrolled growth. According to Knudson's two-hit hypothesis, both alleles must be inactivated for loss of function, which can occur through mutation, deletion, or epigenetic silencing. Hereditary cancer syndromes, such as Li-Fraumeni syndrome (TP53), familial adenomatous polyposis (APC), and hereditary breast and ovarian cancer (BRCA1, BRCA2), involve germline mutations of tumor suppressor genes. Epigenetic silencing through promoter hypermethylation is another common mechanism of inactivation in sporadic cancers.

Urothelial Carcinoma

– Urothelial carcinoma, previously called transitional cell carcinoma, is the most common malignancy

of the urinary tract, arising from the urothelium that lines the renal pelvis, ureters, bladder, and proximal urethra. The most important risk factor is cigarette smoking, which accounts for approximately 50 percent of cases, with other risk factors including occupational exposure to aromatic amines, cyclophosphamide therapy, and chronic schistosomiasis. The pathogenesis involves field cancerization, where the entire urothelium is exposed to carcinogens, leading to multifocal and recurrent tumors. Gross haematuria is the most common presenting symptom. Diagnosis is by cystoscopy and biopsy. Treatment depends on stage: transurethral resection and intravesical therapy for non-muscle-invasive disease, and radical cystectomy for muscle-invasive disease.

Valvular Heart Disease

– Valvular heart disease involves dysfunction of one or more heart valves, leading to stenosis, regurgitation, or a combination of both. The most common causes are degenerative calcification of aortic and mitral valves, rheumatic heart disease, infective endocarditis, and ischemic papillary muscle dysfunction. Aortic stenosis results from calcification of a congenitally bicuspid or tricuspid aortic valve, causing left ventricular outflow obstruction with pressure overload. Aortic regurgitation results from incomplete valve closure, causing volume overload and left ventricular dilation. Mitral stenosis is most commonly rheumatic in origin, causing left atrial enlargement and pulmonary hypertension. Treatment includes medical management and valve replacement or repair for severe symptomatic disease.

Vasodilation

– The widening of blood vessels during inflammation, resulting in increased blood flow to the affected area. This process is mediated primarily by histamine released from mast cell granules acting on H1 receptors, nitric oxide produced by endothelial nitric oxide synthase, and prostaglandins particularly PGE2. The increased blood flow is responsible for the redness and heat characteristic of acute inflammation. Vasodilation occurs within seconds to minutes of tissue injury and represents the earliest vascular response in the inflammatory cascade. The increased blood flow brings oxygen, nutrients, and immune cells to the affected tissue and dilutes toxins.

Vasodilation is accompanied by increased vascular permeability, allowing exudation of protein-rich fluid and formation of tissue edema, contributing to the cardinal signs of inflammation.

Vegetation

– A vegetation is a mass composed of platelets, fibrin, and microorganisms that forms on a heart valve or endocardial surface in the setting of infective endocarditis. The vegetation typically attaches to the valve leaflet on the low-pressure side and may progressively destroy the underlying valve tissue, causing valvular regurgitation. The most common causative organisms include *Staphylococcus aureus* in acute endocarditis, which can affect normal valves, and viridans streptococci in subacute endocarditis, which typically affects previously damaged valves. Diagnosis relies on blood cultures and echocardiography, with transoesophageal echocardiography being more sensitive. Treatment requires prolonged intravenous antibiotics and sometimes surgical valve debridement or replacement.

Virchow's Triad

– Virchow's triad describes three broad categories of factors that contribute to thrombosis: endothelial injury or dysfunction, stasis or turbulent blood flow, and hypercoagulability. Endothelial injury exposes subendothelial collagen and tissue factor, initiating platelet adhesion and the coagulation cascade. Causes include atherosclerosis, hypertension, vasculitis, and direct trauma. Stasis or turbulent flow disrupts laminar blood flow, bringing platelets into contact with the endothelium, preventing dilution of activated clotting factors and causing endothelial hypoxia. Hypercoagulability encompasses inherited conditions such as factor V Leiden, prothrombin gene mutation, and deficiencies of protein C, protein S, or antithrombin III, as well as acquired states including pregnancy, malignancy, and oral contraceptive use.

Wegener's Granulomatosis

– Wegener's granulomatosis, now called granulomatosis with polyangiitis, is a systemic vasculitis characterized by necrotizing granulomatous inflammation of the upper and lower respiratory tracts and pauci-immune necrotizing glomerulonephritis. It is associated with anti-neutrophil cytoplasmic antibodies, specifically c-ANCA targeting proteinase 3. The

disease affects small to medium-sized vessels and can involve virtually any organ system. Upper respiratory tract involvement causes chronic sinusitis, nasal mucosal ulceration, and saddle nose deformity. Pulmonary involvement causes cough, haemoptysis, and cavitating lung nodules. Renal involvement, if untreated, rapidly progresses to end-stage renal disease. Treatment includes high-dose corticosteroids with cyclophosphamide or rituximab, which has dramatically improved outcomes.

White Infarction

– White infarction, also known as anemic infarction, occurs in solid organs with end-arterial circulation where collateral blood supply is limited, resulting in pale, well-demarcated areas of coagulative necrosis. The affected tissue appears pale because compression of the capillary bed by interstitial edema limits secondary hemorrhage into the necrotic area. White infarcts characteristically occur in the heart, kidney, spleen, and other solid organs with single-source arterial supply. The mechanism involves sudden arterial occlusion producing a wedge-shaped area of coagulative necrosis, with the apex pointing toward the occlusion site. The infarct appears pale because the necrotic tissue loses its blood content and surrounding vessels constrict. Organisation and fibrous scar formation follow over several weeks.

Xeroderma Pigmentosum

– A rare autosomal recessive disorder of nucleotide excision repair (NER) characterized by extreme sun sensitivity and a 1000-fold increased risk of skin cancers (basal cell carcinoma, squamous cell carcinoma, and melanoma, often in childhood). Mutations occur in one of eight genes (XPA-XPG and XP-variant/polymerase eta). Defective NER leads to accumulation of UV-induced pyrimidine dimers and other photoproducts, causing mutations in tumor suppressor genes (p53, PTCH). Clinical features: severe sunburn with minimal sun exposure, poikiloderma (hyperpigmentation, hypopigmentation, telangiectasias, atrophy), xerosis (dry skin), actinic keratoses, and multiple skin cancers. Ocular involvement (photophobia, conjunctivitis, keratitis, eyelid skin cancers) and neurological involvement (progressive neurodegeneration in XP-A, -B, -D, -G: microcephaly, spasticity, chorea, sensorineural hearing loss, peripheral neuropathy, cognitive im-

pairment). Diagnosis: clinical criteria with confirmatory DNA repair assay (unscheduled DNA synthesis/UDS) showing reduced NER capacity or gene sequencing. Management: rigorous sun protection (sunscreen SPF 50+, UV-protective clothing, hats, sunglasses), regular dermatological surveillance (every 3-6 months) with early treatment of skin cancers (cryotherapy, photodynamic therapy, surgical excision, topical 5-fluorouracil, imiquimod). Oral retinoids (acitretin) reduce skin cancer incidence by 50-70% in XP patients. Prognosis: reduced life expectancy primarily from metastatic skin cancer or progressive neurodegeneration. Neurological complications are the major determinant of poor prognosis.

Chapter 30

Pediatrics

Acne

– A chronic inflammatory disorder of the pilosebaceous unit, extremely common during adolescence. Pathogenesis involves sebum production, follicular hyperkeratinization, *Cutibacterium acnes* colonization, and inflammation. Grading: comedonal, papulopustular, nodulocystic. Treatment: topical retinoids, benzoyl peroxide, and antibiotics for mild to moderate; isotretinoin for severe or refractory disease. Early treatment prevents scarring.

Acute Otitis Media

– Infection of the middle ear space with acute onset of symptoms and signs of middle ear inflammation. Diagnosis requires middle ear effusion plus acute symptoms (ear pain, fever, irritability) or signs (bulging tympanic membrane, erythema). Most common pathogen: *Streptococcus pneumoniae*. Treatment: amoxicillin for 10 days; amoxicillin-clavulanate for treatment failure or concurrent sinusitis.

ADHD

– Attention deficit hyperactivity disorder: a neurodevelopmental disorder with inattention, hyperactivity, and impulsivity inappropriate for age, affecting function in school/home; onset before 12 years, persistence ≥ 6 months in ≥ 2 settings. Subtypes: inattentive, hyperactive-impulsive, combined. Comorbidities: learning disorders, anxiety, depression, ODD, tics. Diagnosis: clinical (DSM-5 criteria), rating scales (Conners, Vanderbilt), history from parents/teachers; exclude hearing/vision, sleep, anxiety, and trauma. Management: behavioral/parent training first (preschool), stimulants (methylphenidate) or non-stimulants (atomoxetine, guanfacine) for school-age, structured environment, and educational support; monitor growth and side effects.

Adolescent Health

– The health and wellbeing of young people (10-19 years), addressing the physical, psychological, and social transitions of puberty and adolescence. Key issues: growth/development (puberty, menarche), nutrition (obesity, eating disorders), mental health (depression, anxiety, suicide—leading causes of morbidity), sexual health (contraception, STIs, pregnancy), substance use (tobacco, alcohol, drugs), injuries/violence, and preventive care (immunizations—HPV, Tdap; screening). Confidentially provided care, HEADSSS assessment (Home, Education, Activities, Drugs, Sexuality, Suicide, Safety), and a non-judgmental approach are essential. Early identification and intervention improve long-term outcomes.

Alagille Syndrome

– An autosomal dominant disorder caused by mutations in *JAG1* (95%) or *NOTCH2* (<5%), affecting the Notch signaling pathway. Features: chronic cholestasis from paucity of intrahepatic bile ducts (90-100%), cardiac anomalies (peripheral pulmonary stenosis most common, also tetralogy of Fallot), butterfly vertebrae (50%), posterior embryotoxon (a ring in the anterior chamber of the eye, 90%), and characteristic facies (broad forehead, deep-set eyes, pointed chin, 90-95%). Presents in infancy with prolonged jaundice, pruritus, and failure to thrive. Other findings: renal anomalies (30-50%), hypercholesterolemia, and coagulopathy from fat malabsorption. Diagnosis: clinical criteria (Alagille score) and *JAG1*/*NOTCH2* genetic testing. Management: ursodeoxycholic acid for cholestasis, fat-soluble vitamin supplementation, nutritional support, cardiac repair as needed, and liver transplantation for end-stage liver disease (15-20%).

Angelman Syndrome

– A genetic disorder caused by loss of function of

the UBE3A gene on chromosome 15 (maternal deletion or paternal uniparental disomy). Features: severe intellectual disability, absent speech, seizures, ataxia, and frequent laughter. Characteristic happy demeanor with hand-flapping movements. Management: seizure control, physical therapy, and communication support.

Annular Pancreas

– A congenital anomaly where a ring of pancreatic tissue completely or partially encircles the second portion of the duodenum, causing duodenal obstruction. It results from failure of the ventral pancreatic bud to completely rotate around the duodenum during embryogenesis. Associated with Down syndrome, duodenal atresia (coexisting in 50%), and other GI anomalies. Presents in the newborn period with bilious or non-bilious vomiting (depending on the position relative to the ampulla) and polyhydramnios (prenatal). In adults, may present with recurrent pancreatitis or peptic ulcer disease. Diagnosis: upper GI series shows a narrowed, eccentric duodenum with obstructive findings; CT or MRCP demonstrates the pancreatic tissue ring encasing the duodenum. Treatment: surgical bypass (duodeno-duodenostomy or duodeno-jejunostomy) without resection of the annular tissue (risk of pancreatitis and fistula). Prognosis: excellent after surgical repair.

Anorectal Malformation

– A spectrum of congenital anomalies involving the anus and rectum, classified by the location of the rectal pouch relative to the puborectalis sling: Low (passes through the levator muscle, good prognosis) — perineal fistula, vestibular fistula, or covered anus. High (ends above the levator muscle, poor prognosis, 60%) — rectourethral fistula (boys), rectovaginal fistula (girls), or rectobladder neck fistula. Cloaca (girls): a single common channel for the urethra, vagina, and rectum. Presents with absence of a normal anal opening on perineal examination and failure to pass meconium within 24 hours. Associated anomalies (VACTERL workup): vertebral, cardiac (VSD), tracheoesophageal, renal (VUR, renal agenesis), and limb. Diagnosis: invertogram (Wangensteen-Rice X-ray) and cross-table lateral X-ray to determine the level. MRI for complex cases. Treatment: low lesions — primary perineal

anoplasty. High lesions — colostomy in the newborn period, followed by posterior sagittal anorectoplasty (PSARP, deVries-Peña procedure) at 3-6 months. Prognosis: low lesions — excellent bowel control. High lesions — variable fecal continence, requiring bowel management programs (enemas, laxatives, antegrade continence enema).

Anorexia Nervosa

– An eating disorder characterized by restriction of energy intake, intense fear of weight gain, and distorted body image. Highest mortality of any psychiatric disorder. Features: emaciation, lanugo, bradycardia, hypotension, amenorrhea, and electrolyte abnormalities. Diagnosis by DSM-5 criteria. Treatment: nutritional rehabilitation, cognitive behavioral therapy, and family-based therapy. Medical stabilization when severely malnourished.

Apert Syndrome

– An autosomal dominant craniosynostosis syndrome caused by FGFR2 mutations (most commonly Ser252Trp or Pro253Arg). Features: craniosynostosis (bilateral coronal, resulting in turribrachycephaly — tower-shaped skull), midface hypoplasia, proptosis, hypertelorism, and syndactyly of the hands and feet (mitten or spade-like hands, complete fusion of digits). Cleft palate occurs in 30%. May have intellectual disability (variable). Other associations: cervical spine fusion, congenital heart disease, and hydrocephalus. Diagnosis: clinical and genetic testing. Management: staged surgical reconstruction — cranial vault remodeling (3-6 months), midface advancement (Le Fort III, 6-12 years), and syndactyly release (6-18 months). Lifelong neurosurgical and dental monitoring.

Apgar Score

– Rapid clinical assessment of newborn well-being performed at 1 and 5 minutes after birth. Five criteria scored 0-2 each: Appearance (skin color), Pulse (heart rate), Grimace (reflex irritability), Activity (muscle tone), and Respiration. Total score 0-10. Score 7-10 normal; 4-6 moderately depressed; 0-3 severely depressed. Determines need for immediate resuscitation. May extend to 10 and 20 minutes in severely depressed infants.

Apnea of Prematurity

– Cessation of breathing for more than 20 seconds or shorter episodes with bradycardia or desaturation

in infants less than 34-37 weeks gestation. Three types: central (no respiratory effort), obstructive (airway collapse), and mixed. Treatment: caffeine citrate (first-line), continuous positive airway pressure, and methylxanthine therapy. Monitor with cardiorespiratory monitors. Most resolve by 34-44 weeks corrected gestational age.

Arnold-Chiari Malformation

– Herniation of cerebellar tonsils through the foramen magnum into the upper cervical spinal canal. Type II (myelomeningocele-associated) is the most common form in pediatrics. Associated with hydrocephalus, syringomyelia, and spinal cord dysfunction. Symptoms include headache, neck pain, and lower cranial nerve palsies. Treatment: posterior fossa decompression with duraplasty. Often coexists with myelomeningocele requiring concurrent repair.

Babinski Reflex

– An extensor plantar response present from birth to approximately 2 years. When the lateral sole is stroked, the great toe dorsiflexes and other toes fan outward. Disappears as the corticospinal tract myelinates. Persistence beyond age 2 may indicate neurologic abnormality. Pathologic in older children and adults, suggesting upper motor neuron lesion. One of the deep tendon reflexes assessed in infants.

Bacterial Meningitis

– Infection of the meninges by bacteria, a medical emergency. In neonates: Group B Streptococcus, *E. coli*, *Listeria*. In older children: *Neisseria meningitidis*, *Streptococcus pneumoniae*. Presents with fever, headache, neck stiffness, altered consciousness, and Kernig/Brudzinski signs. Diagnosis by lumbar puncture. Treatment: immediate empiric antibiotics (ceftriaxone and vancomycin) without delaying for imaging.

Ballard Score

– Clinical assessment of gestational age in newborns using 6 physical and 6 neuromuscular maturity criteria. Physical parameters: skin texture, ear form and recoil, eye appearance, breast tissue, and genitalia. Neuromuscular: posture, arm and leg recoil, popliteal angle, scarf sign, and heel-to-ear. Each scored 0-5; total converted to gestational age in weeks. Most accurate near term; used when prenatal dating is uncertain.

Beckwith-Wiedemann Syndrome

– An overgrowth disorder associated with 11p15.5 imprinting defects. Features: macrosomia, macroglossia, omphalocele, visceromegaly, and neonatal hypoglycemia. Increased risk of embryonal tumors (Wilms tumor, hepatoblastoma). Management: glucose monitoring, tumor surveillance with abdominal ultrasound and AFP levels, and surgical correction of structural anomalies.

Binge Eating Disorder

– Recurrent episodes of eating large quantities of food with a sense of lack of control, without regular compensatory behavior. Associated with obesity, depression, and anxiety. Diagnosis by DSM-5 criteria. Treatment: cognitive behavioral therapy, interpersonal therapy, and SSRIs. Weight management with dietary counseling and exercise.

Biotinidase Deficiency

– An autosomal recessive inborn error of biotin recycling caused by BTB gene mutations, resulting in inability to cleave biotin from biocytin (proteolytic degradation product of biotin-dependent carboxylases). This leads to multiple carboxylase deficiency affecting four biotin-dependent enzymes: pyruvate carboxylase, propionyl-CoA carboxylase, 3-methylcrotonyl-CoA carboxylase, and acetyl-CoA carboxylase. Presents between 1 week and 10 years of age (mean 3 months). Features: neurological — seizures (myoclonic, infantile spasms), hypotonia, ataxia, hearing loss, and optic atrophy; cutaneous — periorificial dermatitis, alopecia, and candidal infections; metabolic — metabolic acidosis, ketolactic acidosis, and organic aciduria (3-hydroxyisovalerate, 3-methylcrotonylglycine, lactate, propionate). Diagnosis: biotinidase enzyme assay in serum and BTB genetic testing. Included in newborn screening in many countries. Treatment: oral biotin (5-20 mg/day) — a dramatically effective and inexpensive therapy. Starting biotin promptly reverses most symptoms except sensorineural hearing loss and optic atrophy, which may be irreversible if delayed.

Bochdalek Hernia

– A congenital diaphragmatic hernia (CDH) occurring through the posterolateral foramen of Bochdalek, resulting from failure of the pleuroperitoneal membrane to close by the 8th week of gestation. The left side is affected in 85% of cases (the right pleuroperitoneal canal closes earlier). Abdom-

inal organs (stomach, spleen, small intestine, colon, and sometimes the left lobe of the liver) herniate into the chest, causing pulmonary hypoplasia and pulmonary hypertension. Presents at birth with severe respiratory distress, cyanosis, scaphoid abdomen, and decreased breath sounds on the affected side with bowel sounds heard in the chest. Diagnosis: prenatal ultrasound (polyhydramnios, mediastinal shift, herniated organs), postnatal chest X-ray shows abdominal organs in the thorax. Treatment: endotracheal intubation (avoid bag-mask ventilation — distends the stomach), nasogastric decompression, and surgical repair via an abdominal approach once pulmonary hypertension is managed. Delayed surgical repair after physiologic stabilization improves outcomes. High-frequency ventilation, inhaled nitric oxide, and ECMO for severe pulmonary hypertension. Prognosis depends on the degree of pulmonary hypoplasia; LHR (lung-to-head ratio) is the best prenatal predictor.

Brachial Plexus Injury

– Damage to the brachial plexus nerves during birth, most commonly from shoulder dystocia or excessive traction. Erb's palsy (C5-C6) presents with waiter's tip position (arm adducted, elbow extended, forearm pronated). Klumpke's palsy (C8-T1) affects the hand and may cause Horner syndrome. Most cases resolve spontaneously. Physical therapy initiated early; surgical exploration considered if no recovery by 3-6 months.

Bradycardia of Prematurity

– Heart rate less than 100 beats per minute in a premature infant, often associated with apnea and oxygen desaturation. May be caused by vagal stimulation, reflux, or immaturity of the cardiac conduction system. Treatment: gentle stimulation, caffeine, and addressing underlying causes. Usually self-limited and resolves as the infant matures. Monitoring with continuous cardiorespiratory monitoring.

Breast Engorgement

– Swelling and tenderness of neonatal breasts occurring in both male and female infants at 2-5 days of age, caused by maternal estrogen withdrawal. May produce milky secretions (witch's milk). A normal, self-limited condition. No treatment required; typically resolves within 2-4 weeks. Infection is rare.

Historically, traditional practices of pressing the breasts are harmful and should be avoided.

Breath-Holding Spells

– A benign paroxysmal phenomenon in young children (6 months to 6 years), provoked by frustration, pain, or fear. Cyanotic type (more common): child cries, forcefully exhales, becomes cyanotic, and may lose consciousness briefly. Pallid type: triggered by sudden pain/fright, child becomes pale and limp, may have brief seizure-like activity due to reflex anoxic seizure. Pathophysiology: autonomic dysregulation, vagal overactivity. Diagnosis: clinical; EEG normal (distinguishing from epilepsy). Treatment: parental reassurance, management of triggers, iron supplementation if anemic. Spells resolve spontaneously by age 6. No increased risk of epilepsy or other neurological problems.

Bronchiolitis

– Lower respiratory tract infection causing inflammation and obstruction of small airways. Most common cause is respiratory syncytial virus. Affects infants under 12 months. Presents with wheezing, tachypnea, nasal flaring, and retractions. Diagnosis is clinical. Treatment: supportive care with nasal suctioning, supplemental oxygen, and respiratory support. Severe cases may require CPAP or mechanical ventilation. No effective antiviral therapy.

Bronchopulmonary Dysplasia

– A chronic lung disease of premature infants, resulting from lung injury from mechanical ventilation, oxygen toxicity, and inflammation. Most commonly occurs in infants born at less than 28 weeks gestation with birth weight less than 1500 grams. Pathophysiology involves arrested alveolar and vascular development with simplified alveolar structures, decreased alveolar number, and pulmonary vascular remodeling. The National Institutes of Health consensus definition classifies severity at 36 weeks postmenstrual age or at discharge: mild (no supplemental oxygen), moderate (oxygen less than 30%), or severe (oxygen at least 30% or positive pressure ventilation). Pathogenesis is multifactorial: ventilator-induced lung injury, oxygen toxicity, infection, patent ductus arteriosus, and fluid overload. Management: lung-protective ventilation strategies, judicious oxygen therapy targeting saturations 90-95%, fluid restriction, diuretics, caffeine,

and systemic corticosteroids for severe cases not weaning from ventilation. Nutritional support with high-calorie formulas to promote lung growth. Long-term complications include pulmonary hypertension, reactive airway disease, and neurodevelopmental impairment. Most infants improve with lung growth, but pulmonary function abnormalities may persist into adulthood.

Bulimia Nervosa

– An eating disorder characterized by recurrent episodes of binge eating followed by compensatory behaviors (purging, laxatives, excessive exercise). Self-esteem overly influenced by body shape and weight. Complications: electrolyte abnormalities (hypokalemia, metabolic alkalosis), dental erosion, esophageal tears, and parotid gland enlargement. Treatment: cognitive behavioral therapy and SSRIs (fluoxetine).

Caput Succedaneum

– Edema of the scalp presenting as a soft, boggy swelling that crosses suture lines. Caused by pressure of the vaginal walls on the fetal head during labor. Resolves within hours to days. Differentiated from cephalohematoma (subperiosteal, does not cross suture lines) and subgaleal hemorrhage (life-threatening, crosses suture lines). No treatment required; spontaneous resolution.

Cerebral Palsy

– A group of permanent disorders of movement and posture development causing activity limitation, attributed to non-progressive disturbances occurring in the developing fetal or infant brain. It is the most common motor disability in childhood, affecting approximately 1 in 500 live births. Classification by motor type: spastic (80 percent, most common, includes hemiplegia, diplegia, and quadriplegia), dyskinetic (athetoid, choreoathetoid, dystonic), ataxic, hypotonic, and mixed. Spastic cerebral palsy is subclassified by distribution: hemiplegia (unilateral arm and leg), diplegia (lower limbs more affected, common in premature infants with periventricular leukomalacia), and quadriplegia (all four limbs, often with intellectual disability and seizures). Causes: prematurity, intrauterine infection, perinatal hypoxia-ischemia, intracranial hemorrhage, and genetic abnormalities. Diagnosis is clinical, based on delayed motor milestones, abnormal muscle tone,

and persistent primitive reflexes. Management is multidisciplinary: physical therapy, occupational therapy, speech therapy, orthotics, spasticity management (botulinum toxin, oral baclofen, intrathecal baclofen pump), orthopaedic surgery for contractures, and management of associated conditions including epilepsy, feeding difficulties, and learning disabilities. Prognosis depends on severity and associated impairments; most children survive to adulthood with appropriate support.

CHARGE Syndrome

– A genetic disorder caused by CHD7 gene mutations (autosomal dominant, most cases de novo) affecting multiple organ systems. The mnemonic CHARGE describes: Coloboma (coloboma of the eye, 80-90%), Heart defects (tetralogy of Fallot, VSD, ASD, PDA, 75-85%), Atresia choanae (choanal atresia/stenosis, 50-60%), Retarded growth and development (growth hormone deficiency, intellectual disability), Genital hypoplasia (cryptorchidism, micropenis, 50-60% in males), and Ear anomalies (characteristic cup-shaped ears with prominent antihelix, hearing loss, 90-95%). Presents with life-threatening respiratory distress at birth from choanal atresia. Other common features: facial palsy, cleft lip/palate, and feeding difficulties. Diagnosis: clinical criteria (Verloes or Blake) and CHD7 genetic testing. Management: multidisciplinary — airway management, cardiac repair, hearing aids/cochlear implants, growth hormone therapy, and developmental support.

Chickenpox

– Primary infection with Varicella-Zoster Virus, characterized by pruritic, vesicular rash in different stages (macules, papules, vesicles, crusts). Highly contagious via respiratory droplets and contact with lesions. Incubation 10-21 days. Complications include secondary bacterial infection, pneumonia, encephalitis, and Reye syndrome. Prevention by varicella vaccine. Treatment: supportive care; acyclovir for severe cases.

Child Abuse

– Physical, sexual, or emotional harm or neglect of a child by a caregiver. Recognized by inconsistent histories, injury patterns inconsistent with mechanism, and behavioral indicators. Types: physical abuse, sexual abuse, neglect, and emotional abuse. Mandatory reporting requirements for healthcare

providers. Evaluation includes full skeletal survey for suspected physical abuse, laboratory tests, and social work involvement.

Child Neglect

- The failure of a caregiver to provide adequate food, shelter, clothing, supervision, education, or medical care. The most common form of child maltreatment. Types: physical neglect, educational neglect, emotional neglect, and medical neglect. May result in failure to thrive, developmental delay, and chronic illness. Identified through failure to attend appointments, untreated medical conditions, and inadequate living conditions.

Chlamydia

- The most common reportable bacterial STI, caused by *Chlamydia trachomatis*. Often asymptomatic in women, causing cervicitis, urethritis, and pelvic inflammatory disease. Complications include tubal factor infertility and ectopic pregnancy. Diagnosis by nucleic acid amplification test. Treatment: azithromycin or doxycycline. Partner treatment essential to prevent reinfection. Screening recommended for all sexually active women under 25.

Choanal Atresia

- A congenital obstruction of the posterior nasal passage (choana) due to failure of the bucconasal membrane to rupture during embryogenesis. Bilateral choanal atresia presents as a respiratory emergency in the newborn, who is an obligate nasal breather — cyclic cyanosis that improves with crying. Unilateral atresia presents later with persistent unilateral nasal discharge and obstruction. 70% are bony, 30% are membranous. Associated with CHARGE syndrome (coloboma, heart defects, choanal atresia, retardation, genital hypoplasia, ear anomalies) and other anomalies. Diagnosis: inability to pass a nasogastric tube through the nose, confirmed by CT. Treatment: immediate airway management (oral airway, McGovern nipple), followed by surgical repair via transnasal endoscopic choanoplasty with stenting. Unilateral cases are repaired electively.

Clavicle Fracture

- The most common birth-related fracture, occurring in approximately 1-2% of vaginal deliveries. Risk factors include shoulder dystocia, macrosomia, and breech presentation. Presents with asymmetric arm movements, palpable crepitus, and reluctance to

move the affected arm. Diagnosis by X-ray. Treatment: arm immobilization against the body (pinned diaper or arm sling). Heals rapidly in newborns with excellent prognosis.

Cleft Lip

- A congenital malformation: incomplete fusion of the lip (and often palate) during embryologic development, causing a facial cleft; cleft lip and/or cleft palate are the most common craniofacial birth defects. Features: cleft lip (unilateral/bilateral) and/or cleft palate (hard/soft); feeding difficulties, speech problems, recurrent otitis media/hearing loss, dental anomalies, and psychosocial impact; associated with syndromes (Pierre Robin, Van der Woude, trisomy 13/18). Diagnosis: prenatal ultrasound; clinical at birth. Management: multidisciplinary team—feeding support (special nipples), surgical repair (lip 3-6 months, palate 9-18 months), speech therapy, audiology/ENT, dental/orthodontics, and psychologic support.

Cloacal Exstrophy

- The most severe congenital anomaly of the ventral abdominal wall, also called the OEIS complex (Omphalocele, Exstrophy of the bladder, Imperforate anus, Spinal defects). Incidence 1 in 200,000-400,000 births. Features: an exstrophic central bowel segment (cecum, between two hemi-bladders), omphalocele, imperforate anus, and spinal anomalies (myelomeningocele, tethered cord). Girls have a duplicated vagina and uterus; boys have an epispadiac, short phallus. There is near-universal association with Chiari malformation and hydrocephalus. Diagnosis: prenatal ultrasound shows a large midline abdominal wall defect with cystic structures (hemi-bladders) and spinal abnormalities. Treatment: staged surgical reconstruction — immediate bowel coverage (silo), separation of bowel from bladder, closure of the abdominal wall; later — bladder closure, genital reconstruction, and spinal cord repair. Prognosis: survival >90% with modern care. Bowel and bladder function outcomes are guarded; most require intermittent catheterization and bowel management.

Colic

- Excessive, inconsolable crying in an otherwise healthy infant <5 months, lasting >3 hours/day, >3 days/week, for >3 weeks (rule of threes). Peak at 6

weeks, resolves by 3-4 months; cause unknown (immature GI system, gas, temperament, overstimulation). Features: paroxysmal crying (often evening), drawing up of legs, facial flushing. Diagnosis: clinical—exclude organic causes (reflux, milk protein allergy, infection, trauma, hernia, intussusception). Management: reassurance, feeding technique, burping, swaddling, gentle motion (carrying, rocking), white noise, and safe settling; avoid shaken baby injury—educate parents about 'Purple Crying'. No proven medication; probiotics/anti-colic bottles variable benefit.

Congenital CMV

– Cytomegalovirus infection acquired in utero, the most common congenital viral infection. Maternal primary infection poses highest risk of fetal transmission and disease. Can cause microcephaly, sensorineural hearing loss, chorioretinitis, hepatosplenomegaly, and petechiae. Diagnosis by CMV PCR in urine or saliva. Treatment: ganciclovir or valganciclovir for symptomatic congenital CMV. Long-term sequelae include hearing loss and developmental delay.

Congenital Diaphragmatic Hernia

– A defect in the diaphragm allowing abdominal organs to herniate into the thoracic cavity, causing pulmonary hypoplasia and respiratory distress at birth. Most commonly a posterolateral (Bochdalek) defect on the left side. Presents with cyanosis, scaphoid abdomen, and bowel sounds in the chest. Treatment: intubation, nasogastric decompression, stabilization, and surgical repair once pulmonary hypertension is controlled.

Congenital Heart Disease

– Structural heart defects present at birth, the most common congenital anomaly (1% of live births). Common defects: ventricular septal defect (VSD, 30%), atrial septal defect (ASD), patent ductus arteriosus (PDA), tetralogy of Fallot (TOF), transposition of great arteries (TGA), coarctation of aorta, and hypoplastic left heart syndrome. Presentation depends on shunt direction and severity: cyanotic (TOF, TGA, tricuspid atresia) vs. acyanotic (VSD, ASD, PDA). Cyanotic: blue spells, clubbing, polycythemia. Acyanotic: heart murmur, heart failure, failure to thrive. Detected by prenatal ultrasound, newborn pulse oximetry screening, or clinical signs.

Diagnosis: echocardiography. Treatment: surgical repair or palliation, catheter-based interventions for selected defects.

Congenital Heart Murmur

– A heart murmur detected in the newborn period, present in approximately 50-60% of healthy newborns. Most are innocent (functional) murmurs that disappear by 6 months of age. Pathologic murmurs may indicate congenital heart defects. Differentiation based on murmur characteristics, timing, and associated findings. Echocardiography recommended for pathologic murmurs. Innocent murmurs require no treatment.

Congenital Hip Dislocation

– Dislocation of the hip present at birth or developing in infancy, the severe end of developmental dysplasia of the hip (DDH). Features: positive Barlow/Ortolani tests in the neonate, limited abduction, asymmetric thigh folds, and leg length difference; in older infants—delayed walking, limp, Trendelenburg gait. Diagnosis: clinical and ultrasound (neonate/infant), X-ray after ossification. Complications: avascular necrosis of the femoral head, osteoarthritis, and disability if untreated. Management: early Pavlik harness (neonatal), closed reduction with spica casting, or open reduction/osteotomy for late diagnosis. Screening and early detection are critical for good outcomes.

Congenital Pneumonia

– Lung infection acquired in utero, often from ascending chorioamnionitis. Presents with respiratory distress, fever or hypothermia, and sepsis. Common organisms include Group B Streptococcus, *E. coli*, and *Ureaplasma*. Diagnosis by chest X-ray showing infiltrates and blood culture. Treatment: broad-spectrum IV antibiotics (ampicillin and gentamicin) plus respiratory support.

Congenital Rubella Syndrome

– Fetal infection with rubella virus, particularly dangerous in the first trimester. Classic triad: congenital heart disease (patent ductus arteriosus, pulmonary stenosis), cataracts, and sensorineural hearing loss. Also causes hepatosplenomegaly, thrombocytopenia, and blueberry muffin rash. Prevention by maternal vaccination before pregnancy. No specific antiviral treatment; supportive care.

Congenital Syphilis

– *Treponema pallidum* infection acquired transplacentally. Can cause stillbirth, prematurity, hepatosplenomegaly, rash, snuffles, osteochondritis, and Hutchinson teeth. Diagnosed by darkfield microscopy, VDRL/RPR in neonatal serum, or PCR. Treatment: IV penicillin G for 10 days. Prevention through maternal screening and treatment during pregnancy.

Congenital Zika Syndrome

– Fetal brain infection with Zika virus, causing microcephaly, brain abnormalities, eye defects, hearing loss, and limb contractures. Transmission occurs via mosquito bite or sexual contact. Diagnosis by Zika virus PCR in maternal serum or amniotic fluid. No specific treatment. Prevention by avoiding endemic areas during pregnancy. Surveillance and developmental monitoring recommended for exposed infants.

Contraception for Adolescents

– Methods to prevent unintended pregnancy. Options: combined oral contraceptives, progestin-only pills, depot medroxyprogesterone acetate, contraceptive implant (Nexplanon), intrauterine devices (IUDs), condoms, and abstinence. Long-acting reversible contraceptives (LARC) such as IUDs and implants have highest efficacy and are first-line recommendations. Dual protection against STIs requires barrier methods.

Cornelia de Lange Syndrome

– A genetic disorder caused by mutations in genes of the cohesin complex (NIPBL 60%, SMC1A, SMC3, RAD21, HDAC8). Features: characteristic facies — synophrys (confluent eyebrows), long eyelashes, low-set ears, depressed nasal bridge with anteverted nares, thin lips, and micrognathia; prenatal and postnatal growth restriction; hirsutism; microcephaly; limb defects (oligodactyly, ectrodactyly, phocomelia, 30%); and congenital heart disease (VSD, ASD). Intellectual disability ranges from moderate to severe. Gastroesophageal reflux and feeding difficulties are near-universal. Diagnosis: clinical and genetic testing. Management: growth and feeding support (gastrostomy tube often required), antireflux therapy, developmental therapies, and surveillance for hearing loss, vision problems, and scoliosis.

Craniosynostosis

– Premature fusion of one or more cranial sutures, restricting skull growth perpendicular to the affected suture. Presents with abnormal head shape (scaphocephaly from sagittal fusion, plagiocephaly from coronal fusion). May increase intracranial pressure. Diagnosis by physical examination and CT with 3D reconstruction. Treatment: surgical cranioplasty to release fused suture and allow normal brain growth, typically between 3-12 months of age.

Cri-du-Chat Syndrome

– A genetic disorder caused by a deletion of the short arm of chromosome 5 (5p-), with the size of the deletion correlating with severity. Incidence 1 in 15,000-50,000. Features: a characteristic high-pitched, cat-like cry in infancy (due to laryngeal hypoplasia), microcephaly, round face, hypertelorism, epicanthal folds, micrognathia, and hypotonia. Intellectual disability ranges from moderate to severe. Other findings: congenital heart disease (VSD, PDA), scoliosis, and hearing loss. Diagnosis: karyotype, FISH, or chromosomal microarray showing 5p deletion. Management: early intervention programs, speech therapy, physical therapy, and treatment of associated anomalies. Patients have a characteristic friendly, sociable personality. Life expectancy is near normal for mild cases.

Croup

– Acute laryngotracheobronchitis, most commonly caused by parainfluenza virus. Affects children 6 months to 3 years. Presents with barking cough, stridor, hoarseness, and inspiratory distress, worse at night. Diagnosis is clinical; X-ray shows subglottic narrowing (steeple sign). Treatment: single dose of oral dexamethasone and nebulized epinephrine for moderate to severe cases. Self-limited; resolves in 3-7 days.

Crouzon Syndrome

– An autosomal dominant craniosynostosis syndrome caused by mutations in the FGFR2 or FGFR3 genes, leading to premature fusion of multiple cranial sutures. Features: brachycephaly (short, broad head from bilateral coronal synostosis), proptosis (shallow orbits), hypertelorism, midface hypoplasia, beaked nose, and Class III malocclusion. Unlike Apert syndrome, there are no hand or foot anomalies. Intelligence is typically normal. Increased intracranial pressure can occur from progressive synostosis.

Diagnosis: clinical and genetic testing; CT for craniosynostosis confirmation. Management: multidisciplinary — cranial vault remodeling surgery for craniosynostosis (3-6 months), midface advancement (Le Fort III osteotomy, 6-12 years), and orthognathic surgery for malocclusion. Lifelong monitoring for elevated ICP, sleep apnea, and vision changes.

Developmental Milestones

- Skills and abilities that children typically acquire at predictable ages. Examples: social smile at 2 months, rolling over at 4-6 months, sitting independently at 6-8 months, walking at 12 months, and speaking two-word phrases at 2 years. Delays in reaching milestones may indicate developmental delay, autism, or neurologic impairment. Screening at each well-child visit using age-appropriate tools.

DiGeorge Syndrome

- A 22q11.2 microdeletion syndrome affecting the third and fourth pharyngeal pouches. Features: cardiac defects (tetralogy of Fallot, truncus arteriosus), hypocalcemia (parathyroid hypoplasia), immune deficiency (thymic hypoplasia), and characteristic facial features. Diagnosed by FISH testing or chromosomal microarray. Management: cardiac repair, calcium supplementation, immune monitoring, and speech therapy.

Down Syndrome

- Trisomy 21, the most common chromosomal abnormality in live births, occurring in approximately 1 in 700 births. Risk increases with maternal age. Features: characteristic facies (epicanthal folds, flat nasal bridge, protruding tongue), hypotonia, intellectual disability, congenital heart defects (AV canal), and increased risk of leukemia and early-onset Alzheimer's. Diagnosis by karyotype; prenatal screening with nuchal translucency and maternal serum markers.

DTaP Vaccine

- Diphtheria, Tetanus, and acellular Pertussis vaccine given at 2, 4, 6, and 15-18 months, and 4-6 years. Protects against three serious bacterial diseases. Diphtheria causes respiratory and cardiac complications. Tetanus causes lockjaw and muscle rigidity. Pertussis causes whooping cough, most severe in young infants. Acellular formulation reduces side effects compared to whole-cell pertussis vaccine.

Ductal-Dependent Lesions

- Congenital heart defects that require the ductus arteriosus to remain patent for adequate systemic or pulmonary blood flow. Includes pulmonary atresia, critical aortic stenosis, coarctation, hypoplastic left heart syndrome, and transposition of the great arteries. Present with cyanosis or shock when the ductus closes (typically within 24-48 hours). Treatment: prostaglandin E1 to maintain ductal patency until surgical intervention.

Duodenal Atresia

- A congenital obstruction of the duodenum caused by failure of recanalization during the 8th-10th week of gestation. Associated with Down syndrome (30%), polyhydramnios (due to impaired fetal swallowing of amniotic fluid), and other anomalies (VACTERL, congenital heart disease, annular pancreas, malrotation). Presents within hours of birth with bilious vomiting (90%, if distal to the ampulla of Vater), epigastric distension, and failure to pass meconium. The classic X-ray finding is the double bubble sign (air in the stomach and proximal duodenum, with no distal gas). Diagnosis: prenatal ultrasound (polyhydramnios, dilated stomach and duodenum), postnatal abdominal X-ray, and upper GI series to confirm and exclude malrotation. Treatment: nasogastric decompression, IV fluids, and surgical duodeno-duodenostomy (diamond-shaped anastomosis, Kimura technique). Prognosis: excellent with surgical repair (>95% survival), but depends on associated anomalies.

Dyslexia

- A specific learning disorder with neurobiological origin, characterized by difficulties with accurate and fluent word recognition, spelling, and decoding ability, despite adequate intelligence, motivation, and educational opportunity. Affects approximately 5-10% of the population. The underlying cause involves impaired phonological processing (difficulty recognizing and manipulating the sounds of spoken language) and deficits in rapid automatized naming. Functional neuroimaging shows reduced left temporoparietal and occipitotemporal activation during reading. Diagnosis: comprehensive educational assessment evaluating reading accuracy, fluency, comprehension, and phonological processing. Management: structured, explicit, multisensory phonics-

based reading instruction (Orton-Gillingham, Wilson Reading System, Barton), assistive technology, and educational accommodations.

Edwards Syndrome

- Trisomy 18, the second most common autosomal trisomy in live births (1 in 5,000). Caused by complete trisomy 18 (94%), mosaicism, or partial trisomy (translocation). Features: severe intrauterine growth restriction, clenched fists with overlapping fingers (index over middle, fifth over fourth), rocker-bottom feet, low-set malformed ears, micrognathia, prominent occiput, and congenital heart defects (VSD, PDA, polyvalvular disease, 90-95%). Other findings: horseshoe kidney, esophageal atresia, omphalocele, and neural tube defects. Diagnosis: prenatal screening (low PAPP-A, low hCG, high inhibin A), NIPT, and karyotype/CMA. Management: comfort care is the standard (median survival 5-15 days; 5-10% survive to 1 year). Surgical intervention for life-threatening anomalies is controversial. Survivors have severe intellectual disability.

Ehlers-Danlos Syndrome

- A group of hereditary connective tissue disorders caused by defects in collagen synthesis or processing. The most common types: Classic (COL5A1, COL5A2) — skin hyperextensibility, atrophic scarring, and joint hypermobility; Hypermobile (hEDS, unknown genetic cause, most common) — generalized joint hypermobility, chronic pain, and easy bruising; Vascular (COL3A1, most dangerous) — thin translucent skin, easy bruising, arterial rupture (carotid, aortic, visceral), uterine rupture, and sigmoid colon perforation; Kyphoscoliotic (PLOD1) — congenital hypotonia, scoliosis, and joint laxity; and Arthrochalasia (COL1A1, COL1A2) — severe joint hypermobility and congenital hip dislocation. Diagnosis: clinical (Beighton score for hypermobility), collagen typing on skin biopsy (vascular type), and genetic testing. Management: activity modification and joint protection, vascular surveillance for vascular EDS (carotid duplex, aortic imaging, avoidance of invasive procedures), high-dose vitamin C, and genetic counseling. No cure; management is symptomatic and preventive.

Emergency Contraception

- Postcoital contraception to prevent pregnancy after unprotected intercourse or contraceptive failure.

Levonorgestrel (Plan B): effective within 72 hours, available over the counter. Ulipristal acetate (Ella): effective within 120 hours, prescription only. Copper IUD: most effective emergency contraception, placed within 5 days. Not abortifacients; prevent or delay ovulation.

Enuresis (Bedwetting)

- Involuntary urination during sleep in a child aged 5 years or older, affecting approximately 5–10% of 7-year-olds. Primary enuresis: the child has never achieved sustained nighttime dryness. Secondary enuresis: wetting recurs after at least 6 months of dryness, often triggered by psychosocial stress, urinary tract infection, or diabetes. Pathophysiology involves a mismatch between nocturnal bladder capacity, nighttime urine production (lack of circadian ADH rhythm), and inability to arouse from sleep in response to bladder fullness. Evaluation: history (wetting pattern, fluid intake, constipation), urinalysis (glucose, infection). Management: behavioral (timed voiding, reward systems, fluid restriction before bed), enuresis alarm (first-line, 70% success), and pharmacotherapy (desmopressin—synthetic ADH—reduces nighttime urine production).

Epiglottitis

- Inflammation of the epiglottis, a life-threatening emergency. Most commonly caused by *Haemophilus influenzae* type b (now rare due to vaccination). Presents with high fever, drooling, dysphagia, tripod position, and rapid progression to airway obstruction. Do not examine the throat. Treatment: secure airway in operating room, IV antibiotics (ceftriaxone). Requires immediate airway management; mortality high if untreated.

Epispadias

- A congenital anomaly where the urethral meatus opens on the dorsal (top) surface of the penis in boys or in a split, open position on the clitoral hood in girls. Caused by abnormal development of the genital tubercle and cloacal membrane. In boys, the opening may be at the glans (glandular, mildest), penile shaft, or penopubic (most severe, associated with bladder exstrophy). In girls, the urethra is short with a bifid clitoris and separated labia. Epispadias presents as part of the exstrophy-epispadias complex spectrum. The penis is short, wide, and up-

wardly curved (dorsal chordee). Diagnosis: clinical. Treatment: surgical repair (Mitchell or Cantwell-Ransley technique) between 6-12 months — urethral reconstruction, penile straightening, and urethroplasty. Prognosis: urinary continence is achieved in 70-80% with repaired epispadias.

Erb's Palsy

– Upper brachial plexus injury (C5-C6) causing weakness or paralysis of the shoulder and arm muscles. Presents with the characteristic waiter's tip position: arm adducted, elbow extended, forearm pronated, wrist flexed. Most commonly caused by shoulder dystocia during delivery. Approximately 80-90% recover spontaneously. Management includes physical therapy to prevent contractures; surgical intervention if no improvement by 3-6 months.

Esophageal Atresia

– A congenital anomaly where the esophagus ends in a blind pouch, often with a tracheoesophageal fistula connecting the distal esophagus to the trachea. Presents with drooling, inability to pass a nasogastric tube, and choking with feedings. The 3 Es association: Esophageal atresia, Esophageal anomalies, and Extremity anomalies. Treatment: surgical ligation of fistula and esophageal anastomosis.

Exchange Transfusion

– Emergent procedure to rapidly lower severe hyperbilirubinemia by removing small volumes of the infant's blood and replacing with compatible donor blood. Used when phototherapy fails or bilirubin approaches toxic levels (greater than 25 mg/dL in term infants or above exchange threshold on Bhutani curve). Risks include infection, electrolyte imbalances, and air embolism. Double-volume exchange (160-200 mL/kg) replaces approximately 85% of circulating red blood cells.

Failure to Thrive

– Inadequate growth in children, defined as weight below the 5th percentile or crossing two major percentile lines on growth charts. Causes include caloric insufficiency (neglect, poor feeding), organic disease (congenital heart disease, renal disease), and psychosocial factors. Evaluation includes comprehensive history, physical examination, laboratory studies, and calorie counts. Treatment addresses underlying cause and nutritional rehabilitation.

Fanconi Anemia

– An autosomal recessive (or X-linked) bone marrow failure syndrome caused by mutations in at least 22 FANC genes involved in DNA repair (the FA/BRCA pathway). Features: progressive pancytopenia (onset typically at 5-10 years), radial ray anomalies (thumb hypoplasia or aplasia, radial club hand), microcephaly, short stature, café-au-lait spots, and renal anomalies. Increased risk of myelodysplastic syndrome, acute myeloid leukemia, and solid tumors (head and neck squamous cell carcinoma, gynecological cancer). Diagnosis: chromosomal breakage test (diepoxybutane or mitomycin C — increased chromosome breaks) and FANC gene sequencing. Management: androgens (oxymetholone) for cytopenias, hematopoietic stem cell transplant for bone marrow failure (with reduced-intensity conditioning), and lifelong cancer surveillance.

Febrile Seizures

– Seizures occurring in children 6 months to 5 years triggered by fever (temperature greater than 38 degrees Celsius), without intracranial infection or defined cause. Occurs in 2-5% of children. Simple: generalized, single seizure lasting less than 15 minutes, no recurrence within 24 hours. Complex: focal, prolonged (greater than 15 minutes), or recurrent within 24 hours. Diagnosis of exclusion after ruling out meningitis and intracranial infection. In simple febrile seizures, there is no increased risk of epilepsy. Management: parental education on seizure first aid, antipyretics for comfort (do not prevent recurrence), and reassurance. No routine antiepileptic medication is indicated. Lumbar puncture should be considered when meningeal signs are present or in infants under 12 months with incomplete vaccination.

Fetal Distress

– Abnormal fetal status during labor, indicated by abnormal fetal heart rate patterns (late or prolonged decelerations, minimal variability, absent accelerations). May indicate fetal hypoxia, cord compression, or placental insufficiency. Management includes intrauterine resuscitation: change maternal position, stop oxytocin, give IV fluids and oxygen, and amnioinfusion. If persistent, emergent delivery by cesarean or operative vaginal delivery.

Fifth Disease

– Erythema infectiosum caused by Parvovirus B19.

Characterized by bright red cheeks (slapped cheek appearance) followed by a lacy, reticulated rash on the trunk and extremities. Mild febrile illness in children. Concern in pregnancy (hydrops fetalis risk) and immunocompromised patients (pure red cell aplasia). Diagnosis by serology. Self-limited; no specific treatment.

Fine Motor Skills

- The ability to use small muscles (hands/fingers) for precise movements, developing with age: reaching (3-4 months), grasping (5-6 months), pincer grasp (9-12 months), self-feeding (12-18 months), building towers/scribbling (18-24 months), drawing shapes and using utensils (3-5 years), and handwriting. Delays relate to neuromotor conditions (cerebral palsy, developmental delay), visual problems, and autism (with other signs). Assessed at well-child visits; early referral for occupational therapy improves function. Monitor bimanual use, hand dominance, and age-appropriate play skills.

Fontanelle

- Soft membranous spaces between skull bones that allow brain growth and skull molding during delivery. Anterior fontanelle diamond-shaped, closes by 12-18 months. Posterior fontanelle triangular, closes by 2-3 months. Bulging fontanelle suggests increased intracranial pressure; sunken fontanelle indicates dehydration. Palpation is part of the routine infant physical examination.

Formula Feeding

- Alternative to breastfeeding using commercially prepared infant formula. Types include cow's milk-based, soy-based, hydrolyzed protein, and amino acid-based formulas. Iron-fortified formulas standard to prevent iron deficiency anemia. Preparation requires clean water and proper sterilization of bottles. Feeding on demand approximately every 3-4 hours. Provides adequate nutrition when breastfeeding is not possible or desired.

Fragile X Syndrome

- X-linked dominant disorder caused by CGG trinucleotide repeat expansion in the FMR1 gene. Most common inherited cause of intellectual disability. Features: long face, prominent ears, macroorchidism in post-pubertal males, and behavioral problems including autism spectrum features. Diagnosis by DNA testing for CGG repeat expansion. No cure;

behavioral and educational interventions.

Functional Asplenia

- Loss of splenic function due to sickling and infarction in sickle cell disease, typically by age 5 years. Increases risk of overwhelming bacterial infection, particularly from encapsulated organisms (*Streptococcus pneumoniae*, *Haemophilus influenzae*). Management: prophylactic penicillin, pneumococcal vaccines, and parental education about fever as a medical emergency.

Galactocele

- A milk-filled cyst in the breast, typically occurring in lactating women. Caused by obstruction of a milk duct. Presents as a palpable, tense, fluctuant mass that may be tender. Diagnosis is clinical and by ultrasound (simple cyst, may have fat-fluid level). Milky fluid may be aspirated. Differentiated from breast abscess (fever, erythema, tenderness, purulent fluid). Management: conservative (continued breastfeeding, warm compresses), aspiration if symptomatic or for diagnosis. Rarely, galactocele can occur in the breast bud of a neonate (maternal hormone stimulation).

Galant Reflex

- A primitive reflex present from birth to 4 months, elicited by stroking the skin along the side of the infant's back. The infant curves toward the stimulated side. Assessed by running a finger from the lateral back toward the hip while the infant is in ventral suspension. Absence may indicate neurologic abnormality. One of the trunk reflexes evaluated during newborn neurologic examination.

Gastroschisis

- A full-thickness abdominal wall defect, usually to the right of the umbilicus, through which bowel herniates without a covering membrane. Not associated with chromosomal abnormalities. Presents at birth with exposed bowel loops that may be edematous, thickened, and discolored from amniotic fluid exposure. Management: immediate coverage with saline-moistened dressings, nasogastric decompression, and surgical repair (primary closure or staged reduction).

German Measles (Rubella)

- See Rubella.

Glandular Fever (Infectious Mononucleosis)

- See Mononucleosis.

Glycogen Storage Disease

- A group of inherited metabolic disorders caused by defects in glycogen synthesis, breakdown, or regulation, resulting in abnormal glycogen accumulation in tissues. Major types: Type I (von Gierke, G6PC deficiency) — fasting hypoglycemia, lactic acidosis, hepatomegaly, hyperuricemia, and hypertriglyceridemia. Type II (Pompe disease, GAA deficiency) — infantile form: hypertrophic cardiomyopathy, hypotonia, and death by 1 year; late-onset: proximal myopathy and respiratory weakness. Type III (Cori disease, AGL deficiency) — hypoglycemia, hepatomegaly, and myopathy. Type IV (Andersen disease, GBE1 deficiency) — liver failure, cirrhosis, and cardiomyopathy. Type V (McArdle disease, PYGM deficiency) — exercise intolerance, myoglobinuria, and second-wind phenomenon. Type VI (Hers disease, PYGL deficiency) — mild fasting hypoglycemia and hepatomegaly. Type VII (Tarui disease, PFKM deficiency) — exercise intolerance similar to McArdle with hemolytic anemia. Diagnosis depends on the type: enzyme assay in liver or muscle biopsy, genetic testing, and newborn screening for Pompe. Treatment varies by type: Type I — continuous glucose therapy (cornstarch), allopurinol, and lipid-lowering agents. Type II (Pompe) — enzyme replacement therapy (alglucosidase alfa). Types III, VI — high-protein diet. Types V, VII — exercise modification and creatine supplementation.

Goldenhar Syndrome

- A variant of hemifacial microsomia characterized by the triad: epibulbar dermoids (benign conjunctival tumors), preauricular skin tags or sinuses, and vertebral anomalies (hemivertebrae, fused vertebrae, scoliosis). Also involves facial asymmetry, microtia, conductive hearing loss, and macrostomia. Other associations: congenital heart disease (VSD, tetralogy of Fallot), renal anomalies, and cleft lip/palate. Most cases are sporadic. Diagnosis: clinical and imaging (CT for skeletal anomalies, echocardiogram, renal ultrasound). Management: multidisciplinary — ophthalmology (epibulbar dermoid excision), audiology (hearing aids), plastic surgery (auricular reconstruction, mandibular distraction), and orthopedic monitoring for scoliosis.

Gonorrhea

- A bacterial STI caused by *Neisseria gonorrhoeae*, the second most common reportable infection. Can cause cervicitis, urethritis, pharyngeal infection, and disseminated gonococcal infection. Diagnosis by nucleic acid amplification test. Treatment: dual therapy with ceftriaxone and azithromycin (or doxycycline for uncomplicated cases). Increasing antibiotic resistance is a major public health concern.

Gross Motor Skills

- The ability to use large muscle groups for movement and posture, developing in a predictable sequence in infancy/childhood: head control (3 months), sitting (6 months), crawling (9 months), standing (10-12 months), walking (12-18 months), running/jumping (2-3 years), hopping and balance (3-5 years). Delays warrant assessment: cerebral palsy, muscular dystrophy, developmental delay, hypotonia, and environmental factors. Milestone monitoring at well-child visits (screening—ASQ) and early intervention improve outcomes; gross motor regression is always concerning. Encourage tummy time and active play.

Group B Strep

- Group B *Streptococcus* (GBS, *Streptococcus agalactiae*): a gram-positive coccus colonizing the GI and genitourinary tract in 10-30 percent of women; major cause of neonatal sepsis and meningitis. Neonatal disease: early-onset (<7 days—vertical transmission during delivery: sepsis, pneumonia, meningitis) and late-onset (7 days-3 months—sepsis, meningitis, osteomyelitis). Risk: maternal GBS carriage, preterm, prolonged rupture of membranes, intrapartum fever, and previous GBS-affected infant. Prevention: universal screening (35-37 weeks) and intrapartum antibiotic prophylaxis (penicillin) for carriers. Diagnosis: blood/CSF culture, PCR. Management: empiric antibiotics (penicillin/ampicillin + gentamicin), supportive care; also causes UTI and chorioamnionitis in pregnancy.

Growing Pains

- Recurrent, bilateral leg pain in children ages 3-12, typically occurring in the late afternoon or evening and resolving by morning. Pain is deep, aching in the calves, shins, and thighs (not joints). No limping, fever, swelling, or functional impairment. Etiology unclear: may relate to increased activity, musculoskeletal overuse, or decreased pain threshold.

Diagnosis: clinical (diagnosis of exclusion). Red flags suggesting pathology: unilateral pain, joint involvement, morning stiffness, limping, fever, night sweats, nocturnal pain waking the child. Treatment: reassurance, massage, stretching, warm baths, and acetaminophen/ibuprofen as needed. Benign and self-limited.

Growth Chart

- A graphical representation of growth (weight, height/length, head circumference, BMI) plotted against age, standardized by population (WHO growth standards 0-5 years; CDC growth charts 2-20 years; percentiles/z-scores). Used to monitor normal growth, detect growth disorders (failure to thrive, short stature, obesity, microcephaly/macrocephaly), and assess nutritional status. Interpretation: track crossing of percentiles (crossing downward—poor growth; upward—overfeeding/obesity), symmetry, and parental heights (target height). Regular plotting at well-child visits identifies deviations early, prompting evaluation (nutrition, endocrine, chronic disease, genetic).

Gynecomastia

- Enlargement of breast tissue in males, often bilateral, occurring physiologically in neonates, during puberty (40-60% of boys), and in aging men. Pathologic causes include Klinefelter syndrome, testicular tumors, medications (spironolactone, cannabis), and liver disease. Persistent or asymmetric gynecomastia warrants evaluation. Management: observation for physiologic cases; treatment of underlying cause; mastectomy for severe persistent cases.

Hand Foot and Mouth Disease

- A common viral illness (mostly children <10 years) caused by coxsackievirus A16 (and enterovirus 71), transmitted by fecal-oral/respiratory. Features: fever, sore throat, and a vesicular rash on the hands, feet, and mouth (ulcers on buccal mucosa, tongue, palate; vesicles on palms/soles); enterovirus 71 may cause severe CNS disease (meningoencephalitis, polio-like paralysis) and cardiorespiratory failure. Diagnosis: clinical. Management: supportive—hydration, analgesia, and antipyretics; watch for dehydration; severe/neurologic cases (EV71) require hospital care. Highly contagious; hygiene and isolation. Usually self-limiting in 7-10 days.

Hand-Foot-Mouth Disease

- A viral illness caused by Coxsackievirus A16 or Enterovirus 71, common in children under 5. Presents with fever, malaise, and characteristic vesicular rash on hands, feet, and mouth. Oral lesions are painful ulcers on the tongue and buccal mucosa. Self-limited in 7-10 days. Complications are rare but include encephalitis, myocarditis, and nail loss (onychomadesis) weeks later.

Head Circumference

- Measured at the largest circumference above the ears and eyebrows, reflecting brain growth. Plotted on growth charts to detect microcephaly (below 3rd percentile) or macrocephaly (above 98th percentile). Rapid increase may indicate hydrocephalus or intracranial hemorrhage; failure to grow may indicate microcephaly or brain atrophy. Measured at each well-child visit until age 2.

Head lice

- Also known as pediculosis capitis, an infestation of the scalp by the obligate human ectoparasite *Pediculus humanus capitis*, a wingless, blood-sucking insect that feeds on human blood. It is extremely common, especially in school-aged children aged 3-11 years, with an estimated 6-12 million infestations annually in the United States. Transmission is primarily through direct head-to-head contact (the most common route), and less commonly through shared combs, brushes, hats, headphones, pillows, or other personal items. Lice do not jump or fly; they crawl. Diagnosis is confirmed by finding live lice or nits attached to hair shafts within 1 cm of the scalp using a fine-toothed detection comb. Treatment: topical pediculicides containing permethrin 1% or dimeticone; oral ivermectin for treatment-resistant cases; wet combing (bug busting) as a non-insecticidal alternative. Bedding and clothing should be washed in hot water (60 degrees Celsius) and non-washable items sealed in a plastic bag for 2 weeks. Prophylactic treatment of household contacts is not recommended. School exclusion policies vary; the American Academy of Pediatrics and the UK National Institute for Health and Care Excellence recommend children remain in school after first treatment, as no-nit policies are unnecessary and promote stigma.

Hearing Screening

- Newborn hearing screening (universal): otoacous-

tic emissions (OAE) and/or automated auditory brainstem response (AABR) before discharge; referral for comprehensive audiology if failed. Early detection (<6 months) of congenital hearing loss (1-3/1000) allows early intervention (hearing aids, cochlear implants, early communication) with vastly improved language outcomes. Risk factors: family history, prematurity, low birth weight, infections (CMV, meningitis), ototoxic drugs, and jaundice. Ongoing surveillance: behavioral screening and audiometry at well-child visits and school; signs of delayed speech/response to sound prompt referral. Follow-up and documentation are critical.

Hemifacial Microsomia

– A congenital craniofacial disorder involving asymmetric hypoplasia of the structures derived from the first and second branchial arches, most commonly affecting the mandible, ear, and soft tissues on one side. Also known as craniofacial microsomia or Goldenhar syndrome when epibulbar dermoids and vertebral anomalies are present. Presents with asymmetry: mandibular hypoplasia (Pruzansky-Kaban classification I-III), microtia (small or absent pinna), preauricular tags or sinuses, conductive hearing loss, and macrostomia (enlarged oral commissure). Severity ranges from mild asymmetry to severe facial deformity. Diagnosis: clinical, CT for skeletal assessment, and audiometry. Management: reconstructive surgery (mandibular distraction, costochondral graft, or orthognathic surgery), auricular reconstruction, hearing rehabilitation, and speech therapy.

Henoch-Schonlein Purpura

– A systemic vasculitis (IgA-mediated) affecting small vessels, primarily in children. Classic tetrad: palpable purpura (lower extremities), arthritis/arthralgia, abdominal pain, and renal involvement. May follow upper respiratory infection. Diagnosis is clinical. Renal involvement monitored with urinalysis. Most cases self-limited; corticosteroids for severe abdominal or renal disease.

Hepatitis B Vaccine

– Recombinant vaccine given at birth, 1-2 months, and 6-18 months. Protects against hepatitis B virus, which can cause chronic liver disease, cirrhosis, and hepatocellular carcinoma. Also prevents perinatal transmission when given to infants of HBsAg-

positive mothers within 12 hours of birth, plus hepatitis B immune globulin.

Hib

– *Haemophilus influenzae* type b: an encapsulated gram-negative bacterium causing serious invasive disease in unvaccinated children—meningitis, epiglottitis, pneumonia, septic arthritis, cellulitis, and sepsis. Highly prevented by the Hib conjugate vaccine (given in infancy, part of routine schedule). Invasive Hib disease in vaccinated populations is rare. Diagnosis: culture/PCR (blood, CSF). Management: antibiotics (third-generation cephalosporin—ceftriaxone), and respiratory/droplet precautions; treatment of close contacts with rifampin chemoprophylaxis (household/school, especially with young children); monitor for complications (meningitis—deafness). Epiglottitis is an airway emergency.

Hip Dysplasia

– Developmental dysplasia of the hip (DDH): abnormal development of the acetabulum/femoral head causing instability, subluxation, or dislocation. Risk factors: female, breech presentation, family history, firstborn, and tight swaddling. Features: asymmetric skin creases, limited abduction, Ortolani (relocation) and Barlow (dislocation) tests in the newborn; later—gait limp, leg length discrepancy, Trendelenburg. Diagnosis: ultrasound (age <6 months), X-ray (older). Management: early—Pavlik harness (success >90 percent); late—closed reduction/casting or surgery. Screening (clinical ± selective ultrasound) and early referral prevent long-term arthritis and disability.

Holt-Oram Syndrome

– An autosomal dominant disorder caused by TBX5 gene mutations, characterized by congenital heart disease and upper limb malformations. Cardiac anomalies: atrial septal defect (most common), VSD, and conduction abnormalities (heart block, atrial fibrillation). Limb defects are bilateral and asymmetric: thumb anomalies (absent, hypoplastic, triphalangeal, or finger-like thumb, 100%), radial dysplasia (radial club hand), and phocomelia. Diagnosis: clinical (heart defect + preaxial radial ray anomaly) and TBX5 genetic testing. Management: cardiac repair (ASD/VSD closure, pacemaker for heart block), reconstructive hand surgery (polliciza-

tion for absent thumb, centralization for radial club hand), and genetic counseling.

Homocystinuria

– An autosomal recessive inborn error of methionine metabolism caused most commonly by deficiency of cystathionine beta-synthase (CBS), leading to accumulation of homocysteine and methionine. Features (develop in childhood if untreated): ectopia lentis (lens dislocation, typically downward, differentiating from Marfan syndrome), severe myopia, intellectual disability, thromboembolism (the major cause of morbidity/mortality, affecting arteries and veins), osteoporosis, and a Marfanoid habitus (tall stature, pectus deformities, arachnodactyly). Diagnosis: elevated plasma homocysteine and methionine, homocystinuria, and CBS gene sequencing. Newborn screening includes homocystinuria in expanded panels. Treatment: pyridoxine (vitamin B6) responsiveness testing (approximately 50% are responsive), betaine (to remethylate homocysteine to methionine), methionine-restricted diet (especially for non-responders), and anticoagulation (aspirin for thromboprophylaxis). Lifelong monitoring for thromboembolism and lens dislocation.

Horseshoe Kidney

– The most common renal fusion anomaly (1 in 400-500), where the lower poles of both kidneys are fused across the midline by an isthmus of renal parenchyma or fibrous tissue. The fused kidney is located lower in the abdomen than normal (at L3-L5, anterior to the aorta and IVC) due to the isthmus being trapped under the inferior mesenteric artery during ascent. Associated with Turner syndrome, Edwards syndrome, Patau syndrome, and other urogenital anomalies. Often asymptomatic and discovered incidentally. May present (30%) with hydronephrosis from UPJ obstruction (the ureter passes anterior to the isthmus, causing kinking), recurrent UTIs, nephrolithiasis, and increased risk of Wilms tumor. Diagnosis: ultrasound, CT, or IV pyelogram. Treatment: surgical management of complications (pyeloplasty for UPJ obstruction, and nephrolithotomy for stones). Surveillance imaging for Wilms tumor is controversial.

HPV Vaccine

– Human Papillomavirus vaccine given at 11-12 years (can start at 9), with series completion by 15 years.

Two-dose series if started before 15; three-dose series if started at 15 or older. Protects against HPV types causing cervical cancer, oropharyngeal cancer, and genital warts. Gardasil 9 covers nine HPV types. Expected to prevent over 90% of HPV-associated cancers.

Human Papillomavirus

– The most common STI, with over 100 types. High-risk types (16, 18) cause cervical, oropharyngeal, anal, and genital cancers. Low-risk types (6, 11) cause genital warts. Prevention: HPV vaccine (Gardasil 9) protects against 9 HPV types. Screening: Pap smear and HPV testing for cervical cancer prevention. Most infections clear spontaneously.

Hunter Syndrome

– Mucopolysaccharidosis type II (MPS II), an X-linked recessive lysosomal storage disorder caused by iduronate-2-sulfatase deficiency (IDS gene mutations). Accumulation of dermatan sulfate and heparan sulfate (same as Hurler). Two forms: severe (neuronopathic, 2/3 of cases) — progressive intellectual disability, neurodegeneration, and death by 10-15 years; attenuated (no or minimal neurologic involvement) — survival into adulthood. Features: coarse facies, corneal clouding (less prominent than Hurler), hepatosplenomegaly, recurrent hernias, dysostosis multiplex, joint stiffness, short stature, and cardiac valvular disease. A characteristic feature is the pebbled, ivory-white skin lesions (papules) over the back and shoulders (pathognomonic). Diagnosis: urine GAG analysis, iduronate-2-sulfatase enzyme assay, and IDS gene sequencing. Treatment: enzyme replacement therapy (idursulfase, Elaprase) improves somatic features, and intrathecal idursulfase is under investigation for neurologic disease. HSCT is less effective than in MPS I.

Hurler Syndrome

– Mucopolysaccharidosis type I (MPS I), the severe form, an autosomal recessive lysosomal storage disorder caused by alpha-L-iduronidase deficiency (IDUA gene mutations). Accumulation of dermatan sulfate and heparan sulfate leads to progressive multisystem involvement. Features: coarse facies (gargoyle-like appearance), corneal clouding, hepatosplenomegaly, recurrent hernias, dysostosis multiplex (kyphoscoliosis, J-shaped sella, paddle ribs,

claw-hand deformity, hip dysplasia), aortic valve disease, and severe intellectual disability. Hearing loss, obstructive airway disease, and hydrocephalus (communicating) are common. Diagnosis: urine glycosaminoglycan (GAG) analysis (elevated dermatan and heparan sulfate) and IDUA enzyme assay in leukocytes. Newborn screening is available. Treatment: hematopoietic stem cell transplant (HSCT) performed early (<2.5 years) preserves cognitive function and improves somatic features but does not fully correct skeletal or corneal disease. Enzyme replacement therapy (laronidase, iduronidase) improves somatic features but does not cross the blood-brain barrier. Prognosis: untreated, death by 6-10 years from cardiorespiratory failure.

Hydrocephalus

– Abnormal accumulation of cerebrospinal fluid within the ventricular system, causing ventricular dilation and increased intracranial pressure. In neonates, presents with rapid head circumference growth, bulging fontanelle, and irritability. Causes include neural tube defects, intraventricular hemorrhage, aqueductal stenosis, and infection. Treatment: ventriculoperitoneal shunt placement or endoscopic third ventriculostomy.

Hypertelorism

– Increased distance between the orbits (the bony eye sockets), measured as an increased interorbital distance on imaging. Can result from premature fusion of the cranial sutures (craniosynostosis syndromes), frontonasal dysplasia, facial clefting, or can be associated with genetic syndromes (Apert, Crouzon, Noonan, 22q11.2 deletion, and CHARGE). Presents with widely spaced eyes (telecanthus). Diagnosis: clinical measurement of the intercanthal distance and orbital imaging (CT or MRI) to confirm increased interorbital distance. Management: surgical correction by orbital box osteotomy or facial bipartition for severe cases; treatment of the underlying syndrome. Not typically a functional concern.

IgA Vasculitis (Henoch-Schonlein Purpura)

– The most common systemic vasculitis in children (peak age 2-8 years), characterized by IgA1-containing immune complex deposition in small vessels. Often preceded by an upper respira-

tory tract infection (e.g., group A Streptococcus). Classic clinical tetrad: 1) Palpable purpura (non-thrombocytopenic) on lower extremities and buttocks, 2) Arthralgia/arthritis (knees, ankles), 3) Abdominal pain (colicky, risk of intussusception), and 4) Renal involvement (hematuria, proteinuria, IgA nephropathy). Lab workup: normal platelet count, elevated serum IgA, normal complement levels. Management: supportive care, NSAIDs for joint pain; systemic corticosteroids for severe abdominal pain or crescentic glomerulonephritis. Excellent prognosis with >90% spontaneous resolution.

Immune Thrombocytopenic Purpura

– Autoimmune destruction of platelets by antiplatelet antibodies, causing isolated thrombocytopenia. Most common in children 2-6 years, often following viral infection. Presents with petechiae, purpura, and mucosal bleeding. Diagnosis of exclusion. Treatment: observation for mild cases; IVIG or corticosteroids for severe thrombocytopenia or active bleeding. Spontaneous resolution in 80% within 6 months.

Imperforate Anus

– A congenital anomaly where the anus is completely absent or fails to open at the perineum. Classified as low (distal to the levator ani complex) or high (proximal to the levator ani). Often associated with other anomalies including vertebral, anal, cardiac, tracheoesophageal, renal, and limb defects. Presents with absence of anal opening on physical examination. Management: colostomy for high lesions; perineal anoplasty for low lesions.

Impetigo

– A superficial bacterial skin infection, most commonly caused by Staphylococcus aureus or Group A Streptococcus. Presents with honey-colored crusted lesions (nonbullous) or fluid-filled blisters (bullous). Common in children. Diagnosis is clinical. Treatment: topical mupirocin for localized disease; oral antibiotics for extensive disease. Prevention by good hand hygiene and avoiding sharing personal items.

Infantile Colic

– A behavioral syndrome in healthy infants characterized by episodes of excessive, inconsolable crying for >3 hours per day, >3 days per week, for >3 weeks (Wessel criteria). Onset typically at 2-3 weeks,

peaks at 6-8 weeks, and resolves by 3-4 months of age. Etiology poorly understood: possible GI (gas, gut microbiota, cow milk protein intolerance), neurodevelopmental, or behavioral. Diagnosis: clinical; must rule out organic causes (intussusception, GERD, infection, hair tourniquet, corneal abrasion, testicular torsion). Treatment: parental reassurance, carrying/rocking, white noise, and swaddling. Probiotics, simethicone, and hypoallergenic formula may help some infants. Prognosis: excellent, self-limited.

Influenza Vaccine

– Inactivated influenza vaccine given annually starting at 6 months of age. Two doses needed in the first season for children under 9. Live attenuated nasal spray vaccine (FluMist) available for children over 2. Updated annually to match circulating strains. Reduces influenza complications, hospitalizations, and deaths. Recommended for all children.

Intestinal Atresia

– A congenital obstruction of the small intestine (jejunum or ileum) caused by an intrauterine vascular accident (mesenteric ischemia) leading to aseptic necrosis and resorption of a segment of bowel. In contrast to duodenal atresia, it is not associated with Down syndrome. Presents in the first 24-48 hours with bilious vomiting and progressive abdominal distension. Failure to pass meconium is universal with distal atresia. Classification (Grosfeld): Type I — mucosal web with intact bowel wall; Type II — blind ends connected by a fibrous cord; Type IIIa — complete separation of blind ends with a V-shaped mesenteric defect; Type IIIb — apple-peel or Christmas-tree deformity (extensive atresia with a spiral-shaped distal bowel); Type IV — multiple atresias. Diagnosis: abdominal X-ray shows dilated proximal bowel loops (number indicates level of atresia) with no distal gas; contrast enema shows an unused microcolon. Treatment: primary anastomosis after resection of the dilated proximal segment; tapering enteroplasty may be needed for severe proximal dilation. Prognosis: excellent for Type I-IIIa; guarded for IIIb and IV.

Intraventricular Hemorrhage

– Bleeding into the germinal matrix and ventricular system, primarily in premature infants less than 32 weeks gestation. Graded I-IV by severity on cranial

ultrasound. Grade I (germinal matrix only) and Grade II (intraventricular without dilation) have good prognosis. Grade III (with ventricular dilation) and Grade IV (parenchymal involvement) risk neurodevelopmental impairment. Prevention: antenatal corticosteroids, avoiding rapid fluid shifts.

Jaundice in newborns

– Also known as neonatal hyperbilirubinemia, a common condition in newborns caused by increased bilirubin production from the breakdown of fetal red blood cells (high haematocrit, shortened red cell life span of 70-90 days vs. 120 days in adults) and immature hepatic conjugation and excretion. Physiologic jaundice of the newborn appears after 24 hours of life, peaks at 3-5 days in term infants (bilirubin typically less than 12-15 mg/dL) and 5-7 days in preterm infants, and resolves spontaneously within 2 weeks (term) or 3-4 weeks (preterm) without treatment. Pathologic jaundice is characterized by onset within 24 hours of life, rapid rise of bilirubin (greater than 5 mg/dL/day), levels above the physiologic range, or jaundice persisting beyond 2 weeks. Causes include ABO or Rh incompatibility, G6PD deficiency, hereditary spherocytosis, cephalohematoma, breast milk jaundice, and biliary atresia (conjugated hyperbilirubinemia). Assessment involves total and direct bilirubin levels plotted on the Bhutani nomogram to determine intervention thresholds. Phototherapy is first-line treatment, using blue light (460-490 nm) to convert bilirubin into water-soluble isomers excreted in urine and stool. Exchange transfusion is reserved for severe hyperbilirubinemia approaching neurotoxic levels to prevent kernicterus. Adequate feeding and frequent wet nappies facilitate bilirubin elimination. All newborns should be monitored before and after discharge with appropriate follow-up.

Juvenile Idiopathic Arthritis (JIA)

– A heterogeneous group of autoimmune and inflammatory conditions causing persistent arthritis (joint swelling, pain, limited range of motion) in children aged <16 years, lasting >6 weeks. Classification: oligoarticular (most common, 50%, <5 joints, high risk of uveitis), polyarticular (RF-positive or RF-negative, 30%), systemic-onset (Still disease, high spiking fevers, salmon-pink evanescent rash, serositis, hepatosplenomegaly), enthesitis-related (enthe-

sitis, sacroiliitis, HLA-B27 association), and psoriatic arthritis. etiology: complex genetic predisposition (HLA class II associations) plus environmental triggers. Management: NSAIDs (first-line), intra-articular corticosteroid injections, methotrexate (first-line DMARD), biologic agents (anti-TNF—etanercept, adalimumab; anti-IL-6—tocilizumab for systemic JIA; anti-IL-1—anakinra). Uveitis screening is essential (slit-lamp every 3-4 months) as most cases are asymptomatic and can cause blindness.

Kawasaki Disease

– An acute vasculitis of childhood affecting medium-sized arteries, particularly coronary arteries. Diagnosis requires fever greater than 5 days plus 4 of 5 criteria: bilateral conjunctivitis, oral mucosal changes, cervical lymphadenopathy, extremity changes, and polymorphous rash. Complications include coronary artery aneurysms. Treatment: high-dose IV immunoglobulin and aspirin. Most common acquired heart disease in children in developed countries.

Kernicterus

– Bilirubin encephalopathy resulting from severe unconjugated hyperbilirubinemia (typically greater than 25 mg/dL in term infants). Bilirubin deposits in the basal ganglia, hippocampus, and brainstem nuclei. Presents with lethargy, poor feeding, high-pitched cry, opisthotonus, seizures, and choreoathetosis. May cause permanent neurologic damage including hearing loss, cerebral palsy, and intellectual disability. Prevention by treating severe jaundice with phototherapy or exchange transfusion.

Klippel-Trenaunay Syndrome

– A congenital vascular disorder characterized by the triad: capillary malformations (port-wine stains), venous malformations (varicose veins, persistent embryonic veins), and soft tissue or bone hypertrophy of the affected limb (typically a lower extremity). Caused by a somatic activating mutation in PIK3CA (part of the PIK3CA-related overgrowth spectrum). The hypertrophy is disproportionate, involving bone (increased length and girth) and soft tissues. Present at birth; progresses with growth. Complications: chronic venous insufficiency, cellulitis, deep vein thrombosis, pulmonary embolism (from anomalous veins), and life-threatening bleeding from pelvic or abdominal venous malformations. Diagnosis: clinical and MRI/MRV of the affected

limb (shows abnormal venous anatomy and hypertrophy). Treatment: compression stockings for venous insufficiency; epiphyseal stapling or surgical debulking for limb overgrowth; sclerotherapy or surgical excision for symptomatic venous malformations. Anticoagulation for thromboembolic events. Differentiated from Parkes Weber syndrome by the absence of arteriovenous fistulas.

Legg-Calve-Perthes Disease

– Idiopathic avascular necrosis of the femoral head in children, typically ages 4-8 years. More common in boys (4:1) and Caucasian children. Presents with limping (antalgic gait), hip/knee pain, and limited hip range of motion (especially abduction and internal rotation). Etiology: temporary disruption of blood supply to the femoral head. Diagnosis: hip X-ray shows fragmentation, flattening, and collapse of the femoral head (staging: Waldenstrom). MRI for early diagnosis. Prognosis: better in younger children (<6), with preservation of femoral head sphericity. Treatment: observation for mild cases; containment therapy (Petrie cast, abduction brace, or femoral/pelvic osteotomy) for moderate to severe.

Low Birth Weight

– Birth weight <2500 g, often due to prematurity and/or intrauterine growth restriction; further classified: very low (<1500 g), extremely low (<1000 g), and small for gestational age. Risks: increased neonatal mortality, hypothermia, hypoglycemia, respiratory distress, infection, feeding difficulties, and long-term growth and neurodevelopmental problems. Causes: preterm birth, placental insufficiency, maternal hypertension/preeclampsia, smoking, malnutrition, multiple pregnancy, infection, and congenital anomalies. Management: specialized neonatal care (thermal, nutritional—breast milk/fortified feeds, infection prevention), monitoring for complications, catch-up growth, and long-term follow-up. Prevention: antenatal care and treatment of maternal conditions.

Malrotation

– A congenital anomaly of intestinal rotation and fixation in which the midgut fails to complete its normal 270-degree counterclockwise rotation and fixation during embryogenesis. This leaves the midgut suspended on a narrow mesenteric pedicle (Ladd bands), creating a high risk of midgut volvulus —

a surgical emergency. Presents in the first month of life (most commonly in the first week) with bilious vomiting (green, 95%), abdominal distension, and rectal bleeding or shock (indicating vascular compromise with bowel ischemia). Older children may present with intermittent, chronic abdominal pain. Diagnosis: upper GI series is the gold standard — shows the duodenojejunal junction located to the right of the spine (failure to cross the midline) and a corkscrew appearance of the duodenum and proximal jejunum. Treatment: emergent laparotomy with Ladd procedure (division of Ladd bands, reduction of volvulus, widening of the mesenteric base, and appendectomy). A midgut volvulus requires immediate detorsion; irreversible ischemia requires intestinal resection. Prognosis: excellent if treated early; extensive bowel loss from delayed volvulus leads to short bowel syndrome.

Maple Syrup Urine Disease

– An autosomal recessive inborn error of branched-chain amino acid metabolism caused by deficiency of the branched-chain alpha-ketoacid dehydrogenase complex (BCKDC) — mutations in BCKDHA, BCKDHB, DBT, or DLD. Results in accumulation of leucine, isoleucine, and valine (and their ketoacids) in the blood, giving a characteristic maple syrup (burnt sugar) odor to urine and cerumen. The classic neonatal form presents at 3-5 days of life with poor feeding, vomiting, lethargy, hypertonicity (opisthotonus), seizures, and cerebral edema progressing to coma and death if untreated. Diagnosis: plasma amino acid analysis (elevated leucine, isoleucine, valine, and alloisoleucine — pathognomonic) and BCKDHA/B gene testing. Newborn screening detects MSUD in most developed countries. Treatment: acute crises — rapid removal of branched-chain amino acids via hemodialysis or hemofiltration, IV glucose, insulin, and supplementation with isoleucine and valine to promote protein synthesis. Chronic management: strict dietary restriction of leucine, isoleucine, and valine (specialized medical formulas), thiamine supplementation (thiamine-responsive forms, 5%), and metabolic monitoring. Liver transplantation can be curative.

Marfanoid Habitus

– A body habitus characterized by tall stature, long limbs, long fingers (arachnodactyly), and joint lax-

ity. Seen in Marfan syndrome, but also in other connective tissue disorders and homocystinuria. Differentiated from Marfan syndrome by absence of aortic root dilation and lens subluxation. Requires cardiac evaluation to rule out aortic pathology.

Measles

– A highly contagious viral illness caused by Morbillivirus, transmitted by respiratory droplets. Prodrome of fever, coryza, cough, and conjunctivitis, followed by Koplik spots (white buccal mucosal lesions) and maculopapular rash spreading cephalocaudally. Complications: pneumonia, encephalitis, and subacute sclerosing panencephalitis. Prevention by MMR vaccination. Highly contagious with R0 of 12-18.

Meconium Aspiration Syndrome

– Respiratory distress in newborns born through meconium-stained amniotic fluid, caused by aspiration of meconium into the airways. Presents with respiratory distress, barrel-shaped chest, and coarse crackles. Meconium is thick, greenish-black fetal stool passed in utero. Risk factors include post-term pregnancy and fetal distress. Management: airway suctioning, mechanical ventilation, and treatment of complications including pneumothorax.

Meconium-Stained Amniotic Fluid

– Greenish or yellowish discoloration of amniotic fluid due to fetal meconium passage in utero. Associated with fetal distress, post-term pregnancy, and fetal growth restriction. Thick meconium increases risk of meconium aspiration syndrome. Management of non-vigorous newborns: tracheal suctioning before positive pressure ventilation. Vigorous newborns: routine care with close monitoring.

Meningococcal Vaccine

– Conjugate vaccine (MenACWY) and serogroup B vaccine (MenB) given at 11-12 years with booster at 16 years. Protects against *Neisseria meningitidis*, causing meningitis and septicemia. MenACWY booster at 16 years covers the high-risk period for serogroup C and Y disease. MenB given based on shared clinical decision-making or during outbreaks. One of the most devastating pediatric infections.

Menkes Disease

– An X-linked recessive disorder of copper metabolism caused by ATP7A mutations, resulting in impaired intestinal copper absorption and

defective copper transport across the blood-brain barrier. Copper accumulates in intestinal and renal cells but is deficient in the liver and brain. Presents at 2-3 months with progressive neurologic deterioration, seizures, and characteristic hair abnormalities — stubby, white, brittle, and twisted (pili torti, pathognomonic on microscopy). Other features: hypotonia, failure to thrive, metaphyseal spurring (bladder-like metaphyses), wormian skull bones, and arterial tortuosity (cerebral and femoral arteries, prone to thrombosis and aneurysms). Diagnosis: low serum copper and ceruloplasmin (after 6-8 weeks of age), elevated copper in cultured fibroblasts, and ATP7A sequencing. Treatment: early parenteral copper-histidine supplementation (before symptoms) can improve neurologic outcomes. Established neurologic disease is irreversible. Prognosis: severe neurodegeneration and death by 3 years without treatment.

Metaphyseal Corner Fractures

– Bucket-handle or corner fractures at the metaphysis of long bones, characteristic of child abuse. Caused by twisting or pulling forces on extremities. Most common in the knee, ankle, and elbow. Seen on skeletal survey; may not be visible initially. Highly specific for non-accidental trauma in infants. Orthopedic consultation and full skeletal survey recommended.

Micrognathia

– A condition where the mandible is abnormally small, resulting in a retruded chin and decreased size of the oral cavity. May be isolated or syndromic (Pierre Robin sequence, Treacher Collins, Nager syndrome, Stickler syndrome). Presents at birth with potential airway obstruction (glossoptosis) and feeding difficulties. The severity depends on the degree of mandibular hypoplasia and tongue position. Diagnosis: clinical examination and cephalometric analysis. Management: prone positioning or lateral positioning for mild cases (gravity helps keep the tongue forward), nasopharyngeal airway for moderate obstruction, and mandibular distraction osteogenesis for severe obstruction. Most cases show significant mandibular catch-up growth during childhood.

MMR Vaccine

– Measles, Mumps, and Rubella live attenuated vac-

cine given at 12-15 months and 4-6 years. Two doses provide 97% protection against measles and mumps, and 98% against rubella. Contraindicated in pregnancy and immunocompromised individuals. Post-exposure prophylaxis within 72 hours. Measles remains a global health threat; outbreaks occur in under-vaccinated communities.

Morgagni Hernia

– A congenital diaphragmatic hernia occurring through the anterior retrosternal foramen of Morgagni (space of Larrey), resulting from failure of the sternal and costal portions of the diaphragm to fuse. The right side is affected in 90% of cases (the hernia sac is present in 90%). Abdominal contents (typically omentum, transverse colon, and liver) herniate into the anterior mediastinum. Often asymptomatic and incidentally discovered on chest X-ray (seen as a right cardiophrenic angle mass). Presents later in life than Bochdalek hernias (childhood to adulthood) with recurrent chest infections, dyspnea, or abdominal pain. Associated with obesity and trauma (increases intra-abdominal pressure). Diagnosis: chest X-ray shows a well-defined opacity in the right cardiophrenic angle; CT confirms the hernia, the contents, and the defect. Treatment: surgical repair (laparoscopic or open) with reduction of hernia contents and primary closure of the defect with or without mesh. Prognosis: excellent, with low recurrence rates.

Moro Reflex

– A primitive reflex present from birth to 3-6 months, elicited by suddenly startling the infant (loud noise, head drop). The infant extends both arms outward with fingers spread, then draws arms inward as if embracing. Absence at birth suggests central nervous system injury or brachial plexus palsy. Asymmetric response may indicate clavicle fracture or Erb palsy. Used as a marker of neurologic integrity.

Multicystic Dysplastic Kidney

– A congenital renal anomaly where one or both kidneys are replaced by multiple non-communicating cysts of varying sizes, with no functioning renal parenchyma. The most common cause of an abdominal mass in a newborn (unilateral). The ureter is typically atretic. The contralateral kidney may have VUR (20%) or UPJ obstruction (10%). Bilateral MCDK is incompatible with life (Potter syndrome).

Most unilateral cases are asymptomatic and discovered on prenatal ultrasound. Diagnosis: postnatal ultrasound shows multiple non-communicating cysts of varying sizes, no identifiable renal sinus, and a reniform shape may be lost. A DMSA renal scan shows no function in the affected kidney. Treatment: observation is standard — most MCDKs involute (shrink) spontaneously over years. Blood pressure monitoring and urinalysis annually. Nephrectomy is rarely indicated (hypertension, recurrent UTI, or mass effect). Contralateral kidney evaluation (VCUG) for VUR and (US) for UPJ obstruction is essential.

Mumps

- Paramyxovirus infection causing bilateral parotitis, fever, and headache. Complications include orchitis (rarely causing infertility), meningitis, pancreatitis, and sensorineural hearing loss. Prevention by MMR vaccination. Outbreaks occur in unvaccinated populations. Diagnosis by serology or RT-PCR from saliva. Supportive treatment; no specific antiviral therapy.

Myelomeningocele

- The most severe form of spina bifida, where the spinal cord and meninges herniate through a vertebral defect into a sac on the back. Presents with a visible, fluid-filled sac at birth. Associated with hydrocephalus, Arnold-Chiari malformation, and lower extremity paralysis. Management: surgical closure within 24-48 hours, CSF drainage if hydrocephalus develops, and long-term rehabilitation for mobility and bowel/bladder function.

Necrotizing Enterocolitis

- An acquired necrotic inflammatory disease of the intestine, primarily affecting premature infants. Risk factors include prematurity, enteral feeding, and bacterial colonization. Presents with abdominal distension, bloody stools, bilious vomiting, and feeding intolerance. Pneumatosis intestinalis on X-ray is pathognomonic. Management: NPO, nasogastric decompression, IV antibiotics, and supportive care. Complications include perforation, peritonitis, and stricture formation.

Neglect

- A form of child maltreatment: the failure to provide for a child's basic needs—physical (food, clothing, shelter, medical care), educational, or emo-

tional—causing harm or risk of harm. Features: failure to thrive, poor hygiene, untreated illness/injury, missed healthcare appointments, inadequate supervision, and developmental delay. Risk: parental mental illness, substance use, poverty, and domestic violence. Diagnosis: high index of suspicion, history, physical exam, growth assessment, and documentation. Management: safeguarding—report to child protection services, multidisciplinary assessment, support for the family (parenting programs, social services), and child safety planning; hospitalization for severe cases. Prevention: home visiting and family support.

Neonatal Abstinence Syndrome

- A withdrawal syndrome in neonates following in utero exposure to opioids (most common) or other substances (benzodiazepines, SSRIs, alcohol). Onset within 24-72 hours of birth (varies by half-life of substance). Presents with CNS hyperirritability (high-pitched crying, tremors, irritability, hyper-tonia, seizures), autonomic dysfunction (sweating, fever, tachypnea), and GI symptoms (poor feeding, vomiting, diarrhea). Diagnosis: Finnegan Neonatal Abstinence Scoring System quantifies severity. Treatment: non-pharmacologic (swaddling, low stimulation, skin-to-skin contact, breastfeeding if no contraindications) and pharmacologic for moderate-severe (morphine or methadone weaning protocol). Adjunctive: clonidine, phenobarbital. Prognosis: most recover fully with appropriate management.

Neonatal Cephalohematoma

- A subperiosteal hematoma of the skull, occurring in approximately 1-2% of births, usually from forceps or vacuum delivery. Presents as a boggy, fluctuant swelling over the skull that does not cross suture lines (differentiating from caput succedaneum). Resolves spontaneously over weeks to months. Complications include hyperbilirubinemia, anemia, and calcification. No treatment required in most cases.

Neonatal Herpes Simplex

- Herpes simplex virus infection in the first 28 days of life, usually HSV-2 from maternal genital infection. Three forms: skin, eye, and mouth disease; CNS disease; and disseminated disease. Disseminated form mimics sepsis with high mortality. Diagnosis by viral PCR, culture, or Tzanck smear. Treatment: IV acyclovir for 14-21 days. Cesarean delivery rec-

ommended for active genital lesions near term.

Neonatal Hypoglycemia

– Blood glucose less than 40–45 mg/dL in term infants or less than 25 mg/dL in preterm infants. Risk factors include prematurity, small for gestational age, large for gestational age, and maternal diabetes. Presents with jitteriness, lethargy, poor feeding, and seizures. Treatment: early feeding, IV dextrose infusion, and monitoring. Persistent hypoglycemia may require glucagon or hydrocortisone.

Neonatal Hypothermia

– Core body temperature below 36.5 degrees Celsius in a newborn. Classified as mild (36–36.4), moderate (32–35.9), or severe (below 32). Occurs due to rapid heat loss through evaporation, convection, conduction, and radiation. Prevention: skin-to-skin contact, drying, warm environment, and delayed bathing. Treatment: warming methods appropriate to severity; monitor glucose and electrolytes.

Neonatal Jaundice

– Yellowing of the skin and sclera due to elevated bilirubin levels, occurring in approximately 60% of term newborns. Physiologic jaundice appears at 24–48 hours, peaks at day 3–5, and resolves by 2 weeks. Pathologic jaundice appears within 24 hours or persists beyond 2 weeks. Causes include hemolysis, infection, breast milk jaundice, and conjugation defects. Severe hyperbilirubinemia risks kernicterus.

Neonatal Jaundice (Jaundice of the Newborn)

– Yellowish discolouration of the skin and sclerae in newborn infants due to elevated unconjugated bilirubin. Occurs in 60% of term infants and 80% of preterm infants. Physiological jaundice: appears after 24 hours of life, peaks at day 3–5 in term infants (day 5–7 in preterm), resolves by 2 weeks. Caused by: increased RBC mass, shorter RBC lifespan (70–90 days), immature hepatic conjugation (decreased UGT activity), increased enterohepatic circulation. Pathological jaundice: appears within 24 hours, bilirubin rising >85 micromol/L/day, or persisting >14 days (term) or >21 days (preterm). Causes: hemolytic (ABO incompatibility, Rh incompatibility, G6PD deficiency, hereditary spherocytosis), bruising/cephalhaematoma, polycythaemia, sepsis, biliary atresia, galactosaemia, Crigler-Najjar syndrome, Gilbert syndrome. Complications: acute

bilirubin encephalopathy (lethargy, poor feeding, hypotonia, high-pitched cry, opisthotonos, seizures) and kernicterus (chronic, irreversible choreoathetoid cerebral palsy, upward gaze palsy, sensorineural hearing loss, enamel dysplasia). Management: phototherapy (most effective, blue light 460–490 nm, converts bilirubin to water-soluble isomers excreted without conjugation), exchange transfusion (for severe hyperbilirubinaemia failing phototherapy), and treatment of underlying cause. NICE and AAP guidelines provide phototherapy and exchange transfusion thresholds based on gestational age, birth weight, and risk factors.

Neonatal Sepsis

– Systemic bacterial infection in the first 28 days of life, classified as early-onset (within 72 hours, usually from vertical transmission) or late-onset (after 72 hours, often nosocomial). Common organisms: Group B Streptococcus, E. coli, Listeria. Presents with non-specific symptoms: poor feeding, lethargy, temperature instability, tachycardia, and respiratory distress. Diagnosis by blood culture; treatment with empiric IV antibiotics (ampicillin and gentamicin).

Neonatologist

– A pediatrician who specializes in the medical care of newborn infants, particularly premature and critically ill neonates. Neonatologists manage conditions including respiratory distress syndrome, bronchopulmonary dysplasia, intraventricular hemorrhage, necrotizing enterocolitis, neonatal sepsis, hypoxic-ischemic encephalopathy (therapeutic hypothermia), congenital anomalies, and extreme prematurity. They work in neonatal intensive care units (NICU), lead resuscitation teams at high-risk deliveries, and coordinate care with pediatric surgeons, cardiologists, and geneticists. Training: pediatric residency + 3-year neonatal-perinatal medicine fellowship.

Neural Tube Defects

– Congenital malformations resulting from failure of the neural tube to close during the third to fourth week of gestation. Include anencephaly (incomplete cranial closure), encephalocele (herniation through skull defect), and spina bifida (incomplete spinal closure). Spina bifida ranges from occulta (mild, asymptomatic) to myelomeningocele (severe, with

neural tissue protrusion). Prevention with folic acid supplementation before and during pregnancy.

Neurofibromatosis Type 2

- An autosomal dominant disorder caused by NF2 gene mutation on chromosome 22. Characterized by bilateral vestibular schwannomas (acoustic neuromas), meningiomas, and ependymomas. Features: hearing loss, tinnitus, and balance problems. Diagnosis: MRI showing bilateral vestibular schwannomas. Management: hearing preservation surgery, radiation therapy, and surveillance imaging.

Newborn Circumcision

- Surgical removal of the foreskin from the penis, typically performed within the first few days of life. Medical benefits include reduced risk of urinary tract infections, sexually transmitted infections, and penile cancer. Complications include bleeding, infection, and meatal stenosis. Techniques include Plastibell, Gomco clamp, and Mogen clamp. Performed with parental informed consent. Not universally recommended; benefits versus risks should be discussed.

Niemann-Pick Disease

- A group of autosomal recessive lysosomal storage disorders caused by sphingomyelinase deficiency (ASM, types A and B, SMPD1 mutations) or NPC1/NPC2 cholesterol transport defects (type C). Type A (infantile neuropathic): severe, presents at 3-6 months with hepatosplenomegaly, cherry-red macula (50%), developmental regression, neurodegeneration, and death by 2-3 years. Type B (chronic visceral): later onset, hepatosplenomegaly, pulmonary infiltrates (foam cells in alveoli), thrombocytopenia, and dyslipidemia — no or minimal neurologic involvement; survival into adulthood. Type C: variable onset (infantile to adult) with neurologic features: vertical supranuclear gaze palsy (pathognomonic), ataxia, dystonia, seizures, dementia, and cataplexy. Diagnosis: types A/B — acid sphingomyelinase enzyme assay in leukocytes. Type C — filipin staining for cholesterol accumulation in fibroblasts and NPC1/NPC2 sequencing. Treatment: types A/B — olipudase alfa (enzyme replacement therapy, FDA-approved for type A/B non-neurologic). Type C — miglustat (substrate reduction therapy). Supportive care for neurological symptoms.

Non-Accidental Trauma

- Injuries inflicted on a child, suspected when history and examination findings are inconsistent with the reported mechanism. Red flags: multiple fractures at different stages of healing, posterior rib fractures, metaphyseal corner fractures, and retinal hemorrhages. Requires comprehensive evaluation including skeletal survey, CT head, ophthalmologic exam, and laboratory workup. Social work and child protective services involvement mandatory.

Noonan Syndrome

- An autosomal dominant multisystem disorder caused by mutations in the RAS-MAPK pathway genes (PTPN11 50%, SOS1 10-15%, RAF1 5-10%, RIT1, KRAS). Features: characteristic facies (hypertelorism, downslanting palpebral fissures, low-set posteriorly rotated ears, webbed neck, ptosis), short stature, congenital heart disease (pulmonary stenosis 50-60%, hypertrophic cardiomyopathy 20-30%), pectus deformities, and cryptorchidism. Coagulation defects (factor XI deficiency, von Willebrand disease) are common. Intelligence is usually normal, though learning disabilities and speech delays are common. Diagnosis: clinical criteria (van der Burgt) and genetic testing. Management: growth hormone therapy for short stature, cardiology follow-up (pulmonary stenosis balloon valvuloplasty, HCM monitoring), and developmental support.

Omphalitis

- Infection of the umbilical stump in neonates, typically occurring within the first 1-2 weeks of life. Omphalitis is a potentially serious condition requiring prompt treatment due to the risk of spread to the liver (portal vein thrombosis, portal hypertension) and peritoneum via the umbilical vessels. Risk factors: home delivery with unsterile cord care, low birth weight, prolonged rupture of membranes (>18 hours), umbilical catheterisation, and immunocompromised state. Presentation: periumbilical erythema, edema, tenderness, purulent or foul-smelling discharge from the umbilicus. Signs of systemic infection (fever, lethargy, poor feeding, tachycardia, hypotension) indicate severe disease. Pathogens: *Staphylococcus aureus*, Group A *Streptococcus*, *Escherichia coli*, *Klebsiella*, and anaerobes (*Bacteroides fragilis*). Diagnosis is clinical; wound culture, blood culture, and ultrasound (assess for

abscess, thrombophlebitis, necrotising fasciitis) in severe cases. Treatment: IV antibiotics covering Gram-positive, Gram-negative, and anaerobic organisms (flucloxacillin plus gentamicin plus metronidazole). Surgical debridement for necrotising fasciitis or abscess drainage. Complications: necrotising fasciitis (abdominal wall cellulitis with crepitus, high mortality), portal vein thrombosis, peritonitis, and neonatal sepsis. Prevention: chlorhexidine cord care (reduces omphalitis in high-mortality settings per WHO recommendation).

Omphalocele

– A congenital abdominal wall defect where abdominal organs herniate into the base of the umbilical cord, covered by a peritoneal-amniotic membrane. Associated with chromosomal abnormalities (trisomies 13, 18) and other anomalies. Differentiated from gastroschisis by membrane coverage and mid-line location. Small omphaloceles may be repaired primarily; large defects require staged closure with silastic silo and gradual reduction.

Osteogenesis Imperfecta

– A connective tissue disorder caused by collagen type I mutations, ranging from mild to lethal. Features: fractures with minimal trauma, blue sclerae, dental abnormalities, and hearing loss. Severe forms (type II) cause multiple fractures in utero and perinatal death. Diagnosis: clinical features, genetic testing, and bone biopsy. Management: bisphosphonates, physical therapy, and surgical correction of deformities.

Otitis Media

– Middle ear infection, the most common childhood illness after the common cold. Peak incidence between 6-15 months. Risk factors include secondhand smoke, daycare attendance, formula feeding, and anatomy. Presents with ear pain, fever, irritability, and hearing loss. Diagnosis by otoscopic exam showing erythema, bulging tympanic membrane, or effusion. Treatment: antibiotics (amoxicillin first-line) for acute otitis media.

Palmar Grasp Reflex

– A primitive reflex present from birth to 5-6 months, elicited by placing a finger in the infant's palm. The infant grips tightly, strong enough to support the infant's weight briefly. Bilateral symmetry assessed; asymmetry may indicate birth injury. Disappears

as voluntary grasping develops around 3-4 months. Used as a neurologic marker in the newborn examination.

Parvovirus B19

– Human parvovirus B19: a small DNA virus causing erythema infectiosum ('fifth disease') in children, transmitted by respiratory droplets. Features: 'slapped cheek' rash (bright red cheeks) followed by a lace-like (reticular) rash on the trunk/limbs, mild fever; in adults: arthropathy; in chronic hemolytic states (sickle cell): transient aplastic crisis (severe anemia); in pregnancy: fetal hydrops (anemia) and fetal loss; in immunocompromised: chronic anemia. Diagnosis: clinical; serology (IgM/IgG), PCR (aplastic crisis/fetus). Management: supportive—transfusion for aplastic crisis, intrauterine transfusion for severe fetal anemia; no vaccine; respiratory precautions; reassure about benign course in immunocompetent children.

Patau Syndrome

– Trisomy 13, affecting 1 in 10,000-20,000 live births. Features: holoprosencephaly (most characteristic, incomplete forebrain division), microcephaly, microphthalmia or anophthalmia, cleft lip and palate, polydactyly (postaxial), clenched fists with overlapping fingers, and congenital heart defects (VSD, PDA, dextrocardia, 80%). Other findings: cutis aplasia (scalp defect, particularly the occipital scalp), omphalocele, and renal anomalies (polycystic kidneys). Diagnosis: prenatal screening (abnormal first-trimester ultrasound with increased nuchal translucency), NIPT, and karyotype/CMA. Management: comfort care (median survival 7-10 days; <10% survive to 1 year). Survivors have profound intellectual disability and severe growth restriction.

Patent Ductus Arteriosus

– PDA: failure of the ductus arteriosus (fetal connection between pulmonary artery and aorta) to close after birth, causing a left-to-right shunt. Common in preterm infants; term—often small. Features: continuous 'machinery' murmur, bounding pulses, wide pulse pressure; large shunt—heart failure, failure to thrive, pulmonary hypertension (Eisenmenger if long-standing). Diagnosis: echocardiography. Management: preterm—indomethacin/ibuprofen (cyclooxygenase inhibitors) or paracetamol, and surgical ligation if refractory; term/older—transcatheter

closure (coil/device) or surgery; small asymptomatic PDAs—monitoring/elective closure; prevention of endocarditis historically. Closure prevents complications.

Pectus Carinatum

– A congenital chest wall deformity characterized by anterior protrusion of the sternum (pigeon chest), caused by excessive growth of the costal cartilages pushing the sternum forward. Less common than pectus excavatum. Associated with congenital heart disease, Marfan syndrome, Noonan syndrome, and homocystinuria. Presents in childhood and progresses during the adolescent growth spurt. Symptoms are predominantly cosmetic, but some children experience chest pain, exercise intolerance, or psychosocial distress. Diagnosis: clinical examination and CT or X-ray to evaluate symmetry and severity. Treatment: orthotic bracing (dynamic chest compressor, effective for flexible deformities in younger children) is first-line, worn 12-23 hours daily for 6-12 months. Surgical correction (Ravitch-type sternal osteotomy with costal cartilage resection) for severe or rigid deformities or bracing failure. Outcomes are excellent with both methods.

Pectus Excavatum

– The most common congenital chest wall deformity, characterized by depression of the sternum (funnel chest), caused by excessive growth of the costal cartilages that push the sternum inward. Typically sporadic, but associated with Marfan syndrome, Ehlers-Danlos syndrome, Noonan syndrome, and Poland syndrome. Presents in early childhood and progresses during the adolescent growth spurt. Symptoms are usually cosmetic, but severe cases can cause cardiopulmonary impairment (reduced stroke volume, dyspnea on exertion, exercise intolerance). The Haller index (CT ratio of transverse chest diameter to anterior-posterior diameter, >3.25 is severe) quantifies severity. Diagnosis: clinical (the depression is obvious) and CT chest for Haller index. Treatment: observation for mild cases. Surgical correction: Nuss procedure (minimally invasive, pectus bar placed retrosternally under thoracoscopic guidance, removed after 2-4 years) for moderate to severe cases. Modified Ravitch procedure (open resection of costal cartilages and sternal osteotomy) for older patients or failed Nuss. Outcomes: excellent cos-

metic and functional results.

Pediatric Diabetic Ketoacidosis

– A life-threatening complication of type 1 diabetes characterized by hyperglycemia, metabolic acidosis, and ketosis. Presents with polyuria, polydipsia, vomiting, abdominal pain, Kussmaul respirations, and fruity breath odor. Diagnosis: blood glucose greater than 250 mg/dL, pH less than 7.3, bicarbonate less than 15 mEq/L, and positive ketones. Treatment: IV fluids, insulin infusion, and electrolyte replacement with careful potassium monitoring.

Pediatric Health

– Pediatric health encompasses the physical, cognitive, emotional, and social development of children from infancy through adolescence, with emphasis on preventive care, developmental surveillance, and age-appropriate management of acute and chronic conditions. Well-child care follows a schedule: immunizations (per CDC/ACIP: DTaP, IPV, MMR, varicella, HPV, meningococcal, influenza, COVID-19), developmental screening (Ages and Stages Questionnaire, M-CHAT for autism at 18 and 24 months), growth monitoring (WHO/CDC growth charts), vision/hearing screening, and anticipatory guidance (injury prevention, nutrition, sleep, media use, substance use prevention). Common pediatric conditions: otitis media, asthma, atopic dermatitis, allergic rhinitis, ADHD (prevalence 9%), autism spectrum disorder (prevalence 2.8%), anxiety/depression, obesity (affecting 20% of US children), infectious diseases (RSV, croup, gastroenteritis), and congenital anomalies. Adolescent health addresses puberty, sexual health (STI prevention, contraception), mental health (leading cause of disability in teens), substance use, and transition to adult care. Family-centered care and trauma-informed approaches improve outcomes.

Pediatrician

– A medical doctor who specializes in the health and medical care of children from birth through adolescence (typically up to age 16-18). Pediatricians focus on: growth and development, preventive care (immunizations, developmental screening, anticipatory guidance), acute illness (infections, injuries), chronic disease management (asthma, diabetes, epilepsy, allergies), and behavioral/mental health. Subspecialties: neonatology, pediatric cardi-

ology, pediatric oncology, pediatric gastroenterology, pediatric emergency medicine, pediatric intensive care, pediatric endocrinology, pediatric neurology, and developmental pediatrics. Training: medical school + 2 years foundation training (UK) or 3 years pediatrics residency (US) + subspecialty fellowship.

Pediatric Meningitis

– Inflammation of the meninges in children, bacterial forms being the most dangerous. Presents with fever, headache, neck stiffness, photophobia, altered mental status, and petechial rash (meningococcal). Infants may present with irritability, poor feeding, bulging fontanelle, and high-pitched cry. Diagnosis by lumbar puncture showing elevated WBC, elevated protein, low glucose, and positive Gram stain/culture. Treatment: empiric ceftriaxone and vancomycin.

Pediatrics

– The branch of medicine concerned with the health and medical care of infants, children, and adolescents from birth to age 18 (or up to age 16 in the UK). Pediatric care encompasses: well-child visits (growth monitoring, developmental screening, immunisations, anticipatory guidance), management of acute illness (infections, injuries), management of chronic conditions (asthma, diabetes, epilepsy, cystic fibrosis, congenital heart disease), and behavioural/mental health (ADHD, autism, anxiety, depression). Subspecialties: neonatology, pediatric cardiology, pediatric oncology, pediatric gastroenterology, pediatric pulmonology, pediatric neurology, pediatric nephrology, pediatric endocrinology, pediatric rheumatology, pediatric infectious disease, pediatric emergency medicine, pediatric intensive care, developmental pediatrics, and pediatric surgery. Preventive care: the childhood immunisation schedule (UK: 2, 3, 4 months; 12–13 months; 3 years 4 months; 12–14 years—boosters for tetanus, diphtheria, polio, HPV, MenACWY). The UK has a comprehensive child health surveillance programme (health visitor reviews, school entry checks).

Periventricular Leukomalacia

– Ischemic white matter injury in the premature infant brain, a major cause of cerebral palsy. Risk factors include prematurity, hypotension, and inflammation. Diagnosis by cranial ultrasound showing periventricular echodensities or cystic changes.

Prevention: avoiding hypotension, maintaining normothermia, and managing infection. Long-term sequelae include spastic diplegia, cognitive impairment, and visual disturbances.

Pertussis

– A highly contagious bacterial infection caused by *Bordetella pertussis*, producing characteristic paroxysmal cough with whooping inspiratory sound. Three stages: catarrhal (1–2 weeks of URI symptoms), paroxysmal (weeks to months of violent coughing spells), and convalescent. Most dangerous in infants under 6 months. Treatment: macrolide antibiotics (azithromycin). Prevention: DTaP vaccination.

Pfeiffer Syndrome

– An autosomal dominant craniosynostosis syndrome caused by FGFR1 or FGFR2 mutations. Features: craniosynostosis (bilateral coronal), midface hypoplasia, proptosis, hypertelorism, broad thumbs and great toes (medial deviation), and variable syndactyly. Three clinical types: Type 1 (classic, milder, normal intelligence, good prognosis with surgery), Type 2 (cloverleaf skull, severe proptosis, elbow ankylosis, poor prognosis), and Type 3 (similar to Type 2 without cloverleaf skull, severe neurological impairment). Types 2 and 3 have significant mortality. Diagnosis: clinical and genetic testing. Management: staged cranial vault and midface surgery for Type 1; palliative management for Types 2 and 3.

Pierre Robin Sequence

– A congenital anomaly triad: micrognathia (small mandible), glossoptosis (posteriorly displaced tongue causing airway obstruction), and U-shaped cleft palate. The sequence arises from early mandibular hypoplasia, which prevents the tongue from descending, thereby impairing palatal shelf fusion. Presents at birth with respiratory distress (stridor, retractions, cyanosis, worse supine) and feeding difficulties. Diagnosis: clinical examination and polysomnography to assess obstructive sleep apnea severity. Management: prone positioning (first-line, 70% improve), nasopharyngeal airway, and surgical intervention for severe cases (tongue-lip adhesion, mandibular distraction osteogenesis, or tracheostomy). Cleft palate repair is typically performed at 9–18 months.

Pneumococcal Conjugate Vaccine

– PCV13 and PCV15 vaccines given at 2, 4, 6, and 12-15 months. Protects against *Streptococcus pneumoniae* serotypes causing invasive disease, pneumonia, and otitis media. PCV20 now recommended for older children and adults. Has dramatically reduced rates of invasive pneumococcal disease in children since universal vaccination.

Poland Syndrome

– A congenital anomaly characterized by unilateral absence or hypoplasia of the pectoralis major muscle (specifically the sternocostal head) and ipsilateral hand anomalies (syndactyly, most commonly; also brachydactyly, ectrodactyly, or radial club hand). The right side is affected in 60-75% of cases. Males are affected 2-3 times more frequently. Associated findings: rib defects (aplasia or hypoplasia of the second to fifth ribs), chest wall depression, breast and nipple hypoplasia or absence (in females), axillary hair loss, and vertebral anomalies. The cause is thought to be an interruption of the subclavian artery blood supply during the sixth week of gestation. Diagnosis: clinical with ultrasound or CT for chest wall evaluation. Treatment: hand surgery for syndactyly release; breast reconstruction with implants or autologous tissue for females; chest wall reconstruction for severe rib defects.

Posterior Urethral Valves

– The most common cause of lower urinary tract obstruction in male infants, caused by congenital mucosal folds (valves) in the posterior urethra (prostatic urethra) that obstruct urine outflow. Presents prenatally with oligohydramnios, bilateral hydronephrosis, and a distended, thick-walled bladder, and postnatally with poor urinary stream, urinary retention, and abdominal distension. Severe cases present with the prune belly sequence (deficient abdominal wall musculature from massive bladder distension) and Potter sequence (pulmonary hypoplasia from oligohydramnios). Diagnosis: prenatal ultrasound, postnatal voiding cystourethrogram (VCUG) shows a dilated posterior urethra with a sharp cutoff. Treatment: immediate bladder decompression (urethral catheter), endoscopic valve ablation (transurethral incision of the valves, first-line). Temporary vesicostomy for small or premature infants. Prognosis: depends on the degree

of renal impairment at presentation. Even with successful valve ablation, 25-30% develop end-stage renal disease in childhood or adolescence due to preexisting renal dysplasia.

Post-Term Pregnancy

– Pregnancy continuing beyond 42 weeks gestation (294 days from LMP). Risk factors include prior post-term pregnancy, nulliparity, and genetic factors. Complications include macrosomia, oligohydramnios, meconium aspiration, placental insufficiency, and stillbirth. Management: antenatal surveillance with NST and biophysical profile starting at 41 weeks. Induction of labor recommended by 41-42 weeks.

Potter Syndrome

– A sequence of anomalies resulting from severe oligohydramnios (low amniotic fluid volume), most commonly caused by bilateral renal agenesis, but also from autosomal recessive polycystic kidney disease, posterior urethral valves, or chronic amniotic fluid leak. Features: pulmonary hypoplasia (the most critical, incompatible with life), Potter facies (low-set, flattened ears, recessed chin, prominent epicanthal folds, flattened nose), limb deformities (clubfoot, hip dislocation, flexion contractures), and amnion nodosum (nodules on the amnion). Presents at birth with severe respiratory distress, inability to oxygenate, and typical facies. Diagnosis: prenatal ultrasound shows anhydramnios/oligohydramnios and absent or abnormal kidneys. Chest X-ray shows small lung volumes. Prognosis: uniformly fatal in the newborn period due to pulmonary hypoplasia. Management: perinatal palliative care.

Prader-Willi Syndrome

– A genetic disorder caused by loss of function of genes on chromosome 15 (paternal deletion or maternal uniparental disomy). Features: neonatal hypotonia and failure to thrive, followed by hyperphagia and obesity in childhood. Intellectual disability, short stature, hypogonadism, and behavioral problems. Management: controlled diet, growth hormone therapy, and behavioral interventions.

Preterm Infant

– An infant born before 37 completed weeks of gestation; classified by gestational age (late preterm 34-36, moderate 32-33, very preterm <32, extremely <28 weeks) and by birth weight. Causes: preterm la-

bor, PPROM, preeclampsia, multiple pregnancy, infection, and iatrogenic. Complications: respiratory distress syndrome (surfactant deficiency), apnea, intraventricular hemorrhage, necrotizing enterocolitis, infection/sepsis, hypoglycemia, jaundice, thermoregulation difficulty, patent ductus arteriosus, and retinopathy of prematurity; long-term: neurodevelopmental and growth concerns. Management: neonatal intensive care (surfactant, respiratory support, thermal care, nutrition—breast milk, kangaroo care), prevention (progesterone, cervical cerclage), antenatal corticosteroids and magnesium for lung maturity/neuroprotection, and developmental follow-up.

Prune Belly Syndrome

– A congenital syndrome comprising the triad: deficient abdominal wall musculature (wrinkled, prune-like appearance), bilateral cryptorchidism (undescended testes), and urinary tract anomalies (dilated ureters, dilated and trabeculated bladder, and posterior urethral valves or urethral atresia). Almost exclusively affects boys. Other associations: pulmonary hypoplasia from oligohydramnios, orthopedic anomalies (clubfoot, hip dislocation), and cardiac anomalies. The severity ranges from the lethal form (severe oligohydramnios, pulmonary hypoplasia, and renal dysplasia) to the mild form (preserved renal function and mild abdominal wall laxity). Diagnosis: prenatal ultrasound shows a distended bladder with thickened walls and oligohydramnios. Postnatal diagnosis is clinical. Treatment: depends on severity — mild cases: observation and orchiopexy. Moderate-severe: urinary tract reconstruction (reduction cystoplasty, ureteral reimplantation, and abdominoplasty). Renal transplantation for end-stage renal disease. All patients require lifelong urologic and nephrologic surveillance.

Reflux

– Gastroesophageal reflux in infants: effortless regurgitation of gastric contents, very common (physiologic ‘spitting up’) and usually benign, resolving by 12 months with maturation of the lower esophageal sphincter. Pathologic GERD: poor weight gain, irritability, feeding refusal, arching (Sandifer syndrome), apnea/bradycardia, recurrent pneumonia (aspiration), and esophagitis. Diagnosis: clinical; endoscopy/PH-impedance for complications.

Management: reassurance and feeding modifications (thickened feeds, frequent small feeds, upright positioning after feeds) for physiologic reflux; GERD—thickened feeds, alginate, and PPI (omeprazole) for significant disease; alarm signs (hematemesis, bilious vomiting, failure to thrive) require evaluation.

Renal Agenesis

– Congenital absence of one (unilateral, 1 in 1,000) or both (bilateral, 1 in 4,000) kidneys. Unilateral renal agenesis: usually asymptomatic, discovered incidentally — the solitary kidney undergoes compensatory hypertrophy. The contralateral kidney may have VUR, UPJ obstruction, or ectopia. Associated with VACTERL, Mayer-Rokitansky-Kuster-Hauser syndrome (Müllerian agenesis), and other GU anomalies. Bilateral renal agenesis (Potter syndrome): incompatible with life — causes severe oligohydramnios, leading to Potter sequence: pulmonary hypoplasia (the proximal cause of death), limb deformities (clubfoot, contractures), characteristic Potter facies (low-set ears, flat nose, epicanthal folds), and amnion nodosum. Diagnosis: prenatal ultrasound (absent renal tissue, empty renal fossa, severe oligohydramnios). Bilateral renal agenesis is uniformly fatal in the newborn period from pulmonary hypoplasia. Unilateral: annual blood pressure monitoring, urinalysis, and renal function surveillance.

Respiratory Distress Syndrome

– A condition primarily affecting premature infants caused by pulmonary surfactant deficiency, leading to alveolar collapse and respiratory failure. Presents with tachypnea, grunting, nasal flaring, retractions, and cyanosis. Chest X-ray shows diffuse ground-glass opacity. Treatment: surfactant replacement therapy, mechanical ventilation, and continuous positive airway pressure. Prevention with antenatal corticosteroids when preterm delivery anticipated.

Respiratory Syncytial Virus

– A paramyxovirus and the most common cause of bronchiolitis and pneumonia in infants and young children. Seasonal outbreaks in fall, winter, and spring. Transmission by respiratory droplets and fomites. Mild in older children and adults; can be severe or fatal in infants, premature infants, and those with chronic lung or heart disease. Preven-

tion with palivizumab (Synagis) in high-risk infants during RSV season.

Retinal Hemorrhages

- Bleeding within the retina, a hallmark finding in abusive head trauma (shaken baby syndrome). Found on dilated fundoscopic examination, often bilateral and multi-layered. Also seen in severe accidental trauma, bleeding disorders, and increased intracranial pressure. In the context of suspected abuse, strongly suggestive of non-accidental injury. Ophthalmologic consultation essential for documentation.

Retinopathy of Prematurity

- Abnormal vascularization of the retina in premature infants, a leading cause of childhood blindness. Affects infants less than 32 weeks gestation and less than 1500 grams. Stages range from mild (avascular retina) to severe (retinal detachment). Screening began at 31-33 weeks corrected gestational age or 4 weeks chronological age. Treatment: laser photocoagulation or anti-VEGF injection for type 1 ROP.

Rett Syndrome

- An X-linked dominant neurodevelopmental disorder affecting almost exclusively females, caused by mutations in the MECP2 gene. Normal development for the first 6-18 months, followed by regression with loss of acquired language and motor skills, stereotypical hand-wringing movements, deceleration of head growth (acquired microcephaly), seizures, and gait ataxia. Autonomic dysfunction causes breathing irregularities (hyperventilation, breath-holding), cold extremities, and bruxism. Diagnosis: clinical criteria (Neul 2010) and MECP2 genetic testing. Treatment: symptom management — antiepileptic drugs for seizures, physical/occupational therapy, nutritional support, and scoliosis monitoring. Trofinetide is FDA-approved for Rett syndrome in adults and children >2 years.

Rheumatic Fever

- A nonsuppurative inflammatory complication of Group A Streptococcal pharyngitis, occurring 2-4 weeks after infection. Diagnosed by Jones criteria: major manifestations (carditis, polyarthritis, chorea, erythema marginatum, subcutaneous nodules) plus evidence of prior streptococcal infection. Major criterion plus two minor criteria. Treatment: anti-

inflammatory agents and antibiotics. Prevention: prompt treatment of strep throat.

Rooting Reflex

- A primitive reflex present from birth to 3-4 months, triggered by stroking the infant's cheek or corner of the mouth. The infant turns toward the stimulus and opens the mouth, searching for the nipple. Facilitates breastfeeding. Absence may indicate neurologic impairment. Disappears as voluntary feeding develops. One of several primitive reflexes assessed in the newborn period to evaluate neurologic function.

Roseola

- Roseola infantum (sixth disease): a common benign viral illness of infants/young children (6 months-3 years) caused by human herpesvirus 6 (HHV-6; also HHV-7). Features: sudden high fever for 3-5 days (child appears well), followed by defervescence with the appearance of a maculopapular rash (rose-pink) on the trunk (may spread), which fades in 1-3 days; febrile seizures may occur. Diagnosis: clinical. Management: supportive—antipyretics, hydration, and reassurance; no specific antiviral; complications rare (febrile seizures). Exclude serious bacterial infection in a febrile infant before assuming roseola.

Roseola Infantum

- A viral illness caused by Human Herpesvirus 6 (HHV-6), affecting children 6 months to 2 years. Characterized by high fever (39-40.5 degrees Celsius) for 3-5 days followed by defervescence and appearance of a maculopapular rash starting on the trunk and spreading outward. Rash appears as fever resolves. Diagnosis is clinical. Self-limited; treatment is supportive.

Rotavirus Vaccine

- Oral live attenuated vaccine given at 2, 4, and 6 months (RV1) or at 2, 4, and 8 months (RV5). Protects against rotavirus gastroenteritis, a leading cause of severe diarrhea in infants. Reduced rotavirus hospitalizations by over 80% since introduction. Mild side effects include fever and diarrhea. Contraindicated in infants with severe combined immunodeficiency.

RSV

- Respiratory syncytial virus: the most common cause of bronchiolitis and viral pneumonia in infants and young children, transmitted

by droplets/fomites; seasonal (winter). Features: coryza, cough, wheeze, tachypnea, and respiratory distress; apnea in young infants; risk factors for severe disease: prematurity, congenital heart disease, chronic lung disease, and immunodeficiency. Diagnosis: clinical; nasopharyngeal PCR/antigen. Management: supportive—oxygen, hydration/nasal suctioning, and respiratory support; no routine antiviral; palivizumab (monoclonal antibody) prophylaxis for high-risk infants; new vaccines/monoclonals (nirsevimab) emerging; prevention: hand hygiene, and avoid sick contacts.

Rubella

– German measles caused by Rubivirus. Mild illness with fever, rash, and lymphadenopathy in children. Dangerous in pregnancy due to congenital rubella syndrome (cataracts, heart defects, deafness). Rash similar to measles but milder, with postauricular and suboccipital lymphadenopathy. Prevention by MMR vaccination. Eradicated in the Americas since 2015.

Rubinstein-Taybi Syndrome

– A genetic disorder caused by mutations in CREBBP (50-60%) or EP300 (3-8%), encoding histone acetyltransferases involved in transcriptional regulation. Features: characteristic facies — downslanting palpebral fissures, broad nasal bridge, beaked nose, high-arched palate, and low-set ears; broad thumbs and halluces (pathognomonic, 100%); short stature; microcephaly; and moderate to severe intellectual disability. Other findings: congenital heart disease (PDA, ASD, VSD, 30-35%), cryptorchidism, renal anomalies, and increased risk of tumors (benign: meningioma, pilomatrixoma; malignant: leukemia). Diagnosis: clinical and genetic testing. Management: multidisciplinary — cardiac evaluation, developmental therapies, physical therapy for joint laxity, and tumor surveillance. Anesthesia risk: difficult airway from micrognathia and potential malignant hyperthermia.

Scarlatina

– See Scarlet Fever.

Scarlet Fever

– A toxin-mediated illness caused by Group A *Streptococcus* producing erythrogenic toxin. Presents with fever, pharyngitis, and a characteristic diffuse, erythematous, sandpaper-textured rash that

blanches with pressure. Circumoral pallor, Pastia lines (linear petechiae in skin folds), and strawberry tongue are classic findings. Treatment: penicillin or amoxicillin for 10 days. Prevents rheumatic fever complications.

Shaken Baby Syndrome

– A form of abusive head trauma caused by violent shaking, typically in infants under 1 year. The triad: subdural hemorrhage, retinal hemorrhages, and encephalopathy. May present with irritability, lethargy, vomiting, seizures, and apnea. CT shows subdural hematoma; MRI shows diffuse axonal injury. Ophthalmologic exam reveals retinal hemorrhages. High mortality and long-term neurodevelopmental impairment.

Sickle Cell Anemia

– The most severe form of sickle cell disease (HbSS), causing chronic hemolytic anemia and vaso-occlusive crises. Features: jaundice, splenomegaly (infancy), pain crises, acute chest syndrome, stroke, and increased infection risk from functional asplenia. Diagnosis: hemoglobin electrophoresis showing HbS. Management: penicillin prophylaxis, hydroxyurea, pneumococcal vaccines, and folic acid supplementation.

SIDS

– Sudden Infant Death Syndrome; see SIDS entry (sudden unexplained infant death, peak 2-4 months, after full investigation). Prevention: supine sleep, firm sleep surface, room-sharing, no soft bedding/overheating, breastfeeding, and smoke avoidance. Counseling on safe sleep reduces risk. Investigation includes autopsy, scene review, and history to exclude other causes (accidental suffocation, neglect, abuse, metabolic/infectious disease).

Skeletal Survey

– A series of radiographs obtained when child abuse is suspected. Includes AP and lateral views of the skull, chest (including oblique views), abdomen, spine, and bilateral upper and lower extremities. Identifies fractures of varying ages, which is highly suggestive of non-accidental trauma. Initial survey may be negative; repeat at 2 weeks may reveal healing fractures. Interpretation by pediatric radiologist recommended.

Slipped Capital Femoral Epiphysis

– Displacement of the femoral head relative to the

femoral neck through the growth plate (physis) in adolescents. Most common hip disorder in adolescents (10-16 years). Risk factors: obesity, male sex, African American, and endocrine disorders (hypothyroidism, growth hormone deficiency). Presents with hip, groin, or knee pain with limping (antalgic gait). On examination: limited internal rotation and obligatory external rotation with hip flexion. Diagnosis: bilateral hip X-ray (AP and frog-leg lateral) shows femoral head displaced posteriorly and medially relative to the neck (Klein line). Treatment: surgical stabilization with in situ screw fixation of the affected and contralateral hip. Urgent: non-weight-bearing to prevent further slippage.

Smith-Lemli-Opitz Syndrome

– An autosomal recessive disorder of cholesterol metabolism caused by mutations in *DHCR7*, encoding 7-dehydrocholesterol reductase, the final enzyme in the cholesterol biosynthetic pathway. Features: microcephaly, characteristic facies (ptosis, anteverted nares, micrognathia, low-set ears), intellectual disability (mild to profound), syndactyly of the second and third toes (pathognomonic, 95%), postaxial polydactyly, cleft palate, hypospadias (ambiguous genitalia in males), and congenital heart disease. Diagnosis: elevated serum 7-dehydrocholesterol levels and *DHCR7* genetic testing. Treatment: dietary cholesterol supplementation (improves growth and behavior), and symptomatic management of associated anomalies. Prognosis correlates with severity of malformations and cholesterol levels.

Speech Delay

– A delay in language development compared to peers: by 12 months—no single words; 18 months—<10-20 words/no word combinations by 24 months; or regression. Causes: hearing impairment (must exclude—audiology), global developmental delay, autism spectrum disorder (with social communication deficits), expressive language disorder, psychosocial/environmental deprivation, and prematurity. Bilingualism does not cause delay. Evaluation: hearing test (essential), developmental assessment, speech-language evaluation, and screening for autism. Management: early intervention—speech therapy, parent training, treat underlying cause; monitor progress; red flags (loss of skills, poor response to name) prompt urgent referral.

Spina Bifida

– A neural tube defect: incomplete closure of the neural tube (days 22-28), causing spinal cord/meningeal malformation. Types: spina bifida occulta (hidden—no protrusion, often asymptomatic, hairy patch/hemangioma over defect), meningocele (meninges protrude), and myelomeningocele (cord + meninges protrude—most severe, neurologic deficits below the lesion: paralysis, sensory loss, bladder/bowel dysfunction, hydrocephalus, Chiari II malformation). Associated with folate deficiency; prevention: periconceptional folic acid. Prenatal: AFP (elevated), ultrasound. Management: multidisciplinary—surgical closure, VP shunt for hydrocephalus, urologic/orthopedic care, and rehabilitation.

Spina Bifida Occulta

– The mildest form of spina bifida, characterized by incomplete closure of the vertebral arch without herniation of neural elements. Often asymptomatic; may be detected by skin findings (dimple, hair tuft, lipoma) over the lower spine. Incidence approximately 1-2% of the population. Usually requires no treatment unless associated with tethered cord or spinal cord symptoms.

Stepping Reflex

– A primitive reflex present from birth to 2 months, elicited by holding the infant upright with feet touching a flat surface. The infant makes stepping-like movements as if walking. Disappears by 2 months as voluntary motor control develops. Reappears around 9-10 months as voluntary walking emerges. Assessed during newborn and early infant neurologic examination.

Stickler Syndrome

– An autosomal dominant connective tissue disorder caused by mutations in collagen genes (*COL2A1* most common, also *COL11A1*, *COL11A2*, *COL9A1*). Features: Pierre Robin sequence (micrognathia, glossoptosis, cleft palate, 30%), high myopia (present in 90% by 10 years), retinal detachment (highest risk of any pediatric syndrome), sensorineural hearing loss, and early-onset osteoarthritis with mild epiphyseal dysplasia. Pierre Robin sequence in Stickler syndrome mandates ophthalmologic screening. Diagnosis: clinical criteria (major: Pierre Robin-associated cleft palate, high myopia,

retinal detachment, hearing loss, family history) and genetic testing. Management: ophthalmology — annual dilated fundus exams, retinal detachment prevention; audiology — hearing aids; orthopedics — joint protection and pain management; dental palatal repair; avoidance of contact sports.

Strep Throat

– Acute streptococcal pharyngitis caused by group A *Streptococcus* (*S. pyogenes*), most common in children 5-15 years. Features: sudden sore throat, fever, tonsillar exudate, palatal petechiae, anterior cervical lymphadenopathy, and headache/abdominal pain; cough, coryza, and oral ulcers suggest viral. Diagnosis: rapid antigen test or throat culture (confirmatory); clinical criteria (Centor/McIsaac). Complications: suppurative (peritonsillar abscess, otitis) and nonsuppurative (acute rheumatic fever, post-streptococcal glomerulonephritis). Management: antibiotics within 9 days to prevent rheumatic fever—penicillin (or amoxicillin), macrolide if allergic; analgesia and supportive care.

Sturge-Weber Syndrome

– A neurocutaneous syndrome (phakomatosis) characterized by a facial capillary malformation (port-wine stain) in the V1 distribution of the trigeminal nerve (forehead and upper eyelid) and ipsilateral leptomeningeal angiomas (venous malformations of the pia mater). Caused by a somatic activating mutation in *GNAQ*. Presents in infancy with the port-wine stain, which is the visible marker. Neurologic features: seizures (75-90%, often focal or infantile spasms, typically starting in the first year), hemiparesis (contralateral to the angioma, 30-50%), developmental delay, and intellectual disability. Ocular features: glaucoma (30-70%, can be congenital or develop later, ipsilateral to the angioma), and choroidal hemangioma. Diagnosis: clinical with contrast-enhanced brain MRI (leptomeningeal enhancement, cerebral atrophy, gyriform calcification, and choroid plexus enlargement). Skull X-ray may show tram-track calcifications. Treatment: anti-convulsants for seizures; early hemispherotomy or corpus callosotomy for refractory epilepsy. Regular ophthalmologic monitoring for glaucoma (lifelong). Laser therapy for the port-wine stain. Surveillance: developmental assessments and neuroimaging.

Subgaleal Hemorrhage

– A life-threatening accumulation of blood in the subgaleal space (between the periosteum and the epicranial aponeurosis). Can contain up to 50% of the infant's blood volume. Risk factors include vacuum-assisted delivery. Presents with rapidly enlarging, boggy scalp swelling that crosses suture lines, associated with anemia and hemodynamic instability. Requires urgent evaluation, blood transfusion, and resuscitation.

Sucking Reflex

– A primitive reflex present from birth, elicited by placing an object in the infant's mouth. The infant rhythmically sucks on the object. Coordinated sucking and swallowing typically develop by 34-36 weeks gestational age. Premature infants may lack coordinated suck-swallow, requiring gavage feeding. Absence in a term infant may indicate neurologic impairment. Important for successful breastfeeding and oral feeding.

Sudden Infant Death Syndrome

– SIDS: the sudden, unexplained death of an infant <1 year (peak 2-4 months) that remains unexplained after a thorough investigation (autopsy, scene examination, and review of clinical history). Risk factors: prone sleep, bed-sharing, soft bedding, overheating, maternal smoking, prematurity/low birth weight, and co-sleeping. Protective factors: supine sleep ('Back to Sleep'), firm mattress, room-sharing without bed-sharing, breastfeeding, pacifier, and no smoke exposure. Diagnosis is by exclusion after comprehensive investigation. Prevention: safe sleep education is the cornerstone. Grief support and counseling for families; differentiate from accidental suffocation and child abuse.

Sudden Infant Death Syndrome (SIDS)

– The sudden, unexpected death of an infant less than 1 year of age that remains unexplained after thorough investigation. Peak incidence: 2-4 months. Risk factors: prone sleeping position, soft bedding, maternal smoking, prematurity, overheating, and bed-sharing. Triple risk model: vulnerable infant (brainstem abnormalities in arousal), critical developmental period, and exogenous stressors (prone sleep). Prevention: supine sleep position (Back to Sleep campaign reduced SIDS by greater than 50%), firm sleep surface, room-sharing without

bed-sharing, avoiding overheating, pacifier use, and avoiding smoke exposure.

Surfactant

- A phospholipid-protein complex produced by type II pneumocytes that reduces alveolar surface tension, preventing atelectasis. Deficiency causes respiratory distress syndrome in premature infants. Exogenous surfactant (beractant, poractant alfa) administered via endotracheal tube. Natural surfactant contains phosphatidylcholine, phosphatidylglycerol, and surfactant proteins A, B, C, and D. Production begins at approximately 24-28 weeks gestation.

Syphilis

- A bacterial STI caused by *Treponema pallidum*. Primary: chancre at inoculation site. Secondary: rash, mucous patches, condylomata lata. Latent: asymptomatic. Tertiary: gummas, cardiovascular, neurosyphilis. Diagnosis: non-treponemal tests (RPR/VDRL) confirmed by treponemal tests. Treatment: penicillin G benzathine IM. Congenital syphilis preventable with maternal screening and treatment.

Tanner Staging

- A scale for assessing sexual maturity during puberty. Stage 1: prepubertal. Stage 2: breast buds (girls), testicular enlargement (boys). Stage 3: breast enlargement, pubic hair. Stage 4: areolar development, more pubic hair. Stage 5: adult breasts and genitalia, adult hair pattern. Used to track pubertal progression and identify precocious or delayed puberty.

Tdap Vaccine

- Tetanus, Diphtheria, and acellular Pertussis booster given at 11-12 years and during each pregnancy (27-36 weeks gestation). Replaces one dose of Td. Important for pertussis protection, particularly for protecting newborns through maternal antibody transfer. Also given to adolescents and adults to maintain tetanus and diphtheria immunity.

Teenage Pregnancy

- Pregnancy in adolescents (usually 10-19 years), associated with higher maternal and fetal risks: preterm birth, low birth weight, preeclampsia, anemia, and increased neonatal mortality; also socioeconomic and educational consequences. Causes: unprotected intercourse, lack of contraception/education, poverty, and peer/family fac-

tors. Management: comprehensive antenatal care (nutrition, folate), psychosocial support, education continuation, and safe delivery; counseling on contraception postpartum to prevent recurrence. Prevention: sex education, access to contraception, and youth-friendly services. Multidisciplinary support (medical, social, educational) improves outcomes.

Teething

- The eruption of primary (deciduous) teeth, usually starting around 6 months (range 3-12), with lower central incisors first; 20 teeth by 2-3 years. Features: irritability, drooling, gum swelling/tenderness, biting/chewing, disrupted sleep, mild low-grade fever; NOT a cause of high fever, diarrhea, or serious illness (which warrant evaluation). Management: teething rings, gum massage, cool (not frozen) items, acetaminophen/ibuprofen for discomfort; avoid topical benzocaine (risk). Emergence of permanent teeth continues through childhood (6-12 years). Differentiate from infections when fever is significant.

Tetralogy of Fallot

- The most common cyanotic congenital heart defect, accounting for 7-10% of congenital cardiac anomalies. Characterized by four anatomical features: 1) Subpulmonary infundibular stenosis (right ventricular outflow tract obstruction — primary defect), 2) Ventricular septal defect (VSD), 3) Overriding aorta, and 4) Right ventricular hypertrophy (RVH). Associated with chromosome 22q11.2 deletion (DiGeorge syndrome). Clinical presentation: cyanosis ("blue baby") appearing in early infancy; hypercyanotic "tet spells" (triggered by crying, feeding, or exertion; managed by squatting or knee-to-chest position, which increases SVR and reduces right-to-left shunt). Physical exam: harsh holosystolic ejection murmur at upper left sternal border; single S2. Diagnostic imaging: chest X-ray shows classic "boot-shaped heart" (coeur en sabot) with decreased pulmonary vascular markings; echocardiogram confirms 4 defects. Treatment: surgical repair (VSD closure and RVOT relief) typically performed at 3-6 months of age.

Thalassemia Major

- Beta-thalassemia, an autosomal recessive hemoglobin disorder with absent or minimal beta-globin chain production. Presents in infancy with severe anemia, failure to thrive, hepatosplenomegaly,

and skeletal deformities. Diagnosis by hemoglobin electrophoresis showing absent HbA and elevated HbF and HbA2. Treatment: chronic blood transfusions, iron chelation, and hematopoietic stem cell transplant.

Tonic Neck Reflex

– A primitive reflex present from birth to 6 months, also called fencer’s pose. When the head is turned to one side, the arm on that side extends while the opposite arm flexes. Present in both directions. Asymmetry may indicate neurologic injury. Disappears as voluntary head control develops. One of several posture-related reflexes assessed in the newborn period.

Toxoplasmosis

– Parasitic infection with *Toxoplasma gondii*, transmissible transplacentally. Maternal infection from undercooked meat, cat feces, or contaminated soil. Can cause hydrocephalus, intracranial calcifications, chorioretinitis, and seizures in the fetus. Congenital disease may present at birth or manifest later in childhood. Treatment: pyrimethamine and sulfadiazine with folinic acid.

Tracheoesophageal Fistula

– An abnormal connection between the trachea and esophagus, often associated with esophageal atresia. Presents with recurrent aspiration, coughing with feedings, and cyanosis during meals. The H-type fistula may present later in infancy with chronic aspiration and failure to thrive. Diagnosis by esophagram or bronchoscopy. Treatment: surgical ligation and division of the fistula.

Transfusion of Neonate

– Administration of packed red blood cells to neonates for symptomatic anemia or hematocrit below transfusion threshold. Indications include acute blood loss, severe anemia (hematocrit less than 20%), and respiratory distress. Volume: 10-20 mL/kg over 2-4 hours. Blood products must be CMV-negative, irradiated, and crossmatched. Complications include volume overload, infection, and transfusion reactions.

Transposition of the Great Arteries

– A cyanotic congenital heart defect where the aorta arises from the right ventricle and the pulmonary artery arises from the left ventricle (ventriculoarterial discordance). The result: two parallel circulations (systemic and pulmonary) with no mixing.

Survival depends on associated shunts (ASD, VSD, PDA) to allow mixing of oxygenated and deoxygenated blood. Presents in the first days of life with severe cyanosis, tachypnea, and profound hypoxemia. Classic chest X-ray: egg-on-side appearance (narrow superior mediastinum). Treatment: immediate PGE1 infusion to maintain PDA patency, balloon atrial septostomy (Rashkind procedure) to improve mixing, and ultimately arterial switch operation (Jatene procedure) within the first 2 weeks of life.

Treacher Collins Syndrome

– An autosomal dominant craniofacial disorder caused by mutations in TCOF1 (most common), POLR1C, or POLR1D genes, encoding ribosomal RNA transcription factors. Bilateral, symmetric craniofacial anomalies: zygomatic hypoplasia (malar flattening), micrognathia, downward-slanting palpebral fissures, coloboma of the lower eyelid, microtia (small, malformed pinna), and conductive hearing loss (from middle ear anomalies). Intelligence is typically normal. Diagnosis: clinical and genetic testing. Management: multidisciplinary — airway assessment (possible tracheostomy for severe micrognathia), hearing aids or bone-anchored hearing aids for hearing loss, and staged reconstructive surgery (zygomatic and mandibular distraction, eyelid reconstruction, and external ear reconstruction).

Tricuspid Atresia

– Absence of the tricuspid valve, resulting in no direct communication between the right atrium and right ventricle. Blood flow depends on an atrial septal defect and ventricular septal defect for mixing. Presents with cyanosis. Staged surgical repair: modified Blalock-Taussig shunt in infancy, followed by Fontan procedure in early childhood. Oxygen and prostaglandin E1 used for stabilization.

Trisomy 21

– Down syndrome: the most common chromosomal disorder, caused by an extra chromosome 21 (trisomy 21; 95 percent meiotic nondisjunction, mosaicism, translocation). Features: intellectual disability, characteristic facial features (flat facies, upslanting palpebral fissures, epicanthic folds, macroglossia), hypotonia, congenital heart disease (50 percent—AVSD, VSD), GI anomalies (duodenal

atresia), hypothyroidism, hearing/vision problems, and increased risk of leukemia and Alzheimer disease. Antenatal screening (NIPT, quad test) and diagnosis (amniocentesis/CVS). Management: multidisciplinary—cardiac repair, thyroid monitoring, audiology/ophthalmology, early intervention, education, and adult care; life expectancy now ~60 years.

Truncus Arteriosus

– A congenital heart defect where a single large vessel arises from both ventricles, receiving a mixed blood supply. Associated with a large ventricular septal defect and abnormal semilunar valve. Presents with cyanosis and heart failure early in life. Requires surgical repair in the neonatal period, involving VSD closure and placement of a right ventricle-to-pulmonary artery conduit.

Tuberculin Skin Test

– Intradermal injection of purified protein derivative (PPD) to test for *Mycobacterium tuberculosis* infection. Read at 48-72 hours measuring induration (not erythema). Positive: greater than 5 mm in HIV or close contacts; greater than 10 mm in high-risk groups; greater than 15 mm in low-risk populations. Does not differentiate latent from active infection. False positives from BCG vaccination.

Tuberculosis in Children

– Infection with *Mycobacterium tuberculosis*, often from household contacts. Latent TB infection (LTBI) positive tuberculin skin test or interferon-gamma release assay with no symptoms or radiographic findings. Active TB presents with cough, fever, weight loss, and lymphadenopathy. Diagnosis by PPD, chest X-ray, and sputum culture. Treatment: isoniazid, rifampin, pyrazinamide, and ethambutol for active disease.

Tuberous Sclerosis Complex

– An autosomal dominant disorder caused by TSC1 or TSC2 gene mutations, resulting in benign tumors in multiple organs. Features: cortical tubers, subependymal giant cell astrocytomas, renal angiomyolipomas, cardiac rhabdomyomas, and hypomelanotic macules (ash-leaf spots). May present with seizures in infancy. Diagnosis: clinical criteria and genetic testing. Management: seizure control, mTOR inhibitors (everolimus), and organ surveillance.

Tympanostomy Tubes

– Small tubes inserted through the tympanic membrane to ventilate the middle ear and prevent fluid accumulation. Indicated for recurrent acute otitis media (3 episodes in 6 months or 4 in 12 months) or persistent otitis media with effusion greater than 3 months with hearing loss. Performed as outpatient procedure under general anesthesia. Most tubes extrude spontaneously within 6-18 months.

Tyrosinemia

– An autosomal recessive inborn error of tyrosine metabolism. Type I (fumarylacetoacetate hydroxylase deficiency, FAH mutations) is the most severe: presents in infancy with liver failure, renal tubular dysfunction (Fanconi syndrome — hypophosphatemic rickets), neurologic crises (painful paresthesias, autonomic instability, porphyria-like symptoms from succinylacetone accumulation), and hepatocellular carcinoma risk. Type II (tyrosine aminotransferase deficiency, TAT mutations): oculocutaneous tyrosinemia with painful palmar/plantar hyperkeratosis and corneal ulcers; no liver or kidney disease. Type III (4-hydroxyphenylpyruvate dioxygenase deficiency, HPD mutations): rare, mild intellectual disability and ataxia. Newborn screening shows elevated tyrosine and succinylacetone (pathognomonic for Type I). Diagnosis: urine succinylacetone (Type I), plasma amino acids, and FAH/TAT/HPD genetic testing. Treatment: Type I — nitisinone (NTBC, 2-(2-nitro-4-trifluoromethylbenzoyl)-1,3-cyclohexanedione) blocks tyrosine catabolism upstream of FAH, preventing toxic metabolite accumulation, combined with a tyrosine- and phenylalanine-restricted diet. Liver transplantation for refractory liver disease or HCC. Type II — dietary restriction of tyrosine and phenylalanine.

Undescended Testis

– Cryptorchidism: failure of one or both testes to descend into the scrotum, the most common congenital male genital anomaly (preterm 30 percent, term 3-4 percent); often descends spontaneously in the first months. Complications: impaired fertility, increased risk of testicular cancer, torsion, and hernia. Diagnosis: clinical (absent testis in the scrotum—exclude retractile); imaging rarely needed; bilaterally impalpable—hormone/ultrasound evaluation. Management: surgical orchidopexy recom-

mended at 6-12 (ideally 6-18) months to preserve fertility and allow surveillance; if bilateral and hypogonadism—hormonal evaluation. Monitor for malignancy with regular examination after surgery.

Urea Cycle Disorder

– A group of inborn errors of ammonia metabolism caused by deficiency of any of the six enzymes or two transporters in the urea cycle. X-linked: ornithine transcarbamylase deficiency (OTC, most common, 50%). Autosomal recessive: N-acetylglutamate synthase (NAGS), carbamoyl phosphate synthetase I (CPS1), argininosuccinate synthetase (citrullinemia), argininosuccinate lyase (argininosuccinic aciduria), and arginase 1 (argininemia). Presents with hyperammonemic encephalopathy: poor feeding, vomiting, lethargy, tachypnea/respiratory alkalosis (from central hyperventilation), ataxia, seizures, and coma. Onset varies from neonatal (complete deficiency) to late-onset (partial deficiency). Diagnosis: plasma ammonia (elevated $>150 \mu\text{mol/L}$ in neonates is symptomatic), quantitative plasma amino acids (citrulline, arginine, glutamine, alanine), urine orotic acid, and genetic testing. Treatment: acute hyperammonemia — IV sodium phenylacetate/sodium benzoate (Ammonul), IV arginine, nitrogen-free IV fluids, and hemodialysis for severe ($>500 \mu\text{mol/L}$). Chronic management — low-protein diet, ammonia-scavenging drugs (sodium phenylbutyrate, glycerol phenylbutyrate, arginine or citrulline supplementation), and liver transplantation for severe OTC deficiency. NAGS deficiency is uniquely treatable with oral N-carbamylglutamate.

Vaccination Schedule

– The recommended immunization schedule for infants, children, and adolescents (e.g., WHO/CDC): birth—HepB; 2 months—DTaP, IPV, Hib, PCV13, RV; 4 months—same; 6 months—HepB, IPV, PCV, RV, influenza (seasonal); 12 months—MMR, varicella, Hib, PCV; 18 months—DTaP, HepA; 4-6 years—DTaP, IPV, MMR, varicella; 9-16 years—HPV; 11-12 years—Tdap, meningococcal (MenACWY); annual influenza. Catch-up schedules for missed doses. Timing ensures protection at vulnerable ages; vaccines are safe and effective; document and counsel on side effects. School entry requirements often enforce immunization.

VACTERL Association

– A non-random association of congenital anomalies, diagnosed when at least three of the following are present: Vertebral anomalies (hemivertebrae, fused vertebrae, scoliosis, 70%), Anorectal malformations (imperforate anus, 80%), Cardiac defects (VSD, tetralogy of Fallot, 50-80%), Tracheo-Esophageal fistula (with or without esophageal atresia, 70%), Renal anomalies (renal agenesis, horseshoe kidney, hydronephrosis, 60%), and Limb defects (radial dysplasia, thumb anomalies, polydactyly, 50-70%). The acronym also includes non-VACTERL findings: single umbilical artery and rib anomalies. The cause is unknown; most cases are sporadic. Diagnosis: clinical with systematic evaluation of involved organ systems. Management: staged surgical repair (imperforate anus colostomy, TEF repair, cardiac surgery), and long-term follow-up for renal function, growth, and development.

Varicella Vaccine

– Live attenuated vaccine given at 12-15 months and 4-6 years. Protects against chickenpox (varicella-zoster virus). Two doses provide greater than 90% protection. Contraindicated in immunocompromised and pregnant individuals. Also reduces risk of herpes zoster later in life. Universal vaccination significantly reduced varicella incidence and complications.

Viral Meningitis

– Inflammation of the meninges caused by viruses, usually Enteroviruses. Presents similarly to bacterial meningitis but generally less severe. CSF shows lymphocytic pleocytosis, normal glucose, and mildly elevated protein. Self-limited in most cases; supportive treatment. Differentiated from bacterial meningitis by CSF analysis to prevent unnecessary prolonged antibiotic therapy.

Vision Screening

– Screening for visual problems in children: newborn—red reflex examination (cataract, retinoblastoma); 3-5 years—visual acuity, strabismus screening (cover test, photoscreening), and amblyopia risk factors. Goals: detect amblyopia ('lazy eye'), strabismus, and refractive errors early (before 5-7 years, the critical period), since treatment (patching, glasses) is most effective early. Risk factors: prematurity, family history, syndromes. Referral cri-

teria: acuity below age norms, significant refractive error, strabismus, or abnormal red reflex. Regular screening at well-child visits and school entry; early referral to pediatric ophthalmology prevents permanent vision loss.

Whooping Cough

– See Pertussis.

Williams Syndrome

– A microdeletion syndrome involving the elastin gene on chromosome 7q11.23. Features: elfin facies, supraaortic stenosis, hypercalcemia, intellectual disability with strong verbal skills, and overly friendly personality. Often associated with connective tissue abnormalities. Management: cardiac monitoring, calcium management, and educational support.

Wilms' tumor (Nephroblastoma)

– The most common renal malignancy in children, accounting for 95% of pediatric renal tumors (peak incidence 2-5 years). It is an embryonal tumor arising from metanephric blastemal cells. Associated syndromes: WAGR (Wilms, Aniridia, Genitourinary anomalies, Intellectual Disability (formerly mental retardation) — WT1 deletion on 11p13), Beckwith-Wiedemann syndrome (hemihypertrophy, macroglossia, omphalocele — WT2 locus 11p15), and Denys-Drash syndrome (WT1 mutation, male pseudohermaphroditism, nephrotic syndrome). Pathology: triphasic histology (blastemal, stromal, epithelial components). Anaplastic histology (focal or diffuse) confers a worse prognosis. Presents with a large, asymptomatic abdominal mass (often noted by parent while bathing the child), abdominal pain, haematuria (microscopic or gross), and hypertension (from renin secretion by the tumor or renal artery compression). Workup: abdominal ultrasound (distinguishes solid tumor from hydronephrosis, cystic lesions, neuroblastoma) and CT abdomen (staging: tumor extent, lymph node involvement, bilateral disease, IVC thrombus). Staging: Stage I (limited to kidney, capsule intact, completely resected), Stage II (extends beyond kidney, completely resected), Stage III (gross residual disease, positive lymph nodes, tumor spillage), Stage IV (haematogenous metastases — lung, liver, bone, brain), Stage V (bilateral renal involvement). Treatment: multimodal therapy based on staging and histology. Surgery: radical

nephrectomy (transperitoneal approach, remove kidney + Gerota fascia + ipsilateral ureter + lymph node sampling). Chemotherapy: regimen depends on stage and histology (favourable vs. anaplastic) — vincristine, dactinomycin, doxorubicin. Radiation: for high-stage disease (Stage III-IV, anaplastic histology). Bilateral Wilms: neoadjuvant chemotherapy followed by nephron-sparing surgery. Prognosis: overall cure rate exceeds 90% (favourable histology). Anaplastic histology and metastatic disease have lower survival rates (50-70%). Long-term follow-up for renal function, cardiac function (doxorubicin), and second malignancies.

Chapter 31

Pharmacology

31.1 Autonomic & Nervous System Pharmacology

Albuterol

- See Salbutamol (Albuterol).

Antiemetic

- A medication that prevents or treats nausea and vomiting. Classes target different pathways and receptors: 5-HT₃ receptor antagonists (ondansetron, granisetron) — block serotonin receptors in the chemoreceptor trigger zone and GI tract, first-line for chemotherapy-induced nausea and vomiting; NK₁ receptor antagonists (aprepitant, fosaprepitant) — block substance P/neurokinin-1 receptors in the vomiting center, used for highly emetogenic chemotherapy; dopamine D₂ antagonists (metoclopramide, prochlorperazine, droperidol) — block dopamine receptors in the CTZ, used for migraine and postoperative nausea; antihistamines (dimenhydrinate, meclizine) — block H₁ receptors, effective for motion sickness; anticholinergics (scopolamine) — block muscarinic receptors, used for motion sickness; and corticosteroids (dexamethasone) — mechanism unclear, used for chemotherapy-induced nausea and postoperative nausea.

Antiemetics

- Medications that prevent or treat nausea and vomiting. Classes and mechanisms: 5-HT₃ antagonists (ondansetron — block serotonin receptors in CTZ and gut, effective for chemotherapy and postoperative nausea), dopamine antagonists (metoclopramide, prochlorperazine — block D₂ receptors in CTZ, prokinetic effect), antihistamines (cyclizine, promethazine — block H₁ receptors, effective for motion sickness), anticholinergics (hyoscine — motion sickness), neurokinin-1 antagonists (aprepitant —

chemotherapy), and cannabinoids (nabilone). The cause of vomiting dictates drug choice.

Antihistamines

- Medications that block histamine receptors, primarily H₁ and H₂ receptors, used to treat allergic conditions and other histamine-mediated disorders. H₁ antihistamines are classified as first-generation (sedating, with significant anticholinergic effects) and second-generation (non-sedating, with minimal anticholinergic activity). First-generation H₁ antihistamines include diphenhydramine, chlorpheniramine, hydroxyzine, and doxylamine; they cross the blood-brain barrier, causing sedation, cognitive impairment, and anticholinergic side effects including dry mouth, urinary retention, and constipation; second-generation H₁ antihistamines include loratadine, cetirizine, and fexofenadine, which are preferred for long-term use due to their favourable safety profile.

Antiparkinson

- A class of medications used to manage Parkinson disease symptoms by restoring dopaminergic activity or modulating other neurotransmitter systems. Dopaminergic agents: levodopa (combined with carbidopa to prevent peripheral decarboxylation) — the most effective symptomatic treatment, converted to dopamine in the brain; dopamine agonists (pramipexole, ropinirole, rotigotine patch) — directly stimulate dopamine receptors; MAO-B inhibitors (selegiline, rasagiline) — inhibit dopamine breakdown; COMT inhibitors (entacapone, tolcapone) — inhibit peripheral levodopa metabolism, extending its half-life. Anticholinergic agents (benztropine, trihexyphenidyl) — reduce tremor by blocking muscarinic receptors. Amantadine — increases dopamine release and reduces dyskinesias.

Antispasmodic

– A medication that reduces smooth muscle spasm, primarily in the gastrointestinal tract. Anticholinergic agents: hyoscyamine, dicyclomine, atropine — block muscarinic M3 receptors on GI smooth muscle, reducing contractions and peristalsis, used for irritable bowel syndrome and functional dyspepsia. Direct smooth muscle relaxants: mebeverine, papaverine, peppermint oil — act directly on smooth muscle cells without anticholinergic effects, providing relief from GI spasms. Urinary antispasmodics: oxybutynin, tolterodine, solifenacin — block M3 receptors on detrusor muscle in the bladder wall, reducing overactive bladder symptoms.

Antithyroid

– A class of medications that reduce thyroid hormone synthesis, used to treat hyperthyroidism (Graves disease, toxic nodular goiter). Thioamide derivatives: methimazole (propylthiouracil as second-line) — inhibit thyroid peroxidase, blocking iodination of tyrosine residues and coupling of iodotyrosines, reducing production of T3 and T4. PTU also inhibits peripheral conversion of T4 to T3. Methimazole is first-line due to better tolerability and once-daily dosing. Adverse effects: agranulocytosis (0.3-0.5%, the most serious, presenting with fever and sore throat), hepatotoxicity (rare with methimazole, more common with PTU), rash, arthralgia, and cholestatic jaundice. Treatment monitoring: thyroid function tests every 4-6 weeks during dose titration. Beta-blockers (propranolol, atenolol) are used adjunctively to control adrenergic symptoms (tachycardia, tremor) until euthyroid.

Anxiolytic

– A medication that reduces anxiety without producing excessive sedation. First-line for generalized anxiety disorder: SSRIs (escitalopram, paroxetine, sertraline) and SNRIs (venlafaxine, duloxetine) — increase serotonin/norepinephrine activity, require 2-4 weeks for therapeutic effect, first-line for chronic anxiety disorders. Buspirone — a 5-HT1A partial agonist, effective for GAD, no sedation, no dependence, requires 2-4 weeks for effect. Benzodiazepines (alprazolam, lorazepam, diazepam, clonazepam) — enhance GABA-A receptor activity, rapid onset (minutes to hours), effective for acute anxiety and panic attacks, limited to short-term use (2-4 weeks)

due to tolerance, dependence, and withdrawal risks. Beta-blockers (propranolol) — reduce somatic symptoms of performance anxiety (tachycardia, tremor) through peripheral beta-blockade.

Atypical Antipsychotics

– Atypical antipsychotics, also known as second-generation antipsychotics, block both dopamine D2 receptors and serotonin 5-HT2A receptors, which reduces extrapyramidal side effects compared to typical agents and may improve negative symptoms. Common atypical antipsychotics include risperidone, olanzapine, quetiapine, aripiprazole, ziprasidone, lurasidone, and clozapine. The dual D2/5-HT2A blockade in the nigrostriatal pathway reduces EPS risk, while blockade in the mesolimbic pathway treats positive symptoms (delusions, hallucinations) through D2 blockade and improves negative symptoms (apathy, social withdrawal) and cognitive deficits through 5-HT2A blockade; clozapine is reserved for treatment-resistant schizophrenia due to its unique efficacy but requires monitoring for agranulocytosis.

Cardioselective Beta-Blockers

– Cardioselective beta-blockers selectively block beta-1 adrenergic receptors, which are predominant in the heart, while having minimal effects on beta-2 receptors in the bronchial smooth muscle and peripheral vasculature at therapeutic doses. Common cardioselective beta-blockers include metoprolol, atenolol, bisoprolol, and nebivolol. At low to moderate doses, these agents produce cardiac effects including decreased heart rate, reduced myocardial contractility, and decreased cardiac output without significant bronchospasm, making them preferred in patients with asthma or COPD, though cardioselectivity is dose-dependent and may be lost at higher doses.

Cholinesterase Inhibitor

– A class of medications that inhibit acetylcholinesterase, the enzyme that breaks down acetylcholine in the synaptic cleft, thereby increasing cholinergic neurotransmission in the central nervous system and peripheral tissues. Centrally acting cholinesterase inhibitors: donepezil, rivastigmine, and galantamine — used for symptomatic treatment of Alzheimer disease and other dementias by enhancing central cholinergic activity, providing modest cognitive and functional benefit (typically

6-12 months of stabilization before decline resumes). Rivastigmine is also approved for Parkinson disease dementia. Peripherally acting: neostigmine, pyridostigmine — used for myasthenia gravis to increase neuromuscular junction acetylcholine levels; and physostigmine — used as an antidote for anticholinergic poisoning. Adverse effects: GI symptoms (nausea, vomiting, diarrhea, most common), bradycardia, increased gastric acid secretion, muscle cramps, and insomnia.

Decongestants

– Medications that reduce nasal congestion by constricting blood vessels in the nasal mucosa, decreasing swelling and mucus production. Systemic decongestants: pseudoephedrine and phenylephrine (oral), which stimulate alpha-adrenergic receptors causing vasoconstriction. Topical decongestants: oxymetazoline, xylometazoline, naphazoline, phenylephrine (nasal sprays)—more potent and rapid-acting but risk of rhinitis medicamentosa (rebound congestion) with use beyond 3–5 days. Indications: nasal congestion from allergic rhinitis, common cold, sinusitis. Contraindications: uncontrolled hypertension, severe coronary artery disease, narrow-angle glaucoma, and MAOI use.

Domperidone

– A dopamine D2 receptor antagonist used as a prokinetic agent and antiemetic. It increases gastrointestinal motility by enhancing acetylcholine release from the myenteric plexus and facilitates gastric emptying. Unlike metoclopramide, domperidone does not readily cross the blood-brain barrier, causing fewer central nervous system side effects (extrapyramidal symptoms). Indications: gastroparesis (diabetic, postsurgical), dyspepsia, and GERD. Also used for lactation induction (off-label) by stimulating prolactin release. Concerns: QT prolongation with risk of ventricular arrhythmias (requires ECG monitoring with prolonged use). Contraindicated in patients with preexisting QT prolongation or cardiac disease.

Dopamine Agonist

– A class of medications that stimulate dopamine receptors (D1-D5), mimicking the effects of endogenous dopamine. Used primarily in Parkinson disease: pramipexole and ropinirole (non-ergot dopamine agonists) are effective for early and ad-

vanced PD, delaying levodopa initiation and reducing motor fluctuations; rotigotine is available as a transdermal patch providing continuous delivery. Apomorphine is a potent, rapid-acting injectable dopamine agonist used for acute rescue in refractory motor fluctuations and off episodes. Adverse effects: impulse control disorders (pathological gambling, hypersexuality, compulsive shopping, binge eating — unique to dopamine agonists, occurring in 15-25%), nausea, orthostatic hypotension, hallucinations, and daytime somnolence (sudden sleep attacks). Ergot-derived dopamine agonists (bromocriptine, cabergoline) are rarely used due to risk of pulmonary and retroperitoneal fibrosis.

Drug Antagonism

– A drug that binds a receptor without activating it, blocking the effect of agonists. Competitive antagonists (e.g., naloxone vs opioids) can be overcome by increasing agonist concentration; non-competitive antagonists (e.g., phenoxybenzamine vs norepinephrine) cannot. Physiological antagonism occurs when two drugs produce opposing effects through different receptors (e.g., histamine vs epinephrine on bronchial smooth muscle). Chemical antagonism involves direct chemical inactivation (e.g., protamine sulfate neutralises heparin).

Epinephrin (Adrenaline)

– Alternate spelling of epinephrine (adrenaline). See Epinephrine (Adrenaline).

Epinephrine (Adrenaline)

– A catecholamine hormone and neurotransmitter produced by the adrenal medulla and sympathetic nerve terminals, acting on alpha-1, alpha-2, beta-1, beta-2, and beta-3 adrenergic receptors. Effects: alpha-1: vasoconstriction (increases blood pressure), mydriasis; beta-1: increased heart rate and contractility; beta-2: bronchodilation, vasodilation in skeletal muscle, glycogenolysis. Clinical uses: first-line treatment for anaphylaxis (0.3–0.5 mg IM, repeat every 5–15 minutes), cardiac arrest (1 mg IV every 3–5 minutes during ACLS), severe asthma exacerbation (subcutaneous or IV), septic shock (IV infusion), and local vasoconstriction (combined with local anesthetics to prolong duration and reduce bleeding). Side effects: hypertension, tachycardia, arrhythmias, tremor, anxiety, hyperglycemia. Auto-injectors (EpiPen) are prescribed for patients with

severe allergies.

Ganglionic Blocker

– A class of drugs that block nicotinic acetylcholine receptors at autonomic ganglia (both sympathetic and parasympathetic), inhibiting neurotransmission in both divisions of the autonomic nervous system. Due to their non-selective blockade of all autonomic ganglia, they produce widespread and unpredictable effects including severe orthostatic hypotension, blurred vision (cycloplegia), dry mouth, constipation, urinary retention, and impotence. Prototype: hexamethonium. Clinical use: historically used for hypertensive emergencies before the development of safer agents. Currently used rarely, primarily for inducing controlled hypotension during surgery (trimethaphan). Ganglionic blockers are of more pharmacological than clinical importance, serving as tools for understanding autonomic physiology.

Gentamicin

– An aminoglycoside antibiotic produced by *Micromonospora purpurea*. Mechanism: binds 30S ribosomal subunit, inhibits protein synthesis by interfering with initiation complex and causing mRNA misreading. Bactericidal, concentration-dependent killing with a post-antibiotic effect. Spectrum: Gram-negative bacteria (*E. coli*, *Klebsiella*, *Pseudomonas*, *Serratia*, *Enterobacter*, *Proteus*, *Acinetobacter*), synergistic with beta-lactams for Gram-positive infections (enterococcal endocarditis, group B streptococcus in neonates). Resistance: aminoglycoside-modifying enzymes (acetylation, adenylation, phosphorylation), efflux pumps, ribosomal methylation. Clinical uses: (1) Neonatal sepsis (often with ampicillin); (2) Gram-negative bacteraemia and sepsis; (3) Infective endocarditis (enterococcal, viridans group streptococci–synergistic combination therapy); (4) Complicated Gram-negative urinary tract infections; (5) Plague (*Yersinia pestis*). Administration: once-daily dosing (5–7 mg/kg IV) for most indications; multiple daily dosing for enterococcal endocarditis and neonates. Monitoring: trough levels (<1–2 mg/L to avoid toxicity), peak levels (therapeutic 6–10 mg/L). Side effects: nephrotoxicity (5–25%, proximal tubular necrosis, usually reversible), ototoxicity (cochlear and vestibular, often irreversible), neuromuscular blockade (rare).

Inverse Agonist

– An inverse agonist is a drug that binds to a receptor and produces a response opposite to that produced by an agonist, reducing the constitutive activity of the receptor. Receptor activation in the absence of an agonist, which occurs with some receptors that have spontaneous activity. Inverse agonists reduce this baseline activity, producing a negative response rather than simply blocking agonist effects as competitive antagonists do. Examples include certain antipsychotics, such as pimozide and haloperidol, which show inverse agonist activity at D2 receptors and reduce the baseline activity of dopamine signalling, a mechanism that may contribute to both therapeutic efficacy and the development of extrapyramidal side effects.

Isoproterenol

– A nonselective beta-agonist (beta-1 and beta-2) used rarely for bradycardia/AV block (temporary), bronchospasm, and as a diagnostic agent. Increases heart rate, contractility, and bronchodilation; marked tachycardia and arrhythmias limit use. Adverse effects: tachycardia, palpitations, tremors, headache, and myocardial ischemia. Largely replaced by safer agents (atropine, pacing, albuterol). Also used in some stress/EP studies.

MAOIs

– Monoamine oxidase inhibitors are a class of antidepressant drugs that inhibit the enzyme monoamine oxidase, which breaks down serotonin, norepinephrine, and dopamine in the brain. By inhibiting this enzyme, MAOIs increase the levels of these neurotransmitters in the synaptic cleft. There are two forms of MAO: MAO-A preferentially metabolizes serotonin and norepinephrine, while MAO-B preferentially metabolizes dopamine and tyramine. Non-selective MAOIs including phenelzine and tranylcypromine inhibit both MAO-A and MAO-B, while selective MAO-B inhibitors such as selegiline are used in Parkinson disease. MAOIs have significant potential for drug interactions and require dietary restriction of tyramine-containing foods due to the risk of hypertensive crisis.

Methylphenidate

– A central nervous system stimulant, a piperidine derivative that blocks the reuptake of dopamine and noradrenaline (norepinephrine) by inhibiting

the dopamine transporter (DAT) and noradrenaline transporter (NAT) in the prefrontal cortex, increasing their synaptic concentrations. Methylphenidate is the first-line pharmacological treatment for attention deficit hyperactivity disorder (ADHD) in children, adolescents, and adults (NICE guidelines). It improves core ADHD symptoms: inattention, hyperactivity, and impulsivity. Two main formulations: immediate-release (IR—duration 3–4 hours, multiple daily doses) and extended-release (ER/LA/Concerta—duration 10–12 hours, once-daily dosing). Dose is titrated based on response and tolerability (typically 10–60 mg/day). Side effects: decreased appetite, insomnia, headache, abdominal pain, nausea, anxiety, irritability, and increased heart rate/blood pressure (dose-dependent). Contraindications: severe hypertension, hyperthyroidism, glaucoma, tics/Tourette syndrome, severe anxiety or agitation, and monoamine oxidase inhibitor use. Methylphenidate has abuse potential (schedule II controlled substance in the US; class B in the UK). Long-term effects: growth suppression (mild, reversible) and potential for dependence.

Neuroleptic Malignant Syndrome

– A rare but life-threatening idiosyncratic reaction to dopamine receptor-blocking agents, typically antipsychotics, characterized by hyperthermia, severe muscle rigidity, altered mental status, and autonomic dysfunction. The pathogenesis involves sudden blockade of dopamine D2 receptors in the hypothalamus causing thermoregulatory dysfunction, in the nigrostriatal pathway causing extrapyramidal symptoms, and in the mesocortical pathway causing altered mental status; treatment involves immediate discontinuation of the causative agent, supportive care, and pharmacological therapy including dantrolene (a direct-acting muscle relaxant that inhibits calcium release from the sarcoplasmic reticulum), bromocriptine (a dopamine agonist), and benzodiazepines for agitation and muscle rigidity, with careful monitoring of vital signs in an intensive care setting.

Nonselective Beta-Blockers

– Nonselective beta-adrenergic blocking agents block both beta-1 and beta-2 adrenergic receptors, reducing heart rate, myocardial contractility, and cardiac output through beta-1 blockade, while also blocking

beta-2 receptors in the bronchial smooth muscle and peripheral vasculature. Common nonselective beta-blockers include propranolol, nadolol, timolol, and pindolol. Propranolol is the prototype agent, with lipophilic properties allowing good CNS penetration, making it useful for performance anxiety and essential tremor, though this property also increases the risk of CNS side effects including fatigue, depression, and sleep disturbances.

Ondansetron

– A selective 5-HT₃ receptor antagonist used as an antiemetic for chemotherapy-induced nausea and vomiting (CINV), radiation, and postoperative nausea and vomiting; also used in pregnancy (hyperemesis) and gastroenteritis. IV and oral (including orally disintegrating). Adverse effects: headache, constipation, QT prolongation (dose-related—avoid high-dose IV with other QT drugs), and serotonin syndrome with other serotonergic agents. Generally well tolerated; 4–8 mg doses.

Over-the-Counter (OTC) Medications

– Nonprescription drugs approved as safe and effective for self-management of common symptoms, available at pharmacies and retail stores without a prescription. Major categories: analgesics/antipyretics (acetaminophen—max 3000–4000 mg/day, hepatotoxicity risk with overdose; NSAIDs—ibuprofen, naproxen—GI bleeding and cardiovascular risk with chronic use), cough and cold preparations (decongestants—pseudoephedrine, phenylephrine; antihistamines—diphenhydramine, cetirizine; dextromethorphan for cough), gastrointestinal (PPIs/omeprazole, H₂ blockers/famotidine for GERD; antacids; loperamide for diarrhea; psyllium, polyethylene glycol for constipation; bismuth subsalicylate for dyspepsia), allergy (oral/loratadine, cetirizine; intranasal corticosteroids, cromolyn), dermatologic (hydrocortisone, antifungals—clotrimazole, terbinafine), and sleep aids (diphenhydramine, doxylamine, melatonin). Risks: drug–drug interactions (NSAIDs with anticoagulants, antacids with antibiotics), unintentional overdose (especially combination products with acetaminophen), and delayed diagnosis of serious conditions. Pharmacist counseling improves safe OTC selection.

Oxymetazoline

– A topical alpha-1 adrenergic agonist decongestant (nasal spray) that vasoconstricts nasal mucosa, relieving nasal congestion. Used short-term (<3-5 days) for rhinitis/sinusitis; prolonged use causes rebound congestion (rhinitis medicamentosa). Adverse effects: local irritation, epistaxis, and rare systemic effects (hypertension) with overuse. Also available as ophthalmic decongestant (red eye relief). Contraindicated with MAOIs and severe hypertension.

Parasympatholytic

– Also called anticholinergic, a drug that blocks muscarinic (cholinergic) receptors, inhibiting parasympathetic effects. Agents: atropine (bradycardia, organophosphate poisoning), ipratropium/tiotropium (COPD/asthma—bronchodilation), scopolamine (motion sickness), oxybutynin/tolterodine (overactive bladder), and glycopyrrolate. Effects: mydriasis, cycloplegia, tachycardia, dry mouth, urinary retention, constipation, and bronchodilation. Adverse effects: confusion (elderly), heat intolerance, and glaucoma precipitation. Reversed by physostigmine.

Parasympathomimetic

– A drug that mimics or enhances parasympathetic (cholinergic) activity. Direct agonists: muscarinic (pilocarpine—glaucoma, dry mouth) and nicotinic agonists. Indirect (acetylcholinesterase inhibitors): neostigmine (myasthenia gravis, post-operative ileus/urinary retention), physostigmine (anticholinergic poisoning), donepezil/rivastigmine (Alzheimer disease). Effects: miosis, bradycardia, bronchoconstriction, salivation, lacrimation, GI stimulation, and bladder contraction. Adverse effects: bradycardia, bronchospasm, diarrhea, and sweating; reversed by atropine.

Placebo Effect

– The measurable, observable, or felt improvement in a condition that results from the patient's belief in a treatment, despite the treatment having no specific pharmacological activity for the condition being treated. The placebo effect is mediated through psychological and neurobiological mechanisms: expectation and conditioning activate endogenous opioid and dopamine pathways, leading to measurable

pain relief; the nocebo effect is the opposite phenomenon — negative expectations produce adverse effects. Placebo response rates vary by condition: 20-40% in depression, 30-50% in pain, 30-60% in irritable bowel syndrome. In clinical trials, placebos are used as controls to distinguish the specific pharmacological effect from the placebo effect, natural history, and regression to the mean.

Receptor Downregulation

– A decrease in the number or sensitivity of receptors in response to chronic receptor stimulation by agonists. When receptors are chronically activated, the cells compensate by internalizing and degrading receptors, reducing receptor density on the cell surface, and decreasing receptor responsiveness. This process contributes to drug tolerance, where increasing doses are needed to achieve the same therapeutic effect. Chronic use of beta-agonists such as albuterol for asthma leads to reduced bronchodilator response, and tolerance to opioid analgesics develops through downregulation of mu-opioid receptors in the central nervous system.

Receptor Upregulation

– An increase in the number or sensitivity of receptors in response to chronic receptor blockade or decreased neurotransmitter activity. When receptors are chronically blocked by antagonists, the cells compensate by synthesizing more receptors to maintain homeostatic signaling, leading to increased sensitivity to agonists. This phenomenon contributes to drug tolerance, where increasing doses are needed to achieve the same effect, and to withdrawal syndromes when the blocking drug is discontinued; well-recognized examples include the upregulation of beta-adrenergic receptors following chronic beta-blocker therapy, causing rebound tachycardia and hypertension upon abrupt withdrawal, and the upregulation of histamine H₂ receptors after chronic proton pump inhibitor use, leading to rebound acid hypersecretion.

Salbutamol (Albuterol)

– A selective beta-2 adrenergic agonist bronchodilator used for acute relief and prevention of bronchospasm in asthma and COPD. Relaxes airway smooth muscle; short-acting (SABA), onset 5-15 minutes, duration 4-6 hours via inhaler or nebulizer. Adverse effects: tremor, tachycardia, palpitations,

hypokalemia, and headache. First-line rescue therapy; overuse signals poor control. Levalbuterol is the R-enantiomer. Salmeterol and formoterol are long-acting (LABAs, not for acute relief).

Salmeterol

– A long-acting beta-2 agonist (LABA) used for maintenance bronchodilation in asthma and COPD (with inhaled corticosteroid in asthma). Duration 12 hours, twice-daily dosing; not for acute symptom relief (slow onset). Adverse effects: tremor, tachycardia, hypokalemia. Black-box warning: LABA monotherapy in asthma increases asthma-related death risk—always combine with an ICS. Formoterol has a faster onset; indacaterol/olodaterol are ultra-long-acting.

Sedatives

– A class of drugs that produce a calming or drowsy effect by depressing the central nervous system. Sedatives reduce anxiety, promote sleep, and induce relaxation. Classes: (1) Benzodiazepines—enhance GABA_A receptor activity (diazepam, lorazepam, midazolam, temazepam). Used for anxiety, insomnia, seizures, muscle relaxation, procedural sedation, and alcohol withdrawal. (2) Z-drugs—non-benzodiazepine hypnotics (zolpidem, zopiclone, zaleplon)—selective for GABA_A $\alpha 1$ subunit, primarily for insomnia. (3) Barbiturates—enhance GABA_A activity but with a narrower therapeutic index (phenobarbital, thiopental)—now rarely used except for refractory epilepsy and anesthetic induction. (4) Antihistamines—H1 antagonists with sedative properties (diphenhydramine, hydroxyzine, promethazine)—mild sedation. (5) Antipsychotics—low-dose quetiapine, olanzapine—used as sedatives off-label. (6) Melatonin receptor agonists (ramelteon, prolonged-release melatonin)—regulate circadian rhythm. (7) Orexin receptor antagonists (suvorexant, daridorexant)—promote sleep by blocking wake-promoting orexin signalling. (8) $\alpha 2$ -adrenergic agonists (clonidine, dexmedetomidine)—sedation without respiratory depression. Adverse effects: drowsiness, daytime sedation, cognitive impairment, impaired coordination, falls (especially elderly), tolerance, dependence, and withdrawal. Respiratory depression (especially with alcohol, opioids). Long-term use of benzodiazepines is discouraged (dependence, tolerance, cognitive decline, increased demen-

tia risk—controversial).

Serotonin Syndrome

– A potentially life-threatening condition caused by excessive serotonergic activity in the central and peripheral nervous systems, typically resulting from drug interactions or overdose involving serotonergic medications. The classic triad includes neuromuscular hyperactivity with tremor, clonus, rigidity, and hyperreflexia; autonomic dysfunction with hyperthermia, diaphoresis, tachycardia, and hypertension; and altered mental status with agitation, confusion, and delirium. Severe cases may progress to hyperpyrexia, rhabdomyolysis, multi-organ failure, and death. Treatment involves immediate discontinuation of all serotonergic agents, supportive care with intravenous fluids and cooling, and administration of cyproheptadine, a serotonin antagonist, for moderate to severe cases.

Skeletal Muscle Relaxant

– A medication that reduces muscle spasm, spasticity, and associated pain. Centrally acting muscle relaxants: baclofen — GABA-B agonist that reduces spinal reflex activity, first-line for spasticity in cerebral palsy, multiple sclerosis, and spinal cord injury; tizanidine — $\alpha 2$ adrenergic agonist that inhibits spinal motor neuron activity; diazepam — enhances GABA-A activity, effective for acute muscle spasm; cyclobenzaprine — structurally related to tricyclic antidepressants, reduces brainstem descending noradrenergic activity; methocarbamol and carisoprodol — centrally acting, mechanism less defined. Peripherally acting: dantrolene — inhibits calcium release from the sarcoplasmic reticulum by blocking ryanodine receptors, used for malignant hyperthermia and chronic spasticity. Botulinum toxin — blocks acetylcholine release at the neuromuscular junction, used for focal spasticity and dystonia.

SNRIs

– Serotonin-norepinephrine reuptake inhibitors are a class of antidepressant drugs that inhibit the reuptake of both serotonin and norepinephrine from the synaptic cleft, increasing both serotonergic and noradrenergic neurotransmission. Common SNRIs include venlafaxine, duloxetine, desvenlafaxine, and levomilnacipran. They are used for major depressive disorder, generalized anxiety disorder, panic disorder, social anxiety disorder, and chronic pain

conditions. Duloxetine is also approved for diabetic peripheral neuropathy, fibromyalgia, and chronic musculoskeletal pain. Common adverse effects include nausea, dry mouth, insomnia, sweating, and sexual dysfunction; discontinuation syndrome with dizziness and paraesthesias may occur with abrupt cessation, requiring gradual tapering.

Tachyphylaxis

- A rapid, acute decrease in response to a drug after repeated administration over a short period, distinct from tolerance which develops more gradually. Tachyphylaxis results from rapid depletion of neurotransmitter stores, receptor desensitization, or receptor downregulation. A classic example is the rapid development of tachyphylaxis to ephedrine, where repeated doses lead to depletion of norepinephrine stores in nerve terminals, reducing the sympathomimetic effect. Nicotine also demonstrates tachyphylaxis, and this phenomenon contributes to the need for dose escalation during the first few days of therapy. Tachyphylaxis is distinct from tolerance, which develops more slowly, and from desensitization, which results from reduced receptor responsiveness.

TCAs

- Tricyclic antidepressants are a class of drugs that inhibit the reuptake of serotonin and norepinephrine, similar to SNRIs, but also block histamine H1 receptors, muscarinic acetylcholine receptors, and alpha-1 adrenergic receptors, producing numerous side effects. Common TCAs include amitriptyline, nortriptyline, imipramine, and clomipramine. They are effective antidepressants but are now used less frequently for depression due to their side effect profile and toxicity in overdose. TCAs are used for a range of other conditions including neuropathic pain (amitriptyline, nortriptyline), migraine prophylaxis (amitriptyline), chronic pain syndromes, enuresis, and insomnia (doxepin, trimipramine). Their anticholinergic effects cause dry mouth, blurred vision, constipation, urinary retention, and cognitive impairment in elderly patients; cardiotoxicity in overdose manifests as QT prolongation, conduction abnormalities, and potentially fatal arrhythmias, limiting their use in patients with cardiac disease or at risk of suicide.

Tocolytics

- Medications used to suppress preterm labor (contractions before 37 weeks gestation), to delay delivery for corticosteroid administration (fetal lung maturity) and in utero transport to a tertiary care center. First-line: calcium channel blockers (nifedipine) — inhibit smooth muscle contraction by blocking voltage-gated calcium channels, oral administration, fewer side effects than other tocolytics. Beta-2 adrenergic agonists (terbutaline, ritodrine) — activate beta-2 receptors on uterine smooth muscle, causing relaxation via increased intracellular cAMP, side effects include maternal tachycardia, pulmonary edema, and hypokalemia. NSAIDs (indomethacin) — inhibit prostaglandin synthesis by COX inhibition, effective for short-term tocolysis (<48 hours), side effects include oligohydramnios and premature closure of the fetal ductus arteriosus with prolonged use. Magnesium sulfate — blocks calcium entry into smooth muscle cells, used for neuroprotection in preterm infants (<32 weeks) and seizure prophylaxis in preeclampsia, but has marginal tocolytic efficacy.

Typical Antipsychotics

- Typical antipsychotics, also known as first-generation antipsychotics, primarily block dopamine D2 receptors in the mesolimbic pathway, reducing positive symptoms of schizophrenia including hallucinations, delusions, and disorganized thinking. They are classified by potency: high-potency agents including haloperidol and fluphenazine require lower doses and have more extrapyramidal side effects; low-potency agents including chlorpromazine and thioridazine require higher doses and have more anticholinergic side effects including sedation, dry mouth, constipation, and postural hypotension; all typical antipsychotics carry a risk of tardive dyskinesia, a potentially irreversible movement disorder characterized by involuntary, repetitive movements of the face, mouth, and extremities, with higher potency agents posing a greater risk.

Uterotonic

- A medication that stimulates uterine contraction, used for induction/augmentation of labor, prevention and treatment of postpartum hemorrhage, and medical termination of pregnancy. Oxytocin — a synthetic analog of the endogenous hormone, stimulates oxytocin receptors on uterine smooth mus-

cle, producing rhythmic contractions, administered IV for labor induction/augmentation; also used IV or IM for active management of the third stage of labor to prevent postpartum hemorrhage. Ergot alkaloids (ergometrine, methylergonovine) — cause sustained uterine tetanic contraction by acting on alpha-adrenergic and serotonin receptors, used IM/IV for postpartum hemorrhage, contraindicated in hypertension and preeclampsia. Prostaglandins: carboprost (PGF2-alpha) — IM for refractory postpartum hemorrhage; misoprostol (PGE1 analog) — oral, sublingual, rectal, or vaginal for cervical ripening, labor induction, and postpartum hemorrhage; dinoprostone (PGE2) — vaginal insert for cervical ripening.

Xylometazoline

– A direct-acting sympathomimetic decongestant and vasoconstrictor, available as a topical intranasal spray or drops (0.05% for children 2-12 years, 0.1% for adults). Mechanism: xylometazoline is an imidazoline derivative that acts as a potent agonist at alpha-1 and alpha-2 adrenergic receptors on nasal blood vessels. Activation of alpha-1 receptors causes vasoconstriction of the cavernous venous sinuses (erectile tissue of the nasal turbinates), reducing nasal mucosal edema and congestion. It has a rapid onset of action (within 5-10 minutes) and a duration of 8-10 hours. Indications: symptomatic relief of nasal congestion associated with the common cold, allergic rhinitis (seasonal and perennial), and sinusitis; also used as a vasoconstrictor before nasal examination or procedures. It is used as a hemostatic agent in epistaxis (anterior nasal packing with cotton wool soaked in xylometazoline). Contraindications: narrow-angle glaucoma, transsphenoidal hypophysectomy, rhinitis sicca, and concomitant use with MAOIs (risk of hypertensive crisis). Adverse effects: local (nasal dryness, burning, stinging, sneezing, epistaxis), systemic (rare at recommended doses — hypertension, palpitations, headache, insomnia, tremor), and rhinitis medicamentosa (rebound nasal congestion from prolonged use >7-10 days due to downregulation of adrenergic receptors and secondary vasodilation). Patients should be warned to limit use to 3-5 days and not to exceed 7 days.

Yohimbine

– An indole alkaloid derived from the bark of the West African yohimbe tree (*Pausinystalia yohimbe*), historically used as an aphrodisiac and for erectile dysfunction. Mechanism: yohimbine is a selective alpha-2 adrenergic receptor antagonist (blocks presynaptic alpha-2 receptors, increasing norepinephrine release from sympathetic nerve terminals and increasing central sympathetic outflow and peripheral norepinephrine levels). The increased norepinephrine causes vasodilation in the corpus cavernosum (through nitric oxide-independent relaxation of trabecular smooth muscle) and increased penile blood flow, but the evidence for efficacy in erectile dysfunction is weak and its use is not recommended by most guidelines (AUA, EAU). Other claimed (unproven) uses: weight loss (increases lipolysis by blocking alpha-2 receptors on adipocytes), athletic performance enhancement, and orthostatic hypotension. Adverse effects: anxiety, agitation, hypertension, tachycardia, palpitations, headache, dizziness, nausea, insomnia, and panic attacks (contraindicated in panic disorder, PTSD, and bipolar disorder). Yohimbine is not FDA-approved for any indication and is classified as a dietary supplement in the US, which means its manufacture and quality are not regulated. The therapeutic index is narrow, and serious adverse effects (hypertensive crisis, arrhythmias, myocardial infarction) have been reported at high doses or in susceptible individuals (CYP2D6 poor metabolisers). Due to lack of proven efficacy, an unfavourable safety profile, and the availability of effective, well-studied PDE5 inhibitors (sildenafil, tadalafil), yohimbine is rarely used in modern medical practice.

31.2 Cardiovascular & Renal Pharmacology

5-Alpha Reductase Inhibitor

– A class of medications that inhibit the enzyme 5-alpha-reductase, which converts testosterone to dihydrotestosterone (DHT), the more potent androgen responsible for prostate growth and male pattern baldness. Two isoforms: Type I (predominant in skin and scalp) and Type II (predominant in the prostate). Finasteride inhibits primarily Type II (blocks 70% of DHT); dutasteride inhibits both

Type I and Type II (blocks >90% of DHT). Indications: benign prostatic hyperplasia — reduces prostate volume, improves urinary flow, reduces risk of acute urinary retention and need for surgery (requires 6-12 months for maximal effect); male androgenetic alopecia — slows hair loss and promotes regrowth. Adverse effects: decreased libido, erectile dysfunction (2-5%), ejaculatory dysfunction, and gynecomastia. Serum PSA levels decrease by approximately 50% — adjusted PSA values are needed for prostate cancer screening.

Abacavir

- A nucleoside reverse transcriptase inhibitor (NRTI) used in combination antiretroviral therapy for HIV-1 infection. Abacavir is a guanosine analogue that inhibits viral reverse transcriptase by competing with natural deoxyguanosine triphosphate and causing chain termination. A unique and potentially fatal hypersensitivity reaction occurs in approximately 5-8% of patients, presenting with fever, rash, gastrointestinal symptoms, and respiratory distress. This reaction is strongly associated with the HLA-B*5701 allele; genetic screening for this allele is mandatory before initiating therapy, and abacavir should never be used in patients who test positive due to the high risk of a potentially fatal hypersensitivity reaction.

Absorption

- The movement of a drug from its site of administration into the systemic circulation. Depends on the route (oral, IV, IM, SC, topical, inhaled), drug physicochemical properties (lipophilicity, molecular size, ionization), formulation, and GI physiology (pH, motility, blood flow, food). Bioavailability is the fraction reaching systemic circulation, reduced by incomplete absorption and first-pass metabolism. IV drugs bypass absorption (100 percent bioavailability). Passive diffusion is the main mechanism; active transport and P-glycoprotein efflux modulate absorption. Drug interactions affecting absorption alter drug concentrations.

ACE Inhibitors

- Angiotensin-converting enzyme inhibitors are a class of medications that block the conversion of angiotensin I to angiotensin II by inhibiting the angiotensin-converting enzyme (ACE, also known as kininase II). This results in decreased aldosterone secretion, reduced sodium and water retention, de-

creased vasoconstriction, and reduced sympathetic nervous system activity. ACE inhibitors also inhibit the breakdown of bradykinin, a vasodilator, which contributes to their antihypertensive effect but also contributes to the characteristic adverse effect of dry cough, which occurs in approximately 10-20% of patients, and the less common but more serious angioedema.

Acetaminophen Mechanism

- Acetaminophen, also known as paracetamol, is an analgesic and antipyretic drug with weak anti-inflammatory activity, differing from NSAIDs in its mechanism and side effect profile. Its precise mechanism of action remains incompletely understood, but it is thought to inhibit a COX variant in the central nervous system, possibly COX-3, and may also activate descending serotonergic pain inhibition pathways and interact with the endocannabinoid system through its metabolite AM404. Acetaminophen inhibits prostaglandin synthesis in the central nervous system, reducing pain perception and fever, and also activates descending serotonergic pathways that modulate pain signalling at the spinal cord level.

Acetaminophen (Paracetamol)

- An analgesic and antipyretic drug that inhibits central COX enzymes and may have serotonergic and endocannabinoid mechanisms. It is first-line for mild pain and fever with fewer side effects than NSAIDs. Maximum daily dose is 4 grams (reduced to 2-3 grams in liver disease or alcohol use). Acetaminophen overdose causes hepatotoxicity due to the toxic metabolite NAPQI. Antidote is N-acetylcysteine, which replenishes glutathione stores.

Acetazolamide

- A carbonic anhydrase inhibitor diuretic. Blocks carbonic anhydrase in the proximal tubule, reducing bicarbonate reabsorption, producing a mild diuresis and metabolic acidosis. Uses: acute mountain sickness prophylaxis/treatment, glaucoma (reduces aqueous humor production), idiopathic intracranial hypertension, metabolic alkalosis, and as an adjunct in some seizure disorders and urinary alkalization. Given orally or IV. Side effects: paresthesias, hypokalemia, metabolic acidosis, renal stones, sulfonamide allergy cross-reactivity. Contraindicated in hepatic cirrhosis (hepatic encephalopathy risk) and

severe renal impairment.

Acinetobacter baumannii resistance

- *Acinetobacter baumannii* is a gram-negative coccobacillus that has emerged as a significant cause of healthcare-associated infections, particularly in intensive care units. The organism has intrinsic and acquired resistance mechanisms, including beta-lactamases, efflux pumps, and porin mutations. Multidrug-resistant and carbapenem-resistant strains are increasingly common. Treatment options are limited and may include polymyxins, tigecycline, and minocycline. Infection prevention strategies are critical for preventing nosocomial transmission, particularly as *Acinetobacter* can survive on environmental surfaces for extended periods.

Acyclovir

- An antiviral guanosine analog active against herpes simplex virus (HSV-1, HSV-2) and varicella-zoster virus (VZV). Phosphorylated by viral thymidine kinase to the active triphosphate, which inhibits viral DNA polymerase. Used for genital and oral herpes, herpes simplex encephalitis (IV), herpes zoster (shingles), and varicella (chickenpox). Adverse effects: nausea, headache, renal impairment (crystalluria with rapid IV infusion—hydrate), and neurotoxicity at high doses. Valacyclovir (prodrug) has better oral bioavailability; famciclovir is an alternative.

Adverse Drug Reaction

- An adverse drug reaction is any noxious or unintended response to a drug that occurs at doses used for prophylaxis, diagnosis, or therapy. ADRs are classified as type A reactions, which are dose-dependent and predictable extensions of the drug's pharmacological effects, such as bleeding with warfarin or hypoglycemia with insulin; and type B reactions, which are idiosyncratic, unpredictable, and not dose-related, such as drug allergies and Stevens-Johnson syndrome. ADRs are further classified as type C, dose- and time-dependent reactions such as cumulative toxicity; type D, delayed effects such as carcinogenicity and teratogenicity; and type E, withdrawal reactions upon discontinuation.

Adverse Drug Reactions

- Any harmful or unintended response to a drug at normal doses. ADRs are classified as Type A (augmented, dose-dependent, predictable: side effects,

toxicity) or Type B (bizarre, dose-independent, unpredictable: allergy, idiosyncrasy). ADRs are a major cause of morbidity and mortality, accounting for 5-7% of hospital admissions. Risk factors include polypharmacy, renal/hepatic impairment, age extremes, and genetic predisposition. Prevention involves careful prescribing and monitoring.

Agonist-Antagonist

- A drug that has mixed pharmacological activity, acting as an agonist at one receptor type and an antagonist at another, or as a partial agonist at a single receptor. Mixed opioid agonist-antagonists: pentazocine — kappa agonist and mu partial antagonist, producing analgesia with less respiratory depression and lower abuse potential than pure mu agonists; nalbuphine — kappa agonist and mu antagonist; butorphanol — kappa agonist and mu antagonist. Partial agonists: buprenorphine — partial mu agonist and kappa antagonist, used for opioid use disorder due to ceiling effect on respiratory depression and lower abuse liability. The clinical advantage of agonist-antagonists is the reduced risk of respiratory depression and dependence compared to full mu agonists.

Alprazolam

- A short- to intermediate-acting benzodiazepine used for generalized anxiety disorder and panic disorder. Enhances GABA-A receptor chloride conductance, producing anxiolysis, sedation, and muscle relaxation. Rapid onset; short half-life (12 hours) leads to interdose anxiety and withdrawal risk with chronic use; dependence, tolerance, and withdrawal (including seizures) occur with abrupt cessation—taper slowly. Adverse effects: sedation, cognitive impairment, ataxia, and falls in the elderly. Caution with opioids (respiratory depression) and alcohol.

Alteplase

- A recombinant tissue plasminogen activator (tPA) that converts plasminogen to plasmin, lysing fibrin clots. Used for acute ischemic stroke (within 4.5 hours), massive pulmonary embolism, STEMI, and occluded catheters/central lines. IV infusion with a total dose depending on indication. Major adverse effect: hemorrhage (especially intracranial). Contraindications: active bleeding, recent surgery/head trauma, coagulopathy, and uncontrolled hyperten-

sion. Tenecteplase (single bolus) is increasingly used.

Aminoglycoside nephrotoxicity

– Kidney damage caused by aminoglycoside antibiotics, characterized by acute tubular necrosis. Nephrotoxicity is caused by accumulation of aminoglycosides in the proximal tubular cells. The risk is increased with prolonged therapy, high doses, concurrent nephrotoxic drugs, and renal impairment. Gentamicin is considered the most nephrotoxic aminoglycoside. The nephrotoxicity is usually reversible with early detection and discontinuation. Regular monitoring of serum creatinine and drug levels is essential for early detection of nephrotoxicity, and dose adjustment based on renal function is required to minimise the risk of acute kidney injury.

Aminoglycoside ototoxicity

– Damage to the inner ear caused by aminoglycoside antibiotics, resulting in hearing loss and vestibular dysfunction. Ototoxicity is caused by accumulation of aminoglycosides in the inner ear, damaging hair cells. The risk is increased with prolonged therapy, high doses, concurrent ototoxic drugs, and renal impairment. Amikacin is considered the most ototoxic aminoglycoside. Symptoms include tinnitus, hearing loss, and vertigo. Hearing loss may be irreversible. Baseline and periodic audiometry should be performed at baseline and repeated regularly during treatment, particularly in patients receiving high cumulative doses or those with pre-existing hearing impairment.

Aminoglycosides

– A class of bactericidal antibiotics that bind irreversibly to the 30S ribosomal subunit, causing misreading of messenger RNA and inhibiting protein synthesis. They include gentamicin, tobramycin, amikacin, and streptomycin. Aminoglycosides are particularly effective against aerobic gram-negative organisms including *Pseudomonas aeruginosa* and have synergistic activity with beta-lactams against enterococci and staphylococci. They are poorly absorbed from the gastrointestinal tract and must be administered parenterally for systemic infections, with careful monitoring of serum concentrations to balance efficacy against nephrotoxicity and ototoxicity.

Amlodipine

– A dihydropyridine calcium channel blocker used for hypertension and chronic stable angina. Selectively blocks vascular L-type calcium channels, causing vasodilation and reduced peripheral resistance with minimal negative inotropy or chronotropy at therapeutic doses. Half-life 30-50 hours, allowing once-daily dosing. Adverse effects: peripheral edema (most common), flushing, headache, dizziness, gingival hyperplasia. Safer than verapamil/diltiazem in heart failure; dose-adjust in hepatic impairment. Available alone or in fixed combinations with ACE inhibitors/ARBs and statins.

Amoxicillin

– A broad-spectrum aminopenicillin (beta-lactam) active against many gram-positive and gram-negative bacteria. Used for otitis media, sinusitis, pharyngitis, pneumonia, urinary tract infections, and *H. pylori* eradication (with clarithromycin and a PPI). Better oral absorption and longer half-life than ampicillin. Inactivated by beta-lactamases; combined with clavulanate (Augmentin) for beta-lactamase-producing organisms. Adverse effects: rash (higher risk in mononucleosis), diarrhea, nausea, and penicillin allergy.

Amphetamine

– A central nervous system stimulant that increases synaptic dopamine and norepinephrine (via reuptake inhibition and vesicular release). Used for attention deficit hyperactivity disorder and narcolepsy. Immediate and extended-release formulations. Adverse effects: appetite suppression, insomnia, tachycardia, hypertension, anxiety, and growth delay in children; abuse potential (Schedule II). Cardiovascular screening before use. Related agents: dextroamphetamine, lisdexamfetamine, methylphenidate (different mechanism).

Amphotericin B

– A polyene antifungal antibiotic that binds to ergosterol in fungal cell membranes, forming pores that cause leakage of intracellular ions and cell death. It has the broadest spectrum of antifungal activity, effective against *Candida*, *Aspergillus*, *Cryptococcus*, *Mucorales*, and endemic dimorphic fungi including *Histoplasma* and *Blastomyces*. Amphotericin B is considered the gold standard for serious invasive fungal infections, though its use has been limited by significant toxicity. The major dose-limiting adverse

effects include nephrotoxicity, infusion-related reactions (fever, rigors, hypotension), and electrolyte disturbances such as hypokalaemia and hypomagnesaemia.

Ampicillin

– A broad-spectrum aminopenicillin (beta-lactam) active against many gram-positive and some gram-negative organisms (*E. coli*, *Salmonella*, *Haemophilus*, *Listeria*). Used for urinary tract infections, respiratory infections, meningitis (*Listeria*—with gentamicin), and enterococcal endocarditis. Inactivated by beta-lactamases; combined with sulbactam (ampicillin-sulbactam) to extend spectrum. Adverse effects: rash (especially with mononucleosis—avoid), GI upset, diarrhea, and penicillin allergy. Similar to amoxicillin but with IV formulation and broader gram-negative activity.

Amprenavir

– A protease inhibitor (PI) used in combination antiretroviral therapy for HIV-1 infection, now largely replaced by its prodrug fosamprenavir. Amprenavir inhibits the HIV aspartyl protease, preventing viral polyprotein processing and maturation. The drug has moderate oral bioavailability and requires dosing two to three times daily. Common adverse effects include gastrointestinal disturbances such as nausea, diarrhea, and vomiting, as well as perioral paresthesias. Hypertriglyceridemia and hypercholesterolaemia are common metabolic adverse effects associated with protease inhibitor therapy.

Analgesic

– A drug that relieves pain without producing loss of consciousness. Classes: non-opioids (acetaminophen, NSAIDs—act peripherally and on central prostaglandin synthesis), opioids (morphine, oxycodone, fentanyl—act on central and spinal opioid receptors), and adjuvants (anticonvulsants such as gabapentin/pregabalin, tricyclic antidepressants, and local anesthetics) used for neuropathic pain. Selection depends on pain type (nociceptive vs neuropathic), severity (WHO analgesic ladder), and comorbidities. Adverse effects: GI bleeding (NSAIDs), hepatotoxicity (acetaminophen), respiratory depression and dependence (opioids).

Angiotensin Receptor Blockers

– A class of cardiovascular drugs that selectively block the angiotensin II type 1 receptor, preventing

the binding of angiotensin II and its effects including vasoconstriction, aldosterone secretion, and sympathetic activation. Unlike ACE inhibitors, ARBs do not affect bradykinin metabolism, resulting in lower rates of cough and angioedema. Common ARBs include losartan, valsartan, irbesartan, and olmesartan. ARBs have similar hemodynamic effects to ACE inhibitors but are generally better tolerated due to a lower incidence of cough and angioedema.

Anidulafungin

– An echinocandin antifungal agent used in the treatment of invasive candidiasis and esophageal candidiasis. Anidulafungin inhibits beta-(1,3)-D-glucan synthase, disrupting fungal cell wall synthesis. A unique feature is its lack of hepatic metabolism, as it is degraded chemically rather than enzymatically, making it safe in patients with hepatic impairment. The drug is available only intravenously and has a very long half-life of approximately 24–48 hours, allowing for once-daily dosing. Common adverse effects include headache, nausea, diarrhea, and phlebitis at the infusion site, and hepatotoxicity with elevated transaminases has been reported.

Antacids

– Medications that neutralise gastric acid, providing rapid symptomatic relief in dyspepsia, gastroesophageal reflux, and peptic ulcer disease. Commonly contain aluminium hydroxide, magnesium hydroxide, calcium carbonate, or sodium bicarbonate. Aluminium-based antacids can cause constipation; magnesium-based antacids can cause diarrhea; combination preparations balance these effects. Antacids also promote gastric mucosal defence by stimulating bicarbonate and prostaglandin secretion. Drug interactions: reduce absorption of tetracyclines, iron, digoxin, and bisphosphonates (separate dosing by 2 hours). Not first-line for chronic GERD (PPIs preferred).

Antianginal

– A class of medications used to prevent or relieve angina pectoris (chest pain from myocardial ischemia). The three main classes of antianginal drugs target different mechanisms: nitrates (nitroglycerin, isosorbide mononitrate/dinitrate) — venodilators that reduce preload and myocardial oxygen demand; beta-blockers — reduce heart rate, contractility, and oxygen demand; and calcium channel blockers (ver-

apamil, diltiazem, nifedipine) — vasodilators that reduce afterload and coronary spasm. Ranolazine is a newer antianginal agent that inhibits the late sodium current in cardiac myocytes, reducing intracellular calcium overload and improving diastolic function without affecting heart rate or blood pressure.

Antiarrhythmic

- A drug used to treat or prevent cardiac arrhythmias, classified by the Vaughan Williams system: Class I (sodium channel blockers: quinidine, lidocaine, flecainide), Class II (beta-blockers), Class III (potassium channel blockers prolonging repolarization: amiodarone, sotalol), Class IV (calcium channel blockers: verapamil, diltiazem), and Class V (other: digoxin, adenosine). Selection depends on the arrhythmia (AF, SVT, VT) and underlying heart disease. Antiarrhythmics can themselves be proarrhythmic; amiodarone requires monitoring for pulmonary, thyroid, hepatic, and ocular toxicity.

Antibiotic cycling

- The scheduled rotation of antimicrobial agents within a healthcare facility to reduce selective pressure for resistance. The strategy involves periodically changing the preferred antibiotics for specific infections. For example, cycling between carbapenems and fluoroquinolones for gram-negative infections. The evidence for antibiotic cycling is mixed, with some studies showing reductions in resistance and others showing no benefit. Cycling may be combined with other stewardship strategies including education, surveillance, and the development of evidence-based prescribing guidelines tailored to local resistance patterns.

Antibiotic de-escalation

- The process of narrowing antimicrobial spectrum based on microbiological results and clinical response. De-escalation aims to reduce selective pressure for resistance while maintaining therapeutic efficacy. The process involves identifying the causative organism and susceptibility pattern, then switching from broad-spectrum to narrow-spectrum agents. De-escalation should be performed as soon as possible, typically within 48-72 hours when culture results are available. This strategy reduces the risk of antibiotic resistance, selective pressure on the microbiome, superinfection risk, and adverse drug

effects, while also lowering overall treatment costs.

Antibiotic mixing

- A stewardship strategy where different patients with the same indication receive different antibiotics concurrently, with the goal of reducing resistance emergence. For example, using different agents for ventilator-associated pneumonia in different patients within the same unit. The evidence for antibiotic mixing is limited, but theoretical models suggest it may reduce resistance emergence. This strategy may be combined with other stewardship strategies including prospective audit and feedback, formulary restriction, and computerised decision support to achieve optimal antimicrobial use.

Antibiotics

- Medications that kill or inhibit the growth of bacteria, used to treat bacterial infections such as pneumonia, strep throat, and urinary tract infections. They are ineffective against viral infections like colds or influenza. Overuse and misuse have driven antibiotic resistance, a growing public health crisis that makes infections harder to treat.

Anticonvulsants

- Medications used to prevent or control seizures in epilepsy and other seizure disorders. Mechanisms: enhance GABA activity (benzodiazepines, barbiturates, vigabatrin, tiagabine), block voltage-gated sodium channels (phenytoin, carbamazepine, lamotrigine), block calcium channels (gabapentin, pregabalin, ethosuximide), or inhibit glutamate release (levetiracetam). Choice depends on seizure type: sodium valproate for generalised, carbamazepine/lamotrigine for focal. Side effects: sedation, dizziness, ataxia, rash, hepatotoxicity, teratogenicity (valproate). Therapeutic drug monitoring required for phenytoin and carbamazepine.

Antidiabetic

- A class of medications used to manage diabetes mellitus by lowering blood glucose levels through various mechanisms. Major classes include: biguanides (metformin) — reduce hepatic glucose production; sulfonylureas (glipizide, glyburide) — stimulate insulin secretion; meglitinides (repaglinide) — stimulate rapid, short-acting insulin secretion; thiazolidinediones (pioglitazone) — improve insulin sensitivity; DPP-4 inhibitors (sitagliptin) — increase incretin levels; GLP-1 receptor agonists (semaglu-

tide, liraglutide) — stimulate insulin secretion, slow gastric emptying; SGLT2 inhibitors (empagliflozin, dapagliflozin) — increase urinary glucose excretion; insulin preparations — replace endogenous insulin; and alpha-glucosidase inhibitors (acarbose) — delay carbohydrate absorption.

Antidiarrheal

– A drug that reduces the frequency or volume of diarrhea. Loperamide, a peripheral mu-opioid receptor agonist, slows intestinal motility and reduces fluid loss without CNS effects; diphenoxylate/atropine combinations and bismuth subsalicylate are alternatives. Antidiarrheals are avoided in invasive/inflammatory diarrhea (dysentery, *C. difficile* infection) because they may prolong infection or precipitate toxic megacolon. Oral rehydration is first-line for dehydration. Octreotide is used for secretory diarrhea; cholestyramine for bile acid diarrhea.

Antiepileptic Drugs

– Medications used to prevent and control seizures by modulating neuronal excitability through various mechanisms. They can be classified by their primary mechanism of action. Sodium channel blockers including phenytoin, carbamazepine, and lamotrigine stabilize the inactivated state of voltage-gated sodium channels, reducing high-frequency repetitive firing. GABA-enhancing drugs including valproic acid, benzodiazepines, and vigabatrin increase inhibitory GABAergic transmission; glutamate receptor antagonists such as topiramate and felbamate reduce excitatory neurotransmission; and drugs with multiple mechanisms including valproic acid and levetiracetam provide broad-spectrum seizure control through combined action on GABA, sodium channels, and calcium channels.

Antifungal

– A drug used to treat fungal infections. Classes: polyenes (amphotericin B—broad, fungicidal, for severe/systemic mycoses), azoles (fluconazole, itraconazole, voriconazole, posaconazole—inhibit ergosterol synthesis), echinocandins (caspofungin, micafungin, anidulafungin—inhibit cell wall glucan synthesis), and allylamines (terbinafine—for dermatophytes). Griseofulvin, flucytosine, and nystatin (topical/enteral) are additional agents. Selection depends on the organism, site, and host immunity.

Antifungal resistance is emerging (*Candida auris*).

Antifungal prophylaxis

– The use of antifungal agents to prevent the development of invasive fungal infections in high-risk patients. Common indications include prolonged neutropenia following chemotherapy, hematopoietic stem cell transplantation, solid organ transplantation, and advanced HIV infection. Fluconazole is the most widely used agent for prophylaxis in neutropenic patients, with doses of 200–400 mg daily. It is effective against *Candida* species but does not cover *Aspergillus*. Itraconazole provides broader coverage, including *Aspergillus*, and is used for prophylaxis in high-risk patients, though tolerability is limited by gastrointestinal side effects.

Antigout

– A class of medications used to treat gout by reducing uric acid levels or controlling acute inflammation. Acute gout treatment: NSAIDs (indomethacin, naproxen) — first-line for pain and inflammation; colchicine — inhibits microtubule polymerization, reducing neutrophil chemotaxis and inflammation, most effective when started within 24 hours of attack; corticosteroids (oral, intra-articular, or IV) for refractory cases. Long-term urate-lowering therapy: xanthine oxidase inhibitors (allopurinol, febuxostat) — reduce uric acid production by inhibiting xanthine oxidase; uricosuric agents (probenecid, lesinurad) — increase renal uric acid excretion by inhibiting URAT1 transporter; and recombinant uricase (pegloticase) — enzymatically degrades uric acid, reserved for severe tophaceous gout.

Antihistamine

– A drug that blocks histamine receptors. H1 antihistamines treat allergic rhinitis, urticaria, pruritus, and (older sedating agents) insomnia and motion sickness. First-generation (diphenhydramine, chlorpheniramine): CNS-penetrant—sedating, anticholinergic (dry mouth, urinary retention, confusion in elderly). Second-generation (loratadine, cetirizine, fexofenadine): non-sedating, peripherally selective. H2 antihistamines (famotidine, ranitidine) reduce gastric acid (see H2 Blockers). Used in anaphylaxis as adjuncts (after epinephrine).

Antihypertensive

– A drug that lowers blood pressure, used for hypertension management. Major classes: ACE in-

hibitors and ARBs (preferred first-line, renoprotective), calcium channel blockers, thiazide diuretics, beta-blockers (with CAD/heart failure), alpha-blockers, centrally acting agents (clonidine), and direct vasodilators (hydralazine, minoxidil). Combination therapy is often needed; lifestyle modification is foundational. Goals vary by risk (typically <130/80 mmHg). Adverse effects are class-specific; ACE inhibitor cough, hyperkalemia, and angioedema require vigilance. Hypertensive urgency/emergency requires urgent IV therapy.

Anti-inflammatory

– An agent that reduces inflammation. Nonsteroidal anti-inflammatory drugs (NSAIDs) inhibit cyclooxygenase, reducing prostaglandin synthesis; corticosteroids have broader anti-inflammatory actions via glucocorticoid receptor-mediated gene regulation; colchicine, methotrexate, sulfasalazine, and biologic agents (TNF inhibitors, IL-6 inhibitors) are used for inflammatory and autoimmune disease. Anti-inflammatories are used for pain, fever, arthritis, inflammatory bowel disease, asthma, and allergic conditions. Long-term use carries risks: GI ulceration, renal impairment, cardiovascular events (NSAIDs); immunosuppression, hyperglycemia, osteoporosis (corticosteroids).

Antimicrobial desensitization

– A procedure that involves administering gradually increasing doses of an antimicrobial to induce tolerance in patients with allergy. Desensitization is used when the causative agent is the only effective treatment and the patient has a history of hypersensitivity. The procedure is performed under close medical supervision with monitoring for anaphylaxis. It is most commonly performed for beta-lactam antibiotics in patients with severe allergy. Desensitization involves starting with very low doses, typically micrograms, and increasing gradually over several hours until the full therapeutic dose is tolerated, after which desensitisation must be maintained by continuous drug exposure.

Antimicrobial drug interactions

– Numerous drug interactions exist between antimicrobial agents and other medications. Fluoroquinolones chelate divalent cations and can interact with antacids, dairy products, and iron supplements. Macrolides inhibit CYP3A4 and can increase levels

of co-administered medications. Azole antifungals inhibit CYP3A4 and have numerous drug interactions. Rifampin is a potent inducer of CYP enzymes and can decrease levels of many medications. TMP-SMX can increase levels of warfarin and phenytoin. Understanding these interactions is critical for safe prescribing and requires careful review of the patient's complete medication list before initiating antimicrobial therapy.

Antimicrobial hypersensitivity reactions

– Hypersensitivity reactions to antimicrobial agents range from mild rash to life-threatening anaphylaxis. Beta-lactam antibiotics are the most common cause of drug allergy. Cross-reactivity between penicillins and cephalosporins is approximately 2%. Sulfonamide antibiotics can cause severe cutaneous reactions. Fluoroquinolones can cause photosensitivity and rare anaphylaxis. Vancomycin can cause red man syndrome, which is an infusion-related reaction rather than true allergy. Proper allergy assessment is essential, including skin testing when indicated, and documentation of the reaction type and severity to guide future prescribing decisions.

Antimicrobial resistance mechanisms

– Mechanisms by which bacteria develop resistance to antimicrobial agents. Major mechanisms include enzymatic inactivation (beta-lactamases, aminoglycoside-modifying enzymes), target modification (PBP alterations, ribosomal methylation), efflux pumps, and decreased permeability (porin mutations). Resistance can be intrinsic, acquired through mutation, or transferred horizontally via plasmids, transposons, and integrons. Understanding resistance mechanisms is essential for developing new antibioticantibiotics and for guiding empirical therapy based on local resistance surveillance data.

Antimicrobial Stewardship

– A coordinated programme of interventions designed to optimize antimicrobial use, improve patient outcomes, reduce adverse effects, and minimize the development of antimicrobial resistance. Core strategies include prospective audit and feedback where infectious disease specialists review antimicrobial prescriptions and recommend changes; formulary restrictions limiting the use of certain antimicrobials

to specific indications; clinical practice guidelines based on local epidemiology and resistance patterns, with regular review and updating of prescribing policies based on surveillance data.

Antineoplastic

– A drug used to treat cancer (chemotherapy). Categories: alkylating agents (cyclophosphamide, cisplatin), antimetabolites (methotrexate, 5-FU), antitumor antibiotics (doxorubicin), plant alkaloids (vincristine, paclitaxel), topoisomerase inhibitors (irinotecan, etoposide), hormonal agents, targeted therapies (TKIs, monoclonal antibodies), and immunotherapies (checkpoint inhibitors). Most act on rapidly dividing cells, causing myelosuppression, mucositis, alopecia, nausea, and gonadal toxicity. Regimens combine drugs with different mechanisms and toxicities to maximize efficacy and minimize resistance.

Antioxidants

– Substances that prevent or slow oxidative damage to cells caused by free radicals (reactive oxygen and nitrogen species). Endogenous antioxidants: glutathione, superoxide dismutase, catalase. Dietary antioxidants: vitamin C (ascorbic acid — water-soluble, scavenges aqueous-phase radicals), vitamin E (tocopherol — lipid-soluble, protects cell membranes), beta-carotene (provitamin A), selenium (cofactor for glutathione peroxidase), and flavonoids. Despite theoretical benefits, large clinical trials have not consistently demonstrated reduced cardiovascular events or cancer with antioxidant supplementation. A balanced diet rich in fruits and vegetables provides adequate antioxidants.

Antiparasitic

– A drug used to treat infections caused by parasites (protozoa and helminths). Antiprotozoals: metronidazole (Giardia, amebiasis, trichomoniasis), tinidazole, chloroquine and artemisinin combinations (malaria), pyrimethamine (toxoplasmosis), pentamidine, and nifurtimox (Chagas). Anthelmintics: albendazole and mebendazole (roundworm, hookworm, pinworm, tapeworm), ivermectin (strongyloidiasis, onchocerciasis, scabies), praziquantel (schistosomiasis, flukes), and diethylcarbamazine (filariasis). Many require weight-based dosing and repeated courses; adverse effects depend on the class.

Antiparkinsonian

– A drug used to treat Parkinson disease and drug-induced parkinsonism. Classes: levodopa/carbidopa (most effective), dopamine agonists (pramipexole, ropinirole, rotigotine), MAO-B inhibitors (selegiline, rasagiline), COMT inhibitors (entacapone), anticholinergics (benztropine, trihexyphenidyl—for drug-induced parkinsonism and tremor), and amantadine (early/adjunct, dyskinesia). Selection depends on age, severity, and predominant symptoms; levodopa remains the gold standard.

Antipruritic

– A medication that relieves itching (pruritus). First-line for most causes: topical emollients and moisturizers — restore skin barrier function; topical corticosteroids — reduce inflammation in atopic dermatitis, contact dermatitis, and psoriasis; topical antihistamines (diphenhydramine, doxepin) — block histamine H1 receptors in the skin; topical calcineurin inhibitors (tacrolimus, pimecrolimus) — for atopic dermatitis without steroid side effects. Systemic antipruritics: oral antihistamines (cetirizine, loratadine, hydroxyzine) — especially for urticaria; antidepressants (doxepin, mirtazapine) — for chronic pruritus; opioid antagonists (naltrexone) — for cholestatic pruritus; and aprepitant — an NK1 receptor antagonist for refractory pruritus.

Antipsychotic

– A drug used to treat psychotic disorders (schizophrenia, schizoaffective disorder, psychosis in bipolar/manic states and delirium). Typical (first-generation): haloperidol, chlorpromazine—D2 blockade, high EPS/tardive dyskinesia risk, hyperprolactinemia. Atypical (second-generation): clozapine, risperidone, olanzapine, quetiapine—D2/5-HT2A antagonism, fewer EPS but more metabolic side effects (weight gain, diabetes). Long-acting injectable formulations improve adherence. Adverse effects include neuroleptic malignant syndrome and QT prolongation.

Antipyretic

– A drug that reduces fever by lowering the hypothalamic set point, typically by inhibiting prostaglandin synthesis in the preoptic hypothalamus. Acetaminophen and NSAIDs (ibuprofen, aspirin) are the principal antipyretics. Fever is itself a beneficial host response, so antipyretics are reserved

for patient comfort, particularly in children at risk of dehydration. Aspirin is contraindicated in children (Reye syndrome). Antipyretics are used in combination or rotation for control. Overdose of acetaminophen causes hepatotoxicity.

Antipyretics

- Medications that reduce fever by inhibiting cyclooxygenase (COX) enzymes, reducing hypothalamic prostaglandin E₂ synthesis and resetting the thermoregulatory set point. Common antipyretics: paracetamol (acetaminophen — preferred first-line, particularly in children and patients with contraindications to NSAIDs, but hepatotoxic in overdose), ibuprofen (NSAID, also anti-inflammatory, avoid in dehydration, renal impairment, and peptic ulcer disease), and aspirin (avoid in children due to Reye syndrome risk). Antipyretics should be used for symptomatic relief, not routinely for all fevers, as fever is a physiological defence mechanism.

Antiseptic

- An antimicrobial substance applied to living tissue (skin, mucous membranes) or wounds to reduce the risk of infection by destroying or inhibiting microorganisms. Common antiseptics include: alcohol (ethanol, isopropanol, 60-90%) — denatures proteins, effective against bacteria and enveloped viruses, used for hand hygiene and skin preparation; chlorhexidine (2-4%) — disrupts cell membranes, broad-spectrum with persistent activity, used for surgical hand scrub and preoperative skin prep; povidone-iodine (10%) — releases free iodine that oxidizes cell components, broad-spectrum including spores; hydrogen peroxide (3%) — produces free radicals, mechanical debridement through effervescence, limited antimicrobial activity; and octenidine — newer antiseptic with broad activity, common in Europe. Antiseptics are distinct from antibiotics (systemic use) and disinfectants (applied to inanimate objects).

Antitubercular Agents

- Antimicrobial drugs used to treat *Mycobacterium tuberculosis* infections. The first-line agents include isoniazid, which inhibits mycolic acid synthesis; rifampicin, which inhibits RNA polymerase; pyrazinamide, which disrupts membrane energetics; ethambutol, which inhibits arabinosyl transferase; and streptomycin, which inhibits protein synthe-

sis. The standard regimen for drug-susceptible tuberculosis is a four-drug combination of isoniazid, rifampicin, pyrazinamide, and ethambutol for two months followed by a continuation phase of isoniazid and rifampicin for four months; treatment adherence is critical and directly observed therapy is recommended to prevent treatment failure and acquired drug resistance.

Antitussive

- A medication that suppresses the cough reflex, used for dry, non-productive cough. Centrally acting antitussives: dextromethorphan — acts on the cough center in the medulla oblongata, likely through sigma-1 receptor agonism, NMDA antagonism, and serotonin reuptake inhibition; codeine — a prodrug converted to morphine, acts on mu-opioid receptors in the cough center, controlled substance due to abuse potential, not recommended in children. Peripherally acting antitussives: benzonatate — a local anesthetic that reduces cough reflex by numbing stretch receptors in the respiratory tract; inhaled sodium cromoglycate and nedocromil — stabilize mast cells and reduce cough in asthma. Demulcents (honey, glycerin, lozenges) soothe irritated pharyngeal mucosa. Expectorants (guaifenesin) are not antitussives but increase mucus production to facilitate coughing up phlegm.

Antivirals

- Drugs that inhibit the replication of viruses, reducing the severity and duration of viral infections. They are used for conditions such as influenza, herpes, HIV, hepatitis B and C, and COVID-19. Unlike antibiotics, antivirals target specific viral enzymes or life cycle stages and often work best when started early in the infection.

Apixaban

- A direct oral anticoagulant (DOAC) that selectively and reversibly inhibits factor Xa. Used for stroke prevention in nonvalvular atrial fibrillation and for treatment/prophylaxis of venous thromboembolism. Advantages over warfarin: fixed dosing, rapid onset/offset, predictable pharmacokinetics, no routine monitoring, fewer drug/food interactions. Dosing is reduced in renal impairment, advanced age, low weight, or with certain interacting drugs. Major adverse effect is bleeding; reversal agent: andexanet alfa. Avoid in mechanical valves and moder-

ate/severe mitral stenosis.

Aromatase Inhibitor

– A class of medications that inhibit aromatase, the enzyme that converts androgens (androstenedione, testosterone) to estrogens (estrone, estradiol) in peripheral tissues (adipose, breast, muscle, bone). Used primarily in hormone receptor-positive breast cancer in postmenopausal women. Third-generation aromatase inhibitors: anastrozole (nonsteroidal, reversible), letrozole (nonsteroidal, reversible), and exemestane (steroidal, irreversible). In postmenopausal women, AIs are first-line adjuvant therapy and first-line therapy for metastatic breast cancer (superior to tamoxifen). In premenopausal women, AIs are used in combination with ovarian suppression. Adverse effects: arthralgia and myalgia (20-50%, most common cause of discontinuation), accelerated bone loss (osteoporosis, fracture risk), hot flashes, and dyslipidemia. AIs do not cause endometrial cancer or thromboembolism (unlike tamoxifen).

Atazanavir

– A protease inhibitor (PI) used in combination antiretroviral therapy for HIV-1 infection. Atazanavir inhibits the HIV aspartyl protease, preventing viral polyprotein processing and producing immature, non-infectious viral particles. A key advantage of atazanavir is its once-daily dosing and relatively favorable lipid profile compared to other protease inhibitors, with minimal impact on triglycerides and cholesterol levels. The most characteristic adverse effect is indirect hyperbilirubinemia due to inhibition of UGT1A1, causing unconjugated hyperbilirubinemia and clinical jaundice in a subset of patients, which is reversible upon discontinuation but is not associated with hepatotoxicity.

Atenolol

– A cardioselective (beta-1) beta-blocker used for hypertension, angina, and post-myocardial infarction, and for rate control in atrial fibrillation. Hydrophilic—less CNS penetration than propranolol. Adverse effects: bradycardia, hypotension, fatigue, cold extremities, and masking of hypoglycemia; less bronchospasm at low doses than nonselective agents. Avoid abrupt withdrawal (rebound tachycardia/ischemia). Once-daily dosing; renally cleared (reduce dose in renal impairment).

Atomoxetine

– A selective norepinephrine reuptake inhibitor (non-stimulant) used for attention deficit hyperactivity disorder. Increases noradrenergic signaling in prefrontal cortex; no abuse potential. Once or twice daily. Adverse effects: decreased appetite, nausea, insomnia, dry mouth, increased blood pressure/heart rate, and rare hepatotoxicity (discontinue if jaundice). Black-box warning for suicidal ideation in children/adolescents. Slower onset than stimulants; may be preferred when stimulants are contraindicated (tics, substance abuse).

Atorvastatin

– A potent HMG-CoA reductase inhibitor (statin) used for hypercholesterolemia and cardiovascular risk reduction. Reduces LDL cholesterol by inhibiting cholesterol synthesis in the liver, upregulating LDL receptors. Long half-life (14 hours) allows once-daily dosing. Evidence-based for primary and secondary prevention; intensive therapy (40-80 mg) is used in high-risk patients (ACS, diabetes, ASCVD). Adverse effects: myalgia, transaminase elevation, and rare rhabdomyolysis; new-onset diabetes. Metabolized by CYP3A4—interacts with many drugs; avoid with strong CYP3A4 inhibitors.

Azithromycin

– A macrolide antibiotic with an extended half-life allowing for once-daily dosing and short treatment courses. Azithromycin inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. It has activity against gram-positive organisms, atypical pathogens (*Mycoplasma*, *Chlamydia*, *Legionella*), and some gram-negative organisms. The drug is indicated for respiratory tract infections, sexually transmitted infections, and skin infections. Common adverse effects include gastrointestinal upset, diarrhea, and nausea, and azithromycin is associated with a small increased risk of cardiovascular death due to QT prolongation.

Azole Antifungals

– A class of antifungal agents that inhibit the enzyme lanosterol 14- α -demethylase, a cytochrome P450 enzyme essential for ergosterol synthesis in fungal cell membranes. The depletion of ergosterol and accumulation of toxic methylated sterols disrupt membrane integrity and function. Azoles are divided into imidazoles including ketoconazole and clotrimazole,

used primarily for topical infections, and triazoles including fluconazole, itraconazole, voriconazole, and posaconazole, which provide broader antifungal coverage; posaconazole and voriconazole have activity against *Aspergillus* species, while fluconazole has limited activity against this genus.

Aztreonam

– A monobactam antibiotic with activity only against aerobic gram-negative bacteria. Aztreonam inhibits cell wall synthesis by binding to penicillin-binding protein 3 (PBP3). It is resistant to hydrolysis by most beta-lactamases, including extended-spectrum beta-lactamases (ESBLs). Aztreonam is indicated for serious gram-negative infections including pneumonia, urinary tract infections, and bacteremia. It is an alternative for patients with beta-lactam allergy, as there is minimal cross-reactivity with other beta-lactam antibiotics, making it a useful alternative for patients with reported penicillin allergy.

Bacteriophage therapy

– The use of bacterial viruses (bacteriophages) to treat bacterial infections. Bacteriophages are viruses that specifically infect and lyse bacteria. They have narrow specificity for target bacteria and do not affect normal flora. Phage therapy is being studied for multidrug-resistant bacterial infections, particularly those failing conventional antibiotics. Clinical trials have shown promise for chronic pseudomonal infections and prosthetic joint infections. The main challenges include regulatory hurdles including standardised production, stability testing, pharmacokinetic characterisation, and regulatory approval pathways that vary across jurisdictions.

Barbiturate

– A class of CNS depressants derived from barbituric acid that enhance GABA-A receptor activity by increasing the duration of chloride channel opening (as opposed to benzodiazepines, which increase the frequency). At low doses: anxiolysis and sedation. At moderate doses: hypnosis and anesthesia. At high doses: respiratory depression, coma, and death. Classification by duration of action: ultra-short (thiopental, methohexital — IV induction agents), short/intermediate (pentobarbital, secobarbital — sedation, now rarely used), and long-acting (phenobarbital — anticonvulsant). Indications now limited: phenobarbital for neonatal seizures and

status epilepticus when other agents fail; thiopental for rapid sequence induction historically. Adverse effects: narrow therapeutic index, respiratory depression, tolerance, physical dependence, severe withdrawal (anxiety, tremors, seizures, delirium), and enzyme induction (CYP3A4, CYP2C9). Drug interactions: reduces efficacy of oral contraceptives, warfarin, and many other drugs. Barbiturates are Schedule II-IV controlled substances.

Bedaquiline

– A diarylquinoline antibiotic used in the treatment of multidrug-resistant tuberculosis. Bedaquiline inhibits the mycobacterial ATP synthase, disrupting energy production. It is indicated for pulmonary multidrug-resistant tuberculosis in combination with other agents. The drug is administered orally three times weekly for the first 2 weeks, then twice weekly. Common adverse effects include QT prolongation, hepatotoxicity, and arthralgia. Bedaquiline is metabolized by CYP3A4 and has significant drug interactions, particularly as a CYP3A4 substrate, and requires ECG monitoring for QT interval prolongation during therapy.

Benzodiazepines

– A class of drugs that enhance the effect of the inhibitory neurotransmitter gamma-aminobutyric acid at the GABA-A receptor, increasing the frequency of chloride channel opening and producing anxiolytic, sedative, anticonvulsant, and muscle relaxant effects. They bind to an allosteric site on the GABA-A receptor, distinct from the GABA binding site, and potentiate the effect of GABA when it binds. Common benzodiazepines include diazepam, lorazepam, alprazolam, clonazepam, midazolam. They differ in potency, half-life, lipid solubility, and metabolic pathways, influencing their clinical applications for anxiety, insomnia, seizure disorders, and procedural sedation.

Beta Blockers

– A class of drugs that competitively block beta-adrenergic receptors. Cardioselective (beta-1: metoprolol, atenolol, bisoprolol) affect mainly the heart; nonselective (beta-1 and beta-2: propranolol, carvedilol, labetalol) also cause bronchoconstriction and peripheral effects. Uses: hypertension, angina, heart failure (carvedilol, bisoprolol, metoprolol succinate), arrhythmias, migraine prophylaxis, essen-

tial tremor, thyrotoxicosis, glaucoma (timolol), and portal hypertension (propranolol). Adverse effects: bradycardia, hypotension, fatigue, bronchospasm, masking of hypoglycemia, and rebound hypertension on abrupt withdrawal.

Beta-Lactam Antibiotics

– A large class of antimicrobial agents characterized by a beta-lactam ring in their molecular structure, which is essential for their bactericidal activity. They include penicillins, cephalosporins, carbapenems, and monobactams, all of which share the mechanism of inhibiting bacterial cell wall synthesis by binding to penicillin-binding proteins and preventing cross-linking of peptidoglycan chains. Beta-lactams are bactericidal, killing bacteria by weakening the cell wall, leading to osmotic lysis and cell death; they are the most widely used class of antibiotics globally, with spectrum determined by their affinity for specific PBPs and their ability to penetrate the outer membrane of gram-negative organisms.

Beta-lactamase inhibitor combinations

– Combinations of beta-lactam antibiotics with beta-lactamase inhibitors that extend activity against beta-lactamase producing organisms. The major combinations include amoxicillin-clavulanate, ampicillin-sulbactam, piperacillin-tazobactam, cefoperazone-sulbactam, and ceftolozane-tazobactam. Clavulanate, sulbactam, and tazobactam are beta-lactamase inhibitors that bind irreversibly to beta-lactamase enzymes, preventing degradation of the partner beta-lactam. Clavulanate has the strongest beta-lactamase inhibition; tazobactam is the most potent beta-lactamase inhibitor in clinical use, while avibactam is a newer non-beta-lactam inhibitor that effectively restores activity against class A and class C beta-lactamases.

Biguanide

– A class of oral antidiabetic drugs derived from guanidine, with metformin being the only biguanide in current clinical use (phenformin and buformin were withdrawn due to lactic acidosis risk). Metformin is the first-line pharmacotherapy for type 2 diabetes mellitus. Mechanism: activates AMP-activated protein kinase, reducing hepatic gluco-

neogenesis and glycogenolysis; improves peripheral insulin sensitivity (increases glucose uptake in skeletal muscle); and reduces intestinal glucose absorption. Metformin does not stimulate insulin secretion and therefore does not cause hypoglycemia as monotherapy. Effects: lowers HbA1c by 1-1.5%, weight neutral or modest weight loss, and improves lipid profile. Adverse effects: GI intolerance (diarrhea, nausea, metallic taste, 20-30%), vitamin B12 deficiency with chronic use, and lactic acidosis (rare, 3-10 per 100,000 patient-years, primarily in patients with contraindications). Contraindications: eGFR <30 mL/min, acute kidney injury, decompensated liver disease, and acute medical illness with hypoxia (sepsis, MI, shock). Extended-release formulations improve GI tolerability.

Bioavailability

– The fraction of an administered drug that reaches the systemic circulation in its unchanged active form. It is expressed as a percentage and is determined by the route of administration and the extent of first-pass metabolism. For intravenous administration, bioavailability is 100 percent by definition. For oral administration, bioavailability is typically less than 100 percent due to incomplete absorption and pre-systemic metabolism by gut wall enzymes and the liver. The fraction of an oral dose reaching systemic circulation can be increased by altering the formulation, using prodrugs, or co-administering with food or other drugs that affect absorption or first-pass metabolism.

Bioequivalence

– The property of two drug products (brand-name and generic) that have the same rate and extent of absorption when administered at the same molar dose under similar conditions, resulting in comparable bioavailability and therapeutic effect. The FDA requires generic drugs to demonstrate bioequivalence to the reference listed drug through pharmacokinetic studies showing that the 90% confidence interval of the ratio of generic-to-brand for AUC and Cmax falls within 80-125%. Bioequivalence ensures that generic drugs can be substituted for brand-name drugs without dose adjustment, providing the same clinical efficacy and safety profile at a lower cost.

Biotransformation

– The process by which drugs and other xenobiotics are chemically modified by metabolic enzymes, primarily in the liver, to facilitate elimination from the body. Biotransformation occurs in two phases. Phase I reactions (functionalization): oxidation, reduction, and hydrolysis catalyzed primarily by cytochrome P450 enzymes (CYP1A2, CYP2C9, CYP2C19, CYP2D6, CYP3A4), introducing or exposing functional groups (e.g., -OH, -NH₂, -COOH). Phase II reactions (conjugation): glucuronidation (UGT), sulfation (SULT), acetylation (NAT), methylation, and conjugation with glutathione (GST), attaching endogenous hydrophilic molecules to the drug or Phase I metabolite, increasing water solubility and promoting renal or biliary excretion. Biotransformation generally produces inactive, water-soluble metabolites, but some drugs undergo bioactivation (prodrugs) or produce toxic metabolites that contribute to drug toxicity.

Bisacodyl

– A stimulant laxative (diphenylmethane derivative) that stimulates colonic motility and enhances water/electrolyte secretion, producing a bowel movement within 6-12 hours (oral) or 15-60 minutes (suppository). Used for constipation, bowel preparation, and evacuation before procedures. Adverse effects: abdominal cramps, diarrhea, and electrolyte disturbances with overuse; chronic stimulant use may cause melanosis coli and dependence. Generally safe short-term; avoid in intestinal obstruction, acute abdomen, and with caution in inflammatory bowel disease.

Bismuth Subsalicylate

– An antidiarrheal and anti-ulcer agent (e.g., Pepto-Bismol) with antimicrobial, anti-inflammatory, and coating actions. Used for traveler's diarrhea (prophylaxis and treatment), dyspepsia, *Helicobacter pylori* eradication (quadruple therapy), and symptoms of indigestion. Adverse effects: black stools and black tongue (harmless, from bismuth sulfide), constipation, and tinnitus (salicylate); avoid in children/adolescents with viral illness (Reye syndrome risk) and with anticoagulants/aspirin.

Blood-Brain Barrier

– The blood-brain barrier is a highly selective semipermeable membrane that separates the circulating blood from the brain extracellular fluid,

consisting of endothelial cells connected by tight junctions, astrocyte foot processes, and a basement membrane. The BBB restricts the passage of most molecules from the blood into the brain, protecting the central nervous system from toxins and pathogens while maintaining a stable environment for neural function. Only small, lipophilic molecules and gases can cross the BBB via passive diffusion or active transport; the BBB is disrupted in pathological conditions such as meningitis, ischemia, and multiple sclerosis, affecting drug distribution to the brain.

Bromocriptine

– An ergot dopamine agonist (D₂) used for hyperprolactinemia (prolactinomas, galactorrhea), acromegaly (adjunct), Parkinson disease (less common now), and postpartum breast engorgement (historical). Also used for neuroleptic malignant syndrome. Adverse effects: nausea, orthostatic hypotension, dizziness, headache, cardiac valvulopathy (ergot, high doses), retroperitoneal fibrosis, and hallucinations. Cabergoline (longer-acting, better tolerated) is preferred for hyperprolactinemia.

Bumetanide

– A potent loop diuretic inhibiting the Na-K-2Cl cotransporter in the thick ascending limb of the loop of Henle. Used for edema in heart failure, cirrhosis, and renal disease, and for hypertension in renal impairment. Approximately 40 times more potent than furosemide; more bioavailable orally, so equivalent IV-to-oral dosing is possible. Adverse effects: hypokalemia, hyponatremia, hypomagnesemia, hypocalcemia, metabolic alkalosis, ototoxicity (with aminoglycosides), and dehydration/azotemia.

Buprenorphine

– A partial mu-opioid receptor agonist and kappa antagonist used for opioid use disorder (maintenance, with naloxone to deter misuse—Suboxone), chronic pain (transdermal patch, buccal), and acute pain (analgesic). Partial agonism produces a ceiling effect on respiratory depression (safer in overdose). Adverse effects: nausea, constipation, sedation, and precipitated withdrawal if started during active opioid effect. Schedule III; specialized prescriber requirements (waiver/DEA X).

Bupropion

– An atypical antidepressant that inhibits dopamine and norepinephrine reuptake. Used for major depressive disorder, seasonal affective disorder, and smoking cessation (Zyban). Low sexual side effects and weight neutrality; energizing. Also used off-label for ADHD. Adverse effects: insomnia, dry mouth, agitation, lowered seizure threshold (avoid in epilepsy, eating disorders, alcohol/benzodiazepine withdrawal), and hypertension. Contraindicated with MAOIs and bupropion-containing products. Sustained-release forms allow daily dosing.

Caffeine

– A naturally occurring xanthine alkaloid and central nervous system stimulant found in coffee, tea, chocolate, and many soft drinks and energy beverages. Mechanism: adenosine receptor antagonist (primarily A1 and A2A subtypes), increasing neuronal activity and promoting catecholamine release. Effects: increased alertness, reduced fatigue, improved cognitive performance, diuresis, and bronchodilation. Half-life: 3–7 hours in adults, prolonged in pregnancy, liver disease, and with oral contraceptives. Chronic use produces tolerance; abrupt cessation causes withdrawal syndrome (headache, fatigue, irritability, dysphoria) lasting 2–9 days. Acute toxicity (>500 mg): anxiety, insomnia, tremor, tachycardia; severe toxicity (>5 g): seizures, arrhythmias, death.

Carbamazepine

– An anticonvulsant and mood-stabilizing drug used primarily for focal seizures, generalized tonic-clonic seizures, and trigeminal neuralgia. Mechanism: use-dependent blockade of voltage-gated sodium channels, stabilizing neuronal membranes and inhibiting repetitive firing. Also used as a mood stabilizer in bipolar disorder. Notable: potent CYP3A4 inducer (reduces levels of oral contraceptives, warfarin, many other drugs). Side effects: dizziness, ataxia, diplopia, hyponatremia (SIADH-like), agranulocytosis (rare but serious), rash including Stevens-Johnson syndrome (higher risk in Asian populations with HLA-B*1502 allele). Monitoring: CBC, LFTs, and serum levels (therapeutic 4–12 mcg/mL). Dose-dependent nonlinear kinetics require slow titration.

Carbapenem-resistant organisms

– Bacteria that are resistant to carbapenem antibiotics, typically through production of carbapenemases. The most important carbapenemases in-

clude KPC (*Klebsiella pneumoniae* carbapenemase), NDM (New Delhi metallo-beta-lactamase), and OXA-48-like enzymes. CRO are a major public health threat due to limited treatment options. Infections are associated with high mortality rates. Treatment options include ceftazidime-avibactam, meropenem-vaborbactam, and colistin-based combinations. Infection prevention and antimicrobial stewardship are critical for controlling the spread of carbapenem-resistant organisms in healthcare settings.

Carbidopa

– A peripheral dopa decarboxylase inhibitor that does not cross the blood-brain barrier; combined with levodopa to prevent its peripheral conversion to dopamine, reducing side effects (nausea, hypotension) and increasing CNS levodopa delivery. Standard combinations: carbidopa/levodopa (Sinemet), including controlled-release and orally disintegrating forms. Higher carbidopa ratios (25/100) reduce 'wearing off'. Carbidopa itself has no antiparkinsonian effect but reduces peripheral dopamine-related adverse effects.

Carbolic Acid (Phenol)

– An aromatic organic compound (C_6H_5OH) with antiseptic, disinfectant, and caustic properties. Historically significant as the first surgical antiseptic introduced by Joseph Lister in 1867, dramatically reducing post-operative infection and mortality. Mechanism: denatures bacterial proteins and disrupts cell membranes. Phenol is bactericidal, fungicidal, and virucidal but is toxic to human tissues at high concentrations causing chemical burns and systemic toxicity (neurologic depression, cardiovascular collapse). Modern medical uses: phenol-based chemical peels (dermatology), nerve ablation for chronic pain (neurolysis), and as a preservative in some injectable medications. Safer, less toxic antiseptics (chlorhexidine, povidone-iodine) have largely replaced it for routine disinfection.

Carvedilol

– A nonselective beta-blocker with additional alpha-1 adrenergic blockade and antioxidant properties, producing vasodilation with balanced reduction of heart rate, contractility, and afterload. Used for heart failure with reduced ejection fraction (improves survival, NYHA II-IV), hypertension, and

post-myocardial infarction ventricular dysfunction. Also treats angina. Metabolized by CYP2D6; must be titrated slowly (e.g., 3.125 mg BID upward). Adverse effects: dizziness, hypotension, bradycardia, fatigue, bronchospasm, and masking of hypoglycemia.

Caspofungin

– An echinocandin antifungal agent used in the treatment of invasive candidiasis, esophageal candidiasis, and invasive aspergillosis (as salvage therapy). Caspofungin inhibits beta-(1,3)-D-glucan synthase, disrupting fungal cell wall synthesis. The drug is available only intravenously and has a half-life of approximately 9-11 hours, allowing for once-daily dosing. Common adverse effects include headache, nausea, and phlebitis at the infusion site. Fever and rash have been reported. Hepatotoxicity has been reported, and the drug has fewer drug interactions than azole antifungals as it is not a significant CYP inhibitor.

Ceftazidime-avibactam

– A combination of the third-generation cephalosporin ceftazidime with the non-beta-lactam beta-lactamase inhibitor avibactam. Avibactam inhibits class A, class C, and some class D beta-lactamases, including KPC carbapenemases. This combination has activity against many carbapenem-resistant Enterobacteriaceae and *Pseudomonas aeruginosa*. It is indicated for complicated intra-abdominal infections, complicated urinary tract infections, and hospital-acquired pneumonia. The combination is administered intravenously and requires dose adjustment based on renal function; the most common adverse effects include nausea, diarrhea, and headache.

Cephalosporin

– A class of beta-lactam antibiotics derived from the fungus *Cephalosporium acremonium*, with a mechanism identical to penicillins — inhibition of bacterial cell wall synthesis by binding to penicillin-binding proteins and inhibiting transpeptidase. Cephalosporins are classified into five generations based on their antimicrobial spectrum. First generation (cefazolin, cephalexin): good gram-positive coverage (*Staph aureus*, *Strep pyogenes*), limited gram-negative coverage. Second generation (cefuroxime, cefoxitin, cefotetan): expanded gram-negative

coverage including *H. influenzae* and anaerobes (cefoxitin). Third generation (ceftriaxone, cefotaxime, ceftazidime): broad gram-negative coverage including Enterobacteriaceae; ceftazidime also covers *Pseudomonas*. Fourth generation (cefepime): broad coverage including *Pseudomonas* and gram-positive with stability against AmpC beta-lactamases. Fifth generation (ceftaroline): anti-MRSA activity plus standard cephalosporin coverage. Adverse effects: hypersensitivity reactions (cross-reactivity with penicillins 10% based on similar beta-lactam ring structure), GI disturbances, and bleeding (cefotetan, due to N-methylthiotetrazole side chain causing hypoprothrombinemia).

Cetirizine

– A second-generation H1 antihistamine (metabolite of hydroxyzine) used for allergic rhinitis and urticaria. Slightly more sedating than loratadine/fexofenadine (some CNS penetration). Once daily; renally cleared (dose-reduce in renal impairment). Adverse effects: somnolence (dose-related), dry mouth, and fatigue. Available OTC. Levocetirizine is the active enantiomer.

Chloramphenicol

– A broad-spectrum antibiotic with activity against gram-positive and gram-negative organisms, as well as Rickettsia. Chloramphenicol inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. It is indicated for serious infections when other agents are not appropriate, including bacterial meningitis and typhoid fever. Common adverse effects include bone marrow suppression, gray baby syndrome in neonates, and aplastic anemia. The drug is rarely used due to its toxicity profile. Although effective, its use is limited to life-threatening infections due to the availability of safer alternatives.

Ciprofloxacin

– A second-generation fluoroquinolone with excellent gram-negative coverage, including *Pseudomonas aeruginosa*. Ciprofloxacin inhibits bacterial DNA gyrase and topoisomerase IV. It is indicated for urinary tract infections, respiratory infections, gastrointestinal infections, and bone and joint infections. The drug is available in oral and intravenous formulations. Common adverse effects include gastrointestinal upset, tendon rupture, and QT prolongation.

Ciprofloxacin should not be used in children under 18 years of age due to the risk of arthropathy, except for specific indications such as anthrax exposure and complicated urinary tract infections associated with multidrug-resistant organisms.

Citalopram

- A selective serotonin reuptake inhibitor (SSRI) used for major depressive disorder and (off-label) anxiety disorders. Well tolerated; lowest cost among SSRIs. Adverse effects: nausea, insomnia, sexual dysfunction, and dose-dependent QT prolongation (maximum 40 mg/day; 20 mg in elderly/CYP2C19 poor metabolizers—torsades risk). Serotonin syndrome and discontinuation syndrome; black-box warning for suicidality in young adults. Escitalopram (S-enantiomer) has fewer QT effects.

Clarithromycin

- A macrolide antibiotic with activity against gram-positive organisms, atypical pathogens, and *Helicobacter pylori*. Clarithromycin inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. It is indicated for respiratory infections, skin infections, and *H. pylori* eradication. The drug is metabolized by CYP3A4 and has numerous drug interactions. Common adverse effects include gastrointestinal upset, taste disturbance, and QT prolongation. Clarithromycin is available in oral and intravenous formulations; it is commonly used in combination therapy for *H. pylori* eradication as part of a triple regimen with amoxicillin and a proton pump inhibitor.

Clearance

- The volume of plasma from which a drug is completely removed per unit time, typically expressed in milliliters per minute or liters per hour. Total clearance is the sum of all clearance mechanisms, primarily hepatic and renal clearance. Hepatic clearance depends on hepatic blood flow, enzyme activity, and protein binding, with the hepatic extraction ratio determining the contribution of blood flow versus enzyme activity to clearance. High-extraction drugs like lidocaine have clearance that is highly dependent on hepatic blood flow, while low-extraction drugs like warfarin have clearance that is primarily determined by intrinsic enzyme activity and protein binding.

Clindamycin

- A lincosamide antibiotic with activity against gram-positive organisms and anaerobes. Clindamycin inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. It is indicated for skin infections, intra-abdominal infections, dental infections, and bone infections. The drug inhibits bacterial toxin production and is used for toxic shock syndrome and necrotizing fasciitis. Common adverse effects include diarrhea and *Clostridioides difficile* colitis. Clindamycin achieves excellent bone penetration and is used extensively in dental and orthopaedic infections, including chronic osteomyelitis.

Clinical Trial Phases

- The stages of drug development: Phase I (safety, dosing, pharmacokinetics in 20-100 healthy volunteers); Phase II (efficacy and side effects in 100-300 patients with the target condition); Phase III (large-scale efficacy and safety comparison with standard treatment in 1,000-3,000 patients); Phase IV (post-marketing surveillance for long-term effects and rare adverse events). Each phase has specific endpoints and success criteria before advancing to the next phase.

Clonazepam

- A long-acting benzodiazepine used for seizure disorders (absence, myoclonic, Lennox-Gastaut), panic disorder, and movement disorders (REM sleep behavior disorder, parasomnias). Potent GABA-A enhancement. Long half-life (20-50 hours) allows twice-daily dosing but causes accumulation; tolerance and dependence with chronic use; withdrawal seizures with abrupt cessation. Adverse effects: sedation, ataxia, behavioral changes in children, and respiratory depression (with opioids). Schedule IV.

Clonidine

- A centrally acting alpha-2 adrenergic agonist that reduces sympathetic outflow from the CNS, lowering blood pressure, heart rate, and peripheral resistance. Used for hypertension, and off-label for ADHD, opioid/nicotine withdrawal, tic disorders, and sedation/analgesia in anesthesia. Available oral, transdermal patch, and epidural. Adverse effects: sedation, dry mouth, dizziness, bradycardia, rebound hypertension on abrupt discontinuation (withdrawal), and depression. Administer as patch for more stable control.

Clostridioides difficile

- An anaerobic, spore-forming, toxin-producing gram-positive bacillus causing antibiotic-associated diarrhea and pseudomembranous colitis. Risk factors: antibiotics (especially clindamycin, fluoroquinolones, cephalosporins), hospitalization, age >65, PPIs, and immunosuppression. Toxins A and B damage colonic epithelium. Diagnosis: NAAT/PCR for toxin genes or toxin EIA. Treatment: vancomycin or fidaxomicin PO (first-line); metronidazole for mild disease when agents unavailable; fecal microbiota transplantation for recurrent disease. Infection control: contact precautions, handwashing with soap (alcohol gel is less effective).

Clostridioides difficile infection

- An infectious diarrhea caused by the bacterium *Clostridioides difficile*, typically occurring after disruption of normal gastrointestinal flora by antibiotics. *C. difficile* produces toxins A and B that cause colonic inflammation and diarrhea. Risk factors include antibiotic exposure, proton pump inhibitor use, and advanced age. Treatment options include vancomycin, fidaxomicin, and metronidazole. Recurrence occurs in approximately 25% of cases. Fecal microbiota transplantation is highly effective for recurrent *C. difficile* infection, with cure rates exceeding 90%.

Clostridium difficile Infection (CDI)

- See *Clostridioides difficile*.

Clozapine

- An atypical antipsychotic reserved for treatment-resistant schizophrenia and for reducing recurrent suicidal behavior in schizophrenia/schizoaffective disorder. Unique efficacy due to broad receptor profile (D2, 5-HT_{2A}, H₁, M₁, α -1). Adverse effects: agranulocytosis (requires mandatory blood monitoring), seizures, myocarditis, weight gain, metabolic syndrome, sialorrhea, and constipation/ileus. Black-box warnings for agranulocytosis, myocarditis, seizures, and severe constipation. The most effective antipsychotic but the most monitoring-intensive.

Codeine

- An opioid prodrug (metabolized by CYP2D6 to morphine) used for mild to moderate pain and cough suppression (antitussive). Efficacy

depends on CYP2D6 metabolism (poor metabolizers: no effect; ultrarapid metabolizers: toxicity/apnea—contraindicated in children post-tonsillectomy). Adverse effects: constipation, nausea, sedation, respiratory depression, and dependence. Schedule II/III. Generally avoided in favor of more predictable analgesics (ibuprofen, acetaminophen, tramadol, hydrocodone).

Competitive Antagonist

- A competitive antagonist is a drug that binds to the same receptor site as an agonist and competes for binding, reducing the effect of the agonist without producing an effect of its own. The antagonism is surmountable by increasing the agonist concentration, which shifts the dose-response curve of the agonist to the right without reducing the maximal response. This means that with enough agonist, the full effect can still be achieved. The degree of rightward shift depends on the concentration of the agonist and the concentration of the antagonist; the relationship is quantitated using the Schild regression, which yields a pA₂ value representing the concentration of antagonist required to produce a twofold rightward shift of the agonist dose-response curve.

Controlled Substance

- A drug or chemical whose manufacture, possession, and use are regulated by government authorities due to its potential for abuse, dependence, or harm. In the United States, the Controlled Substances Act (CSA) classifies controlled substances into five schedules (I-V) based on their accepted medical use, abuse potential, and dependence liability. Schedule I: high abuse potential, no accepted medical use (heroin, LSD, marijuana federally). Schedule II: high abuse potential, severe dependence liability, accepted medical use with restrictions (morphine, oxycodone, fentanyl, cocaine, amphetamine). Schedule III: moderate to low abuse potential, moderate dependence liability (codeine-containing products, ketamine, anabolic steroids). Schedule IV: low abuse potential, limited dependence liability (benzodiazepines, zolpidem, tramadol). Schedule V: lowest abuse potential, limited dependence liability (codeine-containing antitussives, pregabalin). Healthcare providers must register with the DEA to prescribe controlled substances and comply with state and federal regulations.

Corticosteroids Mechanism

– Corticosteroids exert their anti-inflammatory and immunosuppressive effects primarily by binding to intracellular glucocorticoid receptors, which then translocate to the nucleus and modulate gene transcription. They transactivate anti-inflammatory genes including those encoding lipocortin-1, which inhibits phospholipase A2 and reduces arachidonic acid release, and they transrepress pro-inflammatory genes by inhibiting transcription factors including NF-kappaB and AP-1. This reduces the production of prostaglandins, leukotrienes, and other inflammatory mediators, which underlies their therapeutic efficacy in inflammatory conditions, autoimmune diseases, and allergic reactions.

COX Inhibitor

– A class of drugs that inhibit cyclooxygenase enzymes (COX-1 and COX-2), which catalyze the conversion of arachidonic acid to prostaglandins and thromboxanes. COX-1 is constitutively expressed in most tissues, producing prostaglandins that protect the gastric mucosa, maintain renal blood flow, and support platelet aggregation. COX-2 is induced during inflammation, producing prostaglandins that mediate pain, fever, and inflammation. Non-selective COX inhibitors (aspirin, ibuprofen, naproxen, indomethacin, diclofenac) inhibit both isoforms, providing analgesic, anti-inflammatory, and antipyretic effects but causing GI toxicity (gastritis, ulcers, bleeding) and platelet inhibition. Selective COX-2 inhibitors (celecoxib) provide anti-inflammatory effects with reduced GI toxicity but do not inhibit platelet aggregation and are associated with increased cardiovascular risk (MI, stroke). The COX hypothesis explains the therapeutic and adverse effects of NSAIDs.

Cream

– A semisolid emulsion (oil in water or water in oil) for topical application, containing a drug in an emulsion base. Creams are lighter, less greasy, and easier to spread than ointments, and are preferred for moist or oozing skin lesions. They penetrate less deeply than ointments and are cosmetically acceptable. Used for dermatologic conditions (corticosteroid creams, antifungals), analgesics, and moisturizers. Formulation (cream, ointment, gel, lotion, solution) affects drug delivery, occlusion, and pa-

tient acceptability.

CYP2C19 Polymorphism

– CYP2C19 is a cytochrome P450 enzyme involved in the metabolism of approximately 10 percent of drugs, including the antiplatelet agent clopidogrel, proton pump inhibitors, some antidepressants, and the antiepileptic drug phenytoin. Genetic polymorphisms result in poor metabolizer phenotypes in 2 to 5 percent of Caucasians and 15 to 20 percent of Asian populations. Poor metabolizers have reduced conversion of clopidogrel, a prodrug requiring CYP2C19-mediated activation, to its active metabolite, leading to reduced antiplatelet efficacy and increased risk of stent thrombosis in poor metabolizers; alternative antiplatelet agents such as ticagrelor or prasugrel, which are not dependent on CYP2C19 activation, are preferred in such patients.

CYP2D6 Polymorphism

– CYP2D6 is a cytochrome P450 enzyme responsible for the metabolism of approximately 25 percent of commonly prescribed drugs, including codeine, tamoxifen, many antidepressants, and antipsychotics. Genetic polymorphisms in the CYP2D6 gene result in highly variable enzyme activity among individuals, classified into four phenotype groups: poor metabolizers with two non-functional alleles and absent enzyme activity; intermediate metabolizers with reduced activity; extensive metabolizers with normal activity, and ultrarapid metabolizers with increased enzyme activity due to gene duplication. This phenotypic variability has significant clinical implications for drugs metabolized by CYP2D6: codeine prodrug activation to morphine is reduced in poor metabolizers and enhanced in ultrarapid metabolizers, who may experience opioid toxicity at standard doses; tamoxifen efficacy is reduced in poor metabolizers; and antidepressant dosing may require individualisation based on CYP2D6 phenotype.

Cytochrome P450

– The cytochrome P450 system is a superfamily of heme-containing monooxygenase enzymes primarily located in the endoplasmic reticulum of hepatocytes, responsible for Phase I drug metabolism through oxidation, reduction, and hydrolysis reactions. The most important CYP isoforms in drug metabolism include CYP3A4, which metabolizes approximately 50 percent of all drugs; CYP2D6,

responsible for approximately 25 percent of drug metabolism; CYP2C9, CYP2C19, CYP1A2, and CYP2E1. CYP enzymes can be induced or inhibited by various drugs and xenobiotics, leading to clinically significant drug interactions; enzyme induction occurs over days to weeks through increased gene transcription, while enzyme inhibition occurs rapidly through direct competition for the active site.

Dabigatran

- A direct oral anticoagulant that reversibly inhibits thrombin (factor IIa). Used for stroke prevention in nonvalvular atrial fibrillation and treatment/prophylaxis of venous thromboembolism. Fixed dosing, rapid onset, predictable pharmacokinetics, no routine monitoring. Prodrug requiring acid environment; capsules must not be opened. Adverse effects: bleeding, dyspepsia. Reversal agent: idarucizumab (specific antibody). Avoid in mechanical heart valves (valve thrombosis risk) and severe renal impairment.

Dalbavancin

- A long-acting lipoglycopeptide antibiotic with an extremely long half-life allowing for once-weekly dosing. Dalbavancin inhibits cell wall synthesis and has activity against gram-positive organisms including MRSA. It is indicated for acute bacterial skin infections. The drug is administered intravenously with a loading dose followed by a single maintenance dose. The half-life is approximately 346 hours, allowing for extended dosing intervals. Common adverse effects include nausea, headache, and infusion site reactions, though the long half-life compensates for these minor tolerability concerns.

Dapsone

- A sulfone antibiotic with both antimicrobial and anti-inflammatory properties. Mechanism: inhibits bacterial folate synthesis (competitive inhibitor of dihydropteroate synthase). Used primarily for leprosy (Hansen disease) as part of multi-drug therapy, and for dermatologic conditions including dermatitis herpetiformis, erythema elevatum diutinum, and acne vulgaris. Also used for *Pneumocystis jirovecii* prophylaxis in HIV (alternative to TMP-SMX). Notable side effect: dose-dependent hemolysis (especially in G6PD deficiency), methemoglobinemia, agranulocytosis, and hypersensitivity syndrome

(dapsone syndrome—fever, rash, eosinophilia, hepatitis). G6PD screening required before therapy.

Daptomycin

- A cyclic lipopeptide antibiotic that disrupts bacterial cell membrane integrity. Daptomycin has rapid bactericidal activity against gram-positive organisms including MRSA, VRE, and penicillin-resistant streptococci. It is indicated for complicated skin infections, bacteremia, and right-sided endocarditis. The drug is administered intravenously once daily. Common adverse effects include myopathy and rhabdomyolysis, particularly with concurrent statin therapy. Daptomycin is inactivated by pulmonary surfactant and should not be used for the treatment of community-acquired pneumonia.

Daptomycin resistance

- Resistance to daptomycin can develop through mutations in genes encoding cell membrane phospholipid synthesis. The mechanism involves changes in the bacterial cell membrane that reduce daptomycin binding. Resistance is more common in VRE than MRSA. Resistance can emerge during therapy, particularly in endocarditis and bacteremia. Daptomycin resistance is typically accompanied by vancomycin resistance, a phenomenon known as daptomycin-vancomycin cross-resistance. Combination therapy may be required in selected cases and careful monitoring of creatine kinase levels is recommended during daptomycin therapy.

Darunavir

- A protease inhibitor (PI) used in combination antiretroviral therapy for both treatment-naïve and treatment-experienced HIV-1 patients, including those with resistance to other PIs. Darunavir inhibits the HIV aspartyl protease with high potency and has a high genetic barrier to resistance, requiring multiple mutations for significant resistance to develop. The drug must be co-administered with ritonavir or cobicistat as a pharmacokinetic booster to achieve therapeutic drug levels. Common adverse effects include gastrointestinal disturbances, headache, and rash; hypertriglyceridaemia and hypercholesterolaemia are less common than with other protease inhibitors.

Delamanid

- A nitroimidazole derivative used in the treatment of multidrug-resistant tuberculosis. Delamanid in-

hibits mycolic acid synthesis in *Mycobacterium tuberculosis*, disrupting the cell wall. It is indicated for pulmonary multidrug-resistant tuberculosis in combination with other agents. The drug is administered orally twice daily. Common adverse effects include headache, nausea, and QT prolongation. Delamanid is metabolized by plasma esterases and has minimal CYP450 interactions. The drug has demonstrated efficacy in MDR-TB treatment cohorts, with improved outcomes compared to background regimens alone.

Delavirdine

– A non-nucleoside reverse transcriptase inhibitor (NNRTI) that was previously used in combination antiretroviral therapy for HIV-1 infection but is now rarely used due to the availability of more effective and better-tolerated agents. Delavirdine binds to the HIV reverse transcriptase enzyme at a site distinct from the active site, causing a conformational change that inhibits enzymatic activity. The drug has relatively low potency compared to newer NNRTIs and requires dosing three times daily. Common adverse effects include rash, elevated transaminases, and nausea, and the drug has significant CYP3A4 inhibitory activity leading to numerous drug interactions, limiting its use in contemporary practice.

Dextroamphetamine

– A central nervous system stimulant (d-amphetamine isomer) increasing dopamine and norepinephrine. Used for ADHD and narcolepsy. Available as immediate and extended-release, and in mixed amphetamine salts (Adderall) and lisdexamfetamine (prodrug). Adverse effects: appetite suppression, insomnia, growth delay, tachycardia, hypertension, anxiety, and abuse potential (Schedule II). Cardiovascular screening (ECG for risk factors) before initiation; monitor growth in children.

Diazepam

– A benzodiazepine used for its anxiolytic, sedative, muscle relaxant, anticonvulsant, and amnesic properties. Mechanism: enhances GABA-A receptor activity by increasing the frequency of chloride channel opening. Indications: anxiety disorders, alcohol withdrawal, status epilepticus (IV, first-line for benzodiazepine-responsive seizures), preopera-

tive sedation, muscle spasm, and procedural sedation. Pharmacokinetics: highly lipid-soluble, rapid onset, long half-life (20–50 hours), metabolized by CYP2C19 and CYP3A4 to active metabolites (nordazepam, oxazepam, temazepam). Adverse effects: sedation, ataxia, tolerance, dependence, withdrawal syndrome, and paradoxical agitation (especially in children and older adults). Flumazenil is the reversal agent.

Didanosine

– A nucleoside reverse transcriptase inhibitor (NRTI) used in the treatment of HIV-1 infection, typically as part of combination antiretroviral therapy. Didanosine is an adenosine analogue that inhibits viral reverse transcriptase, leading to chain termination of viral DNA synthesis. The drug requires acidic pH for stability and must be administered with buffer tablets or antacids to prevent gastric acid degradation. Didanosine has a bioavailability of approximately 30–40% when taken with buffer, buffer, and is dosed twice daily; common adverse effects include peripheral neuropathy, pancreatitis, and lactic acidosis, with pancreatitis being a potentially fatal complication that requires immediate discontinuation.

Digoxin

– A cardiac glycoside that inhibits the sodium-potassium ATPase pump in cardiac myocytes, causing intracellular sodium accumulation, which reduces sodium-calcium exchange through the sodium-calcium exchanger, leading to increased intracellular calcium and enhanced myocardial contractility. This positive inotropic effect increases cardiac output in heart failure. Digoxin also increases vagal tone, slowing atrioventricular nodal conduction, making it useful for rate control in atrial fibrillation and atrial flutter; digoxin has a narrow therapeutic index, requiring therapeutic drug monitoring to avoid toxicity, which manifests as nausea, vomiting, visual disturbances (xanthopsia, halos), and arrhythmias including heart block and ventricular tachycardia.

Diltiazem

– A non-dihydropyridine calcium channel blocker (benzothiazepine) with effects on both cardiac (negative chronotropy, dromotropy) and vascular (vasodilation) tissues. Used for rate control in atrial fibrillation/flutter, paroxysmal supraventricular tachy-

cardia, hypertension, and angina. Slows AV conduction; contraindicated in high-grade AV block, sick sinus syndrome (without pacemaker), and cardiogenic shock. In heart failure with reduced EF, it is avoided due to negative inotropy. Adverse effects: bradycardia, hypotension, constipation, peripheral edema. Available IV (rate control) and oral (including extended release).

Diphenhydramine

– A first-generation H1 antihistamine with potent anticholinergic and sedative effects. Used for allergic reactions, urticaria/pruritus, motion sickness, insomnia (OTC sleep aid), and as an antitussive; IV form for anaphylaxis (adjunct) and acute dystonic reactions. Adverse effects: sedation, dry mouth, blurred vision, urinary retention, constipation, confusion (elderly—avoid), and anticholinergic toxicity in overdose (treated with physostigmine). Metabolized by CYP2D6.

Disulfiram

– An aversive agent used to treat alcohol use disorder. Inhibits acetaldehyde dehydrogenase, causing accumulation of acetaldehyde when alcohol is consumed—producing flushing, tachycardia, nausea, vomiting, and hypotension ('acetaldehyde syndrome'). Provides a strong deterrent to drinking but requires motivation and abstinence. Adverse effects: hepatotoxicity, neuropathy, and psychosis. Contraindicated with alcohol-containing products, metronidazole, and severe cardiac/hepatic disease. Must warn patients to avoid all alcohol, including in foods and medications.

Diuretic

– A drug that increases urine production, used for edema (heart failure, cirrhosis, renal disease), hypertension, and electrolyte disorders. Classes: loop diuretics (furosemide, bumetanide, torsemide—most potent, act on the loop of Henle), thiazides (hydrochlorothiazide, chlorthalidone—distal tubule), potassium-sparing (spironolactone, eplerenone, amiloride—collecting duct), and osmotic (mannitol) and carbonic anhydrase inhibitors (acetazolamide). Adverse effects: electrolyte disturbances (hypokalemia, hyponatremia), dehydration, hypotension, and ototoxicity (loop diuretics). Spironolactone/eplerenone improve outcomes in heart failure.

DOACs

– Direct oral anticoagulants are a class of anticoagulant drugs that directly inhibit specific coagulation factors, providing an alternative to warfarin with more predictable pharmacokinetics and no routine monitoring. The factor Xa inhibitors include rivaroxaban, apixaban, and edoxaban, which directly and reversibly bind to the active site of factor Xa. The direct thrombin inhibitor dabigatran directly binds to and inhibits thrombin. DOACs have rapid onset of action, predictable pharmacokinetics, fixed dosing, fewer drug and food interactions than warfarin, and no requirement for routine coagulation monitoring, though they are more expensive and specific reversal agents are limited.

Docusate

– A stool softener (surfactant laxative) that increases water and fat incorporation into stool by lowering surface tension, facilitating defecation in patients who should avoid straining (post-MI, post-surgery, hemorrhoids) and for opioid-related constipation. Onset 12-72 hours. Limited efficacy as a true laxative; better for softening than for stimulating evacuation. Generally well tolerated; may cause mild cramping. Often combined with stimulant laxatives.

Donepezil

– An acetylcholinesterase inhibitor used to treat Alzheimer disease (mild to moderate and severe dementia). Increases synaptic acetylcholine, modestly improving cognition and global function; does not alter disease progression. Once-daily oral dosing. Adverse effects: nausea, diarrhea, vomiting, bradycardia, syncope, muscle cramps, and insomnia; GI effects lessen with titration. Interactions: bradycardic agents, anticholinergics. Rivastigmine and galantamine are alternatives.

Doravirine

– A non-nucleoside reverse transcriptase inhibitor (NNRTI) used in combination antiretroviral therapy for HIV-1 infection. Doravirine binds to the HIV reverse transcriptase enzyme and inhibits its activity through a unique mechanism that maintains activity against strains resistant to first-generation NNRTIs. The drug has a favorable tolerability profile with minimal impact on lipid levels and body weight compared to other antiretrovirals. Common adverse

effects include headache, nausea, and diarrrhiarhoea, and the drug has fewer drug interactions than other NNRTIs as it is not a significant inducer or inhibitor of CYP enzymes.

Dosage

- The amount and frequency of a drug administered to achieve a therapeutic effect while minimizing toxicity. Components: dose (amount, e.g., mg), dosing interval (frequency), route, and duration. Dosing is individualized using weight (mg/kg, especially children), body surface area (chemotherapy), renal and hepatic function (clearance), age, and therapeutic drug monitoring for narrow-therapeutic-index drugs. Loading doses achieve steady state rapidly; maintenance doses sustain it. Overdosing causes toxicity, underdosing causes therapeutic failure and antimicrobial resistance.

Dose-Response Curve

- A graphical representation of the relationship between the dose of a drug and the magnitude of its biological effect. The x-axis represents dose (typically on a logarithmic scale), and the y-axis represents the response (as percentage of maximum effect). The curve is sigmoidal in shape, characterized by: threshold (minimum dose producing a measurable effect), slope (steepness of the curve, indicating how rapidly the effect changes with dose), maximal efficacy (the plateau, E_{max}), and potency (the dose producing 50% of maximal effect, ED_{50}). The therapeutic window is the range between the ED_{50} for the desired effect and the TD_{50} (toxic dose in 50% of patients). The therapeutic index ($TI = TD_{50} / ED_{50}$) measures relative safety. Dose-response curves are essential for determining appropriate dosing regimens and comparing drug potency and efficacy.

Dose-Response Relationship

- The dose-response relationship describes the quantitative relationship between the dose of a drug and the magnitude of the pharmacological response it produces. This relationship is typically represented as a sigmoidal curve when response is plotted against the log of the dose. The curve is characterized by several key parameters: the maximal effect or efficacy represents the maximum response achievable; the EC_{50} or ED_{50} represents the dose producing 50 percent of the maximal response and indicates

the potency of the drug. The slope of the curve reflects the mechanism of drug action, with steeper slopes indicating a more direct relationship between dose and response, as seen with drugs that act on a single receptor type.

Doxazosin

- A selective α -1 adrenergic blocker causing vascular smooth muscle relaxation and reduced peripheral resistance. Used for hypertension and benign prostatic hyperplasia (relaxes prostatic smooth muscle). Extended-release formulation reduces first-dose hypotension. Adverse effects: orthostatic hypotension, dizziness, syncope (especially first dose), nasal congestion, and fatigue. α -blockers are not first-line for hypertension but useful in men with BPH and as add-on therapy. Potential association with heart failure in some trials—use with caution in patients with heart failure.

Doxycycline

- A tetracycline antibiotic with broad-spectrum activity against gram-positive and gram-negative bacteria, as well as atypical organisms including *Mycoplasma*, *Chlamydia*, and *Rickettsia*. Doxycycline inhibits bacterial protein synthesis by binding to the 30S ribosomal subunit. It is indicated for respiratory tract infections, skin infections, sexually transmitted infections, and malaria prophylaxis. The drug is well absorbed orally and can be taken with food. Common adverse effects include photophotosensitivity, and esophageal ulceration; it should be taken with a full glass of water and patients should remain upright for at least 30 minutes after dosing.

DPP-4 Inhibitors

- Dipeptidyl peptidase-4 inhibitors that prevent degradation of endogenous GLP-1 and GIP, enhancing incretin effects on insulin secretion. Examples include sitagliptin, saxagliptin, linagliptin, and alogliptin. They are well-tolerated with low hypoglycemia risk and weight neutrality. They have modest glucose-lowering effects. Saxagliptin was associated with increased heart failure hospitalizations in the SAVOR-TIMI 53 trial. Linagliptin does not require dose adjustment for renal impairment.

Drug Allergy

- An adverse immune-mediated reaction to a medication, representing a hypersensitivity response that

is distinct from side effects, toxicities, and idiosyncratic reactions. Drug allergies can be IgE-mediated causing immediate reactions including urticaria, angioedema, and anaphylaxis within minutes to hours; T-cell mediated causing delayed reactions including contact dermatitis, drug rash with eosinophils and systemic symptoms, and Stevens-Johnson syndrome occurring days to weeks after exposure; diagnosis involves skin testing, in vitro assays for specific IgE, and oral challenge in selected cases, with management based on avoidance of the offending drug and use of alternative agents.

Drug Classification Systems

– Drugs are classified using multiple complementary systems. The Anatomical Therapeutic Chemical (ATC) Classification System, maintained by the WHO, groups drugs into five levels: anatomical main group (e.g., cardiovascular system), therapeutic subgroup (e.g., antihypertensives), pharmacological subgroup (e.g., beta-blockers), chemical subgroup (e.g., selective beta-blockers), and chemical substance (e.g., metoprolol). The Therapeutic Classification groups drugs by their clinical use (e.g., antihypertensives, antidepressants, antibiotics). The Mechanism of Action Classification groups drugs by their molecular target (e.g., ACE inhibitors, calcium channel blockers, SSRIs). The Chemical Structure Classification groups drugs by their molecular composition (e.g., benzodiazepines, statins, penicillins). The Regulatory Classification includes prescription vs. over-the-counter status and controlled substance schedules. The Combination of these systems provides a comprehensive framework for understanding drug actions, interactions, and therapeutic applications.

Drug Dependence

– A state of physiological or psychological adaptation to a drug, characterized by a withdrawal syndrome upon discontinuation or dose reduction. Physical dependence: the body has adapted to the presence of the drug, and abrupt cessation produces a predictable withdrawal syndrome specific to the drug class. Opioid withdrawal: anxiety, mydriasis, lacrimation, rhinorrhea, piloerection, yawning, diarrhea, and muscle cramps. Alcohol withdrawal: anxiety, tremor, autonomic hyperactivity, seizures, and delirium tremens. Benzodiazepine withdrawal: anx-

xiety, insomnia, tremor, and seizures. Psychological (behavioral) dependence: a compulsive pattern of drug use, often associated with craving and difficulty controlling use. Dependence is distinct from addiction (substance use disorder), which involves loss of control over use despite negative consequences.

Drug-Drug Interactions

– When one drug alters the pharmacokinetics or pharmacodynamics of another. Pharmacokinetic interactions affect absorption, distribution, metabolism, or excretion (e.g., CYP inhibitors increasing warfarin levels). Pharmacodynamic interactions involve additive, synergistic, or antagonistic effects at the site of action (e.g., two drugs prolonging QT interval). Clinically significant interactions can be identified through databases, clinical experience, and therapeutic drug monitoring.

Drug-Induced Liver Injury

– Liver damage caused by medications, herbal products, or dietary supplements, representing the most common cause of acute liver failure in the United States. DILI can be dose-dependent and predictable, as with acetaminophen hepatotoxicity from overdose, or idiosyncratic and unpredictable, as with isoniazid, nitrofurantoin, and amoxicillin-clavulanate. The pathogenesis involves formation of reactive metabolites that bind to cellular proteins, triggering immune-mediated hepatocyte injury. DILI ranges from asymptomatic transaminase elevation to fulminant hepatic failure and death; early recognition and discontinuation of the offending agent are critical, as no specific therapy exists for most forms of DILI.

Drug Interactions

– Drug interactions occur when one drug affects the activity of another drug when both are administered together, potentially leading to therapeutic failure or toxicity. Pharmacokinetic interactions alter the absorption, distribution, metabolism, or excretion of a drug. Absorption interactions include chelation of tetracyclines with calcium and antacids reducing absorption, and altered GI motility affecting drug absorption. Distribution interactions include displacement from protein binding sites, and drug interactions affecting protein binding. Pharmacodynamic interactions, where drugs have additive, synergistic, or antagonistic effects at the same recep-

tor or physiological system, are equally important and can lead to enhanced therapeutic effects or unexpected toxicity.

Drug Metabolism Pharmacogenomics

– Pharmacogenomics of drug metabolism examines how genetic variations affect individual responses to drugs, enabling personalized medicine approaches to prescribing. The most clinically relevant pharmacogenes include CYP2D6, affecting metabolism of approximately 25 percent of drugs including codeine, tamoxifen, and many antidepressants; CYP2C19, affecting clopidogrel activation and proton pump inhibitor metabolism; CYP2C9, affecting warfarin metabolism; TPMT, affecting thiopurine metabolism; and Dand DPYD, affecting fluorouracil metabolism and risk of severe toxicity. Pre-emptive pharmacogenomic testing is increasingly being integrated into routine clinical practice to guide drug selection and dosing, with significant benefits in terms of efficacy and safety.

Drug Resistance

– The ability of microorganisms, cancer cells, or parasites to survive and proliferate despite exposure to drugs that were previously effective. In antimicrobial resistance, mechanisms include enzymatic inactivation of the drug such as beta-lactamase hydrolyzing penicillins, target modification such as PBP2a in MRSA conferring resistance to beta-lactams, efflux pumps actively pumping drugs out of the cell, decreased permeability through porin mutations, and metabolic bypassing of the inhibited pathway, allowing the pathogen to survive drug exposure; understanding these diverse mechanisms is essential for the rational design of new therapeutic strategies and for guiding appropriate antimicrobial stewardship interventions.

Drug Tolerance

– A decreased pharmacological response to a drug after repeated administration, requiring dose escalation to achieve the same effect. Tolerance develops through multiple mechanisms: pharmacokinetic tolerance — increased drug metabolism through enzyme induction (e.g., alcohol, barbiturates); pharmacodynamic tolerance — receptor downregulation (decreased number of receptors, e.g., opioids, beta-agonists) or receptor desensitization (uncoupling

of receptors from signal transduction, e.g., beta-agonists); functional tolerance — compensatory physiological adaptations; and behavioral tolerance — learned adaptations to drug effects. Tolerance is distinct from dependence and addiction. Cross-tolerance occurs when tolerance to one drug confers tolerance to another drug in the same class (e.g., morphine and heroin).

Duloxetine

– A serotonin-norepinephrine reuptake inhibitor (SNRI) used for major depressive disorder, generalized anxiety disorder, diabetic peripheral neuropathy, fibromyalgia, chronic musculoskeletal pain (including osteoarthritis), and stress urinary incontinence. Adverse effects: nausea (common), dry mouth, insomnia, fatigue, hypertension, and sexual dysfunction; withdrawal syndrome with abrupt cessation (taper). Contraindicated with MAOIs and in uncontrolled narrow-angle glaucoma; caution in hepatic impairment.

Echinocandins

– A class of antifungal agents that inhibit beta-1,3-glucan synthase, an enzyme essential for synthesis of beta-1,3-glucan, a major component of the fungal cell wall. This unique mechanism targets a structure absent in mammalian cells, resulting in favorable toxicity profiles. The available agents include caspofungin, micafungin, and anidulafungin, all administered intravenously. Echinocandins are fungicidal against *Candida* species and fungistatic against *Aspergillus* species. The three available echinocandins have similar spectra of activity, though minor differences in pharmacokinetics and dosing schedules exist, and they are generally well tolerated with few drug interactions.

Efficacy

– The maximum therapeutic effect a drug or intervention can produce under ideal conditions (e.g., in a clinical trial). Efficacy is determined by the drug's mechanism of action and the receptor-effector system; it is measured by the E_{max} (maximal effect) on the dose-response curve. A drug with high efficacy produces a greater maximal response than one with low efficacy, regardless of dose. Efficacy is distinct from potency (the dose required to produce a given effect). Clinically, efficacy determines whether a drug can achieve the desired therapeutic outcome;

a drug with insufficient efficacy will not be effective even at high doses. Not the same as effectiveness, which reflects real-world performance.

Enalapril

- An ACE inhibitor (prodrug; activated to enalaprilat) used for hypertension, heart failure with reduced ejection fraction, post-MI, and diabetic nephropathy. Reduces angiotensin II and aldosterone, increasing vasodilation, natriuresis, and reducing remodeling. Adverse effects: dry cough (most common), hyperkalemia, hypotension, acute kidney injury in renal artery stenosis, angioedema (rare but life-threatening), and teratogenicity (contraindicated in pregnancy). Monitor creatinine and potassium. Also available as IV enalaprilat.

Enfuvirtide

- A fusion inhibitor used in combination antiretroviral therapy for HIV-1 infection in treatment-experienced patients with multidrug-resistant virus. Enfuvirtide is a synthetic peptide that mimics a region of the HIV-1 gp41 transmembrane protein, preventing the conformational change required for fusion of the viral envelope with the host cell membrane. The drug must be administered twice daily by subcutaneous injection, which is the primary limitation to its use. Common adverse effects include injection site reactions, and the drug is associated with an increased rate of lymph node enlargement and potential immune reconstitution syndromes when used as part of combination antiretroviral therapy.

Enoxaparin

- A low-molecular-weight heparin inhibiting factor Xa (and to a lesser extent thrombin) via antithrombin. Used for prophylaxis and treatment of deep vein thrombosis and pulmonary embolism, acute coronary syndromes, and as a bridge during anticoagulation interruption. Subcutaneous dosing (weight-based, BID or daily), predictable pharmacokinetics, no routine monitoring generally (anti-Xa monitoring in renal impairment/pregnancy). Adverse effects: bleeding, thrombocytopenia (less HIT than UFH), and injection-site hematoma. Reversed by protamine (partial). Caution in renal impairment (reduce dose); contraindicated with epidural/spinal anesthesia unless timing respected (neuraxial hematoma risk).

Entacapone

- A peripheral COMT (catechol-O-methyltransferase) inhibitor used as an adjunct to levodopa/carbidopa in Parkinson disease, extending levodopa's duration of action and reducing 'wearing-off'. Does not cross the blood-brain barrier. Adverse effects: dyskinesias (due to increased levodopa), nausea, diarrhea, urine discoloration (orange-brown), and hepatotoxicity (rare). Must be given with levodopa. Tolcapone (central COMT inhibitor) is rarely used due to hepatotoxicity.

Enterobacteriaceae carbapenem resistance

- Resistance to carbapenem antibiotics in Enterobacteriaceae, primarily through production of carbapenemases. The most important carbapenemases include KPC, NDM, and OXA-48-like enzymes. Carbapenem-resistant Enterobacteriaceae (CRE) are a major public health threat due to limited treatment options. Infections are associated with high mortality rates. Treatment options include ceftazidime-avibactam, meropenem-vaborbactam, and aminoglycosides. Infection prevention and antimicrobial stewardship are essential for controlling the spread of carbapenem-resistant Enterobacteriaceae in healthcare settings.

Enzyme Induction

- A process by which a drug or xenobiotic increases the synthesis or activity of drug-metabolizing enzymes, primarily cytochrome P450 enzymes in the liver, accelerating the metabolism of itself (autoinduction) or other drugs. Enzyme induction typically occurs over days to weeks as it requires new protein synthesis. Important enzyme inducers: rifampin (potent CYP3A4, CYP2C9, CYP2C19 inducer), carbamazepine, phenytoin, phenobarbital, St. John's wort, and chronic alcohol consumption. Clinical consequences: reduced efficacy of co-administered drugs (e.g., rifampin reduces oral contraceptive efficacy, requiring alternative contraception), increased metabolism of warfarin (requiring higher doses), and reduced cyclosporine levels in transplant patients. discontinuing an inducer can lead to increased drug levels of co-administered drugs, requiring dose reduction.

Enzyme Inhibition

- A process by which a drug inhibits the activity

of drug-metabolizing enzymes, leading to increased plasma concentrations of co-administered drugs that are metabolized by the same enzyme. Enzyme inhibition occurs rapidly (hours to days) as it does not require new protein synthesis. Important enzyme inhibitors and their substrates: ketoconazole and ritonavir (potent CYP3A4 inhibitors — increase levels of statins, benzodiazepines, calcium channel blockers); cimetidine (inhibits CYP1A2, CYP2D6, CYP3A4); fluoxetine and paroxetine (CYP2D6 inhibitors — increase levels of atomoxetine, TCAs, and tamoxifen); amiodarone (CYP2C9 inhibitor — increases warfarin levels); grapefruit juice (inhibits intestinal CYP3A4 — increases levels of felodipine, simvastatin, cyclosporine). Clinical consequences: increased drug toxicity (e.g., rhabdomyolysis with simvastatin when given with potent CYP3A4 inhibitors), requiring dose reduction or alternative therapy.

Eplerenone

– A selective aldosterone (mineralocorticoid) receptor antagonist, a potassium-sparing diuretic. Used to reduce mortality in heart failure with reduced ejection fraction (post-MI and chronic HFrEF, NYHA II-IV) and for resistant hypertension. More selective than spironolactone with less gynecomastia/breast tenderness. Adverse effects: hyperkalemia (major), gynecomastia (less than spironolactone), and hypotension. Contraindicated with significant renal impairment, hyperkalemia, and strong CYP3A4 inhibitors (azole antifungals). Monitor potassium and renal function.

Eravacycline

– A fluorocycline antibiotic with activity against gram-positive and gram-negative organisms, including multidrug-resistant strains. Eravacycline inhibits bacterial protein synthesis by binding to the 30S ribosomal subunit. It has activity against MRSA, VRE, ESBL-producing Enterobacteriaceae, and anaerobes. The drug is indicated for complicated intra-abdominal infections. Eravacycline is administered intravenously and achieves high concentrations in abdominal tissues. Common adverse effects including nausea, vomiting, and infusion site reactions; eravacycline has a favourable safety profile with minimal phototoxicity compared to other tetracyclines.

Erythromycin

– The prototype macrolide antibiotic with activity against gram-positive organisms and some gram-negative organisms. Erythromycin inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. It is indicated for respiratory infections, skin infections, and as a prokinetic agent for gastroparesis. Common adverse effects include gastrointestinal upset, hepatotoxicity, and QT prolongation. Erythromycin is a potent inhibitor of CYP3A4 and has numerous drug interactions. The drug is now rarely used as a first-line agent due to the availability of better-tolerated alternatives with broader spectra of activity.

ESBL-producing organisms

– Bacteria that produce extended-spectrum beta-lactamases (ESBLs), enzymes that hydrolyze penicillins, cephalosporins, and monobactams. ESBLs are common in Enterobacteriaceae, particularly *Klebsiella pneumoniae* and *E. coli*. ESBL production confers resistance to most beta-lactam antibiotics except carbapenems. The prevalence of ESBL-producing organisms is increasing globally. Infections are associated with increased morbidity, mortality, and healthcare costs. Treatment typically requires carbapenem carbapenems for serious infections, and antimicrobial stewardship is essential to preserve the utility of remaining effective agents.

Escitalopram

– A selective serotonin reuptake inhibitor (SSRI), the S-enantiomer of citalopram, used for major depressive disorder and generalized anxiety disorder. Increases synaptic serotonin; well tolerated, low drug-interaction profile (less QT prolongation than citalopram). Adverse effects: nausea, insomnia or somnolence, sexual dysfunction, and weight change; serotonin syndrome and discontinuation syndrome (taper); black-box warning for suicidal ideation in young adults. Once-daily dosing; onset of effect 2-6 weeks.

Esomeprazole

– The S-enantiomer of omeprazole, a proton pump inhibitor irreversibly inhibiting gastric H⁺/K⁺ ATPase. Used for GERD, erosive esophagitis, peptic ulcer disease, *H. pylori* eradication, and hypersecretory states. Greater acid suppression than omeprazole at equivalent doses; once daily, with

an IV formulation for acute GI bleeding. Adverse effects: headache, diarrhea, hypomagnesemia, B12 deficiency, fracture risk, and *C. difficile* infection with chronic use. Cytochrome P450 (CYP2C19) metabolism.

Essential Medicines

- Drugs that satisfy the priority healthcare needs of a population, as defined by the WHO Model List of Essential Medicines. Selection criteria include efficacy, safety, comparative cost-effectiveness, and suitability for use in resource-limited settings. The list includes approximately 400 drugs covering major disease areas: analgesics, anesthetics, antibiotics, antiepileptics, antihypertensives, antiretrovirals, antimalarials, vaccines, and others. The concept guides national formulary development, procurement, and rational prescribing worldwide.

Etravirine

- A second-generation non-nucleoside reverse transcriptase inhibitor (NNRTI) used in combination antiretroviral therapy for HIV-1 infection, particularly in treatment-experienced patients with NNRTI resistance. Etravirine binds to the HIV reverse transcriptase enzyme and inhibits its activity through a unique mechanism that maintains activity against strains resistant to first-generation NNRTIs. The drug has a high genetic barrier to resistance due to its flexible structure that allows it to adapt to changes in the reverse transcriptase enzyme structure, maintaining antiviral activity against a broad range of NNRTI-resistant variants.

Expectorants

- Medications that promote the clearance of mucus from the respiratory tract by increasing sputum volume and reducing its viscosity, facilitating productive cough. The most common expectorant is guaifenesin (glyceryl guaiacolate), which increases respiratory tract fluid secretion and reduces sputum adhesiveness. Guaifenesin is used for symptom relief in acute respiratory infections, chronic bronchitis, and COPD. Evidence for efficacy is moderate. Other expectorants: potassium iodide (rarely used due to side effects), ammonium chloride, and sodium citrate. Expectorants are distinguished from mucolytics (acetylcysteine, dornase alfa—break down the chemical structure of mucus) and antitussives (dextromethorphan, codeine—suppress the cough re-

flex). Adequate hydration is essential for expectorant efficacy.

Ezetimibe

- A cholesterol absorption inhibitor that blocks intestinal absorption of dietary and biliary cholesterol at the Niemann-Pick C1-like 1 (NPC1L1) transporter in the small intestine. Used for hypercholesterolemia, usually as add-on to statins or in statin-intolerant patients; reduces LDL and cardiovascular events in combination with statins after ACS. Adverse effects: diarrhea, myalgia, transaminase elevation (with statins). Rare reports of muscle toxicity. Available alone or in combination with simvastatin or atorvastatin.

Famotidine

- An H₂ receptor antagonist reducing gastric acid secretion by blocking histamine H₂ receptors on parietal cells. Used for GERD, peptic ulcer disease, dyspepsia, and acid suppression (including in ICU stress ulcer prophylaxis—IV). Longer duration than cimetidine/ranitidine, fewer drug interactions, and no antiandrogenic effects. Adverse effects: headache, dizziness, diarrhea, and rare thrombocytopenia. Available OTC and prescription, oral and IV.

Fecal microbiota transplantation

- The transfer of fecal material from a healthy donor to a patient with recurrent *Clostridioides difficile* infection. The procedure aims to restore normal gastrointestinal flora and eliminate *C. difficile* colonization. FMT is highly effective, with cure rates exceeding 90% for recurrent *C. difficile* infection. The procedure can be administered by colonoscopy, nasojejunal tube, or oral capsules. Donor screening includes testing for bloodborne pathogens and gastrointestinal pathogens. FMT has revolutionized the management of recurrent *C. difficile* infection and is being investigated for other conditions associated with intestinal dysbiosis, including inflammatory bowel disease and metabolic syndrome.

Fenofibrate

- A fibric acid derivative (fibrate) activating PPAR- α , increasing HDL and reducing triglycerides, with modest LDL effects. Used for severe hypertriglyceridemia (pancreatitis risk), mixed dyslipidemia, and as an adjunct in residual hypertriglyc-

eridemia. Adverse effects: myopathy (especially with statins, more with gemfibrozil), transaminase and creatinine elevation, gallstones, and pancreatitis. Dose-adjust in renal impairment. Fibrates are avoided with severe hepatic disease and in patients on other fibrates.

Fexofenadine

- A second-generation (non-sedating) H1 antihistamine used for allergic rhinitis and chronic urticaria. Peripherally selective with minimal sedation and anticholinergic effects; no significant CNS penetration. Adverse effects: headache, dizziness, and dry mouth. Transported by P-glycoprotein—avoid concurrent aluminum/magnesium antacids and fruit juices (reduce absorption). Available OTC. Loratadine and cetirizine are alternatives.

Fidaxomicin

- A macrolide antibiotic with a narrow spectrum of activity against *Clostridioides difficile*. Fidaxomicin inhibits bacterial RNA polymerase. It is indicated for *Clostridioides difficile* colitis. The drug is administered orally twice daily for 10 days. Common adverse effects include nausea and vomiting. Fidaxomicin has minimal systemic absorption, acting locally in the gastrointestinal tract. The drug has lower rates of recurrence compared to vancomycin for *C. difficile* colitis. Fidaxomicin is not recommended for use in patients with inflammatory bowel disease due to a possible increased risk of gastrointestinal bleeding.

First-Pass Effect

- The metabolism of a drug by the liver and intestinal wall before it reaches the systemic circulation after oral administration. When a drug is absorbed from the gastrointestinal tract, it travels through the portal venous system to the liver, where it may be extensively metabolized by cytochrome P450 enzymes before reaching the general circulation. This process significantly reduces the bioavailability of many drugs. The hepatic extraction ratio quantifies this effect: drugs with high extraction ratios have clearance that depends primarily on hepatic blood flow, while low-extraction drugs have clearance that depends on intrinsic enzyme activity and protein binding; this distinction has important implications for drug dosing in patients with liver disease and for predicting drug interactions.

Flecainide

- A class IC sodium channel blocker that slows conduction velocity with little effect on refractoriness. Used for suppression of supraventricular arrhythmias (atrial fibrillation in patients without structural heart disease—'pill-in-the-pocket', paroxysmal SVT) and ventricular arrhythmias. Contraindicated in ischemic heart disease and structural heart disease (CAST trial showed increased mortality after MI) and in significant LV dysfunction. Adverse effects: proarrhythmia (new/worsened arrhythmia), dizziness, blurred vision, and heart block. Requires ECG/electrolyte monitoring.

Flumazenil

- A competitive benzodiazepine receptor antagonist used to reverse benzodiazepine-induced sedation and overdose (respiratory depression). IV administration; rapid onset, short duration (may require repeat dosing). Use with caution: may precipitate seizures (especially in benzodiazepine-dependent patients, mixed overdoses with tricyclics/anticonvulsants) and is contraindicated in certain overdose settings (co-ingestion of proconvulsants). Adverse effects: agitation, seizures, arrhythmias. Not a general 'coma cocktail'—use is indication-specific.

Fluoroquinolones

- Broad-spectrum bactericidal antibiotics that inhibit bacterial DNA gyrase and topoisomerase IV, enzymes essential for DNA replication, transcription, and repair. They are synthetic derivatives of nalidixic acid and include ciprofloxacin, levofloxacin, moxifloxacin, and others. Fluoroquinolones have excellent bioavailability, with oral dosing achieving serum concentrations comparable to intravenous administration. They distribute widely to tissues including the lungs, prostate, and bone; fluoroquinolones are generally well tolerated but carry boxed warnings for tendonitis and tendon rupture, peripheral neuropathy, CNS effects, and exacerbation of myasthenia gravis, and their use is reserved for situations where alternative treatment options are limited.

Fluoxetine

- A selective serotonin reuptake inhibitor (SSRI) used for major depressive disorder, obsessive-compulsive disorder, bulimia, panic disorder, and premenstrual dysphoric disorder. Long half-life (fluoxetine 1-3

days; active metabolite norfluoxetine 7-15 days) allows once-daily or weekly dosing and produces a washout period (advantageous in discontinuation, problematic in toxicity/interactions). Adverse effects: nausea, insomnia, sexual dysfunction, agitation, hyponatremia (elderly), and serotonin syndrome. Strong CYP2D6 inhibitor—many interactions. Black-box warning for suicidality in young adults.

Fluticasone

- A synthetic corticosteroid used as: an inhaled corticosteroid (fluticasone propionate) for asthma and COPD maintenance; an intranasal spray for allergic rhinitis; and a topical cream for dermatoses. Reduces airway/nasal inflammation; first-line controller therapy for asthma (with a LABA if needed). Adverse effects: oral candidiasis and dysphonia (rinse after inhalation), nasal dryness/bleeding, and minimal systemic absorption at inhaled doses. Budesonide, beclomethasone are related ICS.

Fondaparinux

- A synthetic pentasaccharide that selectively inhibits factor Xa via antithrombin, with no direct thrombin inhibition. Used for prophylaxis and treatment of venous thromboembolism and acute coronary syndromes (as an alternative to LMWH). Subcutaneous, once daily, predictable, no routine monitoring; does not cause HIT (no platelet factor 4 interaction). Adverse effects: bleeding; not reversed by protamine. Contraindicated in severe renal impairment (creatinine clearance <30) and low body weight. Neuraxial anesthesia requires timing precautions.

Fosamprenavir

- A prodrug of amprenavir, used in combination antiretroviral therapy for HIV-1 infection. Fosamprenavir is rapidly hydrolyzed by intestinal alkaline phosphatase to amprenavir, which then inhibits the HIV aspartyl protease. The prodrug formulation improves the pharmacokinetic profile of amprenavir, allowing for twice-daily dosing with improved bioavailability. Fosamprenavir is available as tablets and oral suspension, with the suspension containing calcium carbonate and other buffering agents. Common adverse effects include gastrointestinal disturbances, headache, and rash, and the drug is generally well tolerated with favourable

lipid effects compared to other PIs; fosamprenavir is available as a once-daily or twice-daily formulation.

Fosfomycin

- A phosphonic acid derivative antibiotic that inhibits cell wall synthesis. Fosfomycin has broad-spectrum activity including gram-positive and gram-negative organisms. It is indicated for uncomplicated urinary tract infections and is available as a single oral dose. The drug is also available intravenously for serious infections. Common adverse effects include diarrhea and headache. Fosfomycin achieves high concentrations in urine. The drug maintains activity against many multidrug-resistant organisms, including ESBL-producing Enterobacteriaceae and carbapenem-resistant strains, making it a valuable reserve antibiotic for complicated urinary tract infections.

Fostemsavir

- A prodrug of temsavir, an attachment inhibitor that binds to HIV-1 gp120, preventing viral attachment to the CD4 receptor on human T cells. Fostemsavir is used in combination with other antiretrovirals for the treatment of multidrug-resistant HIV-1 infection in heavily treatment-experienced patients. The drug is administered orally twice daily, which is a significant advantage over injectable agents. Common adverse effects include nausea, diarrhea, headache, and rash. Elevated transaminases have been reported; fostemsavir represents a valuable option for patients with limited therapeutic options due to extensive drug resistance.

Full Agonist

- A full agonist is a drug that binds to a receptor and produces the maximum possible biological response that the receptor can generate, achieving 100 percent of the maximal effect. Full agonists have both high affinity for the receptor and high intrinsic activity, meaning they are very effective at activating the receptor once bound. The efficacy of a full agonist is inherent to the drug-receptor interaction and cannot be exceeded by increasing the dose. Examples include morphine at μ -opioid receptors, with full agonists producing maximal activation, and their effect is determined by both the drug concentration at the receptor site and the receptor density in the target tissue.

Fungal Infection

– See Antifungal. Infections caused by fungi ranging from superficial (dermatophytes: tinea, candidiasis) to invasive/systemic disease (aspergillosis, candidemia, cryptococcosis, histoplasmosis) in immunocompromised hosts. Risk factors: neutropenia, transplantation, HIV/AIDS, corticosteroids, and diabetes. Diagnosis: culture, histopathology, antigen tests (galactomannan, beta-glucan, cryptococcal antigen), and PCR. Treatment depends on severity and organism: azoles, echinocandins, amphotericin B, and terbinafine.

Fungal resistance mechanisms

– Mechanisms by which fungi develop resistance to antifungal agents. Azole resistance occurs through upregulation of efflux pumps (CDR1, CDR2, MDR1), mutations in the target enzyme ERG11, and overexpression of ERG11. Echinocandin resistance is primarily due to mutations in the FKS1 and FKS2 genes encoding beta-(1,3)-D-glucan synthase. Amphotericin B resistance is rare but can occur through alterations in ergosterol biosynthesis. Multidrug resistance is increasingly common in *Candida glabrata*, with azole resistance being the most clinically challenging, particularly in *Candida glabrata* and *Candida auris*, and susceptibility testing is increasingly important for guiding antifungal therapy.

Furosemide

– A potent high-ceiling loop diuretic that reversibly inhibits the $Na^+/K^+/2Cl^-$ cotransporter (NKCC2) in the thick ascending limb of the loop of Henle. Induces rapid diuresis and natriuresis by disrupting the hypertonic medullary osmotic gradient. Indications: acute pulmonary edema, acute decompensated heart failure, edematous states (cirrhosis, nephrotic syndrome), hypercalcemia (increases urinary Ca^{2+} excretion), and hypertension. Adverse effects (mnemonic OH DANG): Ototoxicity (sensorineural hearing loss/tinnitus), Hypokalemia/Hypomagnesemia/Hypocalcemia, Dehydration/Hypotension, Allergy (sulfa drug reaction), Nephrotoxicity (interstitial nephritis), Gout (hyperuricemia due to uric acid reabsorption).

Gabapentin

– An anticonvulsant structurally related to GABA, binding α -2-delta subunits of voltage-gated calcium channels, used for neuropathic pain (pos-

therpetic neuralgia, diabetic neuropathy), partial seizures, restless legs syndrome, fibromyalgia, and off-label for anxiety. Not metabolized significantly; renally cleared (dose-reduce in renal impairment). Adverse effects: sedation, dizziness, ataxia, weight gain, and peripheral edema; abuse potential increasingly recognized. Slow titration improves tolerability.

Galantamine

– An acetylcholinesterase inhibitor used for mild to moderate Alzheimer disease; also modulates nicotinic receptors. Improves cognition and function modestly; does not stop progression. Twice-daily or extended-release dosing. Adverse effects: GI (nausea, vomiting, diarrhea, anorexia—titrate slowly), bradycardia, syncope, and weight loss. Caution in bradyarrhythmias and peptic ulcer disease; interactions with anticholinergics and neuromuscular blockers.

Gamma-Globulin

– A fraction of plasma proteins containing antibodies (immunoglobulins). Historically the term referred to a group of serum proteins with the slowest electrophoretic mobility (gamma region on serum protein electrophoresis). Currently synonymous with immunoglobulin preparations used for passive immunisation and immunotherapy. Indications: (1) Replacement therapy for primary immunodeficiency (X-linked agammaglobulinaemia, common variable immunodeficiency); (2) Immunomodulation for autoimmune and inflammatory diseases (Kawasaki disease, Guillain-Barré syndrome, chronic inflammatory demyelinating polyneuropathy, ITP, myasthenia gravis, Stevens-Johnson syndrome). Administration: intravenous (IVIG) or subcutaneous (SCIG). Side effects: headache, fever, chills, myalgia, aseptic meningitis, thrombosis, anaphylaxis (rare, in IgA deficiency). Prepared by cold ethanol fractionation (Cohn method) from pooled human plasma from thousands of donors.

Ganciclovir

– An antiviral guanosine analog active against cytomegalovirus (CMV). Phosphorylated to the active triphosphate, inhibiting CMV DNA polymerase. Used for CMV retinitis, CMV disease in transplant recipients (preemptive and treatment), and congenital CMV. IV formulation (oral valganciclovir

prodrug). Adverse effects: severe myelosuppression (neutropenia, thrombocytopenia—dose-limiting), renal impairment, and teratogenicity. Resistance occurs with prolonged use; foscarnet is an alternative for resistant CMV.

Gel

- A semisolid pharmaceutical formulation in which a liquid (usually water) is immobilized within a three-dimensional network of a gelling agent (e.g., carbomer, cellulose, alginate). Gels provide controlled drug release, cool sensation, and good skin compatibility; they are used for topical dermatologic products (antibiotics, antifungals, NSAIDs), ocular preparations, and oral gels. They are generally clear, non-greasy, and easily washed off.

Gelfoam

- An absorbable hemostatic agent made from purified porcine gelatin. Used in surgical settings to control bleeding where conventional hemostasis is difficult (liver, bone, neurosurgery). Mechanism: provides a physical matrix that promotes platelet aggregation and clot formation. Absorbed within 4–6 weeks. Prepared as a sterile sponge that can be cut to size and applied dry or saturated with thrombin. Contraindicated: infected wounds, gross contamination, intravascular use (risk of embolism). Brand examples: Gelfoam (Pfizer), Surgifoam (Ethicon).

Gemfibrozil

- A fibrate (PPAR- α agonist) used primarily for severe hypertriglyceridemia (reducing pancreatitis risk) and mixed hyperlipidemia. Raises HDL and lowers triglycerides markedly; modest LDL lowering. Adverse effects: myopathy/rhabdomyolysis—significantly increased with statin coadministration (interaction via glucuronidation inhibition; contraindicated with many statins), GI upset, gallstones, and increased INR with warfarin. Contrast with fenofibrate, which has less drug interaction risk. Not first-line for isolated hypercholesterolemia.

General Anesthetic

- An agent producing reversible loss of consciousness, amnesia, analgesia, and muscle relaxation sufficient for surgery. Inhaled agents (sevoflurane, isoflurane, desflurane, nitrous oxide) and intravenous agents (propofol, thiopental, etomidate, ketamine) are used; balanced anesthesia combines them with opioids,

neuromuscular blockers, and adjuvants. Monitored by depth-of-anesthesia, hemodynamics, and end-tidal agent concentration. Complications: respiratory depression, hypotension, nausea/vomiting, malignant hyperthermia (succinylcholine/volatile agents), and postoperative cognitive dysfunction.

Glipizide

- A second-generation sulfonylurea that stimulates insulin secretion by closing pancreatic beta-cell K-ATP channels. Used for type 2 diabetes. Short-acting—take 30 minutes before meals; lowers A1C. Adverse effects: hypoglycemia (major), weight gain; less hyponatremia than other sulfonylureas. Metabolized by CYP2C9; caution with elderly, renal/hepatic impairment. Avoid in sulfonylurea allergy. Alternatives: glyburide (longer, more hypoglycemia in elderly), glimepiride.

GLP-1 Receptor Agonists

- Glucagon-like peptide-1 receptor agonists are a class of injectable antidiabetic agents that mimic the effects of the incretin hormone GLP-1, which is secreted by intestinal L-cells in response to food intake. GLP-1 stimulates glucose-dependent insulin secretion, suppresses glucagon secretion, delays gastric emptying, and promotes satiety through central nervous system effects. Available agents include exenatide, liraglutide, dulaglutide, semaglutide, and tirzepatide, which is a dual GIP/GLP-1 agonist. GLP-1 receptor agonists improve glycaemic control with a low risk of hypoglycaemia and promote weight loss, making them particularly valuable in overweight or obese patients with type 2 diabetes; gastrointestinal side effects including nausea, vomiting, and diarrhea are common but often diminish with gradual dose titration.

Glyburide

- A second-generation sulfonylurea stimulating beta-cell insulin secretion (K-ATP channel closure). Used for type 2 diabetes; also studied (not first-line in the US) for gestational diabetes. Long duration—high hypoglycemia risk, especially in the elderly and with renal impairment; active metabolites accumulate. Adverse effects: hypoglycemia, weight gain, and hyponatremia (SIADH). Caution in sulfa allergy and hepatic disease. Glipizide is generally preferred for lower hypoglycemia risk.

Glycerin

– A colorless, odorless, sweet-tasting trihydroxy alcohol (glycerol) with humectant, osmotic, and solvent properties. Used as: an osmotic laxative (glycerin suppositories or enemas promote water retention and reflex defecation), a humectant in skin preparations, a vehicle/solvent in pharmaceuticals and cosmetics, and in otolaryngology (glycerin ear drops soften cerumen). Intravenous glycerol is used to reduce intracranial pressure. Generally safe; rectal use may irritate mucosa.

Glycerol (Glycerine)

– A triol compound ($\text{CH}_2\text{OH}-\text{CHOH}-\text{CH}_2\text{OH}$), a colourless, odourless, viscous liquid with a sweet taste. Used in medicine and pharmaceuticals as a: humectant (retains moisture in topical preparations), laxative (glycerol suppositories for constipation), sweetener (in syrups, sugar-free alternatives), solvent for drugs, and osmotherapy agent (intravenous glycerol reduces intracranial pressure). Glycerol is also a by-product of soap manufacturing and biodiesel production (transesterification).

GnRH Agonist

– Gonadotropin-releasing hormone agonists are a class of medications that initially stimulate (flare effect, 1-3 weeks) and then suppress pituitary gonadotropin (LH and FSH) secretion through receptor downregulation, leading to profound suppression of sex steroid production (testosterone in men, estradiol in women). Used in: prostate cancer — medical castration (leuprolide, goserelin, triptorelin); breast cancer — ovarian suppression in premenopausal women; endometriosis and uterine fibroids — suppression of ovarian estrogen; central precocious puberty — halting pubertal progression; and assisted reproduction — controlled ovarian hyperstimulation protocols. The initial testosterone flare in prostate cancer can cause disease exacerbation (bone pain, spinal cord compression, urinary obstruction), mitigated by adding an antiandrogen (bicalutamide) for 2-4 weeks at initiation.

GnRH Antagonist

– A class of medications that competitively block GnRH receptors on pituitary gonadotrophs, producing immediate, reversible suppression of LH and FSH secretion without the initial flare effect seen with GnRH agonists. Used in: prostate cancer — degarelix (monthly subcutaneous injection) and

relugolix (oral daily) provide rapid testosterone suppression without flare; endometriosis and uterine fibroids — elagolix (oral); assisted reproduction — cetrorelix and ganirelix prevent premature LH surge during controlled ovarian stimulation. Advantage over GnRH agonists: no initial flare, faster onset of suppression, and reversibility. Adverse effects: hot flashes, injection site reactions (degarelix), and osteoporosis with long-term use.

Guaifenesin

– An expectorant that thins and loosens bronchial mucus by increasing respiratory tract fluid and reducing mucus viscosity, facilitating productive cough. Used for symptomatic relief of chest congestion and productive cough in upper respiratory infections and COPD. Typical adult dose 200-400 mg every 4 hours. Generally well tolerated; common side effects include nausea, vomiting, and dizziness. Efficacy is debated; hydration is an important adjunct. Available in many combination cold medications.

H2 Blocker (Histamine-2 Receptor Antagonist)

– A drug that blocks histamine H2 receptors on gastric parietal cells, reducing gastric acid secretion. Agents: cimetidine, ranitidine, famotidine, nizatidine. Used for GERD, peptic ulcer disease, and dyspepsia—less potent than PPIs. Adverse effects: headache, diarrhea, confusion (elderly, cimetidine), and rare thrombocytopenia. Cimetidine inhibits CYP450 (warfarin, theophylline, phenytoin) and has antiandrogenic effects (gynecomastia). Famotidine has the fewest interactions. Available OTC.

Half-Life

– Elimination half-life is the time required for the plasma concentration of a drug to decrease by 50 percent after reaching equilibrium. It is calculated from the elimination rate constant using the equation $t_{1/2} \text{ equals } 0.693 \text{ divided by the elimination rate constant}$. Half-life depends on both the volume of distribution and the clearance of the drug, with the relationship $t_{1/2} \text{ equals } 0.693 \text{ times } V_d \text{ divided by clearance}$. Drugs with large volumes of distribution or low clearance have long half-lives; understanding half-life is essential for determining appropriate dosing intervals, time to reach steady state, and duration of drug action after discontinu-

ation.

Haloperidol

– A first-generation (typical) antipsychotic, a butyrophenone blocking D2 dopamine receptors. Used for schizophrenia (acute and maintenance), acute agitation/psychosis, Tourette syndrome, and as an antiemetic. Available oral, IM, IV, and long-acting depot. Adverse effects: extrapyramidal symptoms (dystonia, parkinsonism, akathisia), tardive dyskinesia (long-term), neuroleptic malignant syndrome, QT prolongation (avoid IV with other QT drugs), and hyperprolactinemia. Preferred in delirium due to few anticholinergic effects.

Heparin

– A naturally occurring glycosaminoglycan anticoagulant that enhances the activity of antithrombin, accelerating the inactivation of thrombin and factor Xa. Unfractionated heparin is a mixture of molecules of varying sizes administered intravenously, with rapid onset of action and short half-life of approximately one hour. Low-molecular-weight heparins including enoxaparin, dalteparin, and tinzaparin are produced by depolymerization of unfractionated heparin, providing more predictable pharmacokinetics, longer half-life allowing once- or twice-daily subcutaneous dosing, and reduced risk of heparin-induced thrombocytopenia compared to unfractionated heparin, though they cannot be fully reversed with protamine and accumulate in renal impairment.

Histamine

– A biogenic amine (imidazoleethylamine) synthesised from L-histidine by histidine decarboxylase, stored in basophils, mast cells, and platelets, and released during allergic and inflammatory responses. Histamine acts via four G-protein-coupled receptors: (1) H1 receptor: bronchoconstriction (asthma), vasodilation (hypotension, flushing), increased vascular permeability (urticaria, angioedema), pruritus, pain, mucus secretion, and CNS effects (wakefulness). H1-antihistamines (cetirizine, loratadine, fexofenadine, chlorphenamine, promethazine, diphenhydramine) are used for allergic rhinitis, urticaria, pruritus, insomnia, motion sickness. (2) H2 receptor: gastric acid secretion (parietal cells). H2-antagonists (cimetidine, ranitidine, famotidine) are used for peptic ulcer disease, GORD,

Zollinger-Ellison syndrome. (3) H3 receptor: presynaptic auto- and heteroreceptor in the CNS, inhibits histamine release and synthesis; inverse agonists/antagonists (pitolisant) are used for narcolepsy (increases wakefulness). (4) H4 receptor: expressed on immune cells (eosinophils, neutrophils, mast cells, dendritic cells), involved in chemotaxis and inflammation; H4 antagonists are under investigation for pruritus and asthma. Degradation: histamine N-methyltransferase and diamine oxidase. Histamine is also involved in gastric acid secretion, neurotransmission (wakefulness, appetite, learning), and smooth muscle contraction. Histamine poisoning (scombroid poisoning): from spoiled fish (tuna, mackerel) containing high levels of histamine due to bacterial decarboxylation, causes flushing, headache, urticaria, diarrhea within minutes, treated with H1-antihistamines.

Hydralazine

– A direct arteriolar vasodilator used for hypertension, particularly in preeclampsia/eclampsia (IV), and in combination with isosorbide dinitrate for heart failure with reduced ejection fraction in African Americans (improves survival). Mechanism: smooth muscle relaxation (nitric oxide pathway), reducing afterload. Adverse effects: reflex tachycardia (coadminister beta-blocker), headache, flushing, fluid retention (with diuretic), and drug-induced lupus with long-term high doses. Rapid acetylators have reduced effect. Also available orally (hypertension add-on).

Hydrochlorothiazide

– A thiazide diuretic inhibiting the sodium-chloride cotransporter in the distal convoluted tubule, promoting natriuresis and reducing plasma volume, with long-term vasodilation. Used for hypertension and mild edema. Lowers blood pressure effectively; useful in calcium stones and osteoporosis (reduces calciuria). Adverse effects: hypokalemia, hyponatremia, hyperglycemia, hyperuricemia (gout), hypercalcemia, hyperlipidemia, and photosensitivity. Less potent than chlorthalidone. Contraindicated in sulfonamide allergy and anuria.

Hydrocodone

– A semi-synthetic opioid analgesic (prodrug, converted by CYP2D6 to hydromorphone) used for moderate to severe pain, usually combined with

acetaminophen (e.g., Norco, Vicodin). Schedule II. Adverse effects: constipation, nausea, sedation, pruritus, respiratory depression, tolerance, and dependence. Limited by acetaminophen hepatotoxicity with higher doses. Abuse is a major public health concern; consider risk mitigation (PDMP, naloxone).

Hydrocortisone

– The pharmaceutical name for cortisol, the primary endogenous glucocorticoid hormone produced by the zona fasciculata of the adrenal cortex. Hydrocortisone has both glucocorticoid and mineralocorticoid activity (ratio of approximately 1:1 at therapeutic doses). Indications: (1) Replacement therapy: adrenal insufficiency—primary (Addison disease, autoimmune, TB, bilateral adrenalectomy) and secondary (pituitary/hypothalamic failure). Standard dosing: 15-25 mg/day in divided doses (morning 10-20 mg, afternoon 5-10 mg). Stress dosing: increase dose 2-3 fold during illness or surgery to prevent adrenal crisis. (2) Acute severe inflammatory conditions: anaphylaxis (300 mg IV, then 200 mg IV 6 hourly), severe asthma exacerbation, status epilepticus, Stevens-Johnson syndrome, severe allergic reactions. (3) Topical: eczema, dermatitis, psoriasis (various potencies, from 0.5% to 2.5% cream/ointment). (4) Intra-articular injection: inflammatory arthritis, gout. Side effects: Cushing syndrome with prolonged high-dose use (central obesity, moon face, buffalo hump, striae, osteoporosis, hyperglycaemia, hypertension, immunosuppression, myopathy, cataracts, growth suppression in children).

Hypnotic

– A medication that induces, maintains, or improves sleep, used for insomnia. Major classes: benzodiazepine receptor agonists (Z-drugs: zolpidem, zaleplon, eszopiclone) — selective for GABA-A receptors containing alpha-1 subunits, promoting sleep onset with fewer next-day effects than benzodiazepines; melatonin receptor agonists (ramelteon, prolonged-release melatonin) — activate MT1 and MT2 receptors in the suprachiasmatic nucleus, regulating the sleep-wake cycle, no abuse potential; orexin receptor antagonists (suvorexant, daridorexant) — block orexin signaling that promotes wakefulness, used for sleep maintenance insomnia; sedating

antidepressants (trazodone, doxepin, mirtazapine) — used in low doses for insomnia, especially with comorbid depression; and antihistamines (diphenhydramine, doxylamine) — sedating H1 antagonists available OTC, limited efficacy with chronic use due to tolerance.

Ibalizumab

– A humanized IgG4 monoclonal antibody that binds to domain 2 of the CD4 receptor on human T cells, preventing post-attachment steps required for HIV-1 infection. Ibalizumab is used in combination with other antiretrovirals for the treatment of multidrug-resistant HIV-1 infection in heavily treatment-experienced patients. The drug is administered intravenously every 2 weeks after an initial loading dose, which is a significant advantage over enfuvirtide's twice-daily injections. Common adverse effect, and the drug has a favourable safety profile with no significant organ toxicity, though it may cause immune-related adverse events such as rash and elevated liver enzymes.

Ibuprofen

– A nonsteroidal anti-inflammatory drug (propionic acid derivative) that inhibits COX-1 and COX-2, with analgesic, antipyretic, and anti-inflammatory effects. Used for pain (headache, dysmenorrhea, musculoskeletal), fever, and inflammation. Available OTC and prescription. Adverse effects: GI bleeding/ulceration, renal impairment, fluid retention, hypertension, and cardiovascular risk with high doses/long-term use. Avoid in significant renal disease, active peptic ulcer, and late pregnancy. Naproxen, diclofenac, indomethacin are related.

Idiosyncratic Reaction

– An uncommon, unexpected, and often genetically determined adverse drug reaction that is unrelated to the drug's known pharmacology and usually dose-independent (a Type B reaction). Examples: sulfonamide-induced Stevens-Johnson syndrome, abacavir hypersensitivity (HLA-B*5701), isoniazid-induced hepatitis (slow acetylators), and malignant hyperthermia (ryanodine receptor mutation). Idiosyncratic reactions are unpredictable, potentially severe, and necessitate drug discontinuation; some can be prevented by pharmacogenetic screening.

Imipenem-cilastatin

– A combination of the carbapenem imipenem with the dehydropeptidase inhibitor cilastatin. Imipenem is the broadest-spectrum beta-lactam antibiotic, with activity against most aerobic and anaerobic bacteria, including *Pseudomonas aeruginosa* and *Bacteroides fragilis*. Cilastatin inhibits renal dehydropeptidase, preventing degradation of imipenem and allowing for higher drug levels. The combination is administered intravenously every 6 hours, with dose adjustment required for renal impairment. Common adverse effects include nausea, vomiting, diarrhea, rash, and infusion-related reactions; imipenem has the greatest potential for seizure induction among carbapenems, particularly in patients with renal impairment or CNS disorders, and dose adjustment is essential.

Immunosuppressant

– A drug that reduces immune system activity, used to prevent organ transplant rejection and to treat autoimmune and inflammatory diseases. Agents: calcineurin inhibitors (cyclosporine, tacrolimus), antiproliferatives (azathioprine, mycophenolate), corticosteroids, mTOR inhibitors (sirolimus), and biologic agents (anti-TNF, anti-IL-6, rituximab). Adverse effects include increased infection risk, malignancy (especially lymphoma and skin cancer), nephrotoxicity (calcineurin inhibitors), and bone marrow suppression. Dose is balanced between efficacy and infection risk.

Indinavir

– A protease inhibitor (PI) used in combination antiretroviral therapy for HIV-1 infection. Indinavir inhibits the HIV aspartyl protease, preventing the cleavage of viral polyproteins and resulting in the production of immature, non-infectious viral particles. The drug requires dosing every 8 hours on an empty stomach with water, and patients must maintain adequate hydration to prevent nephrolithiasis, which occurs in approximately 10-15% of patients. Nephrolithiasis presents as flank pain, hematuria, crystalluria, and acute kidney injury; other adverse effects include gastrointestinal intolerance, hyperbilirubinaemia, and metabolic disturbances including hypertriglyceridaemia and diabetes. Indinavir is rarely used today due to its inconvenient dosing schedule and the availability of more convenient protease inhibitors.

Inotrope

– A drug that increases myocardial contractility (positive inotropy), used for cardiogenic shock, decompensated heart failure, and perioperative low-output states. Agents: dobutamine (beta-1 agonist), milrinone (PDE3 inhibitor), dopamine, epinephrine, norepinephrine (also vasopressors), and digoxin (chronic). Inotropes increase cardiac output and oxygen delivery but may worsen ischemia and arrhythmias and increase mortality with prolonged use. Vasopressors (norepinephrine, vasopressin, phenylephrine) raise blood pressure via vasoconstriction. Choice depends on hemodynamic profile (wet vs dry, cold vs warm).

Insulin Aspart

– A rapid-acting insulin analog (modified amino acid sequence) with onset 10-20 minutes, peak 1-3 hours, duration 3-5 hours. Used to cover prandial glucose (injected at or just after meals) in type 1 and type 2 diabetes; also used in continuous subcutaneous insulin infusion (pump) and IV in acute settings. Adverse effects: hypoglycemia, weight gain, and injection-site lipodystrophy (rotate sites). Lispro and glulisine are similar rapid-acting analogs.

Insulin Glargine

– A long-acting basal insulin analog with a flat, peakless profile providing near-24-hour coverage, administered once daily (or twice in some patients). Formed by modification of human insulin producing slow, steady absorption from the injection depot. Used for type 1 and type 2 diabetes (basal component). Adverse effects: hypoglycemia, weight gain, lipodystrophy. Contrast with intermediate (NPH) and short (regular) insulins. U-100 and U-300 (longer duration) strengths available.

Intramuscular (IM)

– A route of drug administration in which the drug is injected into skeletal muscle (deltoid, vastus lateralis, gluteus maximus). IM injection provides rapid absorption (muscle is highly vascular), avoids first-pass metabolism, and is used for vaccines, antibiotics (benzathine penicillin), depot preparations (medroxyprogesterone), and medications poorly absorbed orally. Absorption rate depends on blood flow and drug lipophilicity. Risks: pain, hematoma, nerve injury (sciatic), abscess, and injection into vessels.

Isavuconazole

– A triazole antifungal agent used in the treatment of invasive aspergillosis and mucormycosis. Isavuconazole inhibits fungal lanosterol 14- α demethylase, disrupting ergosterol synthesis and fungal cell membrane integrity. A key advantage is its broad-spectrum activity covering *Aspergillus*, *Candida*, *Cryptococcus*, *Mucorales*, and endemic fungi. The drug has excellent oral bioavailability of approximately 98% and is available as both intravenous and oral formulations. Unlike voriconazole, isavuconazole has minimal effect on CYP3A4 and does not prolong the QT interval to the same degree as voriconazole, giving it a more favourable drug interaction profile.

Isosorbide Dinitrate

– An organic nitrate (and prodrug) that releases nitric oxide, relaxing vascular smooth muscle—predominantly venous (preload reduction) with coronary dilation. Used for chronic stable angina prophylaxis, acute angina (sublingual/IV forms), and, with hydralazine, heart failure with reduced ejection fraction (improves survival in African Americans). Long-term continuous use produces nitrate tolerance (requires nitrate-free interval). Adverse effects: headache, flushing, hypotension, syncope, reflex tachycardia. Contraindicated with PDE5 inhibitors (sildenafil, tadalafil).

Lactulose

– A synthetic disaccharide (galactose + fructose) used as an osmotic laxative and for the treatment of hepatic encephalopathy. As a laxative: it is not absorbed in the small intestine and reaches the colon intact, where it is fermented by colonic bacteria into short-chain fatty acids and gases, creating an osmotic gradient that draws water into the bowel lumen, increasing stool volume and stimulating bowel movement. Onset: 24-48 hours. Dose: 15-30 mL (10-20 g) once or twice daily. For hepatic encephalopathy: lactulose acidifies the colonic pH, favouring the conversion of ammonia (NH_3 , absorbable) to ammonium (NH_4^+ , non-absorbable), reducing systemic ammonia absorption. Dose: 30-50 mL three times daily, titrated to produce 2-3 soft stools per day. Side effects: bloating, flatulence, abdominal cramps, diarrhea (excessive dose), electrolyte disturbances (hypernatraemia) with pro-

longed high doses. Contraindicated in galactosaemia (contains galactose).

Laxative

– A drug that promotes bowel evacuation, used for constipation and bowel preparation. Classes: bulk-forming (psyllium, methylcellulose), osmotic (polyethylene glycol, lactulose, magnesium salts), stimulant (senna, bisacodyl), stool softener (docusate), and lubricant (mineral oil). Choice depends on constipation type and patient factors. Chronic stimulant laxative misuse can cause electrolyte disturbances and colonic dysmotility; bulk and osmotic agents are generally preferred for chronic use. Laxatives are contraindicated in intestinal obstruction.

Lenacapavir

– A first-in-class capsid inhibitor used in combination antiretroviral therapy for HIV-1 infection. Lenacapavir targets the HIV-1 capsid protein, interfering with multiple essential capsid-dependent steps in the viral lifecycle including nuclear import, viral DNA integration, capsid assembly, and virus release. The drug is administered as a subcutaneous injection every 6 months after oral loading, making it the longest-acting antiretroviral available. This extended dosing interval dramatically improves adherence and quality of life for patients with multidrug-resistant HIV-1 infection, though injection site reactions, including nodules and induration, are common and lenacapavir requires careful administration technique.

Levodopa

– The precursor of dopamine that crosses the blood-brain barrier; the most effective symptomatic treatment for Parkinson disease. Converted to dopamine in the brain by aromatic amino acid decarboxylase; always combined with carbidopa (peripheral decarboxylase inhibitor) to prevent peripheral conversion and side effects. Acute benefits: tremor, rigidity, bradykinesia. Long-term complications: motor fluctuations ('wearing off', 'on-off'), dyskinesias, and psychiatric effects. Withheld in psychosis; caution with MAOIs.

Levofloxacin

– A third-generation fluoroquinolone with improved gram-positive coverage, including *Streptococcus pneumoniae*. Levofloxacin inhibits bacterial DNA gyrase and topoisomerase IV. It is indicated for

community-acquired pneumonia, urinary tract infections, and skin infections. The drug is available in oral and intravenous formulations with excellent bioavailability. Common adverse effects include gastrointestinal upset, tendon rupture, and QT prolongation. Levofloxacin is the L-isomer of ofloxacin and has a slightly lower risk of QT prolongation than ciprofloxacin; levofloxacin is commonly used in combination therapy for community-acquired pneumonia and in the treatment of multidrug-resistant tuberculosis.

Levothyroxine

– Synthetic T4 used for hypothyroidism (primary, central) and suppression therapy in thyroid cancer. Converted to active T3 in tissues. Once-daily oral; taken on an empty stomach (30-60 min before food), consistently, and separate from calcium, iron, and PPIs. Dose individualized (age, weight, pregnancy, cardiac status—start low in elderly/ischemic heart disease). Monitor TSH (and free T4 in central hypothyroidism). Adverse effects of over-replacement: thyrotoxicosis (palpitations, weight loss, osteoporosis, AF).

Linezolid

– An oxazolidinone antibiotic that inhibits bacterial protein synthesis by binding to the 23S rRNA of the 50S ribosomal subunit. Linezolid has activity against gram-positive organisms including MRSA, VRE, and penicillin-resistant streptococci. It is indicated for complicated skin infections, pneumonia, and VRE infections. The drug is available in both intravenous and oral formulations with excellent bioavailability. Common adverse effects include thrombocytopenia, which occurs with prolonged use. Thus, appropriate use of linezolid requires monitoring of platelet counts at least weekly in patients receiving treatment courses exceeding two weeks, and patients should be counselled regarding the need to avoid tyramine-rich foods to prevent hypertensive crises.

Liposomal amphotericin B

– A liposomal formulation of amphotericin B used in the treatment of severe systemic fungal infections, with reduced nephrotoxicity compared to conventional amphotericin B. The liposomal formulation encapsulates amphotericin B within lipid vesicles, which alters the drug's biodistribution

and reduces renal tubular damage. It is the preferred formulation for neutropenic patients with fever and suspected fungal infections. The drug has broad-spectrum activity against *Candida*, *Aspergillus*, *Cryptococcus*. Additionally, liposomal amphotericin B is generally better tolerated with fewer infusion-related reactions and lower rates of nephrotoxicity, allowing for higher doses to be administered with improved therapeutic outcomes in critically ill patients with invasive fungal infections.

Lisinopril

– An ACE inhibitor used for hypertension, heart failure, post-MI, and diabetic nephropathy. Directly active (not a prodrug). Reduces angiotensin II, aldosterone, and bradykinin degradation, causing vasodilation, natriuresis, and reduced cardiac remodeling. Long half-life allows once-daily dosing. Adverse effects: dry cough (common), hyperkalemia, hypotension, renal impairment, angioedema, and teratogenicity (contraindicated in pregnancy). Interactions: potassium supplements, K-sparing diuretics, NSAIDs, lithium. Monitor renal function and potassium.

Loading Dose

– A higher initial dose of a drug administered to rapidly achieve therapeutic plasma concentrations, followed by lower maintenance doses to sustain the steady state. The loading dose is calculated as: $\text{Loading dose} = (\text{Vd} \times \text{desired concentration}) / \text{bioavailability}$. Indications: drugs with long half-lives where waiting 4-5 half-lives to reach steady state would delay clinical effect (amiodarone, half-life 40-55 days; digoxin, half-life 36-48 hours); drugs requiring immediate therapeutic effect (phenytoin for status epilepticus, antibiotics in sepsis, antiarrhythmics in unstable arrhythmias). The loading dose does not depend on clearance, only on the volume of distribution and the desired concentration. Caution is required for drugs with narrow therapeutic indices to avoid toxicity from the high initial dose.

Loop Diuretics

– A class of potent diuretics that act on the thick ascending limb of the loop of Henle by inhibiting the sodium-potassium-chloride cotransporter, blocking sodium and chloride reabsorption and producing a powerful natriuresis and diuresis. The prototypical

loop diuretic is furosemide, with other agents including bumetanide and torsemide. Loop diuretics are the most potent diuretics available, producing greater sodium excretion than thiazides. They also increase calcium and magneLoop diuretics are used in the treatment of hypertension, heart failure, and oedematous states including cirrhosis and nephrotic syndrome, and their dosing must be individualised based on renal function and clinical response, with careful monitoring of electrolytes and volume status to avoid hypokalaemia, hypomagnesaemia, and volume depletion.

Loperamide

– A peripheral mu-opioid receptor agonist used as an antidiarrheal. It slows intestinal motility, reduces stool frequency and volume, and increases intestinal transit time without significant CNS effects (does not cross the blood-brain barrier at therapeutic doses) or analgesic activity. Adult dose: 4 mg initially, then 2 mg after each loose stool (max 16 mg/day). Side effects: constipation, abdominal cramps, nausea. Contraindicated in invasive bacterial diarrhea (dysentery, *C. difficile*) and intestinal obstruction; high doses are abused for opioid-like effects and can cause cardiac toxicity (QT prolongation).

Lopinavir

– A protease inhibitor (PI) used in combination antiretroviral therapy for HIV-1 infection, typically co-administered with ritonavir as a fixed-dose combination. Lopinavir inhibits the HIV aspartyl protease, preventing viral polyprotein processing and maturation. Ritonavir significantly increases lopinavir plasma concentrations through CYP3A4 inhibition, allowing for twice-daily dosing. Common adverse effects include gastrointestinal disturbances such as nausea, diarrhea, and abdominal pain, as well as hyperlipidaemia, insulin resistance, and lipodystrophy, which are class effects of the protease inhibitor drug class.

Loratadine

– A second-generation (non-sedating) H1 antihistamine used for allergic rhinitis and chronic urticaria. Peripherally selective—minimal CNS penetration, minimal anticholinergic effects. Once daily; prodrug (desloratadine is active). Adverse effects: headache, dry mouth, and rare sedation. Available OTC. Few

drug interactions; metabolized by CYP3A4/2D6. Cetirizine and fexofenadine are alternatives.

Lorazepam

– A short-to-intermediate-acting benzodiazepine used for anxiety, status epilepticus (IV), sedation (procedural, pre-op), alcohol withdrawal, and insomnia. Enhances GABA-A. Well absorbed; metabolized by glucuronidation (safe in hepatic impairment). Adverse effects: sedation, respiratory depression (with opioids), amnesia, dependence, and withdrawal with abrupt cessation. Preferred benzodiazepine in status epilepticus (IV) and in patients with hepatic dysfunction.

Losartan

– An angiotensin II receptor blocker (ARB) used for hypertension, diabetic nephropathy (type 2), heart failure, and stroke prevention in hypertensive left ventricular hypertrophy. Blocks AT1 receptors, reducing vasoconstriction and aldosterone. Associated with less cough than ACE inhibitors. Adverse effects: dizziness, hyperkalemia, hypotension, renal impairment, angioedema (rare), and teratogenicity (contraindicated in pregnancy). Available with hydrochlorothiazide. Useful as an ACE-inhibitor alternative in ACE-intolerant patients.

Macrolides

– A class of bacteriostatic antibiotics that bind to the 50S ribosomal subunit and inhibit translocation of peptidyl-tRNA during protein synthesis. The major macrolides include erythromycin, clarithromycin, and azithromycin. Erythromycin has a narrow spectrum primarily against gram-positive organisms and is limited by gastrointestinal side effects from motilin receptor agonism. Clarithromycin has improved oral bioavailability and extended spectrum including *Haemophilus influenzae* and azithromycin has become a widely used agent for respiratory infections due to its extended half-life and once-daily dosing. Macrolides also have immunomodulatory and anti-inflammatory properties independent of their antimicrobial activity, which contribute to their efficacy in chronic respiratory diseases including cystic fibrosis, bronchiectasis, and diffuse panbronchiolitis.

Maintenance Dose

– The dose of a drug administered at regular intervals to maintain a desired steady-state concentration,

balancing the rate of drug administration with the rate of elimination. The maintenance dose is calculated as: Maintenance dose rate = (Clearance x desired concentration) / Bioavailability. At steady state, the rate of drug administration equals the rate of elimination. Maintenance doses are determined by the drug's clearance and target therapeutic concentration. Factors affecting maintenance dose requirements: changes in clearance (renal impairment, hepatic impairment, drug interactions affecting metabolism), changes in volume of distribution (obesity, edema), and patient factors (age, weight, organ function). Maintenance dosing intervals are based on the drug's half-life, typically administered every half-life for drugs with short half-lives or at longer intervals for drugs with long half-lives.

Mannitol

- An osmotic diuretic that is freely filtered at the glomerulus but not reabsorbed, increasing tubular osmotic pressure and water excretion. Used to reduce intracranial pressure (cerebral edema) and intraocular pressure (acute glaucoma), and to promote diuresis in rhabdomyolysis/contrast nephropathy prophylaxis. IV infusion; side effects: fluid overload, hyponatremia or hypernatremia, pulmonary edema (with renal failure), and headache. Contraindicated in anuria and congestive heart failure. Filter for crystallization; avoid in significant renal impairment.

Maraviroc

- A CCR5 antagonist (entry inhibitor) used in combination antiretroviral therapy for HIV-1 infection in patients with CCR5-tropic virus. Maraviroc binds to the human CCR5 coreceptor on CD4+ T cells, preventing HIV-1 gp120 binding and viral entry. A critical requirement for maraviroc use is tropism testing to confirm the presence of CCR5-tropic virus, as the drug has no activity against CXCR4-tropic or dual/mixed-tropic virus. Common adverse effects include hepatotoxicity with elevated transaminases levels, which is typically reversible upon discontinuation; postural hypotension, diarrhea, nausea, and headache are also reported.

Maximum Tolerated Dose

- The highest dose of a drug that produces acceptable, manageable toxicity without causing unac-

ceptable adverse effects, determined through dose-escalation studies, most commonly in Phase I clinical trials. The MTD identifies the dose range for subsequent efficacy studies. In oncology, the MTD is typically defined as the dose at which no more than 33% of patients experience dose-limiting toxicity (DLT) during the first treatment cycle. The 3+3 design is the classic approach: 3 patients are treated at each dose level; if 0/3 have DLT, the next cohort is escalated; if 1/3 have DLT, 3 more patients are treated at the same level; if 2/3 have DLT, the previous dose is declared the MTD. Modern adaptive designs (e.g., Bayesian continual reassessment method) are increasingly used.

Medical Cannabis and Cannabidiol (CBD)

- Cannabis (marijuana) and cannabidiol (CBD) are cannabinoid compounds derived from *Cannabis sativa* that interact with the endocannabinoid system (CB1 and CB2 receptors) to modulate pain, appetite, mood, and inflammation. THC (delta-9-tetrahydrocannabinol) is the primary psychoactive component responsible for euphoria, cognitive impairment, and dependence risk; CBD is non-intoxicating and has demonstrated anti-inflammatory, anxiolytic, and anticonvulsant properties. FDA-approved cannabinoid preparations: dronabinol and nabilone for chemotherapy-induced nausea and HIV/AIDS anorexia, and purified CBD (Epidiolex) for Dravet and Lennox-Gastaut syndromes. Evidence supports medical cannabis for chronic neuropathic pain, multiple sclerosis spasticity, and chemotherapy-induced nausea, though data for most other conditions are limited by small trials and regulatory barriers. Risks: impaired driving, psychosis vulnerability (especially high-THC products), cannabinoid hyperemesis syndrome, pulmonary harm from smoking, and addiction (9% of users).

Medication Management

- The systematic process of optimizing pharmacotherapy to achieve therapeutic goals while minimizing adverse effects, encompassing prescribing, dispensing, administration, monitoring, and deprescribing. Key components: medication reconciliation at transitions of care (comparing patient's current regimen against new orders to prevent errors),

adherence assessment (pill counts, pharmacy refill data, electronic monitoring), dose adjustment for renal/hepatic impairment, therapeutic drug monitoring (e.g., warfarin INR, vancomycin trough, lithium levels), and deprescribing (tapering or discontinuing unnecessary or harmful medications). Polypharmacy—use of ≥ 5 medications—increases risk of adverse drug events, falls, cognitive impairment, and hospitalization; an annual medication review using tools like the Beers Criteria and STOPP/START criteria is recommended for older adults. Patient education on indication, dose, timing, side effects, and drug–drug interactions is essential for safe and effective therapy.

Medications and Treatments

– all pharmacologic and therapeutic interventions used to prevent, manage, or cure disease, classified by mechanism of action, therapeutic class, and route of administration. Major drug classes: analgesics (NSAIDs, opioids, acetaminophen), cardiovascular agents (statins, ACE inhibitors, beta-blockers, diuretics, anticoagulants), antimicrobials (antibiotics, antivirals, antifungals), endocrine therapies (insulin, metformin, thyroid hormone, corticosteroids), psychotropics (SSRIs, antipsychotics, benzodiazepines, mood stabilizers), antineoplastics (chemotherapy, targeted therapy, immunotherapy), and disease-modifying biologic agents. Routes include oral, intravenous, intramuscular, subcutaneous, topical, inhaled, transdermal, intrathecal, and intra-articular. The principles of pharmacotherapy: right drug, right dose, right route, right time, right patient—guided by evidence-based guidelines, contraindications, allergies, renal/hepatic function, and cost-effectiveness.

Medication Side Effects

– Unintended harmful responses to medications occurring at standard doses, ranging from mild (nausea, rash, dry mouth) to severe (anaphylaxis, Stevens-Johnson syndrome, QT prolongation, hepatotoxicity). ADRs are classified as Type A (augmented pharmacologic effect, predictable and dose-dependent, 80% of ADRs, e.g., bleeding with warfarin, hypoglycemia with insulin) and Type B (bizarre, unpredictable, immune-mediated or idiosyncratic, e.g., penicillin anaphylaxis, statin-induced myopathy). Risk factors: polypharmacy,

advanced age, renal/hepatic impairment, genetic polymorphisms (CYP450 variants, HLA-B*5701 for abacavir hypersensitivity), and drug–drug interactions (e.g., simvastatin–clarithromycin). Management: prompt recognition, discontinuation or dose reduction, switching to alternative agent, and reporting to pharmacovigilance systems (FDA MedWatch). The Naranjo algorithm and causality assessment tools aid in determining likelihood of ADR.

Memantine

– An NMDA receptor antagonist (uncompetitive, low-to-moderate affinity) used for moderate to severe Alzheimer disease, often added to an acetylcholinesterase inhibitor. Blocks excessive glutamate-mediated excitotoxicity while preserving normal synaptic transmission. Once or twice daily oral. Adverse effects: dizziness, headache, constipation, confusion, and hypertension. Minimal cognitive side effects; renally cleared (reduce dose in renal impairment). Also used off-label for other dementias and neuropathic pain.

Meropenem-vaborbactam

– A combination of the carbapenem meropenem with the cyclic boronate beta-lactamase inhibitor vaborbactam. Vaborbactam inhibits class A and class C beta-lactamases, including KPC carbapenemases, but does not inhibit class D or metallo-beta-lactamases. This combination has activity against many carbapenem-resistant Enterobacteriaceae. It is indicated for complicated urinary tract infections and is being studied for other indications. The combination is administered intravenously every 8 hours, with dose adjustment required for impaired renal function; the most common adverse effects include diarrhea, headache, nausea, and infusion-site reactions.

Metformin

– A biguanide oral antidiabetic agent and first-line treatment for type 2 diabetes mellitus. Its primary mechanism involves activation of AMP-activated protein kinase, which reduces hepatic glucose production through inhibition of gluconeogenesis and glycogenolysis. Metformin also improves peripheral insulin sensitivity and reduces intestinal glucose absorption. It does not stimulate insulin secretion, which is why it does not cause hypoglycemia when used as monotherapy. Metformin produces gastroin-

testinal side effects including diarrhea, nausea, and abdominal discomfort, which often diminish with continued use or dose adjustment; lactic acidosis is a rare but serious adverse effect that requires immediate discontinuation; long-term use is associated with vitamin B12 deficiency due to interference with calcium-dependent absorption.

Methadone

– A long-acting synthetic mu-opioid receptor agonist used for maintenance treatment of opioid use disorder (with buprenorphine/naloxone) and for chronic pain. Long, variable half-life (24-36+ hours) requires careful titration; accumulation causes delayed toxicity (respiratory depression, QT prolongation/torsades—monitor ECG). Cardiotoxic at high doses. Requires specialized supervision in the US (opioid treatment program). Interactions: CYP3A4, CYP2D6. Adverse effects: constipation, sedation, sweating, and dependence.

Methicillin-resistant *Staphylococcus aureus*

– *Staphylococcus aureus* resistant to beta-lactam antibiotics through acquisition of the *mecA* gene encoding penicillin-binding protein 2a (PBP2a). MRSA is a major cause of healthcare-associated and community-associated infections. Treatment options include vancomycin, daptomycin, linezolid, and trimethoprim-sulfamethoxazole. MRSA infections are associated with increased morbidity and mortality. Infection prevention strategies include hand hygiene, contact precautions, and decolonization protocols. MRSA colonisation and infection surveillance, decolonisation strategies using intranasal mupirocin and chlorhexidine bathing, and antimicrobial stewardship to preserve the effectiveness of remaining active agents.

Methimazole

– A thioamide antithyroid drug that inhibits thyroid peroxidase, reducing thyroid hormone synthesis. Used for Graves disease/hyperthyroidism (first-line), including pregnancy (first trimester—propylthiouracil preferred then; methimazole in later trimesters), and preoperatively. Adverse effects: agranulocytosis (rare but serious—sore throat/fever warrants CBC), rash, arthralgia, cholestatic hepatitis, and teratogenicity (aplasia cutis, choanal atresia—first

trimester). Monitoring: CBC, LFTs, thyroid function.

Metoclopramide

– A dopamine (D2) receptor antagonist and 5-HT3 antagonist used as a prokinetic antiemetic for gastroparesis, chemotherapy-induced and postoperative nausea, and GERD (facilitates gastric emptying). Adverse effects: acute dystonic reactions (young women), tardive dyskinesia (chronic use—black-box warning), parkinsonism, hyperprolactinemia, and QT prolongation. Contraindicated in GI obstruction, pheochromocytoma, and Parkinson disease. Domperidone is an alternative (peripheral).

Metoprolol

– A cardioselective (beta-1) beta-blocker used for hypertension, angina, heart failure with reduced ejection fraction (metoprolol succinate—improves survival), post-MI, and rate control in atrial fibrillation. Reduced bronchospasm risk at low doses compared with nonselective agents. Available as tartrate (immediate release, BID/TID) and succinate (extended release, once daily). Adverse effects: bradycardia, fatigue, dizziness, cold extremities, depression, sleep disturbance, masking of hypoglycemia, and rebound on abrupt withdrawal.

Metronidazole

– A nitroimidazole antibiotic and antiprotozoal agent that is selectively toxic to anaerobic organisms and certain parasites. The drug is activated by reduction of its nitro group within anaerobic cells, generating toxic free radicals that damage DNA. Metronidazole is highly effective against anaerobic bacteria including *Bacteroides fragilis*, *Clostridium* species, and *Helicobacter pylori*, as well as protozoa including *Trichomonas vaginalis*, *Giardia lamblia*, and *Entamoeba histolytica*. It is the drug of choice for *C. difficile* infection when used orally, for anaerobic infections above the diaphragm, and for bacterial vaginosis. Common adverse effects include metallic taste, nausea, and a disulfiram-like reaction with alcohol; prolonged use may cause peripheral neuropathy.

Micafungin

– An echinocandin antifungal agent used in the treatment and prophylaxis of invasive candidiasis and esophageal candidiasis. Micafungin inhibits beta-(1,3)-D-glucan synthase, disrupting fungal cell wall

synthesis and leading to osmotic instability and cell death. A key advantage is its fungicidal activity against *Candida* species and fungistatic activity against *Aspergillus*. The drug is available only intravenously, as it is not absorbed orally. Common adverse effects include headache, nausea, and elevated transaminases; micafungin is also associated with an increased risk of hepatocellular tumors in animal studies, though the clinical significance in humans is uncertain.

Milrinone

– A phosphodiesterase-3 inhibitor with positive inotropic and vasodilatory (inodilator) actions, increasing cAMP in cardiac and vascular smooth muscle. Used short-term for acute decompensated heart failure and low cardiac output (bridging therapy, post-cardiac surgery), especially when beta-agonists are inadequate or patients are beta-blocked. IV infusion; half-life 2-3 hours (longer in renal impairment). Adverse effects: hypotension, arrhythmias (including VT), thrombocytopenia, and hypokalemia. May increase mortality with chronic use in class IV heart failure.

Minimum inhibitory concentration

– The lowest concentration of an antimicrobial agent that inhibits visible growth of a microorganism under standardized in vitro conditions. MIC is the gold standard for measuring antimicrobial susceptibility and is determined by broth microdilution or agar dilution methods. The MIC value is used to categorize isolates as susceptible, intermediate, or resistant based on established breakpoints. MIC values guide dosing decisions and can predict clinical outcomes. For some infections, including endocarditis and osteomyelitis, maintaining drug concentrations above the MIC for the entire dosing interval is critical for achieving bacteriological cure, and time above the MIC is the key pharmacodynamic parameter for beta-lactam antibiotics.

Minocycline

– A tetracycline antibiotic with broader spectrum than tetracycline, including activity against MRSA and *Nocardia*. Minocycline inhibits bacterial protein synthesis by binding to the 30S ribosomal subunit. It is indicated for acne, respiratory infections, and meningococcal prophylaxis. The drug is well absorbed orally with excellent tissue penetration,

including the central nervous system. Common adverse effects include vestibular toxicity (dizziness, vertigo), skin hyperpigmentation, and photosensitivity; minocycline has good oral bioavailability and is available in oral and intravenous formulations; it is particularly useful for infections caused by MRSA and *Nocardia*, and for the treatment of acne vulgaris due to its anti-inflammatory properties.

Minoxidil

– A direct arteriolar vasodilator (potassium channel opener) used for severe refractory hypertension (usually with a beta-blocker and loop diuretic to counter reflex tachycardia and fluid retention), and topically for androgenetic alopecia (promotes hair regrowth). Adverse effects: hypertrichosis, pericardial effusion, reflex tachycardia, fluid retention, and headache. Dose is titrated; discontinue slowly. Topical use is generally well tolerated with minimal systemic effects.

Mirtazapine

– A noradrenergic and specific serotonergic antidepressant (NaSSA) blocking alpha-2 autoreceptors and 5-HT₂/5-HT₃ receptors, increasing norepinephrine and serotonin. Used for major depressive disorder, especially with insomnia, poor appetite, or weight loss (sedating, appetite-stimulating); useful in the elderly and in cancer/anorexia. Adverse effects: somnolence, increased appetite/weight gain, dizziness, dry mouth, and rare agranulocytosis. Minimal sexual dysfunction and nausea compared with SSRIs. Once daily at bedtime.

Modafinil

– A wakefulness-promoting agent (mechanism not fully understood, likely dopaminergic) used for narcolepsy, obstructive sleep apnea residual sleepiness, and shift work sleep disorder; used off-label for fatigue and ADHD. Less abuse potential and fewer sympathomimetic effects than amphetamines. Adverse effects: headache, nausea, nervousness, and rare severe rash (SJS); decreases effectiveness of hormonal contraceptives (CYP3A4 induction). Once daily.

Montelukast

– A leukotriene receptor antagonist (LTRA) blocking cysteinyl leukotrienes (LTC₄, LTD₄, LTE₄) that cause bronchoconstriction, mucus secretion, and air-

way inflammation. Used as add-on maintenance therapy for asthma (particularly exercise-induced and aspirin-sensitive), allergic rhinitis, and bronchospasm prophylaxis. Oral, once daily. Generally well tolerated; adverse effects include headache and abdominal pain. A boxed warning addresses neuropsychiatric events (mood changes, agitation, depression, suicidal ideation). Not indicated for acute bronchospasm.

Morphine

– The prototypic opioid agonist (mu-opioid receptor) used for moderate to severe pain (acute, post-operative, cancer, and palliative). Available oral, IV, IM, subcutaneous, and epidural; immediate and extended-release. Adverse effects: respiratory depression (dose-limiting, potentiated by other CNS depressants), constipation (prophylax), nausea, vomiting, sedation, pruritus, urinary retention, tolerance, and dependence/withdrawal. Overdose treated with naloxone. Schedule II. Caution in renal impairment (accumulation of active metabolite M6G).

Moxifloxacin

– A fourth-generation fluoroquinolone with broad-spectrum activity including anaerobes. Moxifloxacin inhibits bacterial DNA gyrase and topoisomerase IV. It is indicated for community-acquired pneumonia, intra-abdominal infections, and sinusitis. The drug is available in oral and intravenous formulations. Common adverse effects include gastrointestinal upset, tendon rupture, and QT prolongation. Moxifloxacin has the broadest spectrum of any fluoroquinolone, including activity against *Bacteroides fragilis*, and it is used as monotherapy for community-acquired pneumonia and complicated intra-abdominal infections.

Mycobacterium avium complex

– A group of closely related mycobacterial species that cause pulmonary disease and disseminated infection in immunocompromised patients. MAC is the most common NTM causing pulmonary disease. Treatment for pulmonary MAC requires a macrolide (azithromycin or clarithromycin) combined with ethambutol and a rifamycin. Disseminated MAC in HIV patients requires macrolide therapy with antiretroviral therapy. The organism is ubiquitous in the environment. Diagnosis requires

isolation of MAC from clinical MAC infection from respiratory specimens in the presence of compatible clinical and radiological findings, and treatment is prolonged, typically lasting 12-18 months following culture conversion.

Naltrexone

– A long-acting opioid receptor antagonist used for alcohol use disorder (reduces craving) and opioid use disorder (after detoxification—blocks opioid effects). Available oral and long-acting injectable (depot). Adverse effects: nausea, headache, hepatotoxicity (dose-related—avoid in active hepatitis/liver failure), and opioid withdrawal if given to opioid-dependent patients. Must be opioid-free before initiation. Naloxone (short-acting) is used for acute overdose reversal.

Narcotic

– A term derived from the Greek *narkotikos* (to numb or stupor), historically referring to opium-derived drugs that induce sleep or stupor and relieve pain. In modern medical usage, the term is largely replaced by the more specific term opioid. Legally, the term narcotic in the Controlled Substances Act refers broadly to any drug, including cocaine and coca leaves, that is considered addictive and abused, though cocaine and coca are pharmacologically stimulants, not narcotics. The imprecise legal definition has led to confusion. In clinical practice, the preferred term for morphine-like analgesics is opioid, which specifies drugs acting at opioid receptors.

Narrow Therapeutic Index

– A drug characteristic where there is a small difference between the therapeutic dose and the toxic dose, requiring careful dosing and therapeutic drug monitoring to ensure efficacy while avoiding toxicity. Narrow therapeutic index drugs have a therapeutic index <2-3 (the ratio of toxic dose to effective dose). Examples: warfarin (TI 2), digoxin, aminoglycosides (gentamicin, tobramycin, amikacin), vancomycin, cyclosporine, tacrolimus, lithium, phenytoin, carbamazepine, valproic acid, theophylline, and thyroid hormones. Managing NTI drugs requires: regular monitoring of drug concentrations; individualized dosing based on pharmacokinetic parameters; awareness of drug interactions that can alter levels; and patient education about signs of toxicity.

Nelfinavir

– A protease inhibitor (PI) used in combination antiretroviral therapy for HIV-1 infection. Nelfinavir inhibits the HIV aspartyl protease, blocking viral polyprotein processing and producing immature, non-infectious viral particles. Unlike many other protease inhibitors, nelfinavir does not require ritonavir boosting and is administered twice daily, though its efficacy may be slightly lower than boosted PI regimens. The most common adverse effect is diarrhea, occurring in approximately 20-30% of patients, which can be managed with antidiarrhoeal agents and typically resolves with continued therapy.

Neuraminidase Inhibitors

– A class of antiviral drugs that inhibit the neuraminidase enzyme on the surface of influenza viruses, preventing the release of newly formed viral particles from infected cells and thereby limiting viral spread. The two available agents are oseltamivir, administered orally, and zanamivir, administered by inhalation. These drugs are effective against both influenza A and influenza B viruses. Neuraminidase cleaves sialic acid residues from glycoproteins on the cell surface, allowing release of newly formed viral particles; inhibition of neuraminidase prevents this release, limiting viral spread within the respiratory tract and reducing the duration and severity of influenza symptoms when started within 48 hours of symptom onset.

Nifedipine

– A dihydropyridine calcium channel blocker with predominant vascular selectivity, causing arteriolar vasodilation. Used for hypertension and chronic stable angina. Immediate-release is avoided for hypertension (reflex tachycardia, hypotension) and reserved for tocolysis/Prinzmetal angina; extended-release is used for chronic therapy. Adverse effects: peripheral edema, flushing, headache, dizziness, reflex tachycardia, gingival hyperplasia. Safe in pregnancy (labetalol is preferred). Contraindicated in cardiogenic shock.

Nitrates

– Vasodilator drugs that release nitric oxide, causing relaxation of vascular smooth muscle through activation of guanylyl cyclase and increased cyclic GMP. They primarily cause venodilation at low doses, re-

ducing preload and myocardial oxygen demand, and arterial dilation at higher doses, reducing afterload. Nitroglycerin is the prototype nitrate, available in sublingual tablets for acute angina, intravenous infusion for acute coronary syndromes, topical patches for prophylaxis, and oral sustained-release formulations for long-term prophylaxis. Nitrate tolerance develops rapidly with continuous exposure and requires a daily nitrate-free interval of 8-12 hours to maintain therapeutic efficacy; common adverse effects include headache, flushing, and postural hypotension.

Nitrofurantoin

– A nitrofurantoin antibiotic used for uncomplicated urinary tract infections. Nitrofurantoin is concentrated in the urine, achieving high levels in the bladder while having minimal systemic concentrations. The drug inhibits bacterial enzymes involved in aerobic metabolism. Common adverse effects include gastrointestinal upset, pulmonary toxicity with chronic use, and peripheral neuropathy. Nitrofurantoin is not effective for systemic infections due to poor tissue penetration. The drug is available in oral and intravenous formulations; nitrofurantoin is contraindicated in patients with impaired renal function (creatinine clearance below 60 mL/min) due to inadequate urine concentrations and increased risk of toxicity.

Nitroglycerin

– An organic nitrate that releases nitric oxide, relaxing vascular smooth muscle—predominantly venous. Used for acute angina (sublingual spray/tablet, IV for ACS/heart failure), angina prophylaxis, and preload reduction in acute pulmonary edema. Rapid onset (1-3 min sublingual). Adverse effects: headache, flushing, hypotension, syncope, reflex tachycardia; tolerance with continuous use (nitrate-free interval required). Contraindicated with PDE5 inhibitors (sildenafil/tadalafil—severe hypotension) and in right ventricular infarction, severe aortic stenosis, and raised intracranial pressure.

Nitroprusside

– A direct-acting vasodilator (arterial and venous) releasing nitric oxide, used for hypertensive emergencies and controlled hypotension during surgery. IV infusion with rapid onset and offset; reduces both preload and afterload. Metabolized to cyanide and

thiocyanate—toxicity (with prolonged/high-dose infusion, renal/hepatic impairment) causes lactic acidosis, confusion, and seizures. Protect from light. Adverse effects: hypotension, cyanide/thiocyanate toxicity, and methemoglobinemia. Monitor blood pressure continuously and cyanide levels with prolonged use.

Noncompetitive Antagonist

- A noncompetitive antagonist is a drug that reduces the effect of an agonist by a mechanism that cannot be overcome by increasing the agonist concentration. This occurs either through irreversible binding to the receptor, preventing agonist binding permanently, or through binding to an allosteric site that reduces receptor function regardless of agonist binding. The dose-response curve of the agonist is shifted to the right with a decrease in maximal response, meaning the full effect of the agonist is reduced or eliminated, distinguishing noncompetitive antagonism from competitive antagonism; this type of antagonism is often irreversible on the timescale of clinical drug therapy and requires synthesis of new receptors for recovery of full agonist responsiveness.

Non-tuberculous mycobacteria

- A group of mycobacterial species other than *M. tuberculosis* complex that cause disease in humans. NTM include rapidly growing species (*M. abscessus*, *M. chelonae*, *M. fortuitum*) and slowly growing species (*M. avium* complex, *M. kansasii*). NTM infections are increasingly recognized, particularly in patients with chronic lung disease and immunocompromise. Treatment requires combination therapy based on species identification and susceptibility testing. Macrolides are backbone agents for many NTM infections; treatment is prolonged and requires multiple agents, with regimens tailored to species identification and susceptibility results, and outcomes vary widely depending on the species, extent of disease, and host immune status.

NSAIDs

- Nonsteroidal anti-inflammatory drugs are a class of drugs that inhibit cyclooxygenase enzymes, COX-1 and COX-2, reducing the synthesis of prostaglandins and thromboxanes from arachidonic acid. They produce analgesic, anti-inflammatory, antipyretic, and antiplatelet effects. COX-1 is constitutively

expressed and maintains gastric mucosal protection, renal blood flow, and platelet aggregation. COX-2 is inducible and upregulated during inflammation. Traditional NSAIDs including ibuprofen, naproxen, and diclofenac have analgesic, antipyretic, and anti-inflammatory effects but carry risks including gastrointestinal bleeding and ulceration, renal impairment, and cardiovascular events; the risk-benefit profile must be evaluated for each patient based on their individual risk factors.

NSAIDs (Nonsteroidal Anti-Inflammatory Drugs)

- A class of analgesic, antipyretic, and anti-inflammatory drugs that inhibit cyclooxygenase (COX-1 and/or COX-2), reducing prostaglandin and thromboxane synthesis. Nonselective NSAIDs (ibuprofen, naproxen, indomethacin) block both COX-1 (gastric protection, platelets) and COX-2 (inflammation); COX-2 selective agents (celecoxib) reduce GI ulceration but retain cardiovascular risk. Uses: pain, inflammation, fever, arthritis, gout, dysmenorrhea. Adverse effects: GI bleeding/ulceration, renal impairment, fluid retention, hypertension, cardiovascular events, and aspirin-exacerbated respiratory disease.

Nucleoside Analogs

- A class of antiviral drugs that structurally resemble natural nucleosides and inhibit viral replication by interfering with DNA or RNA synthesis. They require intracellular phosphorylation by viral or cellular kinases to their active triphosphate form, which then competes with natural nucleotides for incorporation into the growing viral nucleic acid chain, causing chain termination or lethal mutagenesis. Examples include acyclovir for herpes simplex virus and varicella-zoster virus, tenofovir for HIV and hepatitis B, and ribavirin for hepatitis C, with resistance developing through mutations in the target viral enzymes that reduce drug binding affinity.

Off-Label Use

- The use of a licensed medication for an indication, dose, route, or patient population not included in its marketing authorization (product licence). Off-label prescribing is legal, common in many areas of medicine (pediatrics—up to 50% of hospital prescriptions, oncology, psychiatry, obstetrics), and may represent best clinical practice when evidence

supports the use (e.g., β -blockers in heart failure were off-label before regulatory approval). The prescriber bears responsibility for the patient's safety and should: (1) be satisfied that there is a sufficient evidence base (published studies, guidelines, expert consensus) to support the off-label use; (2) explain the off-label nature to the patient and obtain informed consent; (3) document the rationale in the medical record. Regulatory frameworks: in the UK, the MHRA allows off-label prescribing under the prescriber's professional responsibility; the FDA prohibits pharmaceutical companies from promoting off-label use but does not restrict physician prescribing. Notable examples: ketamine for treatment-resistant depression, metformin for gestational diabetes, and aspirin for primary prevention of cardiovascular disease (controversial).

Ointment

– A semi-solid, greasy topical preparation for application to the skin, mucous membranes, or eyes. Ointments are typically composed of a hydrophobic base (petrolatum, lanolin, paraffin, beeswax, vegetable oils) and may contain dissolved or suspended active pharmaceutical ingredients. Ointments have high occlusivity (form a water-repellent barrier, preventing transepidermal water loss) and are preferred for dry, scaly, or lichenified skin conditions (psoriasis, chronic eczema, xerosis). They have higher drug penetration than creams (oil-in-water emulsions) or lotions due to their lipophilic nature. Disadvantages: greasy feel, staining of clothing, and less cosmetic acceptability than creams. Eye ointments (e.g., chloramphenicol, tetracycline) provide prolonged ocular contact time and are often used at bedtime. Ointment bases can be classified as hydrocarbon (petrolatum), absorption (lanolin—can absorb water), water-removable (emulsifying ointment), and water-soluble (polyethylene glycol).

Olanzapine

– An atypical antipsychotic with D2 and 5-HT_{2A} antagonism plus antihistaminergic and antimuscarinic effects. Used for schizophrenia, bipolar disorder (mania and maintenance), and treatment-resistant depression (adjunct); also for nausea/cachexia and agitation (with IM forms). Adverse effects: significant weight gain, metabolic syndrome, hyperglycemia/diabetes, sedation, and anticholinergic ef-

fects. Black-box warning in elderly with dementia-related psychosis. Often combined with antidepressants in refractory depression.

Omadacycline

– A newer aminomethylcycline antibiotic with activity against gram-positive, gram-negative, and atypical organisms. Omadacycline inhibits bacterial protein synthesis by binding to the 30S ribosomal subunit. It has activity against MRSA, vancomycin-resistant enterococci, community-acquired pneumonia pathogens, and skin infections. The drug is available in both intravenous and oral formulations, allowing for IV-to-oral step-down therapy. Omadacycline is indicated for community-acquired bacterial pneumonia and acute bacterial skin infections, with common adverse effects including nausea, vomiting, and infusion-site reactions; photosensitivity is less common than with earlier tetracyclines.

Omeprazole

– A proton pump inhibitor (PPI) that irreversibly inhibits the gastric H⁺/K⁺ ATPase (proton pump) on parietal cells, profoundly reducing acid secretion. Used for GERD, peptic ulcer disease, *H. pylori* eradication (triple therapy), Zollinger-Ellison syndrome, and stress ulcer prophylaxis. Prodrug activated in acidic canaliculi; once daily before breakfast. Adverse effects: headache, diarrhea, hypomagnesemia, B12 deficiency with long-term use, osteoporosis/fracture risk, *C. difficile* infection, and drug interactions (CYP2C19). Pantoprazole, esomeprazole, lansoprazole are alternatives.

Opiate

– A natural alkaloid derived from the opium poppy (*Papaver somniferum*) or a semi-synthetic derivative that binds to opioid receptors. Natural opiates: morphine (prototypical opioid analgesic, gold standard for severe pain), codeine (prodrug metabolized to morphine by CYP2D6—poor metabolisers derive minimal analgesia), and thebaine (used in synthesis of semi-synthetic opioids—oxycodone, buprenorphine, naloxone). Semi-synthetic opiates: heroin (diamorphine—more lipid-soluble than morphine, rapid CNS penetration), oxycodone, and hydromorphone. See also Opioid for the broader class including synthetic opioids (fentanyl, methadone, tramadol). Historically, opium has been used for pain relief, diarrhea, and cough suppression for millen-

nia. Opiates produce euphoria, miosis, respiratory depression, constipation, and physical dependence. Overuse leads to opioid use disorder (addiction).

Opioid Analgesics

- A class of drugs that bind to opioid receptors in the central and peripheral nervous systems, producing analgesia and other effects. There are three main opioid receptor types: mu receptors mediating analgesia, respiratory depression, euphoria, and physical dependence; delta receptors involved in analgesia and mood; and kappa receptors mediating analgesia and sedation. Morphine is the prototype opioid, derived from opium, with other natural opioids including codeine and semisynthetic opioids including fentanyl and methadone. Common adverse effects include respiratory depression, constipation, nausea and vomiting, sedation, tolerance, physical dependence, and the potential for addiction; careful dosing and monitoring are required to balance effective pain relief with the risk of adverse events.

Opioids

- See Opioid Analgesics.

Oral Hypoglycemic

- A class of drugs used to treat type 2 diabetes (with lifestyle). Classes: biguanides (metformin—first-line), sulfonylureas (glipizide, glyburide), meglitinides, thiazolidinediones (pioglitazone), DPP-4 inhibitors (sitagliptin), SGLT2 inhibitors (empagliflozin), GLP-1 receptor agonists (semaglutide, liraglutide—injectable), and alpha-glucosidase inhibitors. Choice based on glycemic control, weight, cardiovascular/renal risk, and hypoglycemia risk. SGLT2 inhibitors and GLP-1 agonists have cardiovascular and renal benefits; sulfonylureas and insulin carry hypoglycemia risk.

Oritavancin

- A lipoglycopeptide antibiotic with a long half-life allowing for single-dose dosing. Oritavancin inhibits cell wall synthesis and disrupts cell membrane integrity. It has activity against gram-positive organisms including MRSA. The drug is indicated for acute bacterial skin infections. It is administered as a single intravenous dose, providing complete therapy in one administration. The drug achieves high concentrations in skin and soft tissues. Common adverse effects include nausea, headache, and infusion-site reactions, and oritavancin has a

favourable safety profile for a single-dose regimen, though it may interfere with coagulation testing for up to 24 hours after administration.

Orphan Drug

- A pharmaceutical agent developed specifically to treat a rare medical condition (affecting fewer than 200,000 people in the United States, as defined by the Orphan Drug Act of 1983). Orphan drug designation provides incentives including seven-year market exclusivity after FDA approval, tax credits for clinical trial costs, waived FDA application fees, and research grants. Examples include lumacaftor/ivacaftor for cystic fibrosis, nusinersen for spinal muscular atrophy, and eliglustat for Gaucher disease. The Orphan Drug Act has successfully stimulated development of treatments for previously neglected rare diseases.

Orphan Drugs

- Medicinal products developed for the diagnosis, prevention, or treatment of rare diseases (defined in the EU as affecting <5 per 10,000 people; in the US as affecting <200,000 people). Orphan drug designation provides incentives for pharmaceutical companies: 7 years of market exclusivity in the US (Orphan Drug Act 1983), 10 years in the EU (2000), reduced regulatory fees, tax credits for clinical research costs (25% in the US), and protocol assistance from regulatory agencies. More than 600 orphan drugs have been approved in the US since 1983. Examples: imiglucerase and miglustat (Gaucher disease), ivacaftor (cystic fibrosis—G551D mutation), eculizumab (paroxysmal nocturnal haemoglobinuria, atypical hemolytic uraemic syndrome), nusinersen (spinal muscular atrophy), and eliglustat (Gaucher disease type 1). Challenges: high drug costs (often >\$200,000 per patient per year), limited natural history data, small trial populations, and ethical concerns about equitable access. The UK Rare Diseases Framework (2021) prioritises timely diagnosis and access to treatment for rare diseases.

Oseltamivir

- A neuraminidase inhibitor antiviral active against influenza A and B. Blocks viral neuraminidase, preventing release of progeny virions from infected cells. Used for treatment of influenza (within 48 hours of symptom onset, reduces duration and complications) and prophylaxis after exposure. Oral cap-

sules/suspension. Adverse effects: nausea, vomiting, and rare neuropsychiatric events (children). Resistance (H275Y in H1N1) emerges; zanamivir (inhaled) and peramivir (IV) are alternatives.

Over-the-Counter Drug

– A medication that can be purchased without a prescription, deemed safe and effective for self-medication when used according to label instructions. OTC drugs have established safety profiles, low toxicity, and clear dosing guidelines suitable for consumer use. Examples include acetaminophen, ibuprofen, antihistamines (loratadine, diphenhydramine), antacids, and topical antifungals. The FDA determines OTC status based on safety, labeling adequacy, and the condition being treatable without professional supervision. Some drugs are switched from prescription to OTC status after post-marketing safety data accumulate.

Over-the-Counter (OTC)

– Medications available without a prescription, considered safe and effective for self-care with appropriate labeling and low abuse potential. Examples: acetaminophen, ibuprofen, antacids, antihistamines, decongestants, laxatives. Regulated in the US by the FDA (OTC monograph system) and Rx-to-OTC switches (e.g., omeprazole, loratadine). Despite availability, OTC drugs carry risks (hepatotoxicity from acetaminophen overdose, NSAID GI/renal effects, interactions with warfarin and antihypertensives). Pharmacists counsel on appropriate use.

Oxycodone

– A semi-synthetic mu-opioid agonist used for moderate to severe pain. Available immediate-release and extended-release (OxyContin; abuse-deterrent formulations). Higher oral bioavailability than morphine. Adverse effects: respiratory depression, constipation, nausea, sedation, pruritus, dependence, and overdose risk. Schedule II; combination with acetaminophen (Percocet) limits dosing. The opioid epidemic has driven stricter prescribing controls and risk mitigation strategies.

Palliative Care

– See the oncology and general chapters; interdisciplinary care focusing on relief of symptoms (pain, dyspnea, nausea), psychosocial and spiritual support for patients with serious illness, and quality of life, regardless of prognosis. Palliative care is not

limited to end of life and can be provided alongside curative treatment. Hospice is a subset for patients with terminal illness (prognosis <6 months). Pharmacologic tools include opioids, antiemetics, and sedatives; communication and advance care planning are central.

Pantoprazole

– A proton pump inhibitor reducing gastric acid secretion by irreversibly inhibiting the H⁺/K⁺ ATPase of parietal cells. Used for GERD, peptic ulcer disease, dyspepsia, *H. pylori* eradication, and acid hypersecretory states. Available oral and IV (used for stress ulcer prophylaxis in the ICU). Generally well tolerated; long-term use is associated with hypomagnesemia, vitamin B12 deficiency, increased fracture risk, and *C. difficile* infection. Fewer CYP interactions than omeprazole; esomeprazole is the S-enantiomer of omeprazole.

Paracetamol

– A widely used analgesic and antipyretic, also known as acetaminophen. Paracetamol is a non-opioid, non-NSAID analgesic; its mechanism is not fully understood but involves inhibition of cyclooxygenase (COX) enzymes in the central nervous system (weak peripheral COX inhibition—hence no anti-inflammatory effect) and interaction with the serotonergic and cannabinoid systems. Indications: mild to moderate pain (headache, musculoskeletal pain, dental pain, dysmenorrhoea, osteoarthritis), fever reduction. Dose: adults 500–1000 mg every 4–6 hours (max 4 g/day). Children: 10–15 mg/kg every 4–6 hours (max 60 mg/kg/day). It is the analgesic of choice in children and patients with contraindications to NSAIDs (peptic ulcer disease, renal impairment, asthma, anticoagulation). Paracetamol is safe in pregnancy and breastfeeding. Toxicity: overdose (single dose >150 mg/kg or >7.5 g in adults) causes hepatocellular necrosis due to accumulation of the toxic metabolite N-acetyl-p-benzoquinone imine (NAPQI) when hepatic glutathione stores are depleted. N-acetylcysteine (NAC) is the antidote, most effective when given within 8 hours of overdose. Paracetamol is available in combination with opioids (codeine, dihydrocodeine, tramadol) and decongestants.

Partial Agonist

– A partial agonist is a drug that binds to a recep-

tor and produces a biological response that is less than the maximum possible response, even when all receptors are occupied. Partial agonists have affinity for the receptor but lower intrinsic activity compared to full agonists, producing a submaximal response regardless of dose. The maximal effect of a partial agonist is always less than that of a full agonist acting at the same receptor. An important property of partial agonists is that they can act as functional antagonists in the presence of a full agonist: by occupying receptors that would otherwise be activated by the full agonist, the partial agonist reduces the net response, which is the basis for their use in maintenance therapy for opioid dependence and smoking cessation.

Penicillin

- The prototypical beta-lactam antibiotic discovered in 1928 by Alexander Fleming, derived from the *Penicillium* mold. Penicillins inhibit bacterial cell wall synthesis by binding to penicillin-binding proteins (transpeptidases) and inhibiting the final transpeptidation step in peptidoglycan cross-linking, leading to cell lysis. Classes: Natural penicillins (penicillin G, penicillin V) — narrow spectrum, mostly gram-positive (*Strep*, oral anaerobes, *Treponema pallidum*). Penicillinase-resistant (methicillin, nafcillin, oxacillin) — active against penicillinase-producing *Staph aureus*. Aminopenicillins (ampicillin, amoxicillin) — expanded activity including gram-negative (*E. coli*, *Proteus*, *H. influenzae*). Extended-spectrum (piperacillin, ticarcillin) — broader gram-negative coverage including *Pseudomonas*. Antipseudomonal penicillins combined with beta-lactamase inhibitors: piperacillin-tazobactam (Zosyn), amoxicillin-clavulanate (Augmentin), ampicillin-sulbactam (Unasyn). Adverse effects: hypersensitivity reactions (5-10%, from mild rash to anaphylaxis 0.01%), GI disturbances (diarrhea), and neurotoxicity (seizures with high doses, especially in renal impairment). Penicillin is the most common drug allergy reported (though >90% of labeled patients tolerate penicillin).

Pharmacodynamics

- The study of the biochemical and physiological effects of drugs on the body and their mechanisms of action, describing what the drug does to the body. It encompasses drug-receptor interactions (binding

affinity, intrinsic activity, efficacy), signal transduction pathways (second messengers, gene expression), dose-response relationships, and therapeutic vs. adverse effects. Key concepts: receptors — proteins or macromolecules that drugs bind to exert their effects; agonists — drugs that activate receptors to produce a response; antagonists — drugs that block receptor activation; partial agonists — drugs that produce a submaximal response even at full receptor occupancy; and allosteric modulators — drugs that bind to sites distinct from the orthosteric binding site to modulate receptor activity.

Pharmacogenomics

- The study of how genetic variations influence individual responses to drugs, including drug efficacy, toxicity, and metabolism. Genetic polymorphisms in drug-metabolizing enzymes, transporters, and receptors can lead to significant inter-individual variability in drug response. Examples: CYP2D6 poor metabolizers have reduced codeine activation to morphine, leading to ineffective analgesia; CYP2C19 poor metabolizers require reduced clopidogrel dosing; TPMT deficiency increases risk of severe myelosuppression with azathioprine; HLA-B*5701 testing is required before abacavir to prevent hypersensitivity reaction; UGT1A1*28 homozygotes have increased risk of irinotecan toxicity. Pharmacogenomic testing is increasingly integrated into clinical practice, guiding drug selection and dosing to optimize efficacy and minimize adverse effects.

Pharmacokinetics

- The study of drug movement through the body, describing what the body does to the drug, defined by four processes: Absorption — the process by which a drug enters the systemic circulation from its site of administration (oral, IV, IM, subcutaneous, topical, inhalation); Distribution — the movement of drug from the circulation to body tissues, determined by blood flow, protein binding, tissue affinity, and barriers (blood-brain barrier, placental barrier); Metabolism — the chemical modification of drugs by enzymes (primarily hepatic CYP450) through Phase I (oxidation, reduction, hydrolysis) and Phase II (conjugation) reactions; and Excretion — the elimination of drugs and their metabolites from the body, primarily through the kidneys (glomerular filtration, tubular secretion, reabsorption) and also through

bile, feces, lungs, and sweat. Pharmacokinetic parameters: half-life, clearance, volume of distribution, bioavailability, and steady state concentration.

Pharmacovigilance

– The science and activities relating to the detection, assessment, understanding, and prevention of adverse drug reactions and other drug-related problems. It encompasses post-marketing surveillance of drugs after they have been approved for clinical use, as pre-marketing clinical trials may not detect rare adverse effects, long-term effects, or effects in special populations. Pharmacovigilance systems collect adverse event reports from healthcare professionals, patients, and pharmaceutical companies, and uses data from multiple sources including clinical trials, spontaneous reporting, electronic health records, and published literature to generate safety signals that may lead to regulatory actions including label changes, warnings, and market withdrawals.

Phase II Metabolism

– Phase II metabolism, also known as conjugation reactions, involves the attachment of endogenous hydrophilic molecules to drugs or their Phase I metabolites, dramatically increasing water solubility and facilitating renal excretion. The major Phase II reactions include glucuronidation catalyzed by UDP-glucuronosyltransferases, which is the most common conjugation reaction and accounts for approximately 35 percent of Phase II metabolism; sulfation catalyzed by sulfotransferases; acetylation catalyzed by N-acetyltransferases; methylation; and conjugation with glutathione. Phase II metabolites are generally pharmacologically inactive and are rapidly excreted in urine or bile; the efficiency of these conjugation pathways depends on the availability of the endogenous substrate and the activity of the conjugating enzymes, which can be influenced by genetic polymorphisms, drug interactions, and disease states.

Phase I Metabolism

– Phase I metabolism involves chemical modification of drug molecules through oxidation, reduction, and hydrolysis reactions, primarily catalyzed by the cytochrome P450 enzyme system in the liver. These reactions introduce or expose functional groups such as hydroxyl, amino, sulfhydryl, and carboxyl groups, typically increasing the polarity and water solubility

of the parent compound. The most common Phase I reaction is oxidation, catalyzed by CYP enzymes requiring molecular oxygen and NADPH. Oxidation reactions introduce hydroxyl, carboxyl, or epoxide groups, while reduction reactions add hydrogen or remove oxygen, and hydrolysis reactions cleave ester or amide bonds; the resulting metabolites may be pharmacologically inactive, less active, equally active, or occasionally more active than the parent compound, and some undergo further Phase II conjugation for elimination.

Phenylephrine

– A selective alpha-1 adrenergic agonist causing vasoconstriction and increased blood pressure (systemic vascular resistance) with reflex bradycardia. Used for hypotension/shock (IV bolus/infusion, common in anesthesia and sepsis), nasal congestion (topical decongestant), and mydriasis (ophthalmic). Adverse effects: hypertension, reflex bradycardia, headache, and tissue ischemia with extravasation. Caution in hypertensive and cardiac patients; contraindicated in severe hypertension, hyperthyroidism, and narrow-angle glaucoma (ophthalmic use).

Phosphodiesterase Inhibitor

– A class of drugs that inhibit phosphodiesterase enzymes, which break down cyclic nucleotides (cAMP and cGMP), thereby increasing intracellular levels of these second messengers and potentiating their downstream effects. Nonselective PDE inhibitors: theophylline (PDE3 and PDE4 inhibition) — bronchodilator for asthma and COPD, also has anti-inflammatory effects. PDE3 inhibitors: milrinone — positive inotrope and vasodilator for acute decompensated heart failure. PDE4 inhibitors: roflumilast — used for severe COPD with chronic bronchitis and frequent exacerbations; apremilast — used for psoriasis and psoriatic arthritis. PDE5 inhibitors: sildenafil, tadalafil, vardenafil — inhibit cGMP-specific PDE5 in corpus cavernosum, used for erectile dysfunction; also treat pulmonary arterial hypertension (sildenafil, tadalafil). Each PDE isozyme has distinct tissue distribution, allowing targeted therapeutic effects.

Pioglitazone

– A thiazolidinedione (PPAR-gamma agonist) insulin sensitizer used for type 2 diabetes. Increases peripheral glucose uptake and reduces hepatic glu-

cose output. Adverse effects: fluid retention/edema, weight gain, congestive heart failure (avoid in NYHA III/IV), bone loss/fractures, and bladder cancer concern (debated). No hypoglycemia as monotherapy; can cause dilutional anemia. Interacts with CYP2C8. Contraindicated in active bladder cancer and significant heart failure.

Plazomicin

- An aminoglycoside antibiotic with activity against many multidrug-resistant gram-negative organisms including carbapenem-resistant Enterobacteriaceae. Plazomicin inhibits protein synthesis by binding to the 30S ribosomal subunit. It is indicated for complicated urinary tract infections caused by resistant organisms. The drug is administered intravenously once daily. Common adverse effects include nephrotoxicity and ototoxicity. Plazomicin is designed to resist most aminoglycoside-modifying enzymes, maintaining activity against many aminoglycoside-resistant gram-negative pathogens; however, nephrotoxicity and ototoxicity remain significant concerns and require close monitoring, particularly in patients receiving prolonged therapy or those with pre-existing renal impairment.

Polyethylene Glycol (PEG)

- An osmotic laxative used for constipation and bowel preparation for colonoscopy. PEG (e.g., Miralax, GoLYTELY) is a non-absorbable polymer that draws water into the colonic lumen, softening stool and stimulating defecation without significant electrolyte shifts. For chronic constipation: 17 g daily in water. For bowel prep: large-volume balanced electrolyte solutions (PEG-ELS) or low-volume with ascorbate. Generally well tolerated; bloating and cramping may occur; contraindicated in bowel obstruction.

Potassium-Sparing Diuretics

- Potassium-sparing diuretics act on the distal nephron to promote sodium excretion while minimizing potassium loss. They include epithelial sodium channel blockers such as amiloride and triamterene, and mineralocorticoid receptor antagonists such as spironolactone and eplerenone. Amiloride and triamterene directly block the epithelial sodium channel in the collecting duct, reducing sodium reabsorption and potassium secretion. Spironolactone and eplerenone competitively inhibit aldosterone

binding to the mineralocorticoid receptor, blocking aldosterone-mediated sodium reabsorption and potassium excretion. Spironolactone is used as a diuretic in conditions associated with secondary hyperaldosteronism, including heart failure and hepatic cirrhosis, and as an antiandrogen in the treatment of acne, hirsutism, and female pattern hair loss. Hyperkalemia is the most important adverse effect and requires regular monitoring of serum potassium levels, particularly in patients with renal impairment or those receiving concurrent ACE inhibitors or ARBs.

Potency vs Efficacy

- Potency is the amount of drug required to produce a given effect, measured by the EC₅₀ (the concentration producing 50% of maximal effect). Drugs with higher potency achieve effects at lower doses (e.g., fentanyl is more potent than morphine). Potency is clinically relevant for dosing but does not indicate which drug is therapeutically superior. Efficacy is the maximum effect a drug can produce at saturating concentrations, measured by the E_{max} (plateau of the dose-response curve). Efficacy determines the clinical utility of a drug — a drug with high efficacy can produce an effect that a low-efficacy drug cannot. For example, morphine (high efficacy mu-opioid agonist) can relieve severe pain that codeine (low efficacy partial agonist) cannot. A drug can have high potency but low efficacy and vice versa.

Pramipexole

- A non-ergot dopamine agonist (D₂/D₃) used for Parkinson disease (as monotherapy in early disease or adjunct to levodopa) and restless legs syndrome. Activates striatal dopamine receptors. Adverse effects: nausea, orthostatic hypotension, somnolence (sudden sleep attacks—caution driving), impulse control disorders (pathological gambling, hypersexuality—important to warn), hallucinations, and leg edema. Renally cleared—reduce dose in renal impairment. Ropinirole and rotigotine (patch) are alternatives.

Prasugrel

- A thienopyridine antiplatelet prodrug that irreversibly inhibits the P₂Y₁₂ ADP receptor on platelets. Used with aspirin (dual antiplatelet therapy) in acute coronary syndromes undergoing PCI, with rapid and potent platelet inhibition. More

effective than clopidogrel but higher bleeding risk; contraindicated in prior TIA/stroke and generally avoided in age >75 and low body weight. Not affected by CYP2C19 polymorphisms (unlike clopidogrel). Adverse effects: bleeding, TTP (rare). Hold before surgery; no reversal agent (platelet transfusion).

Pravastatin

– An HMG-CoA reductase inhibitor (statin) used for hypercholesterolemia and cardiovascular risk reduction. Less potent than atorvastatin/rosuvastatin but has a favorable drug-interaction profile (not significantly metabolized by CYP3A4; less myopathy risk with interacting drugs). Used in primary and secondary prevention and in transplant and HIV populations where interactions matter. Adverse effects: myalgia, transaminase elevation, rare rhabdomyolysis, and new-onset diabetes. Renal adjustment for higher doses.

Prazosin

– A selective alpha-1 adrenergic antagonist causing vasodilation and reduced peripheral resistance. Used for hypertension, benign prostatic hyperplasia, and post-traumatic stress disorder-related nightmares (off-label). Marked first-dose orthostatic hypotension/syncope—start low and take at bedtime. Adverse effects: dizziness, orthostatic hypotension, headache, palpitations, and priapism (rare). Not first-line for hypertension but useful in combination. Shorter-acting than doxazosin/terazosin.

Prednisone

– A synthetic corticosteroid (glucocorticoid) prodrug (activated to prednisolone in the liver) with potent anti-inflammatory and immunosuppressive effects. Used for asthma/COPD exacerbations, allergic reactions, autoimmune and inflammatory diseases (RA, lupus, vasculitis, IBD, nephrotic syndrome), transplant immunosuppression, and many others. Adverse effects with chronic use: hyperglycemia, weight gain, Cushingoid features, osteoporosis, adrenal suppression, infection, cataracts, mood changes, and peptic ulcer. Always taper to avoid adrenal crisis. Methylprednisolone, dexamethasone are related.

Pregabalin

– An anticonvulsant binding alpha-2-delta subunits of voltage-gated calcium channels, used for neuropathic pain, postherpetic neuralgia, fibromyalgia,

partial seizures, and generalized anxiety disorder. Renally cleared (dose-adjust). Adverse effects: dizziness, somnolence, ataxia, blurred vision, weight gain, peripheral edema, and euphoria (abuse potential; controlled substance Schedule V). Better absorption and faster onset than gabapentin. Withdrawal seizures with abrupt cessation—taper.

Prescription

– A written or electronic order by a licensed prescriber (physician, NP, PA, dentist) authorizing a pharmacy to dispense a specific drug to a specific patient. Components: patient identifiers, drug name, dose, route, frequency, quantity, refills, and prescriber signature. Controlled substances require DEA numbers and are scheduled by abuse potential (Schedule II-V). Prescription medications are regulated to ensure safety, require professional supervision, and are dispensed with labeling and counseling. Errors in prescribing are a leading cause of adverse drug events.

Prescription Drug

– A medication that can only be dispensed with a valid prescription from a licensed healthcare provider, requiring professional oversight due to the drug's complexity, toxicity, or potential for harm. Prescription drugs undergo rigorous FDA approval through clinical trials (Phase I-IV) to establish safety and efficacy before marketing. Examples include antibiotics, antihypertensives, antidepressants, and most psychotropic medications. Prescribing requires consideration of indication, dosing, drug interactions, and monitoring parameters.

Prescription Medications

– Pharmaceutical drugs that require authorization from a licensed healthcare provider before they can be dispensed to a patient. These medications are regulated because they carry risks that necessitate professional oversight, including potential side effects, drug interactions, and the need for precise dosing. Physicians prescribe them based on a specific diagnosis, and patients must follow the prescribed regimen closely to achieve therapeutic benefits while minimizing adverse outcomes.

Procalcitonin-guided antibiotic therapy

– The use of procalcitonin levels to guide initiation and discontinuation of antibiotics. Procalcitonin

is a biomarker that rises in bacterial infections and falls with effective treatment. Elevated levels support the need for antibiotic therapy, while declining levels support discontinuation. Procalcitonin-guided protocols have been shown to reduce antibiotic duration and exposure in respiratory infections and sepsis. The approach is most validated for lower respiratory tract infections and sepsis; however, false-positive results can occur in non-infectious inflammatory conditions and false-negative results in localised infections, so procalcitonin should be used as an adjunct to, rather than a replacement for, clinical judgement.

Prodrug

- A prodrug is a pharmacologically inactive compound that is converted to an active drug through metabolic processes within the body. Prodrugs are designed to overcome limitations of the parent drug including poor bioavailability, rapid metabolism, lack of tissue selectivity, or unacceptable side effects. Examples include enalapril, which is hydrolyzed by hepatic esterases to the active form enalaprilat, an ACE inhibitor that is poorly absorbed orally; clopidogrel, which requires CYP2C19-mediated activation to its active metabolite; and valacyclovir, which undergoes hepatic hydrolysis to acyclovir, significantly improving oral bioavailability from 20% to 55%.

Propafenone

- A class IC antiarrhythmic with sodium channel blockade and weak beta-blocking activity. Used for paroxysmal atrial fibrillation (in patients without structural heart disease, including ‘pill-in-the-pocket’), supraventricular tachycardias, and ventricular arrhythmias. Contraindicated in ischemic heart disease, structural heart disease, and significant LV dysfunction (proarrhythmia). Metabolized by CYP2D6 (poor metabolizers need lower doses). Adverse effects: proarrhythmia, dizziness, metallic taste, bronchospasm (weak beta-blockade), and GI upset.

Propranolol

- A nonselective beta-blocker (beta-1 and beta-2) used for hypertension, angina, arrhythmias, migraine prophylaxis, essential tremor, thyrotoxicosis symptoms, portal hypertension/variceal bleeding prophylaxis, and infantile hemangioma. Highly

lipophilic (CNS effects: nightmares, depression, fatigue). Adverse effects: bradycardia, hypotension, bronchospasm (avoid in asthma), masking of hypoglycemia, cold extremities, and rebound hypertension on abrupt withdrawal. Available short and long-acting forms.

Propylthiouracil (PTU)

- A thioamide antithyroid drug that inhibits thyroid peroxidase (hormone synthesis) and blocks peripheral T4-to-T3 conversion. Used for hyperthyroidism/Graves disease—preferred in the first trimester of pregnancy (lower teratogenicity than methimazole) and in thyroid storm. Adverse effects: agranulocytosis, hepatotoxicity (fulminant hepatitis—black-box warning, more than methimazole), ANCA vasculitis, rash, and arthralgia. Requires monitoring of CBC and LFTs. Longer action allows less frequent dosing.

Protease Inhibitors

- A class of antiviral drugs that block viral proteases, enzymes essential for processing viral polyproteins into functional components needed for viral assembly and maturation. In HIV treatment, protease inhibitors including ritonavir, lopinavir, atazanavir, and darunavir inhibit HIV-1 protease, preventing the cleavage of Gag and Gag-Pol polyproteins into structural proteins and enzymes. This results in the production of immature, non-infectious viral particles. Protease inhibitors are also used in the treatment of hepatitis C, where NS3/4A protease inhibitors including simeprevir, grazoprevir, and glecaprevir block viral polyprotein processing and are used in combination with other direct-acting antiviral agents to achieve high rates of sustained virological response.

Protein Binding

- The reversible association of drug molecules with plasma proteins, primarily albumin for acidic drugs and alpha-1 acid glycoprotein for basic drugs. Only unbound or free drug is pharmacologically active and available for distribution to tissues, metabolism by the liver, and excretion by the kidneys. The fraction of drug bound to protein is described by the binding ratio, which depends on the total drug concentration, total protein concentration, and the association constant; changes in protein binding can significantly affect drug disposition, par-

ticularly for highly bound drugs (greater than 90% bound), where small changes in binding can lead to large changes in free drug concentration, potentially affecting both efficacy and toxicity.

Proton Pump Inhibitor

– A class of medications that irreversibly inhibit the gastric H^+/K^+ ATPase (proton pump) in parietal cells, the final common pathway of gastric acid secretion, producing profound and sustained suppression of both basal and stimulated acid production. PPIs are prodrugs that require activation in the acidic environment of the parietal cell canaliculus, where they form a sulfenamide that binds covalently to cysteine residues of the proton pump. Available agents: omeprazole, lansoprazole, pantoprazole, rabeprazole, esomeprazole, and dexlansoprazole. Indications: gastroesophageal reflux disease (GERD), erosive esophagitis, peptic ulcer disease, *Helicobacter pylori* eradication (with antibiotics), Zollinger-Ellison syndrome, and prevention of NSAID-induced ulcers. Adverse effects: increased risk of *Clostridioides difficile* infection, pneumonia, hypomagnesemia, vitamin B12 deficiency, and osteoporosis-related fractures with long-term use. Rebound acid hypersecretion occurs upon discontinuation after >8 weeks of use.

Proton Pump Inhibitors (PPIs)

– A class of antisecretory drugs (e.g., omeprazole, lansoprazole, pantoprazole, esomeprazole) that irreversibly inhibit the H^+/K^+ ATPase enzyme (proton pump) in gastric parietal cells. Prodrugs activated in the acidic canaliculi of parietal cells. Indications: GERD, peptic ulcer disease, *H. pylori* eradication (triple therapy), Zollinger-Ellison syndrome, NSAID-induced ulcer prophylaxis. Long-term adverse effects: hypomagnesemia, Vitamin B12 deficiency, increased risk of *Clostridioides difficile* infection, hip fractures (decreased calcium absorption), and interstitial nephritis.

Pseudoephedrine

– A sympathomimetic (alpha-1 agonist, some beta effects) oral decongestant used for nasal congestion in colds and sinusitis. Increases nasal mucosal vasoconstriction. Adverse effects: insomnia, nervousness, tachycardia, hypertension, and urinary retention (BPH); avoid in uncontrolled hypertension, severe CAD, hyperthyroidism, and with MAOIs. Sched-

ule/POS (behind-the-counter) in the US due to methamphetamine precursor use. Phenylephrine (oral) is an alternative with less efficacy.

Pseudomonas aeruginosa resistance

– *Pseudomonas aeruginosa* has intrinsic and acquired resistance mechanisms making it inherently resistant to many antibiotics. Intrinsic resistance includes low outer membrane permeability, efflux pumps, and chromosomal beta-lactamase. Acquired resistance can develop through mutations in target genes, acquisition of resistance plasmids, and overexpression of efflux pumps. Treatment typically requires antipseudomonal beta-lactams (piperacillin-tazobactam, cefepime, ceftazidime, carbapenems) or fluororoquinolones (ciprofloxacin, levofloxacin), often in combination therapy due to the high rate of resistance emergence during monotherapy; susceptibility testing is essential to guide treatment decisions.

Psittacosis

– See the infectious disease chapter; a zoonotic infection caused by *Chlamydia psittaci* transmitted from birds (parrots, poultry), presenting with fever, atypical pneumonia, headache, and myalgia (often with splenomegaly). Diagnosis: serology (CFT, MIF) or PCR. Treatment: doxycycline (first-line) or macrolides; tetracycline for pregnant patients. Prevention: caution handling birds. Notifiable in many regions.

QT Prolongation

– An electrocardiographic finding characterized by prolongation of the QT interval, representing the time from ventricular depolarization to repolarization, which predisposes to the potentially fatal arrhythmia torsades de pointes. The corrected QT interval should be less than 440 milliseconds in men and 460 milliseconds in women. Numerous medications can prolong the QT interval by blocking the cardiac potassium channel encoded by the *KCNH2* gene, prolonging phase 3 of the cardiac action potential, prolonging repolarisation and increasing the risk of triggered activity, torsades de pointes, and sudden cardiac death; risk factors include female sex, advanced age, electrolyte disturbances (hypokalaemia, hypomagnesaemia), bradycardia, structural heart disease, and the use of multiple QT-

prolonging medications.

Quetiapine

– An atypical antipsychotic blocking D2 and 5-HT_{2A} receptors with strong H₁ and α -1 antagonism. Used for schizophrenia, bipolar disorder (mania, depression), major depressive disorder (adjunct), and off-label for insomnia/anxiety (low doses). Adverse effects: sedation (marked at low doses), orthostatic hypotension, weight gain, metabolic syndrome, hyperglycemia, and rare cataracts; dose-related. Caution in the elderly (falls, mortality risk in dementia-related psychosis). Extended-release forms available.

Quinidine

– A class Ia antiarrhythmic agent, a stereoisomer of quinine. Quinidine prolongs the action potential duration and effective refractory period by blocking sodium channels (slow phase 0 upstroke) and potassium channels (prolongs repolarisation). Indications: atrial fibrillation (conversion and maintenance of sinus rhythm), supraventricular tachycardia, and ventricular arrhythmias (now rarely used due to safer alternatives). It also has vagolytic effects (increases sinus rate and AV conduction—may paradoxically increase ventricular rate in atrial flutter). Side effects: cinchonism (tinnitus, hearing loss, headache, nausea, visual disturbance—dose-related), QT prolongation (risk of torsades de pointes—monitor ECG), diarrhea (most common, up to 30%), thrombocytopenia (immune-mediated), and hepatotoxicity. Drug interactions: increases digoxin levels (P-glycoprotein inhibition), potentiates warfarin, and interacts with CYP3A4 inhibitors/inducers. Therapeutic range: 2–6 $\mu\text{g/mL}$ (free). Rarely used in contemporary practice; reserved for refractory cases or Brugada syndrome (prevents VF storms).

Quinine

– An alkaloid derived from cinchona bark, with antimalarial, antipyretic, and skeletal muscle relaxant properties. Quinine is a blood schizonticide with activity against all *Plasmodium* species, but resistance has emerged in *P. falciparum*. Current indications: (1) Treatment of severe/complicated *falciparum* malaria (WHO—quinine IV infusion plus doxycycline or clindamycin; artesunate IV is now preferred due to lower mortality). (2) Babesiosis (combined with clindamycin). (3) Nocturnal

leg cramps (used off-label—risk of serious adverse effects outweighs benefit; only if cramps are disabling and no alternative exists). Mechanism: accumulates in the parasite's food vacuole, inhibits haem polymerase, and prevents detoxification of haem (toxic to the parasite). Side effects: cinchonism (tinnitus, dizziness, headache, nausea, visual disturbances—dose-related, reversible), QT prolongation, hypoglycaemia (stimulates insulin secretion—dangerous in severe malaria), hypersensitivity (urticaria, flushing, hemolytic anemia), blackwater fever (massive intravascular haemolysis—rare, idiosyncratic). Contraindications: G6PD deficiency (hemolytic anemia), QT prolongation, myasthenia gravis, optic neuritis. Therapeutic range: 8–15 $\mu\text{g/mL}$. Quinine is also used in tonic water (bitter flavouring, subtherapeutic concentrations).

Quinupristin-dalfopristin

– A combination streptogramin antibiotic that inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. The combination is bactericidal against most gram-positive organisms including MRSA. It is indicated for vancomycin-resistant *Enterococcus faecium* infections. The drug is administered intravenously every 8–12 hours. Common adverse effects include arthralgia, myalgia, and infusion-related reactions including phlebitis. The drug is a potent inhibitor of CYP3A4 and can interact with numerous medications, particularly those that inhibit CYP3A4 and prolong the QT interval.

Ranitidine

– An H₂ receptor antagonist reducing gastric acid secretion (see H₂ Blockers). Formerly widely used for GERD, peptic ulcers, and dyspepsia. Largely withdrawn/limited globally due to NDMA (a probable carcinogen) contamination found in ranitidine products; famotidine and PPIs are used instead. Adverse effects: headache, diarrhea, confusion in the elderly, and rare cytopenias. Fewer CYP interactions than cimetidine.

Receptor Desensitization

– A rapid decrease in the response of a receptor to continuous or repeated agonist stimulation, occurring within minutes to hours. Desensitization mechanisms: receptor phosphorylation by G protein-coupled receptor kinases which uncouples the receptor from G proteins, leading to rapid functional

desensitization; beta-arrestin binding which sterically prevents G protein coupling and targets the receptor for internalization; receptor internalization (endocytosis) into intracellular compartments, reducing cell-surface receptor number; and receptor degradation (downregulation) after prolonged stimulation, reducing total receptor protein. Desensitization contributes to drug tolerance (e.g., beta-agonist desensitization in asthma, opioid receptor desensitization in chronic pain) and can be reversed by removing the agonist, allowing receptor recycling to the cell surface.

Remdesivir

– A nucleoside analog prodrug that inhibits viral RNA-dependent RNA polymerase, used for COVID-19. Metabolized to the active triphosphate, causing premature chain termination. Reduces recovery time in hospitalized patients with COVID-19 requiring oxygen (modest benefit). IV administration. Adverse effects: nausea, transaminase elevation, and infusion reactions; renal dose adjustment. Also studied for Ebola. Selectivity index favorable; resistance emerges in immunosuppressed patients with prolonged replication.

Renin Inhibitor

– A class of antihypertensive drugs that directly inhibit renin, the first and rate-limiting enzyme in the renin-angiotensin-aldosterone system. Renin catalyzes the conversion of angiotensinogen to angiotensin I, which is then converted to angiotensin II by ACE. Aliskiren is the only direct renin inhibitor available. It binds to the active site of renin, preventing angiotensinogen cleavage and reducing angiotensin I, angiotensin II, and aldosterone levels. Indication: hypertension. Aliskiren is used alone or in combination with other antihypertensives. Adverse effects: diarrhea (especially at higher doses), cough, hyperkalemia, and angioedema. Contraindicated in pregnancy (fetal renin-angiotensin system toxicity). Combination with ACE inhibitors or ARBs in diabetic patients with renal impairment is contraindicated due to increased risk of hyperkalemia, hypotension, and renal impairment.

Rezafungin

– A long-acting echinocandin antifungal agent used in the treatment of invasive candidiasis and candidemia. Rezafungin inhibits beta-(1,3)-D-glucan

synthase with a unique pharmacokinetic profile characterized by an extremely long half-life of approximately 130 hours, allowing for once-weekly dosing after an initial loading regimen. This extended dosing interval is a significant advantage over other echinocandins and may improve adherence. The drug has excellent stability in solution and can be stored at room temperature, maintaining potency during extended infusion periods; common adverse effects include headache, nausea, diarrhea, and hypokalaemia; hepatotoxicity has been observed in clinical trials.

Rifampin

– A rifamycin antibiotic that inhibits bacterial DNA-dependent RNA polymerase. Used for tuberculosis (with other agents), latent TB, leprosy, meningococcal prophylaxis, staphylococcal prosthetic infection (with another agent), and brucellosis. Potent CYP450 inducer (CYP3A4, CYP2C9, etc.)—many significant drug interactions (warfarin, oral contraceptives, methadone, azoles, antiretrovirals). Adverse effects: orange-red discoloration of body fluids, hepatotoxicity, flu-like syndrome, and rash. Rifabutin and rifapentine are related agents.

Rifaximin

– A rifamycin derivative with minimal systemic absorption, acting locally in the gastrointestinal tract. Rifaximin inhibits bacterial RNA polymerase. It is indicated for traveler's diarrhea caused by non-invasive *E. coli* and hepatic encephalopathy. The drug is administered orally twice or three times daily. Common adverse effects include nausea and flatulence. Rifaximin maintains activity against many gram-negative and gram-positive organisms in the gut. The drug is used for hepatic encephalopathy at a dose of 550 mg twice daily, which reduces the risk of hospitalisation and improves cognitive function in patients with recurrent hepatic encephalopathy by reducing ammonia-producing gut bacteria.

Risperidone

– An atypical antipsychotic (benzisoxazole) with potent D2 and 5-HT2A antagonism. Used for schizophrenia, bipolar mania, irritability in autism, and Tourette syndrome. Available oral, oral dissolving, long-acting injectable. Adverse effects: hyperprolactinemia (galactorrhea, gynecomastia—dose-dependent), extrapyramidal symptoms (higher than

other atypicals), sedation, orthostatic hypotension, weight gain/metabolic effects, and QT prolongation. Reduce dose in renal/hepatic impairment and the elderly.

Ritalin

- See Methylphenidate.

Ritonavir

- A protease inhibitor (PI) with potent cytochrome P450 3A4 (CYP3A4) inhibitory activity, widely used as a pharmacokinetic booster in combination antiretroviral therapy for HIV-1 infection. Ritonavir inhibits viral maturation by blocking the HIV aspartyl protease, but its clinical utility primarily lies in its ability to significantly increase plasma concentrations of co-administered protease inhibitors through CYP3A4 inhibition. This pharmacokinetic boosting allows for lower doses and reduced dosing frequency, reducing pill burden, and improving adherence. Common adverse effects when used as a booster are limited, but at full therapeutic doses, ritonavir causes significant gastrointestinal intolerance, hyperlipidaemia, and insulin resistance, and it has a high potential for drug interactions due to potent CYP3A4 inhibition.

Rivaroxaban

- A direct oral anticoagulant and selective factor Xa inhibitor. Used for stroke prevention in nonvalvular atrial fibrillation, treatment/prophylaxis of venous thromboembolism, and thromboprophylaxis after hip/knee replacement. Fixed once-daily dosing, rapid onset, no routine monitoring. Reduces dose in renal impairment (avoid if CrCl <15-30 depending on indication) and with strong CYP3A4/P-gp inhibitors. Adverse effects: bleeding; reversal agent: andexanet alfa. Avoid in mechanical valves and moderate/severe mitral stenosis.

Rivastigmine

- An acetylcholinesterase and butyrylcholinesterase inhibitor used for mild to moderate Alzheimer disease and dementia in Parkinson disease. Available oral and transdermal patch (better GI tolerability). Modest cognitive/functional benefit; does not alter progression. Adverse effects: nausea, vomiting, diarrhea, anorexia, weight loss, bradycardia, and syncope—titrate slowly; transdermal reduces GI effects. Caution in bradyarrhythmias and peptic ulcer disease.

Ropinirole

- A non-ergot dopamine agonist (D2/D3) used for Parkinson disease and restless legs syndrome. Adverse effects: nausea, dizziness, somnolence (sudden sleep attacks), orthostatic hypotension, impulse control disorders (gambling, hypersexuality), hallucinations, and leg edema. Extended-release for once-daily Parkinson dosing. Renally cleared (caution in renal impairment). Dose slowly; risk of augmentation in restless legs syndrome with long-term use.

Rosuvastatin

- A high-potency HMG-CoA reductase inhibitor (statin) reducing LDL cholesterol substantially and raising HDL. Used for hypercholesterolemia and cardiovascular risk reduction (primary and secondary prevention). Minimal CYP metabolism (fewer drug interactions than atorvastatin/simvastatin) but has a CYP2C9 component. Adverse effects: myalgia, transaminase elevation, rare rhabdomyolysis, proteinuria at high doses (tubular, benign), and new-onset diabetes. Reduce dose in severe renal impairment; caution in Asian patients (higher exposure).

Route of Administration

- The path by which a drug enters the body, influencing absorption, onset, bioavailability, and first-pass metabolism. Enteral routes: oral, sublingual, buccal, rectal. Parenteral: intravenous (100 percent bioavailability, immediate onset), intramuscular, subcutaneous, intradermal. Other routes: inhalation, topical/transdermal, ophthalmic, otic, intranasal, vaginal, intrathecal, and intra-articular. Choice depends on drug properties (stability, absorption), therapeutic goal, and patient factors. Oral is most convenient; IV is used for emergencies and drugs with poor oral absorption.

Saquinavir

- A protease inhibitor (PI) used in combination antiretroviral therapy for HIV-1 infection. Saquinavir was the first protease inhibitor approved for clinical use and inhibits the viral aspartyl protease responsible for cleaving Gag and Gag-Pol polyproteins into functional structural proteins. By blocking this essential step in viral maturation, saquinavir produces immature, non-infectious viral particles. The drug has poor oral bioavailability due to extensive first-pass metabolism by cytochrome Pp450

CYP3A4, resulting in variable plasma concentrations. Saquinavir is now rarely used due to the availability of more effective and better-tolerated protease inhibitors with improved pharmacokinetic profiles.

Saquinavir/ritonavir

– A combination of the protease inhibitor saquinavir with ritonavir as a pharmacokinetic booster, used in antiretroviral therapy for HIV-1 infection. The ritonavir component inhibits CYP3A4, significantly increasing saquinavir plasma concentrations and allowing for reduced dosing frequency and improved bioavailability. This combination allows saquinavir to be dosed twice daily instead of three times daily, improving patient adherence. The combined regimen inhibits HIV aspartyl protease, preventing viral polyprotein processing and maturation. Common adverse effects include gastrointestinal disturbances, hyperlipidaemia, and hepatotoxicity, and the combination requires careful monitoring of liver enzymes and lipid profiles throughout therapy.

Sedative

– A medication that reduces central nervous system activity, producing calming effects, drowsiness, and sleep at higher doses. Sedatives are used for anxiety, procedural sedation, insomnia, and as adjuncts in anesthesia. Classes include: benzodiazepines (midazolam, lorazepam, diazepam) — enhance GABA-A receptor activity, used for sedation, anxiolysis, and amnesia; barbiturates (phenobarbital, thiopental) — enhance GABA-A activity with broader CNS depression, largely replaced by benzodiazepines due to narrow therapeutic index and high dependence potential; propofol — an IV anesthetic that potentiates GABA-A receptors, rapid onset and offset, used for procedural sedation and general anesthesia; dexmedetomidine — an alpha-2 agonist producing sedation with minimal respiratory depression; and chloral hydrate — older sedative/hypnotic used for short-term sedation in children.

Selective Estrogen Receptor Modulator

– A class of medications that bind to estrogen receptors (ER-alpha and ER-beta) with tissue-specific agonist or antagonist activity, depending on the target tissue and differential co-regulator recruitment. Tamoxifen: antagonist in breast tissue (first-line ad-

juvant therapy for hormone receptor-positive breast cancer in premenopausal women), partial agonist in bone (preserves bone density) and endometrium (increases risk of endometrial cancer and hyperplasia), and improves lipid profile. Raloxifene: antagonist in breast and agonist in bone without endometrial stimulation (used for osteoporosis prevention and treatment in postmenopausal women, reduces breast cancer risk). Toremifene: similar to tamoxifen for metastatic breast cancer. Bazedoxifene: used for postmenopausal osteoporosis, often combined with conjugated estrogens (duavee). Adverse effects: tamoxifen — hot flashes, vaginal dryness, and thromboembolism (2-3% risk). SERMs do not cause the systemic side effects of estrogen therapy.

Selegiline

– A selective, irreversible MAO-B inhibitor used for Parkinson disease (mild early disease or adjunct to levodopa) and (as oral disintegrating/selegiline transdermal) for depression. Sparing MAO-A in the gut at low oral doses, reducing tyramine risk (still require dietary precautions with higher doses or patch). Adverse effects: nausea, insomnia, dyskinesias, hypotension, and interactions with opioids (meperidine—serotonin syndrome) and SSRIs/SNRIs (avoid overlap).

Senna

– A stimulant laxative containing anthraquinone glycosides (sennosides) that are activated by colonic bacteria to stimulate colonic motility and fluid secretion. Onset: 6-12 hours; used for constipation and bowel preparation. Common side effects: abdominal cramps, nausea; chronic use may cause melanosis coli and electrolyte disturbances. Safe in pregnancy (short-term) and generally first-line among stimulants. Available as tablets, syrup, and suppositories.

Sertraline

– A selective serotonin reuptake inhibitor (SSRI) used for major depressive disorder, panic disorder, PTSD, OCD, social anxiety disorder, and premenstrual dysphoric disorder. Effective and well tolerated; mild CYP2D6 inhibition. Adverse effects: nausea, diarrhea, insomnia, sexual dysfunction, and hyponatremia (elderly); serotonin syndrome and discontinuation syndrome (taper); black-box warning for suicidality in young adults. Once-daily dosing;

available in pregnancy-adjacent indications (postpartum depression) with monitoring.

SGLT2 Inhibitors

- Sodium-glucose co-transporter 2 inhibitors are a class of oral antidiabetic agents that block the reabsorption of glucose in the proximal convoluted tubule of the kidney, promoting glycosuria and reducing blood glucose levels. The kidney normally filters approximately 180 grams of glucose daily, with SGLT2 responsible for approximately 90 percent of glucose reabsorption. By blocking this transporter, SGLT2 inhibitors increase urinary glucose excretion by 60 to 80 grams per day. Common agents include dapagliflozin, empagliflozin, and canagliflozin. In addition to glycaemic control, SGLT2 inhibitors have demonstrated significant cardiovascular and renal benefits in major outcome trials, reducing the risk of heart failure hospitalisation and progression of chronic kidney disease, making them an important treatment option in patients with type 2 diabetes and established cardiovascular or renal disease.

Side Effect

- An unintended pharmacological effect of a drug occurring at therapeutic doses, usually predictable from the drug's mechanism of action (a Type A reaction). Side effects are dose-dependent and may be bothersome but are often tolerable or transient (e.g., dry mouth with anticholinergics, sedation with antihistamines, cough with ACE inhibitors, GI upset with antibiotics). Side effects differ from toxicity (excessive dose), allergic reactions, and idiosyncratic reactions. Management includes dose reduction, alternate dosing, adjunctive treatment, or switching drugs.

Simvastatin

- An HMG-CoA reductase inhibitor (statin) used for hypercholesterolemia and cardiovascular prevention. Metabolized by CYP3A4—many significant drug interactions (amiodarone, verapamil, azole antifungals, macrolides; maximum dose restrictions when combined). Adverse effects: myalgia, transaminase elevation, rare rhabdomyolysis, and new-onset diabetes. Once-daily evening dosing (cholesterol synthesis peaks at night). Dose reduced in renal impairment; avoid high doses (80 mg) due to myopathy risk. Available alone or with ezetimibe.

Sitagliptin

- A DPP-4 inhibitor used for type 2 diabetes. Blocks degradation of incretin hormones (GLP-1, GIP), increasing glucose-dependent insulin secretion and decreasing glucagon. Oral, once daily; weight-neutral, low hypoglycemia risk, no cardiovascular harm (neutral). Adverse effects: nasopharyngitis, headache, pancreatitis (rare), arthralgia, and hypersensitivity (angioedema, SJS). Dose-reduce in renal impairment. Related agents: saxagliptin, linagliptin, alogliptin.

Sleep Medications and Supplements

- Pharmacological agents used to treat insomnia and other sleep disorders when behavioral interventions alone are insufficient. Prescription sleep aids include benzodiazepine receptor agonists such as zolpidem, melatonin receptor agonists, and low-dose sedating antidepressants, while common over-the-counter options include antihistamines and melatonin supplements. These agents should be used with caution due to risks of dependence, tolerance, daytime drowsiness, and potential interactions with other medications, and are typically recommended for short-term use under medical supervision.

Solution

- A homogeneous mixture in which a drug (solute) is dissolved in a liquid vehicle (solvent, usually water, saline, alcohol, or polyethylene glycol). Solutions provide rapid absorption (oral solutions, parenteral IV solutions), ease of swallowing, and flexible dosing; they require preservatives and have limited stability. Used for oral (syrups, drops), injectable (IV/IM), topical, ophthalmic, otic, and nasal administration. Contrast with suspensions (particles) and emulsions. Isotonicity, pH, and sterility are important for parenteral and ophthalmic solutions.

Somatostatin Analog

- A class of synthetic peptides that mimic the actions of native somatostatin, a hormone that inhibits the secretion of growth hormone, thyroid-stimulating hormone, insulin, glucagon, gastrin, and other GI hormones. Octreotide (short-acting, subcutaneous TID) and lanreotide (long-acting, IM every 4 weeks) are somatostatin analogs with longer half-lives (1-2 hours for octreotide vs. 2-3 minutes for native somatostatin). Indications: acromegaly — suppress GH and IGF-1 levels, reduce tumor size; neu-

roendocrine tumors (carcinoid syndrome, VIPoma, glucagonoma) — control hormone-related symptoms and may slow tumor growth; variceal bleeding — reduce splanchnic blood flow (octreotide infusion); and refractory diarrhea from chemotherapy or short bowel syndrome. Adverse effects: gallstones (25–50% due to inhibition of gallbladder contraction), bradycardia, hyperglycemia/hypoglycemia, and GI symptoms.

Sotalol

- A class III antiarrhythmic with nonselective beta-blocking activity, prolonging repolarization (QT) and slowing heart rate. Used for ventricular arrhythmias and atrial fibrillation maintenance. Proarrhythmic—can cause torsades de pointes (dose/renally adjusted, monitor QT, electrolytes, and heart rate; initiated with inpatient ECG monitoring). Adverse effects: bradycardia, hypotension, bronchospasm, fatigue, and proarrhythmia. Avoid in asthma, significant heart failure, and renal impairment unless dose-adjusted.

Spirolactone

- A nonselective aldosterone (mineralocorticoid) receptor antagonist and potassium-sparing diuretic. Used for heart failure with reduced ejection fraction (NYHA II–IV—reduces mortality, often with ACE/ARB + beta-blocker), resistant hypertension, primary hyperaldosteronism, ascites in cirrhosis, and acne/hirsutism in women (off-label). Adverse effects: hyperkalemia, gynecomastia (common, limiting), breast tenderness, menstrual irregularities, and hypotension. Monitor potassium and renal function; avoid with potassium supplements and strong potassium-raising drugs.

SSRIs

- Selective serotonin reuptake inhibitors are a class of antidepressant drugs that selectively inhibit the reuptake of serotonin from the synaptic cleft into the presynaptic neuron by blocking the serotonin transporter, increasing serotonergic neurotransmission. Common SSRIs include fluoxetine, sertraline, paroxetine, citalopram, escitalopram, and fluvoxamine. They are first-line agents for major depressive disorder, generalized anxiety disorder, panic disorder, obsessive-compulsive disorder, posttraumatic stress disorder, premenstrual dysphoric disorder, and bulimia nervosa. Common adverse effects in-

clude nausea, insomnia, sexual dysfunction, and weight changes; SSRIs have a favourable safety profile in overdose compared to TCAs and MAOIs, making them the preferred first-line pharmacotherapy for most depressive and anxiety disorders.

Statin

- A class of lipid-lowering drugs inhibiting HMG-CoA reductase, the rate-limiting enzyme of hepatic cholesterol synthesis; LDL receptor upregulation lowers LDL cholesterol. Agents (potency): rosuvastatin, atorvastatin (high); simvastatin, pravastatin, lovastatin (moderate); fluvastatin (low). Used for hypercholesterolemia and primary/secondary cardiovascular prevention; pleiotropic (anti-inflammatory, plaque stabilization) effects. Adverse effects: myalgia, transaminase elevation, rare rhabdomyolysis, and small new-onset diabetes risk. Some (atorvastatin, simvastatin) are CYP3A4 substrates with interactions.

Steady State

- The condition where the rate of drug administration equals the rate of elimination, resulting in constant average plasma concentrations with repeated dosing. During regular dosing at fixed intervals, steady state is achieved after approximately 4 to 5 half-lives, regardless of the dosing frequency or dose size. At steady state, the peak and trough concentrations fluctuate within a therapeutic range, with the degree of fluctuation determined by the dosing interval relative to the drug's half-life; the concept of steady state is fundamental to therapeutic drug monitoring and ensures that drug concentrations remain within the therapeutic window for optimal efficacy and safety.

Stenotrophomonas maltophilia resistance

- *Stenotrophomonas maltophilia* is a gram-negative bacterium with intrinsic resistance to many antibiotics including carbapenems. The organism produces a chromosomal beta-lactamase (L1) that confers resistance to beta-lactams. Treatment options include trimethoprim-sulfamethoxazole, fluoroquinolones, and minocycline. *S. maltophilia* is an emerging opportunistic pathogen, particularly in immunocompromised patients and those with cystic fibrosis. The organism forms biofilms and is resistant to many disinfectants, contributing to its

persistence in healthcare environments; treatment requires combination therapy based on susceptibility testing, and antimicrobial stewardship is critical for preserving the limited treatment options available for this organism.

Stevens-Johnson Syndrome

- A severe, life-threatening mucocutaneous reaction characterized by extensive necrosis and detachment of the epidermis and mucous membranes, typically triggered by medications or infections. It is considered a medical emergency requiring burn unit or intensive care management. The pathogenesis involves a cell-mediated immune reaction with cytotoxic T lymphocytes attacking keratinocytes, causing widespread apoptosis and epidermal necrolysis. Drugs are the most common trigger including sulfonamides, anticonvulsants (carbamazepine, lamotrigine, phenytoin, phenobarbital), allopurinol, NSAIDs, and antiretrovirals (nevirapine). Management involves immediate discontinuation of the suspected causative drug, supportive care in a burn unit or intensive care setting, wound care, fluid and electrolyte management, and ophthalmological evaluation to assess ocular involvement and prevent long-term visual impairment.

Streptokinase

- A thrombolytic agent that forms a plasminogen activator complex, converting plasminogen to plasmin and lysing fibrin clots. Used for STEMI, massive pulmonary embolism, and deep vein thrombosis (largely replaced by tissue plasminogen activator, which is more fibrin-specific and less antigenic). Given IV; associated with allergic reactions and antibodies after prior exposure (reduced efficacy with repeat use). Bleeding is the major adverse effect; contraindicated in active hemorrhage, recent surgery, and intracranial pathology.

Sulfonamide

- A class of antibiotics (sulfamethoxazole, sulfadiazine, sulfasalazine) that inhibit bacterial dihydropteroate synthase, blocking folate synthesis—bacteriostatic. Often combined with trimethoprim (co-trimoxazole: TMP-SMX). Used for UTIs, PCP (pneumocystis pneumonia), toxoplasmosis, Nocardia, and MRSA. Adverse effects: hypersensitivity reactions (rash, Stevens-Johnson syndrome), crystalluria (hydrate, alkalinize), photosensitivity, hemoly-

sis in G6PD deficiency, and hyperkalemia (TMP). Avoid in sulfa allergy and in pregnancy near term.

Sulfonamides

- A class of bacteriostatic antibiotics that competitively inhibit dihydropteroate synthase, an enzyme essential for folic acid synthesis in bacteria. They are structural analogs of para-aminobenzoic acid and compete with PABA for the active site of the enzyme. Trimethoprim is combined with sulfamethoxazole to produce synergistic bactericidal activity by blocking sequential steps in folate synthesis. Cotrimoxazole, the combination of trimethoprim and sulfamethoxazole, is used for urinary tract infections, Pneumocystis jirovecii pneumonia, and other infections; hypersensitivity reactions to sulfonamides are common, particularly in patients with HIV infection, and range from mild rash to severe cutaneous adverse drug reactions including Stevens-Johnson syndrome.

Sulfonylureas

- Oral antidiabetic agents that stimulate insulin secretion from pancreatic beta cells by blocking ATP-sensitive potassium channels on the beta cell membrane. This causes membrane depolarization, opening of voltage-gated calcium channels, calcium influx, and exocytosis of insulin-containing granules. They are effective at lowering blood glucose but carry a risk of hypoglycemia because they stimulate insulin secretion regardless of glucose levels. First-generation sulfonylureas include tolbutamide and chlorpropamide; second-generation sulfonylureas including glipizide, glyburide, and glimepiride are more potent, have a more favourable side effect profile, and are dosed once or twice daily. Sulfonylureas remain an important treatment option for type 2 diabetes, particularly in resource-limited settings where cost is a significant consideration.

Sulphonamides

- A class of antimicrobial agents containing the sulfonamide group (SO_2NH_2). Sulphonamides were the first effective systemic antibacterial agents (Prontosil, 1935—Gerhard Domagk). Mechanism: competitive inhibition of dihydropteroate synthase, blocking folate synthesis (para-aminobenzoic acid analogue)—bacteriostatic. Spectrum: broad—Gram-positive (Streptococcus, Staphylococcus), Gram-negative (E. coli, Klebsiella,

Haemophilus, Nocardia), and some protozoa (Toxoplasma, Plasmodium). Clinical uses: (1) Sulfamethoxazole combined with trimethoprim (co-trimoxazole)—first-line for Pneumocystis jirovecii pneumonia (PCP), Nocardia, Toxoplasma encephalitis, and UTIs. (2) Sulfadiazine—with pyrimethamine for toxoplasmosis. (3) Sulfasalazine—used in inflammatory bowel disease and rheumatoid arthritis (5-ASA prodrug). (4) Mafenide and silver sulfadiazine—topical for burn wounds. (5) Sulfacetamide—ophthalmic drops for conjunctivitis. Adverse effects: hypersensitivity reactions (rash, Stevens–Johnson syndrome/toxic epidermal necrolysis—rare but life-threatening, fever, serum sickness), crystalluria (prevented by adequate hydration and urine alkalinisation—risk with older, less soluble sulphonamides), hemolytic anemia in G6PD deficiency, bone marrow suppression, photosensitivity, and kernicterus in neonates (displaces bilirubin from albumin—contraindicated in pregnancy, breastfeeding, and infants <2 months). Drug interactions: potentiates warfarin, methotrexate, and sulfonylureas.

Suppository

– A solid, single-dose dosage form designed to be inserted into a body orifice (rectum, vagina, or urethra) where it melts, softens, or dissolves, releasing the active pharmaceutical ingredient for local or systemic effects. Rectal suppositories (the most common): base materials (cocoa butter/theobroma oil, hard fat/Witepsol, glycerogelatin, polyethylene glycol). Indications: local—hemorrhoids (anusoal, hydrocortisone), constipation (glycerol, bisacodyl); systemic—antiemetics (prochlorperazine, promethazine), antipyretics/analgesics (paracetamol, diclofenac), bronchodilators (theophylline), and antiemetics when oral route is unavailable (nausea/vomiting, post-operative). Advantages: bypasses first-pass hepatic metabolism (some drugs achieve higher bioavailability), useful when oral route is unavailable (NPO, vomiting, unconscious patients), and avoids GI irritation. Insertion: supine or lateral position, push past the internal anal sphincter, retain for 15–30 minutes. Vaginal suppositories (pessaries): for local treatment of vaginal infections (clotrimazole, metronidazole, oestrogen) and contraception.

Suspension

– A pharmaceutical formulation in which fine solid drug particles are dispersed (not dissolved) in a liquid vehicle, often with suspending agents and stabilizers. Suspensions are used when a drug is poorly soluble, for oral (antibiotic suspensions, antacids), topical, ophthalmic, and parenteral (depot) administration. They require shaking before use to ensure uniform dosing and may settle over time. Bioavailability depends on particle size. Contrast with solutions (dissolved) and emulsions (liquid-liquid).

Sympatholytic

– An agent that blocks the sympathetic nervous system, used to treat hypertension, sympathetic overactivity, and catecholamine excess. Classes: beta-blockers (propranolol, metoprolol), alpha-blockers (prazosin, doxazosin, phenoxybenzamine), centrally acting agents (clonidine, methyl dopa), and neuron blockers (reserpine, guanethidine). Effects: reduced heart rate and contractility, vasodilation, lowered blood pressure, and reduced sympathetic reflexes. Adverse effects: bradycardia, hypotension, fatigue, bronchospasm (beta-blockers in asthma), and rebound hypertension on abrupt withdrawal.

Tablet

– A solid dosage form of compressed drug plus excipients (binders, fillers, disintegrants, lubricants, coatings). Types: immediate-release, enteric-coated (resistant to gastric acid), sustained/controlled-release, sublingual, buccal, effervescent, chewable, and orally disintegrating. Tablets provide dose accuracy, stability, ease of administration, and mass production. They should generally not be crushed (sustained-release/enteric forms) unless directed. Some tablets are scored for splitting.

Tadalafil

– A phosphodiesterase type 5 (PDE5) inhibitor used for erectile dysfunction, benign prostatic hyperplasia symptoms, and pulmonary arterial hypertension. Prolonged half-life (17.5 hours) allows once-daily dosing (long duration of action compared with sildenafil/vardenafil). Increases cGMP in corpus cavernosum and pulmonary vasculature. Adverse effects: headache, flushing, dyspepsia, back pain/myalgia, nasal congestion; rare priapism and NAION. Contraindicated with nitrates (severe hypotension) and with alpha-blockers (caution).

Tedizolid

– An oxazolidinone antibiotic related to linezolid with improved pharmacokinetic properties and activity. Tedizolid inhibits bacterial protein synthesis by binding to the 23S rRNA of the 50S ribosomal subunit. It has activity against gram-positive organisms including MRSA, VRE, and penicillin-resistant streptococci. Tedizolid is indicated for acute bacterial skin and skin structure infections. The drug is available in both intravenous and oral formulations with once-daily dosing. A key advantage over linezolid is once-daily dosing and a more favourable safety profile with reduced risk of thrombocytopenia and myelosuppression, as tedizolid has less inhibitory effect on mitochondrial protein synthesis than linezolid.

Tedizolid pharmacokinetics

– Tedizolid has a longer half-life than linezolid, allowing for once-daily dosing. The drug has approximately 90% oral bioavailability. Tedizolid is metabolized to an active metabolite (tzd-M1) that contributes to efficacy. The drug achieves high concentrations in skin and soft tissues. Tedizolid does not inhibit monoamine oxidase to the same degree as linezolid, reducing drug interaction potential. The drug is excreted primarily in feces.

Teicoplanin

– A glycopeptide antibiotic related to vancomycin with a longer half-life allowing for less frequent dosing. Teicoplanin inhibits cell wall synthesis by binding to D-Ala-D-Ala precursors. It has activity against gram-positive organisms including MRSA. The drug is administered intravenously or intramuscularly, with once-daily or less frequent dosing after loading. Common adverse effects include injection site reactions, rash, and nephrotoxicity. Teicoplanin achieves higher tissue concentrations than vancomycin, making it useful for deep-seated infections including bone and joint infections, endocarditis, and prosthetic device infections; teicoplanin is not available in the United States but is widely used in Europe and other regions.

Telavancin

– A lipoglycopeptide antibiotic derived from vancomycin with a lipophilic side chain that enhances membrane binding. Telavancin inhibits cell wall synthesis and disrupts cell membrane integrity. It

has activity against gram-positive organisms including MRSA. The drug is indicated for complicated skin infections and hospital-acquired pneumonia. It is administered intravenously once daily. Common adverse effects include QT prolongation, taste disturbance, and nephrotoxicity. Telavancin achieves concentrations in pulmonary surfactant, making it effective for hospital-acquired pneumonia, and it does not require routine therapeutic drug monitoring, though renal function should be monitored during therapy.

Tenecteplase

– A modified tissue plasminogen activator (TNK-tPA) thrombolytic with longer half-life, higher fibrin specificity, and resistance to PAI-1. Used for acute ischemic stroke and STEMI. Given as a single IV bolus (weight-based), simplifying administration. Adverse effects: hemorrhage (intracranial—major concern), allergic reactions. Contraindications: active bleeding, recent surgery/trauma, uncontrolled hypertension, and intracranial pathology. Time to treatment is critical.

Teratogenicity

– The ability of a drug, chemical, or infectious agent to cause birth defects or developmental abnormalities when exposure occurs during pregnancy. The risk of teratogenic effects depends on the timing of exposure, with the embryonic period from 3 to 8 weeks after fertilization being the most critical for organogenesis. Certain drugs have well-established teratogenic effects: thalidomide causes limb defects, isotretinoin causes craniofacial, cardiac, and CNS abnormalities, and sodium valproate is associated with neural tube defects; the management of drug therapy during pregnancy requires careful risk-benefit assessment, minimising exposure during organogenesis whenever possible, and using alternative agents with established safety profiles for the treatment of chronic conditions in women of childbearing potential.

Terazosin

– A selective alpha-1 adrenergic blocker causing vascular and prostatic smooth muscle relaxation. Used for benign prostatic hyperplasia (improves urinary flow) and hypertension. Adverse effects: first-dose orthostatic hypotension/syncope (start low, at bedtime), dizziness, nasal congestion, and fatigue. Not

first-line for hypertension but useful in men with BPH. Doxazosin and prazosin are related alpha-blockers.

Terbinafine

- An allylamine antifungal agent that inhibits squalene epoxidase, an early enzyme in the ergosterol biosynthesis pathway, causing accumulation of squalene and depletion of ergosterol in the fungal cell membrane. The accumulation of squalene is fungicidal, while ergosterol depletion disrupts membrane function. Terbinafine has excellent activity against dermatophytes including *Trichophyton*, *Microsporum*, and *Epidermophyton* species, making it the treatment of choice for dermatophyte infections of the skin and nails. Unlike azole antifungals, terbinafine does not significantly inhibit CYP450 enzymes and has a lower potential for drug interactions; adverse effects include mild gastrointestinal disturbances, headache, and taste disturbance, with rare cases of hepatotoxicity requiring periodic liver function monitoring during prolonged therapy.

Tetracycline

- The prototype tetracycline antibiotic with broad-spectrum activity against gram-positive and gram-negative bacteria, as well as atypical organisms. Tetracycline inhibits bacterial protein synthesis by binding to the 30S ribosomal subunit. It is indicated for respiratory infections, acne, and chlamydial infections. Common adverse effects include gastrointestinal upset, photosensitivity, and tooth discoloration in children. Tetracycline chelates divalent cations, so it should not be taken with dairy products, antacids, and iron-containing preparations; tetracycline is now rarely used due to the availability of more effective and better-tolerated alternatives, particularly doxycycline and minocycline.

Tetracyclines

- A class of bacteriostatic antibiotics that bind reversibly to the 30S ribosomal subunit and block the attachment of aminoacyl-tRNA to the acceptor site, inhibiting protein synthesis. They include tetracycline, doxycycline, and minocycline. Tetracyclines have a broad spectrum of activity against gram-positive and gram-negative bacteria, atypical organisms including *Chlamydia*, *Mycoplasma*, and *Rickettsia*, and the malaria parasite. Doxycycline is the most commonly used tetracycline for clinical use,

with excellent oral bioavailability, favourable pharmacokinetics allowing once- or twice-daily dosing, and a well-established safety profile; tetracyclines also have anti-inflammatory and immunomodulatory properties that are independent of their antimicrobial activity and contribute to their efficacy in acne vulgaris and rosacea.

Thalidomide

- A synthetic glutamic acid derivative with immunomodulatory, anti-inflammatory, and anti-angiogenic properties. Thalidomide was introduced in the 1950s as a sedative and antiemetic in pregnancy, but was withdrawn in 1961 after causing one of the worst pharmaceutical disasters: over 10,000 infants born with phocomelia (severe limb shortening or absence) and other congenital malformations (cardiac, renal, ear, eye defects) due to its potent teratogenicity. Mechanism: binds to cereblon (CRBN), a substrate receptor of the E3 ubiquitin ligase complex, leading to ubiquitination and degradation of the transcription factors Ikaros (IKZF1) and Aiolos (IKZF3), which inhibits multiple myeloma cell proliferation and enhances T-cell and NK-cell anti-tumor immunity. Anti-angiogenic: inhibits VEGF and FGF-induced angiogenesis. Current indications: (1) Multiple myeloma—first-line combination therapy (with dexamethasone, lenalidomide, bortezomib). (2) Erythema nodosum leprosum (ENL) in leprosy—FDA approved. (3) Behçet disease—refractory oral/genital ulcers. Side effects: teratogenicity (strict pregnancy prevention programme required—two forms of contraception, monthly pregnancy testing), peripheral neuropathy (dose-limiting, often irreversible, 20–50% of patients), sedation, rash, constipation, venous thromboembolism (prophylactic anticoagulation recommended). Thalidomide analogues (lenalidomide, pomalidomide) have improved potency and safety profiles.

Therapeutic Drug Monitoring

- The clinical practice of measuring specific drug concentrations in blood or plasma to individualize drug dosing and ensure therapeutic effectiveness while minimizing toxicity. TDM is particularly important for drugs with narrow therapeutic indices, where small changes in concentration can lead to therapeutic failure or toxicity. Examples

include aminoglycoside antibiotics where both sub-therapeutic and supratherapeutic concentrations can occur, vancomycin with target trough concentrations for vancomycin requiring trough monitoring in the range of 10-20 mcg/mL depending on the infection type and severity; other drugs requiring TDM include digoxin, lithium, theophylline, cyclosporine, tacrolimus, and certain anticonvulsants including phenytoin and valproic acid.

Therapeutic Index

- The therapeutic index is a quantitative measure of the relative safety of a drug, defined as the ratio of the dose that produces toxicity in 50 percent of the population to the dose that produces the desired therapeutic effect in 50 percent of the population. A wider therapeutic index indicates a larger margin of safety, meaning there is a greater difference between effective and toxic doses. Drugs with narrow therapeutic indices require careful dosing and monitoring because small changes in doses in drug concentration produce significant clinical consequences; drugs with narrow therapeutic indices require individualised dosing based on patient factors, therapeutic drug monitoring, and careful management of drug interactions to maintain concentrations within the therapeutic window and avoid toxicity.

Therapeutics

- The branch of medicine concerned with the treatment of disease, encompassing all interventions used to prevent, manage, or cure illness. Therapeutics includes: pharmacotherapy (drug treatment—most common), surgery (therapeutic procedures), radiotherapy (ionizing radiation for cancer), physical therapy (physiotherapy, rehabilitation), psychological therapy (CBT, psychotherapy), gene and cell therapy, immunotherapy, and complementary/alternative medicine. Principles: (1) Evidence-based medicine: treatment decisions based on the best available evidence (randomised controlled trials, systematic reviews, meta-analyses, clinical guidelines). (2) Individualised therapy: patient-specific factors (age, genetics, comorbidities, concurrent medications, preferences) guide treatment choice. (3) Risk–benefit assessment: consider efficacy, safety, tolerability, cost, and quality of life. (4) Therapeutic index: the ratio of toxic to therapeutic dose; drugs with a narrow therapeutic index (warfarin, lithium,

digoxin, phenytoin) require therapeutic drug monitoring. (5) Adherence/compliance: the extent to which a patient follows prescribed treatment; poor adherence (50% of chronic disease patients) is a major cause of treatment failure. (6) Polypharmacy: use of multiple medications (≥ 5) increases risk of adverse drug reactions, drug interactions, and non-adherence. (7) Deprescribing: systematic withdrawal of inappropriate or unnecessary medications.

Therapeutic Window

- The range of plasma drug concentrations between the minimum effective concentration (producing a therapeutic effect) and the minimum toxic concentration (producing toxicity), in which efficacy is achieved with acceptable toxicity. Drugs with a narrow therapeutic window (digoxin, warfarin, lithium, aminoglycosides, cyclosporine) require therapeutic drug monitoring and careful dosing because small changes in concentration cause therapeutic failure or toxicity. The width of the window relates to the therapeutic index (TD₅₀/ED₅₀).

Thiazide Diuretics

- Thiazide diuretics act on the distal convoluted tubule by inhibiting the sodium-chloride cotransporter, reducing sodium and chloride reabsorption and producing natriuresis and diuresis. They are less potent than loop diuretics but have a longer duration of action, typically 6 to 12 hours. Common thiazides include hydrochlorothiazide, chlorthalidone, and metolazone. Thiazides are first-line anti-hypertensive agents, particularly effective in elderly patients with isolated systolic hypertension and in patients of African descent; adverse effects include hypokalaemia, hyperuricaemia, hyperglycaemia, hypercalcaemia, and metabolic alkalosis, and they should be used with caution in patients with diabetes mellitus, gout, and electrolyte imbalances.

Thiopental Sodium

- An ultra-short-acting barbiturate, used for induction of general anesthesia (IV, onset 30–60 seconds, duration 5–10 minutes) and as a third-line agent for raised intracranial pressure (cerebroprotective effect: reduces cerebral metabolism, cerebral blood flow, and intracranial pressure). Mechanism: enhances GABA_A receptor activity (prolongs chloride channel opening). Side effects: dose-dependent res-

piratory depression, hypotension (decreased cardiac output, peripheral vasodilation), laryngospasm, and tissue necrosis/extravasation injury (highly alkaline, pH 10.5—administer through a secure IV line). Contraindications: porphyria (acute intermittent porphyria—induces haem oxygenase, precipitates attack), severe shock, status asthmaticus, and hypersensitivity to barbiturates. Thiopental was also used in lethal injection protocols (US) and for barbiturate coma (refractory intracranial hypertension). Now largely replaced by propofol (faster recovery, fewer side effects) for routine anesthetic induction. Historical: 'truth serum' myth—thiopental reduces inhibition but does not produce truthful statements reliably.

Thrombolytic

– A drug that dissolves blood clots by activating plasminogen to plasmin, which degrades fibrin. Agents: alteplase (tPA), tenecteplase (TNK-tPA), reteplase, streptokinase, urokinase. Indications: acute ischemic stroke (within 4.5 hours), STEMI, massive pulmonary embolism, and acute limb ischemia. Administration is IV; the major risk is hemorrhage (especially intracranial). Contraindications include active bleeding, recent surgery/trauma, and uncontrolled hypertension. Time to treatment is critical for benefit.

Ticagrelor

– A direct, reversible P2Y₁₂ ADP receptor antagonist antiplatelet used (with aspirin) in acute coronary syndromes and after PCI, and for secondary prevention after MI. Rapid, potent, consistent inhibition (not affected by CYP2C19 genotype, unlike clopidogrel); requires twice-daily dosing. Adverse effects: bleeding, dyspnea, bradyarrhythmias (AV block), and elevated uric acid. Avoid in active bleeding and with strong CYP3A4 inhibitors/inducers. Hold before CABG (5 days).

Tigecycline

– A glycylcycline antibiotic derived from minocycline with expanded spectrum of activity. Tigecycline inhibits bacterial protein synthesis by binding to the 30S ribosomal subunit. It has activity against gram-positive organisms including MRSA and VRE, gram-negative organisms including ESBL-producing Enterobacteriaceae, and anaerobes. Tigecycline is indicated for complicated intra-abdominal infec-

tions, complicated skin infections, and community-acquired pneumonia. The drug is administered intravenously twice daily, with common adverse effects including nausea, vomiting, abdominal pain, and hepatotoxicity; tigecycline carries a FDA black box warning for increased all-cause mortality compared to comparator agents, particularly in patients treated for hospital-acquired pneumonia, and should be reserved for situations where alternative treatment options are limited or inadequate.

Tipranavir

– A non-peptidic protease inhibitor (PI) used in combination antiretroviral therapy for treatment-experienced HIV-1 patients with resistance to multiple other PIs. Tipranavir inhibits the HIV aspartyl protease with a unique binding mechanism that maintains activity against strains resistant to other PIs. The drug must be co-administered with ritonavir to achieve adequate drug levels due to extensive CYP3A4 metabolism. Tipranavir has a significant drug interaction profile and is a potent inducer of CYP3A4 and CYP2C9, contributing to a high potential for drug interactions and requiring careful management of concomitant medications, including dose adjustment of statins and other CYP3A4 substrates.

Tolbutamide

– A first-generation sulfonylurea oral hypoglycaemic agent used in the management of type 2 diabetes. Mechanism: stimulates insulin secretion from pancreatic β -cells by binding to the sulfonylurea receptor (SUR1) on ATP-sensitive potassium (K_{ATP}) channels, causing membrane depolarisation, calcium influx, and exocytosis of insulin granules. Tolbutamide has a short half-life (4–7 hours) and is metabolized by the liver to inactive metabolites (CYP2C9). It is less potent and shorter-acting than second-generation sulfonylureas (glibenclamide/glyburide, gliclazide, glipizide, glimepiride). Clinical use: now rarely used (largely replaced by newer sulfonylureas and other oral agents). Indication: adjunct to diet and exercise in type 2 diabetes when metformin is contraindicated or not tolerated. Side effects: hypoglycaemia (less frequent than with longer-acting sulfonylureas), weight gain, and hypersensitivity reactions (rash, photosensitivity). The University Group Diabetes Program (UGDP) trial

(1970s) suggested an increased cardiovascular mortality with tolbutamide, though this finding has been disputed. Drug interactions: potentiates effect of alcohol (disulfiram-like reaction), warfarin, and NSAIDs; diminished effect with thiazide diuretics, corticosteroids, and rifampicin.

Tolerance

– A decreased response to a drug after repeated administration, requiring dose escalation to achieve the same effect. Unlike tachyphylaxis, tolerance develops over weeks to months of chronic use. The mechanisms include pharmacokinetic tolerance from increased drug metabolism through enzyme induction, pharmacodynamic tolerance from receptor down-regulation and desensitization, and learned or behavioral tolerance from compensatory physiological responses. Opioid tolerance is a major clinical challenge in chronic pain management, leading to the need for gradual dose escalation, careful assessment of risk versus benefit, and the use of multidisciplinary approaches including non-opioid analgesics, interventional procedures, and behavioural therapies.

Torsemide

– A potent loop diuretic inhibiting the Na-K-2Cl cotransporter in the loop of Henle. Used for edema in heart failure, cirrhosis, and renal disease, and hypertension. More consistently absorbed than furosemide; long duration; oral-to-IV conversion is nearly 1:1. May have less mortality effect than furosemide in heart failure trials. Adverse effects: hypokalemia, hyponatremia, hypomagnesemia, hypocalcemia, dehydration, ototoxicity, and hyperuricemia. Half-life 3-4 hours (longer in renal/hepatic failure).

TPMT Polymorphism

– Thiopurine S-methyltransferase is an enzyme that metabolizes thiopurine drugs including azathioprine, 6-mercaptopurine, and thioguanine, which are used in the treatment of leukemia, inflammatory bowel disease, and autoimmune conditions. TPMT catalyzes the S-methylation of thiopurines, diverting them away from the formation of active thioguanine nucleotides that cause cytotoxicity. Genetic polymorphisms in the TPMT gene result in variable enzyme activity, with approximately 10 percent of the population having intermediate activity and

approximately 0.3% having low or absent activity; patients with intermediate or low TPMT activity are at increased risk of severe myelosuppression when treated with standard doses of thiopurines, and pre-treatment TPMT genotyping or phenotyping is recommended to guide initial dosing and minimise the risk of haematological toxicity.

Tramadol

– An atypical opioid analgesic (weak mu-agonist plus serotonin and norepinephrine reuptake inhibition) used for moderate pain. Prodrug (M1, via CYP2D6) contributes analgesia; efficacy varies with CYP2D6 genotype. Adverse effects: nausea, dizziness, sedation, constipation, seizures (at high doses, in epilepsy, with SSRIs/SNRIs/TCAs), serotonin syndrome, and dependence (Schedule IV). Caution in renal/hepatic impairment; avoid in opioid-naïve children post-tonsillectomy.

Tranquillisers

– A class of drugs that have a calming or sedative effect, reducing anxiety, tension, and agitation. Historically classified as major tranquilisers (antipsychotics/neuroleptics—for psychosis) and minor tranquilisers (anxiolytics—for anxiety). The term is now less common in clinical practice. Major tranquilisers (antipsychotics): first-generation/typical (chlorpromazine, haloperidol, fluphenazine—block D₂ receptors), second-generation/atypical (risperidone, olanzapine, quetiapine, aripiprazole, clozapine—block D₂ and 5-HT_{2A} receptors). Used for schizophrenia, bipolar mania, agitation, and treatment-resistant depression. Minor tranquilisers (anxiolytics): benzodiazepines (diazepam, lorazepam, alprazolam—enhance GABA_A activity), buspirone (5-HT_{1A} partial agonist—non-sedating, no dependence), and β -blockers (propranolol—for performance anxiety, somatic symptoms). Adverse effects: (1) Benzodiazepines—dependence, tolerance, withdrawal (rebound anxiety, insomnia, seizures), sedation, cognitive impairment, falls. (2) Antipsychotics—extrapyramidal side effects (dystonia, parkinsonism, akathisia, tardive dyskinesia), weight gain, metabolic syndrome, hyperprolactinaemia, QT prolongation. Non-pharmacological alternatives: cognitive behavioural therapy, relaxation techniques, and mindfulness.

Transdermal

- A route of drug administration delivering drug through intact skin into the systemic circulation via a patch or gel, bypassing first-pass metabolism and providing steady plasma concentrations over hours to days. Examples: nitroglycerin, fentanyl, nicotine, estrogen, clonidine, rotigotine. Absorption depends on drug lipophilicity, molecular size, skin site, and occlusion. Advantages: sustained release, improved adherence, avoidance of GI irritation. Risks: skin irritation, dosing limitations (potent, lipophilic drugs only), and accidental exposure (fentanyl patch).

Triamcinolone

- A synthetic corticosteroid with potent anti-inflammatory and immunosuppressive properties. Triamcinolone is intermediate-acting (duration 12–36 hours) and is available in multiple formulations: topical (cream, ointment, lotion—0.025–0.5% for dermatological conditions: eczema, psoriasis, contact dermatitis, lichen planus); intralesional (Kenalog—intra-articular injection for inflammatory arthritis—rheumatoid, psoriatic, gout; intralesional for hypertrophic scars, keloids, alopecia areata, cystic acne); inhaled (for asthma—delivers active drug to the lungs, but less commonly used now); and intramuscular (for systemic inflammatory conditions—not recommended due to adrenal suppression risk). Triamcinolone acetonide is the most widely used formulation. Side effects: depend on dose, route, and duration. Topical: skin atrophy, striae, telangiectasias, perioral dermatitis, and systemic absorption with prolonged use over large areas. Intralesional: post-injection flare, infection, tendon rupture (avoid direct injection into tendons), fat atrophy, and depigmentation. Systemic: adrenal suppression, osteoporosis, hyperglycaemia, hypertension, immunosuppression, weight gain, Cushing syndrome, and growth suppression in children.

Trimethoprim

- A folate antagonist antibiotic that inhibits bacterial dihydrofolate reductase, blocking tetrahydrofolate synthesis—bacteriostatic. Usually combined with sulfamethoxazole (co-trimoxazole) for synergistic sequential blockade of folate synthesis. Used for UTIs, PCP, toxoplasmosis, and shigellosis. Adverse effects: hyperkalemia, megaloblastic anemia (folate), rash, and GI upset; caution in renal impairment, folate deficiency, and with drugs causing hyperkalemia.

Trimethoprim-sulfamethoxazole

- A fixed-dose combination of trimethoprim and sulfamethoxazole that synergistically inhibits folate synthesis. TMP-SMX is indicated for urinary tract infections, *Pneumocystis jirovecii* pneumonia, and community-acquired pneumonia. The combination is bactericidal against many gram-positive and gram-negative organisms. Common adverse effects include hypersensitivity reactions, bone marrow suppression, and hyperkalemia. The drug is contraindicated in patients with folate deficiency and in late pregnancy; resistance is increasingly common among many bacterial species, particularly *E. coli*, and susceptibility testing is essential before prescribing TMP-SMX for urinary tract infections.

Triptan

- A class of medications used for acute migraine treatment, acting as 5-HT_{1B}/1D receptor agonists. 5-HT_{1B} receptors are located on cranial blood vessels; activation causes vasoconstriction of dilated meningeal arteries. 5-HT_{1D} receptors are located on presynaptic trigeminal nerve terminals; activation inhibits the release of vasoactive neuropeptides (calcitonin gene-related peptide, substance P), reducing neurogenic inflammation and pain transmission. Available triptans: sumatriptan (first, available as oral, subcutaneous, intranasal, and rectal), rizatriptan, zolmitriptan, naratriptan, eletriptan, almotriptan, and frovatriptan. Contraindications: ischemic heart disease, Prinzmetal angina, uncontrolled hypertension, hemiplegic migraine, and basilar migraine. Adverse effects: chest tightness/pressure (may mimic cardiac ischemia but typically benign), paresthesias, dizziness, and injection site reactions. Triptans should be taken early in the migraine attack for optimal efficacy.

Tyrosine Kinase Inhibitor

- A class of targeted cancer therapy drugs that inhibit tyrosine kinases, enzymes that phosphorylate tyrosine residues on proteins and activate signaling pathways involved in cell growth, proliferation, differentiation, and survival. Tyrosine kinase mutations or overexpression drive many cancers. TKIs are small molecules (oral) or monoclonal antibodies (IV). Examples: imatinib — BCR-ABL inhibitor for chronic myeloid leukemia (first TKI approved, revolutionized CML treatment); erlotinib and gefitinib

— EGFR inhibitors for non-small cell lung cancer with EGFR mutations; sorafenib and sunitinib — multi-kinase inhibitors (VEGFR, PDGFR, RAF) for renal cell carcinoma and hepatocellular carcinoma; osimertinib — third-generation EGFR TKI for T790M mutant NSCLC. Adverse effects vary by target: hypertension (VEGF inhibitors), rash and diarrhea (EGFR inhibitors), fatigue, and hand-foot skin reaction.

Unguentum

– See Ointment.

Valacyclovir

– An oral prodrug of acyclovir with greatly improved bioavailability (approximately 3-5x acyclovir). Active against HSV-1, HSV-2, and VZV. Used for genital and oral herpes (treatment and suppression), herpes zoster, and varicella. Dosing convenience (1 g TID for shingles vs acyclovir 800 mg five times daily). Adverse effects: nausea, headache, and dose-related neurotoxicity in renal impairment/HIV (confusion, hallucinations). Requires renal dose adjustment.

Valproate (Sodium Valproate)

– Valproate (valproic acid, sodium valproate, divalproex sodium) is a broad-spectrum antiepileptic drug effective against all seizure types (generalised tonic-clonic, absence, myoclonic, and partial seizures). It is also used as a mood stabiliser in bipolar disorder (particularly for acute mania and maintenance) and for prophylaxis of migraine headaches. Mechanism: multiple actions including enhancement of GABAergic transmission (by increasing GABA synthesis via glutamic acid decarboxylase activation and inhibiting GABA transaminase), blockade of voltage-gated sodium channels, and inhibition of T-type calcium channels. Pharmacokinetics: well absorbed orally, highly protein-bound (90%), extensively metabolized in the liver (glucuronidation, beta-oxidation, and CYP-mediated oxidation), half-life 9-16 hours. Adverse effects: dose-related (tremor, weight gain, alopecia, sedation, thrombocytopenia, elevated liver enzymes), idiosyncratic (hepatotoxicity — highest risk in children under 2 years on polytherapy, pancreatitis), teratogenic (neural tube defects, spina bifida — absolute contraindication in pregnancy unless no alternative, requiring high-dose folic acid supplementation), and polycystic ovary syndrome with long-term use. Monitoring:

serum levels (therapeutic range 50-100 mcg/mL), LFTs, CBC, and pregnancy testing. Drug interactions: inhibits CYP2C9, displaces protein-bound drugs (phenytoin).

Valsartan

– An angiotensin II receptor blocker (ARB) used for hypertension, heart failure (including post-MI), and diabetic nephropathy. Blocks AT1 receptors, reducing vasoconstriction and aldosterone release; no ACE cough. Adverse effects: dizziness, hyperkalemia, hypotension, renal impairment, and teratogenicity (contraindicated in pregnancy). Historically recalled over trace nitrosamine impurities. Available with sacubitril in a combined heart failure product (sacubitril/valsartan).

Vancomycin

– A glycopeptide antibiotic that inhibits cell wall synthesis by binding to D-Ala-D-Ala terminal of peptidoglycan precursors. Vancomycin is the drug of choice for MRSA infections and serious gram-positive infections. It is indicated for bacteremia, endocarditis, pneumonia, and complicated skin infections. The drug is administered intravenously every 8-12 hours, with dosing guided by therapeutic drug monitoring to achieve target AUC/MIC ratios. Common adverse effects include nephrotoxicity, ototoxicity, and red man syndrome (an infusion-related reaction caused by histamine release), and therapeutic drug monitoring of trough concentrations is recommended to optimise efficacy and minimise the risk of nephrotoxicity and ototoxicity; vancomycin dosing is based on actual body weight and requires adjustment for impaired renal function.

Vancomycin-resistant Enterococcus

– Enterococci resistant to vancomycin through acquisition of vanA or vanB gene clusters encoding altered cell wall precursors. VRE is a significant cause of healthcare-associated infections, particularly in immunocompromised patients. Treatment options include linezolid, daptomycin, and quinupristin-dalfopristin (for *E. faecium* only). VRE infections are associated with increased mortality and healthcare costs. Infection prevention strategies include hand hygiene, contact precautions, and environmental decontamination, and antimicrobial stew-

ardship to preserve the effectiveness of remaining active agents.

Vaughan Williams Classification

– The Vaughan Williams classification categorizes antiarrhythmic drugs into four classes based on their primary mechanism of action. Class I agents block sodium channels and slow conduction velocity, further subdivided into IA with moderate sodium channel blockade and action potential prolongation including quinidine and procainamide, IB with fast sodium channel binding and action potential shortening including lidocaine and mexiletine, and IC with slow sodium channel binding and minimal effect on action potential duration; class II agents are beta-blockers that reduce sympathetic activity and slow AV conduction; class III agents block potassium channels, prolonging repolarisation; and class IV agents are calcium channel blockers that slow AV conduction; while clinically useful, the classification has limitations as many drugs have multiple mechanisms of action and it does not account for all clinically important antiarrhythmic drugs.

Venlafaxine

– A serotonin-norepinephrine reuptake inhibitor (SNRI) used for major depressive disorder, generalized anxiety disorder, panic disorder, social anxiety disorder, and (at higher doses) neuropathic pain. Norepinephrine effects increase with dose. Extended-release once-daily. Adverse effects: nausea, hypertension (dose-related—monitor BP), insomnia, diaphoresis, sexual dysfunction, and discontinuation syndrome (notorious—taper slowly). Rare QT prolongation; caution with CYP2D6 inhibitors. Duloxetine is a related SNRI.

Verapamil

– A phenylalkylamine calcium channel blocker used as an antiarrhythmic (class IV) and antihypertensive agent. Verapamil blocks L-type calcium channels in cardiac myocytes and vascular smooth muscle, with greater selectivity for the heart (particularly the sinoatrial node and atrioventricular node) than dihydropyridine CCBs (nifedipine, amlodipine), making it effective for supraventricular tachycardias (AV nodal reentrant tachycardia, atrial fibrillation with rapid ventricular response), angina (stable and vasospastic/Prinzmetal), and hypertension. It causes negative chronotropy (slows SA node rate), nega-

tive dromotropy (slows AV conduction — prolonged PR interval), and negative inotropy (reduced contractility), contraindicating its use in heart failure with reduced ejection fraction, sick sinus syndrome, and second/third-degree AV block (without a pacemaker). Adverse effects: constipation (most common), hypotension, bradycardia, edema, headache, and gingival hyperplasia. Drug interactions: verapamil is a CYP3A4 substrate and inhibitor, contraindicating concomitant use with strong CYP3A4 inducers; also increases levels of digoxin, statins, and immunosuppressants.

Viagra (Sildenafil)

– Sildenafil is a phosphodiesterase type 5 (PDE5) inhibitor used primarily for erectile dysfunction (ED) and pulmonary arterial hypertension (PAH, as Revatio). Mechanism: PDE5 degrades cGMP in penile corpus cavernosum smooth muscle; sildenafil inhibits PDE5, increasing cGMP levels and enhancing nitric oxide (NO)-mediated vasodilation and smooth muscle relaxation, improving penile blood flow during sexual stimulation. For PAH: sildenafil dilates pulmonary vasculature, reducing pulmonary vascular resistance. Pharmacokinetics: oral, onset within 30-60 minutes, duration 4-6 hours, metabolized by CYP3A4. Adverse effects: headache, flushing, dyspepsia, nasal congestion, visual disturbances (blue tinged vision/cyanopsia due to PDE6 inhibition in retinal photoreceptors), and myalgia. Serious: priapism (erection >4 hours — medical emergency), hypotension (especially when combined with nitrates — absolute contraindication due to risk of severe hypotension and syncope), and non-arteritic anterior ischemic optic neuropathy (NAION, rare). Contraindications: concurrent nitrate therapy, severe hepatic impairment, severe hypotension, and recent stroke or MI.

Vibrio vulnificus infections

– Infections caused by *Vibrio vulnificus*, a gram-negative bacterium found in warm seawater and raw seafood. *V. vulnificus* can cause wound infections, septicemia, and gastroenteritis. The most severe form is necrotizing fasciitis and primary septicemia, which can be fatal. Risk factors include liver disease, immunocompromise, and iron overload states. Treatment requires doxycycline combined with a third-generation cephalosporin. Early wound care

and antibiotic therapy are essential. The organism has a high case-fatality rate, and prevention involves avoiding consumption of raw or undercooked seafood, particularly in patients with liver disease or immunocompromising conditions.

Volume of Distribution

- A theoretical pharmacokinetic parameter that relates the total amount of drug in the body to the plasma concentration, calculated as V_d equals amount of drug in the body divided by plasma concentration. It represents the apparent volume into which a drug distributes and is not a true anatomical volume. A small volume of distribution, such as 3 to 5 liters, indicates that the drug remains primarily in the plasma and does not extensively distribute into tissues, as seen with drugs that are highly protein-bound and extensively distributed to tissues; understanding volume of distribution is critical for calculating loading doses, interpreting drug concentrations, and predicting the extent of drug distribution to the site of action.

Voriconazole

- A triazole antifungal agent used in the treatment of invasive aspergillosis, candidemia, and other serious fungal infections. Voriconazole inhibits the fungal cytochrome P450 enzyme lanosterol 14- α demethylase, preventing ergosterol synthesis and disrupting fungal cell membrane integrity. The drug has broad-spectrum activity against *Aspergillus*, *Candida*, *Cryptococcus*, and other fungi. A key advantage of voriconazole over itraconazole is its excellent oral bioavailability of approximately 96% and has a long half-life allowing for twice-daily oral dosing after an initial intravenous loading regimen; voriconazole is associated with visual disturbances (photopsia, altered color perception), hepatotoxicity, and QT prolongation, and requires therapeutic drug monitoring due to non-linear pharmacokinetics and significant inter-individual variability in plasma concentrations; drug interactions are numerous due to CYP2C19 and CYP3A4 inhibition.

Warfarin

- A vitamin K antagonist that inhibits the enzyme vitamin K epoxide reductase, preventing the recycling of vitamin K and thereby blocking the gamma-carboxylation of clotting factors II, VII, IX, and X as well as proteins C and S. This post-translational

modification is essential for the calcium-binding activity of these factors. Warfarin has a slow onset of action, requiring several days to achieve therapeutic anticoagulation, as existing clotting factors must be cleared before the effect is fully established; warfarin has a narrow therapeutic index and requires regular INR monitoring to maintain the INR within the target range of 2-3 for most indications, with dose adjustments based on numerous factors including dietary vitamin K intake, drug interactions, and genetic polymorphisms in CYP2C9 and VKORC1 that affect warfarin metabolism and pharmacodynamics; bleeding is the most important adverse effect and requires prompt reversal with vitamin K, fresh frozen plasma, or prothrombin complex concentrate depending on the severity of bleeding and the INR.

Weight Loss Medications

- Pharmacologic agents approved for the treatment of obesity when used in conjunction with lifestyle modifications. These medications work through various mechanisms, including appetite suppression through GLP-1 receptor agonists such as semaglutide, inhibition of fat absorption with orlistat, or combination therapies targeting multiple neuropeptide pathways. They are indicated for individuals with a body mass index of 30 or higher, or 27 or higher with obesity-related comorbidities, and require ongoing medical supervision due to potential side effects and the need for monitoring.

Withdrawal Symptoms

- See Withdrawal Syndrome. used primarily for erectile dysfunction (ED) and pulmonary arterial hypertension (PAH, as Revatio). Mechanism: PDE5 degrades cGMP in penile corpus cavernosum smooth muscle; sildenafil inhibits PDE5, increasing cGMP levels and enhancing nitric oxide (NO)-mediated vasodilation and smooth muscle relaxation, improving penile blood flow during sexual stimulation. For PAH: sildenafil dilates pulmonary vasculature, reducing pulmonary vascular resistance. Pharmacokinetics: oral, onset within 30-60 minutes, duration 4-6 hours, metabolized by CYP3A4. Adverse effects: headache, flushing, dyspepsia, nasal congestion, visual disturbances (blue tinged vision/cyanopsia due to PDE6 inhibition in retinal photoreceptors), and myalgia. Serious: priapism (erection >4 hours —

medical emergency), hypotension (especially when combined with nitrates — absolute contraindication due to risk of severe hypotension and syncope), and non-arteritic anterior ischemic optic neuropathy (NAION, rare). Contraindications: concurrent nitrate therapy, severe hepatic impairment, severe hypotension, and recent stroke or MI.

Withdrawal Syndrome

– A predictable set of signs and symptoms that occur when a drug is discontinued or the dose is reduced after chronic use, reflecting the physiological rebound from drug adaptation. Specific withdrawal syndromes: Opioid withdrawal (not life-threatening but intensely uncomfortable): yawning, lacrimation, rhinorrhea, piloerection (cold turkey), mydriasis, abdominal cramps, diarrhea, nausea, vomiting, muscle aches, and drug craving. Alcohol withdrawal (potentially life-threatening): tremor, anxiety, autonomic hyperactivity (tachycardia, hypertension, diaphoresis), insomnia, seizures (6-48 hours after last drink), and delirium tremens (48-96 hours later: agitation, hallucinations, autonomic instability, and altered mental status). Benzodiazepine withdrawal: anxiety, insomnia, tremor, palpitations, and seizures (may be delayed with long-acting agents). SSRI discontinuation syndrome: dizziness, paresthesias, nausea, headache, and irritability (not life-threatening). Management involves gradual tapering (detoxification), supportive care, and pharmacotherapy (benzodiazepines for alcohol withdrawal, methadone/buprenorphine for opioid withdrawal).

Xanthine Oxidase Inhibitor

– A class of medications that inhibit xanthine oxidase, the enzyme that catalyzes the final steps of purine metabolism: hypoxanthine to xanthine and xanthine to uric acid. By inhibiting this enzyme, XOIs reduce uric acid production and lower serum uric acid levels, used for management of chronic gout and tumor lysis syndrome. Allopurinol (first-line, 40+ years of clinical use): a purine analog that acts as a competitive substrate and is metabolized to oxypurinol (active metabolite with a long half-life of 18-30 hours). Dosing starts at 100 mg daily, titrated to target serum urate <6 mg/dL. Febuxostat: a non-purine selective XOI, metabolized in the liver, dose 40-80 mg daily, preferred in

patients with allopurinol hypersensitivity or renal impairment. Cardiotoxicity warning: febuxostat has a higher risk of cardiovascular death compared to allopurinol in patients with preexisting CVD. Adverse effects: allopurinol hypersensitivity syndrome (DRESS, Stevens-Johnson syndrome, most severe, risk increased in HLA-B*5801 carriers, especially Han Chinese and African Americans), rash, and GI upset.

Zalcitabine

– A nucleoside reverse transcriptase inhibitor (NRTI) that was previously used in combination antiretroviral therapy for HIV-1 infection but is now rarely used due to the availability of more effective and better-tolerated agents. Zalcitabine is a cytidine analogue that inhibits viral reverse transcriptase by competing with deoxycytidine triphosphate and causing DNA chain termination. The drug has a relatively short half-life of approximately 1-2 hours, requiring dosing three times daily. The primary adverse effect was peripheral neuropathy, which occurred in a significant proportion of patients and was the dose-limiting toxicity; pancreatitis and lactic acidosis were also reported. Zalcitabine was withdrawn from the market in 2006 due to limited clinical use and the availability of safer, more effective NRTIs.

Zidovudine (AZT)

– Zidovudine (azidothymidine, AZT, ZDV) is a nucleoside analogue reverse transcriptase inhibitor (NRTI), the first antiretroviral drug approved for the treatment of HIV infection (FDA approval 1987). Mechanism: zidovudine is a thymidine analogue that is phosphorylated intracellularly to zidovudine triphosphate by cellular kinases. Zidovudine triphosphate competes with endogenous thymidine triphosphate for incorporation into the growing viral DNA chain by HIV-1 reverse transcriptase. Because zidovudine lacks the 3'-hydroxyl group needed for further chain elongation, its incorporation results in premature termination of the viral DNA chain. Zidovudine has a higher affinity for HIV-1 RT than for human DNA polymerases (particularly DNA polymerase gamma, the mitochondrial enzyme), which accounts for its relative selectivity for viral inhibition. The historical landmark ACTG 019 trial (1989) showed that zidovudine monotherapy delayed disease progression in asymptomatic HIV-infected

patients. Zidovudine was the first drug shown to reduce maternal-fetal HIV transmission (ACTG 076, 1994: zidovudine given antepartum and intrapartum to the mother and then for 6 weeks to the neonate reduced transmission by 67%). Combination therapy (HAART, highly active antiretroviral therapy) replaced monotherapy in 1996 due to rapid development of resistance. Current use: zidovudine is still used in fixed-dose combinations (Combivir = zidovudine + lamivudine) and in resource-limited settings, and for prevention of mother-to-child transmission. Resistance: mutations at codons 41, 67, 70, 210, 215, and 219 of HIV-1 RT (thymidine analogue mutations, TAMs) confer zidovudine resistance. TAMs are selected by zidovudine and stavudine and confer cross-resistance to all NRTIs. Adverse effects: bone marrow suppression (macrocytic anemia, neutropenia — the dose-limiting toxicity, more common with advanced HIV, monitored by serial CBC), myopathy (mitochondrial toxicity due to inhibition of DNA polymerase gamma, causing skeletal muscle weakness and wasting, elevated CK, myalgia, and histologic findings of ragged red fibers on muscle biopsy), lactic acidosis and hepatic steatosis (mitochondrial toxicity, hepatic steatosis and severe hepatomegaly with lactic acidosis, a rare but potentially fatal complication), headache, nausea, vomiting, and skin rash. Zidovudine should be avoided in patients with low baseline hemoglobin (<9 g/dL) or neutrophil count (<750 cells/microlitre), the enzyme that catalyzes the final steps of purine metabolism: hypoxanthine to xanthine and xanthine to uric acid. By inhibiting this enzyme, XOIs reduce uric acid production and lower serum uric acid levels, used for management of chronic gout and tumor lysis syndrome. Allopurinol (first-line, 40+ years of clinical use): a purine analog that acts as a competitive substrate and is metabolized to oxypurinol (active metabolite with a long half-life of 18-30 hours). Dosing starts at 100 mg daily, titrated to target serum urate <6 mg/dL. Febuxostat: a non-purine selective XOI, metabolized in the liver, dose 40-80 mg daily, preferred in patients with allopurinol hypersensitivity or renal impairment. Cardiotoxicity warning: febuxostat has a higher risk of cardiovascular death compared to allopurinol in patients with preexisting CVD. Adverse effects: allopurinol hypersensitivity syndrome

(DRESS, Stevens-Johnson syndrome, most severe, risk increased in HLA-B*5801 carriers, especially Han Chinese and African Americans), rash, and GI upset.

Zolpidem

– A non-benzodiazepine hypnotic (Z-drug) acting on GABA-A alpha-1 subunits, used for short-term treatment of insomnia (sleep-onset). Rapid onset—take immediately before bed; duration 6-8 hours. Adverse effects: somnolence, dizziness, complex sleep-related behaviors (sleepwalking, sleep-driving—black-box warning), anterograde amnesia, falls (elderly), and dependence with long-term use. Lower dose in women and the elderly (recommended 5 mg). Alternatives: eszopiclone, zaleplon, ramelteon.

Chapter 32

Physiology

Acetylcholine

– A major neurotransmitter in both the central and peripheral nervous systems. In the peripheral nervous system, it is released at the neuromuscular junction (nicotinic receptors) to excite skeletal muscle, at all autonomic ganglia (nicotinic receptors), and at parasympathetic postganglionic terminals (muscarinic receptors). In the CNS, acetylcholine modulates arousal, attention, learning, and memory, and its degeneration in the basal forebrain contributes to Alzheimer disease. Synthesized from choline and acetyl-CoA by choline acetyltransferase; degraded rapidly by acetylcholinesterase. Anticholinesterases (neostigmine, physostigmine) prolong its action; botulinum toxin blocks its release.

Acid Base Balance

– The physiological regulation of hydrogen ion concentration in body fluids, maintaining arterial pH between 7.35 and 7.45. Three lines of defense: chemical buffers (bicarbonate, proteins, phosphate) act instantaneously; the respiratory system adjusts PaCO₂ within minutes via CO₂ exhalation; and the kidneys adjust bicarbonate reabsorption and H⁺ excretion over hours to days. Disturbances are classified as acidosis or alkalosis and by etiology as metabolic (primary bicarbonate abnormality) or respiratory (primary PaCO₂ abnormality). Compensatory responses attempt to restore pH toward normal. Arterial blood gas analysis is essential for evaluation.

Action Potential

– A rapid, all-or-nothing depolarization of the cell membrane that propagates along excitable membranes (neurons, muscle, some endocrine cells). Phases: resting potential (–70 mV in neurons, maintained by the Na⁺/K⁺ ATPase and potassium

leak channels), threshold (typically –55 mV) opens voltage-gated sodium channels causing rapid depolarization, followed by sodium channel inactivation and opening of voltage-gated potassium channels producing repolarization and a brief hyperpolarization (afterhyperpolarization). Refractory periods (absolute then relative) ensure one-way propagation and limit firing frequency. Conduction velocity is increased by myelination (saltatory conduction) and larger axon diameter.

Active Transport

– Movement of substances across cell membranes against their concentration gradient, requiring energy input, typically from ATP hydrolysis. Primary active transport directly uses ATP: the Na⁺/K⁺ ATPase pumps 3 Na⁺ out and 2 K⁺ in per ATP, maintaining the electrochemical gradient essential for neuronal signaling, cell volume regulation, and secondary active transport. Other examples include the Ca²⁺ ATPase, H⁺/K⁺ ATPase (gastric acid secretion), and ABC transporters. Secondary active transport uses the Na⁺ gradient established by the Na⁺/K⁺ ATPase to cotransport or countertransport other solutes (e.g., SGLT1 for glucose and amino acid cotransport in the intestine, Na⁺/Ca²⁺ exchanger in cardiac muscle).

Aldosterone

– A mineralocorticoid hormone produced by the zona glomerulosa of the adrenal cortex, the final effector of the renin-angiotensin-aldosterone system (RAAS). Aldosterone acts on principal cells of the collecting duct, increasing ENaC (epithelial sodium channel) expression on the apical membrane and Na⁺/K⁺ ATPase on the basolateral membrane, promoting sodium reabsorption and potassium secretion. Water follows sodium osmotically, expanding extra-

cellular fluid volume and increasing blood pressure. Aldosterone secretion is stimulated by angiotensin II, hyperkalaemia, and ACTH, and inhibited by ANP and hypokalaemia. Excessive aldosterone (Conn syndrome) causes hypertension with hypokalaemia, metabolic alkalosis, and suppressed renin.

Allele

– One of two or more alternative forms of a gene occupying the same locus on homologous chromosomes. Diploid organisms have two alleles per gene (one maternal, one paternal). Homozygous: two identical alleles; heterozygous: two different alleles. Dominant allele: expressed in heterozygote; recessive allele: expressed only in homozygote. Co-dominance: both alleles expressed (e.g., ABO blood groups). Allele frequency in populations determines genetic diversity.

Allosteric Regulation

– The regulation of enzyme activity by the binding of an effector molecule at a site other than the active site (allosteric site), causing a conformational change that alters the enzyme's activity. Allosteric enzymes typically have multiple subunits with cooperative binding kinetics (sigmoidal rather than hyperbolic velocity curves). Positive allosteric effectors (activators) shift the curve leftward (increase affinity for substrate, decrease K_m), while negative allosteric effectors (inhibitors) shift the curve rightward (decrease affinity, increase K_m). Classic examples include oxygen binding to hemoglobin (cooperative, with 2,3-BPG as a negative allosteric effector), aspartate transcarbamoylase (ATCase) in pyrimidine synthesis, and feedback inhibition in metabolic pathways.

Alveolar Ventilation

– The volume of fresh air reaching the alveoli per minute, representing the portion of minute ventilation that participates in gas exchange. Calculated as (tidal volume - dead space volume) $\times$ respiratory rate. Normal alveolar ventilation is approximately 4-5 L/min. It is the physiologically relevant determinant of arterial CO_2 and O_2 : decreased alveolar ventilation causes hypercapnia and hypoxemia, while increased alveolar ventilation produces hypocapnia. Anatomic dead space (150 mL) plus alveolar dead space (ventilated but unperfused alveoli) constitutes physiologic dead space. In health, physiologic and

anatomic dead space are nearly equal.

Amino Acid Catabolism

– The breakdown of amino acids after protein digestion, with the amino group removed and the carbon skeleton metabolized for energy or gluconeogenesis/ketogenesis. Transamination: amino groups are transferred to α -ketoglutarate, forming glutamate, by aminotransferases requiring pyridoxal phosphate (PLP, vitamin B6) as a cofactor. ALT (alanine aminotransferase) and AST (aspartate aminotransferase) are clinically important: elevated levels indicate liver damage (ALT is more liver-specific) or myocardial injury (AST). Following transamination, the α -keto acids enter gluconeogenesis or the TCA cycle, and ammonium is converted to urea in the urea cycle.

Apoptosis

– Programmed cell death, a controlled process essential for development, tissue homeostasis, and immune regulation. Two main pathways: intrinsic (mitochondrial, triggered by DNA damage, stress) and extrinsic (death receptor, e.g., Fas/TNF). Both converge on caspase cascade (initiator caspases 8/9 $\rightarrow$ effector caspases 3/7). Morphology: cell shrinkage, chromatin condensation, nuclear fragmentation, membrane blebbing, apoptotic bodies phagocytosed without inflammation. Key regulators: Bcl-2 family (pro-apoptotic BAX/BAK vs anti-apoptotic Bcl-2/Bcl-xL), IAPs, p53. Dysregulation: cancer (evolution), autoimmune disease, neurodegeneration (excess).

Atrial Natriuretic Peptide

– A peptide hormone secreted by atrial myocytes in response to atrial stretch from volume expansion. ANP promotes natriuresis and diuresis by increasing glomerular filtration rate, inhibiting sodium reabsorption in the collecting ducts, and reducing renin and aldosterone secretion. It also relaxes vascular smooth muscle, reducing blood pressure and afterload. Actions oppose the renin-angiotensin-aldosterone system. B-type natriuretic peptide (BNP) from ventricular myocytes is released with ventricular wall stress and is a widely used biomarker for heart failure diagnosis and prognosis.

Autophagy

– Cellular self-degradation process delivering cytoplasmic components to lysosomes for recycling.

Macroautophagy: phagophore forms, expands to autophagosome (LC3-II on membrane), fuses with lysosome (autolysosome) for degradation. Selective autophagy: mitophagy (damaged mitochondria), xenophagy (pathogens), aggrephagy (protein aggregates). Regulated by mTOR (inhibits) and AMPK (activates). Functions: nutrient recycling during starvation, quality control, development, immunity. Dysregulation: cancer, neurodegeneration, infection, aging.

Baroreceptor Reflex

- The rapid neural mechanism for short-term blood pressure regulation, involving baroreceptors (mechanoreceptors) in the carotid sinus (innervated by CN IX) and aortic arch (innervated by CN X). When blood pressure rises, baroreceptors increase their firing rate, signaling the cardiovascular center in the medulla. The response: increased parasympathetic (vagal) output to the heart (decreasing HR) and decreased sympathetic output (decreasing HR, contractility, and peripheral resistance), lowering blood pressure towards normal. The reflex is essential for maintaining blood pressure stability during postural changes and blood volume fluctuations.

Basal Metabolic Rate (BMR)

- The minimum energy expenditure required to maintain vital physiological functions at rest in a thermoneutral environment, measured after 12 hours of fasting and 8 hours of sleep. BMR accounts for approximately 60–75% of total daily energy expenditure in sedentary individuals. It is influenced by body composition (lean mass is the primary determinant), age (declines 1–2% per decade after age 20), sex (5–10% higher in males), thyroid status, and genetics. BMR is estimated using predictive equations (Harris-Benedict, Mifflin-St Jeor) or measured by indirect calorimetry. Clinical relevance: assessing nutritional needs, managing obesity, and diagnosing hyper- or hypometabolic states.

Bile Salt Emulsification

- Bile salts (derived from cholesterol in the liver) are amphipathic molecules with hydrophobic and hydrophilic regions that act as biological detergents, emulsifying dietary lipids into smaller droplets (micelles). This increases the surface area of lipid substrate available for pancreatic lipase action. Bile salts form mixed micelles with phospholipids, cholesterol,

and fat-soluble vitamins (A, D, E, K), facilitating their transport across the unstirred water layer to the enterocyte brush border for absorption. Bile salts are reabsorbed in the terminal ileum via the apical sodium-dependent bile acid transporter (ASBT) and returned to the liver through the enterohepatic circulation, recycling 6–10 times daily.

Blood Coagulation

- The cascade of enzymatic reactions converting circulating fibrinogen into an insoluble fibrin clot. The extrinsic pathway is initiated by tissue factor (factor III) released from damaged vessels; the intrinsic pathway is initiated by contact activation (factor XII); both converge on a common pathway: factor X activation, prothrombin (factor II) to thrombin, and thrombin converting fibrinogen to fibrin, which is cross-linked by factor XIII. Coagulation requires vitamin K-dependent factors (II, VII, IX, X) and calcium. Regulated by antithrombin, protein C/protein S, and tissue factor pathway inhibitor. Tested clinically by PT (extrinsic/common) and aPTT (intrinsic/common).

Blood Flow

- The volume of blood passing through a vessel, organ, or the systemic circulation per unit time, typically expressed in mL/min. Governed by the hemodynamic equivalent of Ohm's law: flow = pressure gradient / resistance. Total cardiac output (5 L/min at rest) equals systemic blood flow. Local blood flow is regulated by autoregulation (myogenic, metabolic), endothelial factors (nitric oxide, endothelin), and sympathetic innervation. Flow may be laminar or turbulent (Reynolds number >2000). Organs with high flow per gram (kidneys, heart, brain) are most vulnerable to reduced perfusion.

Blood Pressure

- The force exerted by blood against arterial walls, measured in millimeters of mercury (mmHg). Systolic pressure (peak during ventricular ejection, normally approximately 120 mmHg) and diastolic pressure (minimum during ventricular relaxation, normally approximately 80 mmHg). Mean arterial pressure (MAP) is approximately diastolic + one-third pulse pressure (approximately 93 mmHg). MAP is the average pressure driving blood through the systemic circulation. Blood

pressure depends on cardiac output and systemic vascular resistance ($MAP = CO \times SVR$). It is regulated by short-term mechanisms (baroreceptor reflex, chemoreceptor reflex, and hormonal responses: ADH, adrenaline) and long-term mechanisms (renin-angiotensin-aldosterone system and renal body fluid regulation by the kidneys).

Blood Viscosity

- The internal friction of blood that resists flow, determined primarily by hematocrit (red cell concentration), with smaller contributions from plasma proteins and temperature. Normal whole-blood viscosity is approximately 3-4 times that of water. Increased viscosity (polycythemia, hyperproteinemia, dehydration) raises vascular resistance and cardiac workload, while reduced viscosity (anemia, low protein) lowers resistance. Viscosity has greatest effect in small vessels and at low flow rates; at the capillary level, viscosity falls due to the Fahraeus-Lindqvist effect.

Body Temperature

- See Temperature (Body Temperature).

Bohr Effect

- The decrease in hemoglobin's oxygen affinity (right shift of the dissociation curve) caused by decreased pH (increased H^+) and increased PCO_2 . In metabolically active tissues, CO_2 production and lactic acid accumulation lower the local pH, causing hemoglobin to release more oxygen precisely where it is needed most. The mechanism involves protonation of hemoglobin histidine residues, which stabilize the T (tense, low-affinity) state. The Bohr effect is quantified as approximately 0.48 pH units per $\log_{10} PCO_2$ change and is clinically significant in conditions that alter acid-base status, enhancing oxygen delivery in exercising muscle and hypoxic tissues.

Calciferol

- See Vitamin D: Calcitriol.

Calorie

- A unit of energy measurement used in nutrition to quantify the energy content of foods and energy expenditure of the body. One kilocalorie (kcal, commonly called a Calorie with capital C) equals the energy required to raise 1 kilogram of water by 1 degree Celsius. The body derives energy from macronutrients: carbohydrates and proteins pro-

vide 4 kcal/g, fats provide 9 kcal/g, and alcohol provides 7 kcal/g. Total daily energy expenditure comprises basal metabolic rate (60–75%), thermic effect of food (10%), and physical activity (15–30%). Caloric balance determines body weight: excess calories are stored as fat; caloric deficit leads to weight loss.

Capillary

- The smallest blood vessel in the body, forming a microscopic network (capillary bed) that connects arterioles to venules. Capillary walls consist of a single layer of endothelial cells (frequently fenestrated) and a basement membrane, allowing exchange of oxygen, carbon dioxide, nutrients, wastes, and other substances between blood and interstitial fluid. Types: continuous (most common, in muscle, skin, lung, CNS–blood-brain barrier), fenestrated (kidney, intestine, endocrine glands, with pores for rapid filtration), and sinusoidal/discontinuous (liver, bone marrow, spleen with large gaps allowing passage of cells and large molecules). Starling forces—hydrostatic and oncotic pressures—govern fluid movement across capillary walls.

Carbon Dioxide Transport

- The movement of CO_2 from tissues to lungs. CO_2 is carried in blood in three forms: dissolved (approximately 10 percent), bound to hemoglobin as carbamino compounds (approximately 20 percent), and as bicarbonate (approximately 70 percent). In red cells, carbonic anhydrase converts CO_2 and water to carbonic acid, which dissociates to H^+ (buffered by hemoglobin) and bicarbonate, which exits via the chloride shift (Hamburger phenomenon). In the lungs the reactions reverse, and CO_2 diffuses into the alveoli. The Haldane effect: deoxygenated hemoglobin binds CO_2 and H^+ more readily, enhancing CO_2 uptake in tissues.

Cardiac Cycle

- The sequence of mechanical and electrical events occurring during one heartbeat, lasting approximately 0.8 seconds at 75 bpm. The cycle has two main phases: systole (ventricular contraction and ejection) and diastole (ventricular relaxation and filling). Isovolumetric contraction: all valves closed, ventricles contract, pressure rises rapidly. Ventricular ejection: aortic/pulmonary valves open, blood is ejected (stroke volume approximately 70 mL). Iso-

volumetric relaxation: all valves closed, ventricles relax, pressure falls rapidly below atrial pressure. Ventricular filling (diastole): AV valves open, passive filling occurs (80 percent), followed by atrial contraction (20 percent, the "atrial kick"). Heart sounds: S1 (AV valve closure), S2 (semilunar valve closure), S3 (rapid ventricular filling, normal in children, abnormal in adults indicating heart failure), S4 (atrial contraction against a stiff ventricle).

Cardiac Output

– The volume of blood pumped by each ventricle per minute, calculated as heart rate multiplied by stroke volume ($CO = HR \times SV$). Normal resting CO is approximately 5 liters per minute (70 mL stroke volume $\times$ 70 bpm). Stroke volume depends on preload (Frank-Starling), afterload (resistance to ejection), and contractility (inotropic state). Heart rate is modulated by the autonomic nervous system: sympathetic stimulation increases HR (positive chronotropy) via norepinephrine acting on beta-1 receptors; parasympathetic (vagal) stimulation decreases HR (negative chronotropy) via acetylcholine acting on M2 receptors. Cardiac output increases during exercise up to 4-5 times resting levels through combined increases in HR and stroke volume, with trained athletes achieving higher maximal CO.

Cell

– The fundamental structural and functional unit of all living organisms. Human cells are eukaryotic, characterized by a nucleus containing DNA and membrane-bound organelles. Major components: cell membrane (phospholipid bilayer with embedded proteins, regulates transport and signaling), cytoplasm (cytosol + organelles), nucleus (chromosomes, nucleolus), mitochondria (ATP production through oxidative phosphorylation), endoplasmic reticulum (protein/lipid synthesis), Golgi apparatus (modification and sorting of proteins), lysosomes (intracellular digestion), peroxisomes (fatty acid oxidation), and cytoskeleton (microfilaments, intermediate filaments, microtubules—maintains shape and enables movement). Cells differentiate into 200 specialized types with distinct functions (neurons, myocytes, hepatocytes, etc.). Cell division occurs via mitosis (somatic cells) and meiosis (gametes). Cell death occurs by apoptosis (programmed) or necrosis (pathologic).

Chemoreceptor

– A sensory receptor that responds to changes in blood or CSF chemistry, involved in respiratory and cardiovascular regulation. Peripheral chemoreceptors (carotid bodies at the carotid bifurcation, innervated by CN IX; aortic bodies by CN X) detect arterial hypoxemia ($PaO_2 < 60$ mmHg), hypercapnia, and acidemia, and stimulate increased ventilation and sympathetic activity. Central chemoreceptors in the ventrolateral medulla respond primarily to CO_2/H^+ in the CSF. Peripheral chemoreceptors are essential for the hypoxic ventilatory response and become dominant ventilatory drivers in chronic CO_2 retainers (e.g., COPD).

Cholecystokinin

– CCK is a peptide hormone produced by I-cells in the duodenal and jejunal mucosa in response to fatty acids (long-chain fatty acids are the most potent stimuli) and amino acids in the chyme. CCK's primary actions: stimulates gallbladder contraction (promoting bile release for fat emulsification and absorption), stimulates pancreatic enzyme secretion (acinar cells), relaxes the sphincter of Oddi, slows gastric emptying (reducing the rate of acid delivery to the duodenum), and promotes satiety (acting on the hypothalamus via CCK-B receptors). CCK is also found in the brain as a neurotransmitter. Its secretion is inhibited by trypsin and chymotrypsin (negative feedback via trypsin-sensitive CCK-releasing factor). CCK analogues are used as diagnostic agents in gallbladder imaging.

Cholesterol Synthesis

– Occurs in all nucleated cells (primarily liver and intestine) through a complex 30+ step pathway beginning with acetyl-CoA. Key steps: three acetyl-CoA molecules condense to form HMG-CoA, which is reduced to mevalonate by HMG-CoA reductase (the rate-limiting enzyme, located in the endoplasmic reticulum). Mevalonate is converted through multiple steps to squalene, then lanosterol, then cholesterol. HMG-CoA reductase is the target of statins (competitive inhibitors), the most widely prescribed cholesterol-lowering drugs. Cholesterol is the precursor for bile salts, steroid hormones (cortisol, aldosterone, sex hormones), and vitamin D, and is a key component of cell membranes where it modulates fluidity.

Chromosome

- A single DNA molecule complexed with histone proteins (chromatin) forming a thread-like structure visible during cell division. Human somatic cells: 46 chromosomes (23 pairs: 22 autosomes + XX/XY). Each chromosome has a centromere (kinetochore attachment), telomeres (protective ends, TTAGGG repeats), and banding patterns (G-banding). Karyotype: chromosome number and appearance. Abnormalities: aneuploidy (trisomy 21, 18, 13), translocations, deletions, inversions, ring chromosomes.

Circadian Rhythm

- The approximately 24-hour endogenous biological cycle regulating sleep-wake behavior, hormone secretion, body temperature, metabolism, and other physiological processes. Generated by the suprachiasmatic nucleus of the hypothalamus, which is entrained to the environment primarily by light via the retinohypothalamic tract. Key hormones: melatonin (secreted by the pineal gland at night, promoting sleep) and cortisol (peak in early morning). Disruption from shift work, jet lag, or light exposure at night is associated with sleep disorders, metabolic dysfunction, and cardiovascular risk.

Clotting

- See Blood Coagulation.

Competitive Inhibition

- A type of enzyme inhibition where the inhibitor (I) competes with the substrate (S) for binding to the enzyme's active site. The inhibitor structurally resembles the substrate and binds reversibly to the free enzyme (E), forming an EI complex that cannot proceed to product. The apparent K_m increases (lower apparent affinity for substrate) while V_{max} remains unchanged (since the inhibition can be overcome by sufficiently high substrate concentrations). On a Lineweaver-Burk plot: lines intersect on the y-axis (same $1/V_{max}$) but have different slopes and x-intercepts (increasing apparent K_m). Competitive inhibition is reversible and clinically exploited by enzyme inhibitors such as statins (HMG-CoA reductase), ACE inhibitors, and many chemotherapeutic agents that resemble natural substrates.

Cytokine

- Small signaling proteins (5-25 kDa) mediating cell-to-cell communication in immunity, inflammation, and hematopoiesis. Families: interleukins (IL-

1 to IL-38), interferons (IFN-alpha/beta/gamma), tumor necrosis factors (TNF-alpha/beta), colony-stimulating factors (G-CSF, GM-CSF), chemokines (IL-8, MCP-1, RANTES), growth factors (TGF-beta, PDGF). Actions: autocrine, paracrine, endocrine. Receptors: cytokine receptor superfamilies (type I/II, hematopoietin, interferon, TNF receptor). Cytokine storm: hyperinflammatory syndrome (severe infection, CAR-T therapy, COVID-19). Therapeutic: monoclonal antibodies (anti-TNF, anti-IL6, anti-IL1), recombinant cytokines (filgrastim, erythropoietin).

Cytoskeleton

- Dynamic protein filament network providing structural support, cell shape, intracellular transport, and cell division. Three main components: (1) Microfilaments (actin, 7 nm): cell cortex, stress fibers, contractile ring (cytokinesis), lamellipodia/filopodia (motility), myosin interaction (muscle contraction). (2) Intermediate filaments (10 nm): mechanical strength, nuclear lamina (lamins), keratin (epithelia), vimentin (mesenchymal), neurofilaments (neurons). (3) Microtubules (25 nm, alpha/beta tubulin): mitotic spindle, cilia/flagella (axoneme: 9+2), intracellular transport (kinesin/dynein), centriole/centrosome organization. Motor proteins: dynein (minus-end directed), kinesin (plus-end directed, except kinesin-14).

Dead Space

- The volume of ventilated air that does not participate in gas exchange. Anatomic dead space: the conducting airways (nose, pharynx, trachea, bronchi, terminal bronchioles) that warm, humidify, and filter inspired air but contain no alveoli for gas exchange. Approximately 150 mL in a 70 kg adult. Physiologic dead space includes anatomic dead space plus alveolar dead space (ventilated alveoli that are not perfused, as in pulmonary embolism). Normally, physiologic dead space equals anatomic dead space (approximately 150 mL), but in pulmonary embolism, hypotension, or lung disease, alveolar dead space increases, reducing effective alveolar ventilation. The dead space fraction (VD/VT) is measured by the Bohr equation and is clinically important in assessing ventilatory efficiency.

Defecation

- The process of eliminating feces from the body.

Filling of the rectum triggers stretch receptors that initiate the defecation reflex via the sacral spinal cord (S2-S4), causing contraction of the rectal wall and relaxation of the internal anal sphincter. Voluntary control of the external anal sphincter (innervated by the pudendal nerve) permits deferral of defecation until socially appropriate. The gastrocolic reflex (mass movements stimulated by eating) and colonic peristalsis move feces into the rectum. Constipation and diarrhea reflect disturbances in motility, water absorption, or sphincter function.

Depolarization

- The change in membrane potential toward a less negative (more positive) value, typically caused by inward sodium or calcium current. In neurons, depolarization to threshold triggers an action potential. In cardiac muscle, depolarization (phase 0) is mediated by fast sodium channels in ventricular/atrial myocytes and by L-type calcium channels in the SA and AV nodes. Depolarization spreads via gap junctions. On the ECG, atrial depolarization produces the P wave and ventricular depolarization the QRS complex. Sustained depolarization inactivates voltage-gated sodium channels, contributing to the refractory period.

Diffusion

- The net movement of molecules from an area of higher concentration to lower concentration due to random thermal motion (Brownian motion). Fick's first law states that the rate of diffusion is proportional to the concentration gradient, surface area, and diffusion coefficient, and inversely proportional to membrane thickness: $J = -P \times A \times (C_1 - C_2)/d$, where J is flux, P is the permeability coefficient, A is surface area, and d is thickness. Simple diffusion occurs for small, nonpolar molecules (O_2 , CO_2 , N_2 , steroid hormones) that can dissolve in and pass through the lipid bilayer without a transporter. Factors affecting diffusion rate include: concentration gradient, temperature, molecular size, lipid solubility, membrane surface area, and membrane thickness. In biological systems, diffusion is effective over short distances (less than 100 micrometres), which is why capillaries are narrow and alveoli are thin-walled.

DNA

- Deoxyribonucleic acid, the hereditary material in

humans and most organisms. Double helix of two antiparallel strands (sugar-phosphate backbone, nitrogenous bases: A-T, G-C). Human genome: 3 billion base pairs, 20,000 protein-coding genes. Organized into 23 chromosome pairs (22 autosomes + XY/XX) in nucleus; mitochondrial DNA (mtDNA) separate. DNA replication: semi-conservative, bidirectional from origins. Mutations: point mutations, insertions, deletions, copy number variations, translocations.

DNA Double Helix

- The molecular structure of DNA described by Watson and Crick in 1953, consisting of two antiparallel polynucleotide chains wound around each other in a right-handed helix. The sugar-phosphate backbone is on the exterior; nitrogenous bases project inward. Complementary base pairing: adenine (A) pairs with thymine (T) via two hydrogen bonds; guanine (G) pairs with cytosine (C) via three hydrogen bonds. The helix has a major groove (22 Angstrom) and minor groove (12 Angstrom) where proteins interact with specific base sequences without unwinding the DNA. This structure enables information storage, replication, transcription, and repair, and is the foundation of molecular genetics.

DNA Repair Mechanisms

- Cellular processes that correct DNA damage caused by replication errors, chemicals, radiation, and reactive oxygen species. Mismatch repair (MMR): corrects base-base mismatches and insertion-deletion loops that escape proofreading during replication. MutS (MSH2/MSH6 in eukaryotes) recognizes the mismatch; MutL (MLH1/PMS2) nicks the newly synthesized strand; exonuclease removes the error; DNA polymerase and ligase fill the gap. Deficiency causes Lynch syndrome (hereditary nonpolyposis colorectal cancer, HNPCC), the most common cause of hereditary colorectal cancer. Base excision repair (BER): repairs small, non-helix-distorting lesions such as oxidised or alkylated bases. Nucleotide excision repair (NER): repairs bulky, helix-distorting lesions such as UV-induced pyrimidine dimers. Double-strand break repair: homologous recombination (HR, error-free, uses sister chromatid as template) and non-homologous end joining (NHEJ, error-prone, active in G1 phase).

DNA Replication

– The semi-conservative process by which DNA duplicates before cell division, producing two identical daughter molecules each containing one original and one new strand. Key steps: (1) initiation at origins of replication (*oriC* in bacteria, multiple origins in eukaryotes), where helicase (*DnaB* in bacteria, MCM complex in eukaryotes) unwinds the double helix; (2) single-strand binding proteins (SSB) stabilize unwound DNA; (3) primase (*DnaG*) synthesizes short RNA primers; (4) DNA polymerase III (prokaryotes) or DNA polymerase delta/epsilon (eukaryotes) extends the primer, adding nucleotides to the 3' end; (5) on the leading strand, synthesis is continuous; on the lagging strand, synthesis is discontinuous, producing Okazaki fragments; (6) RNA primers are removed by DNA polymerase I (prokaryotes) or RNase H and FEN1 (eukaryotes); (7) DNA ligase seals the nicks between fragments. Telomerase extends telomeres to prevent chromosome shortening in germ cells and stem cells.

Electrolytes

– Ions in body fluids that carry an electrical charge and are essential for normal physiologic function. Major electrolytes: sodium (Na^+ , 135–145 mEq/L, primary extracellular cation, regulates fluid balance and membrane potential), potassium (K^+ , 3.5–5.0 mEq/L, primary intracellular cation, critical for cardiac and neuromuscular function), chloride (Cl^- , 98–106 mEq/L, major extracellular anion, follows sodium), bicarbonate (HCO_3^- , 22–28 mEq/L, buffer in acid-base balance), calcium (Ca^{2+} , 8.5–10.5 mg/dL, bone structure, muscle contraction, coagulation), magnesium (Mg^{2+} , 1.7–2.2 mg/dL, enzyme cofactor, neuromuscular stability), and phosphate (PO_4^{3-} , 2.5–4.5 mg/dL, energy metabolism, bone structure). Electrolyte imbalances cause a wide range of symptoms and are routinely measured by basic metabolic panel or comprehensive metabolic panel.

Electron Transport Chain

– A series of protein complexes (I–IV) and mobile carriers embedded in the inner mitochondrial membrane that transfer electrons from NADH and FADH₂ to molecular oxygen (the final electron acceptor), generating a proton gradient used for ATP synthesis. Complex I (NADH dehydrogenase): accepts electrons from NADH, pumps 4 H⁺ across

the membrane. Complex II (succinate dehydrogenase): accepts electrons from FADH₂, does not pump protons. Coenzyme Q (ubiquinone) transfers electrons from Complexes I and II to Complex III; Complex III (cytochrome bc₁) transfers electrons to cytochrome c (pumps 4 H⁺); Complex IV (cytochrome c oxidase) transfers electrons to O₂, forming H₂O (pumps 2 H⁺). The resulting proton gradient powers ATP synthase (Complex V), which produces approximately 2.5 ATP per NADH and 1.5 ATP per FADH₂. Rotenone (Complex I inhibitor), antimycin A (Complex III), and cyanide/carbon monoxide (Complex IV) are potent toxins.

Endocytosis

– Process by which cells internalize extracellular material by engulfing it with the cell membrane, forming intracellular vesicles. Phagocytosis ("cell eating") involves engulfing large particles (>0.5 micrometers) such as bacteria or debris, forming a phagosome that fuses with lysosomes for digestion. This is performed by macrophages, neutrophils, and dendritic cells as part of innate immunity. Pinocytosis ("cell drinking") non-specifically engulfs extracellular fluid and dissolved solutes in small vesicles (approximately 0.1 micrometres). Receptor-mediated endocytosis (clathrin-dependent) is highly specific: ligands bind to surface receptors, which cluster in clathrin-coated pits, forming coated vesicles that are uncoated and delivered to early endosomes. Examples include LDL uptake (deficiency causes familial hypercholesterolaemia), transferrin-bound iron uptake, and growth factor internalisation.

Endoplasmic Reticulum

– Interconnected network of membranous tubules and sacs continuous with the nuclear envelope. Rough ER: studded with ribosomes, site of synthesis of secretory, membrane, and lysosomal proteins; co-translational insertion into ER lumen. Smooth ER: lacks ribosomes, site of lipid synthesis (steroids, phospholipids), detoxification (cytochrome P450), calcium storage, and glycogen metabolism (in liver). ER quality control: chaperones (BiP, calnexin, calreticulin) fold proteins; misfolded proteins undergo ER-associated degradation (ERAD). Unfolded protein response (UPR) activated by ER stress (IRE1, PERK, ATF6 pathways).

Endorphin

– Endogenous opioid peptides (beta-endorphin, enkephalins, dynorphins) produced by the pituitary, hypothalamus, and immune cells that bind opioid receptors (μ , δ , κ) to produce analgesia, euphoria, and modulation of pain perception and stress responses. Beta-endorphin is derived from proopiomelanocortin and released with ACTH during stress and exercise ('runner's high'). Endorphins act in the periaqueductal gray and spinal dorsal horn to inhibit pain transmission. They are degraded by enkephalinases; naloxone is an opioid receptor antagonist.

Enzyme

– A protein catalyst that accelerates biochemical reactions by lowering activation energy without being consumed. Nomenclature: substrate + -ase (e.g., lactase). Classification (EC): oxidoreductases, transferases, hydrolases, lyases, isomerases, ligases, translocases. Kinetics: Michaelis-Menten (K_m , V_{max}), Lineweaver-Burk. Regulation: allosteric (feedback), covalent modification (phosphorylation), proteolytic activation (zymogens), compartmentalization. Inhibition: competitive, non-competitive, uncompetitive, irreversible. Clinically important: cardiac troponin (MI), CK (muscle), ALT/AST (liver), lipase (pancreas), ALP (bone/liver).

Excitation-Contraction Coupling

– The sequence of events linking an action potential to muscle contraction. In skeletal muscle: the action potential travels down the T-tubule, triggering calcium release from the sarcoplasmic reticulum via ryanodine receptors (calcium-induced calcium release mediated by voltage-gated dihydropyridine receptors). Calcium binds troponin C, moving tropomyosin to expose actin binding sites for cross-bridge formation; contraction continues while cytosolic calcium is elevated, and relaxation follows calcium reuptake by SERCA. In cardiac muscle, calcium also enters through L-type channels and triggers greater SR release. The mechanism couples electrical excitation to mechanical contraction.

Exocytosis

– Process by which intracellular vesicles fuse with the plasma membrane, releasing their contents into the extracellular space and incorporating membrane proteins/lipids into the cell membrane. The SNARE complex (v -SNARE on vesicles and t -SNARE on tar-

get membrane) mediates vesicle docking and fusion. Calcium-triggered exocytosis occurs in neurons (neurotransmitter release at synapses), endocrine cells (hormone secretion), and exocrine cells (enzyme secretion). Constitutive exocytosis continuously delivers membrane components and secreted proteins (collagen, matrix proteins) in all cells. Regulated exocytosis stores secretory vesicles until a signal (typically increased cytosolic Ca^{2+}) triggers fusion. Defects in exocytosis underlie diseases such as botulism (toxin cleaves SNARE proteins) and familial haemophagocytic lymphohistiocytosis.

Facilitated Diffusion

– Passive transport of molecules across cell membranes via specific transmembrane protein carriers or channels, moving substances down their concentration gradient without energy expenditure. Channel-mediated facilitated diffusion uses ion channels (voltage-gated, ligand-gated, or mechanically-gated) for rapid ion movement. Carrier-mediated facilitated diffusion uses specific carrier proteins that undergo conformational changes to transport molecules like glucose (via GLUT transporters) and amino acids. GLUT1 (erythrocytes, brain), GLUT2 (liver, pancreas), GLUT3 (neurons), GLUT4 (muscle, adipose, insulin-responsive). The rate of facilitated diffusion is limited by transporter number (saturable, following Michaelis-Menten kinetics) and is specific, saturable, and inhibitable.

Filtration Fraction

– The fraction of renal plasma flow that is filtered at the glomerulus, calculated as GFR divided by renal plasma flow (RPF). Normal GFR is approximately 125 mL/min and RPF is approximately 625 mL/min, yielding a filtration fraction of approximately 0.20 (20 percent). This means that approximately 20 percent of the plasma entering the glomerulus is filtered; the remaining 80 percent continues through the efferent arteriole to the peritubular capillaries. Changes in filtration fraction reflect changes in glomerular capillary hydrostatic pressure, plasma oncotic pressure, or renal blood flow. Increased filtration fraction (as in diabetic nephropathy) raises peritubular capillary oncotic pressure, enhancing reabsorption. Decreased filtration fraction suggests reduced GFR relative to RPF, as seen in prerenal azotaemia.

Forced Expiratory Volume

– The volume of air forcibly exhaled in a specified time during a maximal expiratory effort. FEV1 is the volume exhaled in the first second; normally at least 70-80 percent of the forced vital capacity (FEV1/FVC ratio). An obstructive ventilatory defect (asthma, COPD) reduces FEV1 and the FEV1/FVC ratio (below 0.70), while a restrictive defect (pulmonary fibrosis, chest wall disease) reduces both FEV1 and FVC with a normal or elevated ratio. FEV1 is used to grade COPD severity (GOLD staging) and to assess bronchodilator responsiveness.

Frank-Starling Mechanism

– The relationship between ventricular end-diastolic volume (preload) and stroke volume: within physiological limits, increased venous return stretches the ventricular wall, increasing the force of contraction and stroke volume. This occurs because stretching the myocardium optimizes the overlap between actin and myosin filaments, increasing the number of active cross-bridges and enhancing calcium sensitivity. The mechanism allows the heart to automatically match its output to the volume of blood returning to it, balancing left and right ventricular outputs over successive beats. It is the basis for the clinical use of fluid resuscitation in heart failure and the relationship between central venous pressure and cardiac output on the Starling curve.

Functional Residual Capacity

– The volume of air remaining in the lungs at the end of a normal expiration, equal to the sum of expiratory reserve volume plus residual volume (approximately 2.2-3 L in adults). FRC represents the lung volume at which the outward recoil of the chest wall balances the inward recoil of the lungs, the resting equilibrium position. FRC maintains alveolar stability and continuous gas exchange during breathing. It is increased in COPD/emphysema and obstructive disease (air trapping, hyperinflation), decreased in restrictive lung disease, obesity, and supine posture. Measured by body plethysmography or gas dilution methods.

Galactosemia

– An inborn error of galactose metabolism, most commonly caused by deficiency of galactose-1-phosphate uridylyltransferase (GALT, autosomal recessive),

which converts galactose-1-phosphate to glucose-1-phosphate. Deficiency causes accumulation of galactose-1-phosphate and galactitol (from galactose reduction by aldose reductase) in tissues. Newborn screening detects elevated galactose. Symptoms appear after milk feeding (containing lactose, which is hydrolysed to glucose and galactose): vomiting, diarrhea, failure to thrive, hypoglycaemia, hepatomegaly, jaundice, and cataracts. Treatment is a galactose-restricted diet. Long-term complications despite dietary management include intellectual disability, speech delay, and premature ovarian failure in females.

Galvanism

– The application of a direct electric current for therapeutic or diagnostic purposes. Named after Luigi Galvani (1737-1798). Historical uses: galvanic stimulation of muscles, iontophoresis (introduction of ionised drugs through skin), electroconvulsive therapy (modified). Modern context: galvanic vestibular stimulation (research tool), dental galvanism (electrochemical reaction between dissimilar dental metals causing oral discomfort or metallic taste).

Gastric Acid

– Hydrochloric acid secreted by gastric parietal cells, producing an intragastric pH of 1-3. Secretion is stimulated by histamine (H₂ receptors), gastrin (CCK-B/gastrin receptors), and acetylcholine (M₃ muscarinic receptors), and inhibited by somatostatin, prostaglandins, and luminal acid (negative feedback). Acid activates pepsinogen to pepsin, aids protein digestion, sterilizes ingested bacteria, and promotes iron and calcium absorption. Excessive acid causes peptic ulcer disease and GERD; deficient acid (achlorhydria) predisposes to infections and vitamin B12 malabsorption. Inhibited therapeutically by PPIs, H₂ blockers, and anticholinergics.

Gastrin Secretion

– Gastrin is a peptide hormone produced by G-cells in the gastric antrum and duodenum, stimulating hydrochloric acid secretion by parietal cells, pepsinogen secretion by chief cells, and growth of the gastric mucosa. Stimuli for release include: gastric distension, amino acids (especially phenylalanine and tryptophan) and peptides in the stomach, and vagal stimulation (via GRP, gastrin-releasing peptide). Gastrin acts on cholecystokinin-B (CCK-B)

receptors on parietal cells and histamine-releasing enterochromaffin-like (ECL) cells (which in turn stimulate parietal cells via histamine H₂ receptors). Gastrin release is inhibited by low antral pH (negative feedback via somatostatin from D-cells). Zollinger-Ellison syndrome (gastrinoma) causes severe peptic ulcer disease from unregulated gastrin secretion.

Gaucher Disease

– The most common lysosomal storage disease, caused by deficiency of glucocerebrosidase (glucosylceramidase, beta-glucocerebrosidase, GBA), an autosomal recessive disorder leading to accumulation of glucocerebroside (glucosylceramide) in macrophages of the reticuloendothelial system. These lipid-laden macrophages are called "Gaucher cells" with a characteristic "crinkled tissue paper" cytoplasmic appearance. Type 1 (non-neuronopathic, most common, approximately 90 percent of cases): hepatosplenomegaly, anemia, thrombocytopenia, bone pain crises, and Erlenmeyer flask deformity of the distal femurs. Type 2 (acute neuronopathic, infantile): severe neurodegeneration with brainstem involvement and death by age 2. Type 3 (chronic neuronopathic): later onset with myoclonus, seizures, and progressive neurological deterioration.

Gene

– A segment of DNA that encodes a functional product (protein or functional RNA). Human genes: 20,000 protein-coding, plus non-coding RNA genes. Structure: promoter, exons (coding), introns (spliced out), regulatory elements (enhancers, silencers). Expression: transcription → pre-mRNA → splicing (removes introns) → mature mRNA → translation. Regulation: transcription factors, epigenetic modifications (DNA methylation, histone marks), chromatin remodeling, non-coding RNAs. Mutations: loss-of-function, gain-of-function, dominant-negative.

Gene Therapy

– The therapeutic delivery of nucleic acids into cells to treat or prevent disease by altering gene expression. Two main approaches: (1) gene replacement/supplementation (adding a functional copy of a defective gene), and (2) gene editing (correcting the defective gene in situ). Viral vectors: adeno-associated virus (AAV, non-integrating,

low immunogenicity, limited packaging capacity), lentivirus (integrates into the host genome, effective for dividing and non-dividing cells), and adenovirus (episomal, highly immunogenic, large packaging capacity). Non-viral methods include lipid nanoparticles (mRNA vaccines, siRNA delivery) and electroporation. Major challenges include immunogenicity, off-target effects, delivery efficiency, and long-term expression durability.

Glomerular Filtration Rate

– The volume of plasma filtered through the glomerular capillaries per unit time, normally approximately 125 mL/min or approximately 180 L/day. GFR depends on Starling forces across the glomerular capillary wall: glomerular capillary hydrostatic pressure (approximately 55 mmHg, favoring filtration) minus Bowman's capsule hydrostatic pressure (approximately 15 mmHg) minus glomerular capillary oncotic pressure (approximately 30 mmHg, opposing filtration), yielding a net filtration pressure of approximately 10 mmHg. GFR is autoregulated between MAP of approximately 80-180 mmHg by the myogenic response (afferent arteriolar constriction in response to increased pressure) and tubuloglomerular feedback (macula densa sensing NaCl delivery). Clinical GFR measurement uses creatinine clearance or cystatin C. Reduced GFR defines acute kidney injury and chronic kidney disease staging.

Gluconeogenesis

– The synthesis of glucose from non-carbohydrate precursors (lactate, glycerol, glucogenic amino acids, and propionate) primarily in the liver (90 percent) and kidneys (10 percent). It uses most glycolytic enzymes in reverse but must bypass three irreversible glycolytic reactions using different enzymes: (1) pyruvate carboxylase converts pyruvate to oxaloacetate, then PEPCK (phosphoenolpyruvate carboxykinase) converts oxaloacetate to phosphoenolpyruvate; (2) fructose-1,6-bisphosphatase converts fructose-1,6-bisphosphate to fructose-6-phosphate; (3) glucose-6-phosphatase (present in liver and kidney but not muscle) converts glucose-6-phosphate to free glucose for release into the blood. Gluconeogenesis is energy-intensive (6 ATP equivalents per glucose) and is stimulated by glucagon, cortisol, and catecholamines, and inhibited by insulin and ethanol.

Glutamate

– The principal excitatory neurotransmitter in the central nervous system. Synthesized from glutamine or alpha-ketoglutarate and acting on ionotropic receptors (AMPA, kainate, NMDA) for fast synaptic transmission and metabotropic receptors (mGluR1-8) for modulation. Glutamate is essential for normal synaptic transmission, learning, and memory (long-term potentiation). However, excessive glutamate release causes excitotoxicity—neuronal injury mediated by excessive calcium influx—implicated in stroke, traumatic brain injury, status epilepticus, and neurodegenerative diseases. Uptake by excitatory amino acid transporters terminates its action.

Glycogenesis

– The synthesis of glycogen from glucose, primarily in liver (for blood glucose maintenance) and skeletal muscle (for local energy use). The process involves two key enzymes: glycogen synthase (adding glucose residues from UDP-glucose to the non-reducing ends of glycogen via alpha-1,4-glycosidic bonds) and the branching enzyme (creating alpha-1,6-glycosidic bonds every 8-12 residues, creating branch points). Glycogen synthase is the rate-limiting enzyme, regulated by phosphorylation (inactivated by PKA, activated by dephosphorylation via protein phosphatase 1) and allosteric activation by glucose-6-phosphate. Insulin promotes glycogenesis by activating protein phosphatase 1 and inactivating glycogen synthase kinase 3 (GSK-3). Glucagon and adrenaline inhibit glycogenesis via cAMP-mediated phosphorylation.

Glycogenolysis

– The breakdown of glycogen to glucose, primarily in the liver (to maintain blood glucose) and muscle (for local energy use). Key enzyme: glycogen phosphorylase, which cleaves alpha-1,4-glycosidic bonds by phosphorylating glucose residues to produce glucose-1-phosphate. The debranching enzyme handles branch points (alpha-1,6 bonds). In the liver, glucose-1-phosphate is converted to glucose-6-phosphate by phosphoglucomutase, then to free glucose by glucose-6-phosphatase (released into blood). In muscle, glucose-6-phosphate enters glycolysis directly (cannot be released as free glucose). Glycogenolysis is activated by glucagon (liver), adrenaline (liver and muscle), and AMP (muscle, during exercise), and inhibited by insulin

and glucose.

Glycogen Storage Diseases

– A group of inherited disorders caused by deficiencies in enzymes involved in glycogen metabolism, affecting the liver, muscle, or both. Type I (von Gierke disease): glucose-6-phosphatase deficiency, causing severe fasting hypoglycemia, hepatomegaly (massive glycogen and fat accumulation), lactic acidosis, hyperuricemia, and hyperlipidemia. Type II (Pompe disease): acid alpha-glucosidase (lysosomal acid maltase) deficiency, causing accumulation of glycogen in lysosomes, leading to cardiomegaly, hypertrophic cardiomyopathy, and muscle weakness; infantile form is fatal without enzyme replacement therapy. Type III (Cori disease): debranching enzyme deficiency, milder hypoglycaemia and hepatomegaly. Type V (McArdle disease): muscle glycogen phosphorylase deficiency, causing exercise intolerance, myoglobinuria, and second wind phenomenon.

Glycolysis

– The metabolic pathway converting glucose to pyruvate, occurring in the cytoplasm of all cells. Ten enzymatic steps divided into two phases: the energy investment phase (steps 1-5, consuming 2 ATP) and the energy payoff phase (steps 6-10, producing 4 ATP and 2 NADH). Key regulatory enzymes: hexokinase/glucokinase (step 1, phosphorylating glucose), phosphofructokinase-1 (PFK-1, step 3, the rate-limiting step, allosterically activated by AMP, fructose-2,6-bisphosphate, and inhibited by ATP and citrate). The net yield per glucose is 2 ATP and 2 NADH (under aerobic conditions); under anaerobic conditions, NAD⁺ is regenerated by lactate dehydrogenase reducing pyruvate to lactate, allowing continued glycolysis but with net 2 ATP per glucose.

Golgi Apparatus

– Membrane-bound organelle (Golgi complex) consisting of flattened cisternae (cis, medial, trans) that modifies, sorts, and packages proteins and lipids from the ER for secretion or delivery to other organelles. Key functions: N- and O-linked glycosylation (addition/modification of carbohydrate chains), proteolytic processing, sulfation, phosphorylation, and sorting via signal sequences (M6P for lysosomes, KDEL for ER retrieval). Vesicles bud

from trans-Golgi network (TGN) to plasma membrane (constitutive/regulated secretion), lysosomes, or endosomes. Brefeldin A disrupts Golgi by inhibiting ARF1.

Golgi Tendon Organ

– A mechanoreceptor located at the junction between a skeletal muscle and its tendon, innervated by Ib afferent fibers. The Golgi tendon organ detects tension generated by muscle contraction or passive stretch. Unlike the muscle spindle, it is arranged in series with the muscle fibers and is therefore more sensitive to active contraction than to stretch. Activation inhibits the homonymous muscle via the Ib inhibitory interneuron (autogenic inhibition) and excites antagonists, providing a protective reflex against excessive tension that could damage the muscle or tendon.

G-Protein Coupled Receptors

– The largest family of cell surface receptors with seven transmembrane alpha-helical domains. Upon ligand binding, the receptor undergoes a conformational change that activates an associated heterotrimeric G-protein (G α , G β , G γ). The G α subunit exchanges GDP for GTP and dissociates from the G β -gamma complex. Gs-proteins activate adenylyl cyclase (increasing cAMP), Gi-proteins inhibit adenylyl cyclase (decreasing cAMP), and Gq-proteins activate phospholipase C (producing IP₃ and DAG, increasing intracellular Ca²⁺). The system provides signal amplification and is the target of many drugs (beta-blockers, antihistamines, opioids) and bacterial toxins (cholera toxin permanently activates Gs, pertussis toxin inactivates Gi).

Graded Potentials

– Local changes in membrane potential that vary in magnitude proportional to stimulus strength, unlike all-or-none action potentials. They include receptor potentials (in sensory receptors), postsynaptic potentials (EPSPs and IPSPs at synapses), and pacemaker potentials (in cardiac/specialized cells). Graded potentials decay with distance from their source (decremental conduction) because they spread passively through the cytoplasm. They can summate temporally (rapid successive stimuli) and spatially (simultaneous stimuli from multiple sources), integrating signals at the axon hillock. If

the summed depolarisation reaches threshold (approximately -55 mV), an action potential is triggered. Graded potentials are essential for sensory transduction and synaptic communication and are the basis for the all-or-none law of neural signalling.

Growth Factor

– Proteins that stimulate cell growth, proliferation, differentiation, and survival. Major families: EGF (epidermal growth factor), FGF (fibroblast growth factor), PDGF (platelet-derived), VEGF (vascular endothelial), TGF-beta (transforming), NGF (nerve), IGF (insulin-like), HGF (hepatocyte). Receptors: receptor tyrosine kinases (RTKs), dimerization → autophosphorylation → downstream signaling (RAS/MAPK, PI3K/Akt). Roles: wound healing, angiogenesis, development, tissue regeneration. Clinical: growth factor therapy (EPO, G-CSF, VEGF inhibitors in cancer, anti-VEGF in AMD).

Haldane Effect

– The decrease in hemoglobin's CO₂ carrying capacity when oxygen binds to it, facilitating CO₂ release at the lungs. Deoxygenated hemoglobin (deoxyhemoglobin) is a better buffer for H⁺ ions and forms more carbaminohemoglobin than oxyhemoglobin. In the tissues: oxygen unloading increases hemoglobin's ability to bind CO₂ (as carbaminohemoglobin) and buffer H⁺ (from CO₂ hydration to carbonic acid), enhancing CO₂ loading. In the lungs: oxygen binding displaces CO₂ from hemoglobin and reduces H⁺ buffer capacity, promoting CO₂ release into the alveoli. The Haldane effect explains that approximately 20 percent of CO₂ transport is via carbaminohemoglobin. Together with the Bohr effect, it optimizes O₂ delivery and CO₂ removal, a concept known as the "Haldane-Bohr coupling" that is essential for efficient gas exchange.

Homeostasis

– The maintenance of a stable internal environment despite external changes, achieved through physiological regulation and feedback mechanisms. The concept was introduced by Walter Cannon (1929) building on Claude Bernard's milieu intérieur. Homeostasis involves: (1) Set point: the ideal or normal value for a physiological variable (e.g., body temperature 37°C, blood pH 7.4, blood glucose 4-6 mmol/L). (2) Sensors (receptors): detect deviations

from the set point (e.g., thermoreceptors in the hypothalamus for temperature, chemoreceptors for pH and O₂/CO₂, baroreceptors for blood pressure). (3) Integrating center: compares input to the set point and coordinates a response (e.g., hypothalamus, brainstem, endocrine glands). (4) Effectors: muscles, glands, or organs that produce the corrective response (e.g., sweat glands and shivering for temperature; insulin and glucagon for glucose; heart, vessels, and kidneys for BP). Feedback mechanisms: (1) Negative feedback (most common): reverses the direction of change (e.g., rising blood glucose stimulates insulin release, which lowers glucose; blood pressure increase triggers baroreceptor-mediated vasodilation and bradycardia). (2) Positive feedback: amplifies the initial change, driving a process to completion (e.g., oxytocin release during childbirth intensifies uterine contractions; sodium channel opening during action potential depolarisation; blood clotting cascade). Disorders of homeostasis: failure of temperature regulation (hyperthermia, hypothermia), pH (acidosis, alkalosis), glucose (diabetes, hypoglycaemia), blood pressure (hypertension, hypotension), and water/electrolyte balance (dehydration, hyponatraemia, hyperkalaemia).

Hormone

– A chemical messenger secreted by endocrine glands into the bloodstream to regulate distant target cells. Classification: peptide/protein (insulin, GH, ACTH), steroid (cortisol, aldosterone, sex steroids), amine (thyroid hormone, catecholamines), eicosanoid (prostaglandins), gas (NO). Mechanisms: membrane receptors (peptides/amines) → second messengers; intracellular receptors (steroids/thyroid) → gene transcription. Regulation: negative feedback (HPA, HPT, HPG axes), pulsatile secretion, circadian rhythms. Endocrine disorders: hyper/hypofunction (pituitary, thyroid, adrenal, gonads, pancreas).

Humoral Immunity

– The component of adaptive immunity mediated by antibodies produced by B lymphocytes (plasma cells) that neutralize extracellular pathogens and toxins. Humoral responses defend against bacteria, viruses outside cells, and parasites. Primary response: naïve B cells recognize antigen, undergo activation, class switching, and affinity maturation

in germinal centers, producing IgM then IgG; the secondary response to re-exposure is faster, larger, and of higher affinity due to memory B cells. Antibodies act by neutralization, opsonization, complement activation, and antibody-dependent cellular cytotoxicity. Defective humoral immunity causes recurrent sinopulmonary bacterial infections.

Hyperpolarization

– A change in membrane potential to a more negative value, moving it further from threshold and making the cell less excitable. Occurs when potassium leaves the cell (opening of voltage-gated potassium channels, as in the afterhyperpolarization after an action potential) or when chloride enters (GABA-A receptor activation). In neurons, GABAergic hyperpolarization inhibits firing; in cardiac cells, hyperpolarization of the resting potential by acetylcholine slows SA node rate (bradycardia). Hyperkalemia also hyperpolarizes, paradoxically reducing excitability.

Hypoxic Pulmonary Vasoconstriction

– The unique response of pulmonary arterioles to low alveolar oxygen tension (PO₂ less than approximately 60 mmHg), causing vasoconstriction. Unlike systemic vessels that dilate in response to hypoxia, pulmonary vessels constrict, redirecting blood flow away from poorly ventilated alveoli toward better-ventilated regions, optimizing ventilation-perfusion (V/Q) matching. The mechanism involves inhibition of voltage-gated K⁺ channels in pulmonary artery smooth muscle cells, causing membrane depolarization, Ca²⁺ influx via L-type Ca²⁺ channels, and vasoconstriction. Chronic global hypoxia (as in COPD, high altitude) causes sustained vasoconstriction leading to pulmonary hypertension, right ventricular hypertrophy (cor pulmonale), and vascular remodelling. This response is unique to the pulmonary circulation; systemic vessels dilate in hypoxia.

Immune Response

– The coordinated reaction of the immune system to foreign substances (antigens), pathogens, or abnormal cells. The innate immune response acts rapidly and non-specifically (physical barriers, phagocytes, complement, NK cells, inflammation). The adaptive immune response is slower, antigen-specific, and pro-

vides immunological memory: humoral immunity via antibodies (B cells) and cell-mediated immunity via T cells (CD4+ helpers, CD8+ cytotoxic). The primary response occurs on first exposure; secondary responses are faster and stronger. Dysregulation causes autoimmunity, allergy/hypersensitivity, or immunodeficiency. Vaccination exploits the adaptive memory response.

JAK-STAT Pathway

– A rapid signaling pathway for cytokines and growth factors (interferons, interleukins, erythropoietin, growth hormone) that lack intrinsic enzymatic activity. Ligand binding to the cytokine receptor causes receptor dimerization and activation of associated Janus kinases (JAK1, JAK2, JAK3, TYK2) by trans-phosphorylation. Activated JAKs phosphorylate tyrosine residues on the receptor cytoplasmic domain, creating docking sites for STAT (signal transducers and activators of transcription) proteins, which are phosphorylated by JAKs, form homo- or heterodimers, and translocate to the nucleus where they bind gamma-interferon activation site (GAS) or interferon-stimulated response element (ISRE) sequences to regulate gene transcription. The pathway is negatively regulated by SOCS (suppressor of cytokine signalling) proteins, PTPs (protein tyrosine phosphatases), and PIAS (protein inhibitor of activated STAT).

Ketogenesis

– The hepatic synthesis of ketone bodies (acetoacetate, beta-hydroxybutyrate, and acetone) from acetyl-CoA during periods of prolonged fasting, starvation, uncontrolled diabetes, or very low carbohydrate diets. When oxaloacetate is depleted for gluconeogenesis, accumulated acetyl-CoA cannot enter the TCA cycle and is diverted to ketogenesis. The process occurs in the mitochondrial matrix: two acetyl-CoA molecules condense to form acetoacetyl-CoA (by thiolase), which combines with another acetyl-CoA to form HMG-CoA by HMG-CoA synthase. HMG-CoA lyase cleaves HMG-CoA to acetoacetate and acetyl-CoA. Acetoacetate is reduced to beta-hydroxybutyrate by beta-hydroxybutyrate dehydrogenase (NADH-dependent) or spontaneously decarboxylated to acetone. Ketone bodies are important alternative fuels for the brain during fasting and starvation, providing up to 70 percent of cere-

bral energy needs.

Leukopoiesis

– The production and development of white blood cells (leukocytes) from hematopoietic stem cells in the bone marrow, regulated by colony-stimulating factors and interleukins. Neutrophils, eosinophils, and basophils derive from the myeloid lineage; lymphocytes (B, T, NK cells) from the lymphoid lineage; monocytes develop into macrophages and dendritic cells in tissues. Each lineage is stimulated by specific growth factors (e.g., G-CSF for neutrophils, IL-5 for eosinophils, IL-7 for lymphocytes). Leukopoiesis increases during infection and inflammation. Growth factors (filgrastim) are used clinically to treat neutropenia.

Ligand

– Any molecule that binds specifically to a biological receptor, macromolecule, or active site. In pharmacology and physiology, ligands include hormones, neurotransmitters, drugs, and toxins that bind receptors to initiate (agonist), block (antagonist), or modulate signaling. Binding is governed by affinity (tightness) and is typically reversible. The ligand-receptor interaction produces a conformational change that initiates intracellular signal transduction. Examples: insulin binding to the insulin receptor, acetylcholine to muscarinic receptors, oxygen to hemoglobin.

Lipoprotein Metabolism

– Lipoproteins transport hydrophobic lipids (triglycerides, cholesterol, cholesterol esters, fat-soluble vitamins) in the aqueous blood. Four main classes: chylomicrons (from intestine, largest, transport dietary triglycerides; ApoB-48; acted on by lipoprotein lipase), VLDL (from liver, transport endogenous triglycerides; ApoB-100; converted to IDL), LDL (from VLDL metabolism, carry cholesterol to tissues; ApoB-100; the "bad" cholesterol; taken up by LDL receptors), and HDL (from liver/intestine, reverse cholesterol transport, ApoA-I, the "good" cholesterol, protective against atherosclerosis). Lipoprotein lipase (LPL) hydrolyses triglycerides in chylomicrons and VLDL, releasing free fatty acids for tissue uptake. HDL mediates reverse cholesterol transport, delivering excess cholesterol from peripheral cells to the liver for excretion or recycling.

Lysosome

– Membrane-bound organelles containing hydrolytic enzymes (acid hydrolases: proteases, lipases, nucleases, glycosidases) functioning at low pH (4.5–5.0) maintained by V-ATPase proton pump. Degrade macromolecules from endocytosis, phagocytosis, and autophagy. Lysosomal enzymes synthesized in rough ER, tagged with mannose-6-phosphate (M6P) in Golgi, targeted to lysosomes. Lysosomal storage diseases (Tay-Sachs, Gaucher, Niemann-Pick, Pompe, Fabry) result from enzyme deficiencies causing substrate accumulation. Lysosomes also involved in plasma membrane repair, cholesterol homeostasis (NPC1), and exocytosis.

Meiosis

– Specialized cell division producing four haploid gametes from one diploid germ cell. Meiosis I (reductional): homologous chromosomes pair (synapsis), recombine (crossing over at chiasmata), and segregate. Meiosis II (equational): sister chromatids separate (similar to mitosis). Results in genetic diversity (independent assortment, crossing over). Oogenesis: one ovum + polar bodies (asymmetric cytokinesis). Spermatogenesis: four spermatids (symmetric). Errors: nondisjunction (trisomy 21 Down syndrome, Turner syndrome, Klinefelter syndrome).

Membrane Potential

– The electrical potential difference across a cell membrane, approximately -70 mV in most neurons (resting membrane potential). Established by the unequal distribution of ions (primarily K⁺, Na⁺, Cl⁻) across the membrane and selective permeability. The Nernst equation calculates the equilibrium potential for a single ion: $E = (RT/zF) \ln([ion\ outside]/[ion\ inside])$. At body temperature for a monovalent cation, this simplifies to $E = 61.5 \log([out]/[in])$ mV. The Goldman equation accounts for multiple ion permeabilities to calculate the resting membrane potential: $V_m = 61.5 \log((P_K[K^+]_o + P_{Na}[Na^+]_o + P_{Cl}[Cl^-]_i)/(P_K[K^+]_i + P_{Na}[Na^+]_i + P_{Cl}[Cl^-]_o))$. The resting membrane is most permeable to K⁺ (via leak channels), so V_m is close to E_K (approximately -94 mV for K⁺). Changes in ion permeability (e.g., Na⁺ channels opening during depolarisation) drive electrical signalling.

Michaelis-Menten Kinetics

– The mathematical model describing the rate of enzyme-catalyzed reactions as a function of substrate concentration. The Michaelis-Menten equation: $v = (V_{max} \times [S]) / (K_m + [S])$, where v is the reaction velocity, V_{max} is the maximum velocity (when all enzyme is saturated with substrate), $[S]$ is the substrate concentration, and K_m is the Michaelis constant (the substrate concentration at which $v = V_{max}/2$). K_m reflects the enzyme's affinity for its substrate: a low K_m indicates high affinity (the enzyme reaches half-maximal velocity at a low substrate concentration). The turnover number ($k_{cat} = V_{max}/[Et]$) describes the catalytic efficiency; the ratio k_{cat}/K_m is the best measure of enzyme specificity, approaching the diffusion limit for perfect enzymes. Lineweaver-Burk (double reciprocal) plots linearise the equation: $1/v = K_m/V_{max} \times 1/[S] + 1/V_{max}$.

Micturition

– The process of urination, coordinated by the pontine micturition center, parasympathetic (pelvic nerve, S2-S4) contraction of the detrusor muscle, and relaxation of the internal (involuntary) and external (voluntary, pudendal nerve) urethral sphincters. The bladder fills at low pressure (compliance) until stretch receptors trigger the micturition reflex. In infants and animals, micturition is a spinal reflex; in adults, cortical control permits voluntary initiation and deferral. Disorders include urinary retention, incontinence, overactive bladder, and neurogenic bladder. Urodynamic studies evaluate the process.

Migrating Motor Complex

– Cyclical patterns of intense gastrointestinal motility occurring during fasting (interdigestive period), sweeping residual food, bacteria, and debris from the stomach through the small intestine to the colon. Each cycle lasts approximately 90–120 minutes and has four phases: Phase I (quiescence, approximately 45–60 minutes), Phase II (irregular contractions, approximately 30 minutes), Phase III (regular high-amplitude contractions at maximum frequency, approximately 5–15 minutes, the "housekeeper" phase that propels luminal contents distally), and Phase IV (declining activity returning to Phase I). The MMC is regulated by the migrating motor complex, motilin (released during fasting), and the enteric

nervous system. Disruption of the MMC is associated with small intestinal bacterial overgrowth (SIBO).

Mitochondria

– Double-membrane organelles known as the "powerhouse of the cell," generating ATP through oxidative phosphorylation. Outer membrane is permeable; inner membrane is highly folded (cristae) and contains the electron transport chain and ATP synthase. Mitochondrial matrix contains TCA cycle enzymes, fatty acid beta-oxidation, and mitochondrial DNA (mtDNA, 16.5 kb, maternal inheritance). Mitochondria also regulate apoptosis (cytochrome c release), calcium homeostasis, ROS production, and heme/iron-sulfur cluster synthesis. Dysfunction causes mitochondrial diseases (MELAS, MERRF, LHON), contributes to neurodegeneration, aging, and metabolic disorders.

Mitosis

– Cell division producing two genetically identical daughter cells from one somatic cell. Phases: prophase (chromosome condensation, spindle formation, nuclear envelope breakdown), prometaphase (kinetochore-microtubule attachment), metaphase (chromosomes aligned at metaphase plate, spindle assembly checkpoint), anaphase (sister chromatid separation, anaphase A: chromatids to poles; anaphase B: spindle elongation), telophase (chromosome decondensation, nuclear envelope reformation), cytokinesis (cytoplasmic division, contractile ring). Regulated by cyclin-dependent kinases (CDKs) and cyclins. Errors cause aneuploidy, cancer.

Motor Unit

– A single alpha motor neuron and all the skeletal muscle fibers it innervates. The number of muscle fibers per motor unit determines precision of control: small motor units (few fibers, e.g., extraocular and hand muscles) provide fine movement; large motor units (hundreds to thousands of fibers, e.g., gastrocnemius) provide gross power. All fibers of a motor unit contract synchronously (all-or-none). Recruitment follows the size principle: small (slow, fatigue-resistant) motor units are recruited first, followed by larger (fast, fatigable) units as force demand increases.

Muscle Contraction

– The shortening or tension generation of muscle

produced by the interaction of actin and myosin myofilaments. In skeletal and cardiac muscle, contraction follows excitation-contraction coupling: calcium binds troponin, tropomyosin moves aside, and myosin cross-bridges cycle against actin (sliding filament mechanism) using ATP. Types: isometric (tension without length change) and isotonic (shortening against constant load). Skeletal muscle contracts only when stimulated by a motor neuron; cardiac muscle contracts rhythmically by pacemaker activity; smooth muscle contraction is sustained, calcium-dependent, and regulated by autonomic nerves, hormones, and local factors.

Mutation

– A permanent change in the DNA sequence. Types: point mutation (single base: missense, nonsense, silent), frameshift (insertion/deletion not multiple of 3), copy number variation (duplication/deletion), chromosomal rearrangement (translocation, inversion). Germline mutations are heritable; somatic mutations are not (cause cancer, mosaicism). Causes: replication errors, mutagens (UV, chemicals, radiation), transposons. Effects: benign, pathogenic, disease-causing (Mendelian disorders, cancer predisposition).

Na⁺/K⁺ ATPase

– The sodium-potassium pump is a P-type ATPase found in the plasma membrane of all animal cells, directly consuming approximately 20-30 percent of cellular ATP. It pumps 3 Na⁺ ions out of the cell and 2 K⁺ ions in per ATP hydrolyzed, establishing steep electrochemical gradients: high Na⁺ outside, high K⁺ inside. This gradient is essential for maintaining the resting membrane potential (approximately -70 mV), driving secondary active transport (e.g., glucose and amino acid absorption in the intestine and kidney, Na⁺/Ca²⁺ exchange), and regulating cell volume. The pump is inhibited by cardiac glycosides such as ouabain and digoxin (used in heart failure to increase intracellular Ca²⁺ and contractility).

Natural Killer Cell

– A type of innate lymphoid cell (lymphocyte) that provides early defense against virus-infected cells and tumor cells without prior sensitization. NK cells recognize stressed or missing-self cells (absent or altered MHC class I) and kill them by releasing perforin and granzymes, or through antibody-

dependent cellular cytotoxicity. They also secrete cytokines (interferon-gamma, TNF) that activate macrophages and shape the adaptive response. Regulated by activating and inhibitory receptors. Deficiencies cause severe herpesvirus infections. Large granular lymphocyte morphology on blood smear.

Necrosis

- Uncontrolled, pathological cell death resulting from severe injury (ischemia, toxins, trauma, infection). Morphology: cell swelling, organelle rupture, plasma membrane rupture, release of intracellular contents causing inflammation. Types: coagulative (ischemia, most organs), liquefactive (brain, abscess), caseous (TB, granulomas), fat necrosis (pancreatitis, trauma), gangrenous (limb ischemia + infection). Unlike apoptosis, necrosis elicits strong inflammatory response.

Negative Feedback

- A regulatory mechanism in which the output of a system feeds back to decrease or reverse the initiating stimulus, maintaining homeostasis around a set point. Examples: insulin secretion in response to hyperglycemia lowers blood glucose, which then reduces insulin secretion; the hypothalamic-pituitary-thyroid axis (TRH, TSH, thyroid hormone) is self-limiting; baroreceptors counteract changes in blood pressure; body temperature regulation opposes deviations from the set point. Negative feedback is the dominant homeostatic mechanism and underlies normal endocrine, cardiovascular, and metabolic regulation. Disruption causes disease (e.g., autonomous hormone secretion).

Nephron Function

- The nephron is the functional unit of the kidney, with approximately 1 million per kidney. Each nephron consists of a renal corpuscle (glomerulus and Bowman's capsule) and a renal tubule (proximal convoluted tubule, loop of Henle, distal convoluted tubule, and collecting duct). The nephron performs three primary functions: filtration (at the glomerulus, producing approximately 180 L/day of ultrafiltrate), reabsorption (reclaiming approximately 99 percent of filtered water and solutes), and secretion (transporting substances from the blood into the tubular lumen for elimination). The loop of Henle establishes the medullary osmotic gradient for urine concentration; the collecting duct performs final

regulation of water and electrolyte balance under the control of ADH and aldosterone.

Noncompetitive Inhibition

- A type of enzyme inhibition where the inhibitor binds at a site distinct from the active site (allosteric site), and can bind to both the free enzyme (E) and the enzyme-substrate complex (ES) with equal affinity. The inhibitor does not compete with the substrate and cannot be overcome by increasing substrate concentration. The apparent V_{max} decreases (fewer functional enzyme molecules) while K_m remains unchanged (substrate affinity is unaffected since the inhibitor does not compete for the active site). On a Lineweaver-Burk plot: lines intersect on the x-axis (same $-1/K_m$) with different slopes and y-intercepts. Noncompetitive inhibition is less common than competitive inhibition in pharmacology but is important in metal ion toxicity and certain pesticide actions.

Nucleus

- The membrane-bound organelle containing the genetic material (DNA) in eukaryotic cells. Surrounded by the nuclear envelope (double membrane with nuclear pores for transport). Contains chromatin (DNA + histone proteins), nucleolus (ribosome biogenesis), and nuclear matrix. The nuclear pores regulate nucleocytoplasmic transport of proteins, RNA, and ribosomal subunits. During mitosis, the nuclear envelope breaks down (open mitosis) and reforms in daughter cells. The nucleus is the site of DNA replication, transcription, and RNA processing.

Oncotic Pressure

- Also called colloid osmotic pressure, the osmotic pressure exerted by plasma proteins (predominantly albumin) that do not freely cross the capillary wall. Normal plasma oncotic pressure is approximately 25-28 mmHg. It opposes the hydrostatic pressure that drives fluid out of capillaries, favoring fluid reabsorption at the venular end. According to Starling forces, net filtration = $K_f [(P_c - P_i) - (\pi_c - \pi_i)]$. Reduced plasma proteins (hypoalbuminemia in cirrhosis, nephrotic syndrome, malnutrition) lower oncotic pressure, decreasing fluid reabsorption and causing edema and ascites.

Osmosis

- The net movement of water molecules across a

semipermeable membrane from a region of lower solute concentration (higher water concentration) to a region of higher solute concentration (lower water concentration). Driven by the osmotic pressure difference, which is proportional to the number of solute particles. Osmolarity is measured in osmoles per liter (mOsm/L); normal plasma osmolarity is approximately 285-295 mOsm/L. Tonicity describes the effect of a solution on cell volume: hypotonic solutions cause cell swelling (osmotic lysis), hypertonic solutions cause cell shrinkage (crenation). The concept is clinically critical for intravenous fluid therapy: normal saline (0.9 percent NaCl, approximately 308 mOsm/L) is isotonic and does not cause red blood cell lysis; hypotonic fluids (0.45 percent NaCl) may cause haemolysis if infused rapidly.

Osmotic Pressure

– The pressure required to prevent the movement of water across a semipermeable membrane when a solute concentration gradient exists, proportional to the number of dissolved particles (van't Hoff law: $\pi = iCRT$). It is a colligative property depending on particle number, not particle identity. In physiology, tonicity describes the effective osmotic pressure for impermeant solutes: isotonic solutions (0.9 percent saline, 5 percent dextrose) cause no red cell volume change; hypotonic solutions cause cell swelling/lysis; hypertonic solutions cause cell shrinkage. Plasma osmolality (275-295 mOsm/kg) is regulated by ADH and thirst.

Oxidative Phosphorylation

– The process by which ATP is synthesized using the energy stored in the proton gradient (proton motive force) across the inner mitochondrial membrane, established by the electron transport chain. ATP synthase (F1F0-ATPase) is a molecular turbine with two components: F0 (membrane-spanning proton channel) and F1 (catalytic head projecting into the matrix). Protons flow through F0 down their electrochemical gradient, causing the gamma subunit to rotate relative to the alpha3beta3 hexamer of F1, driving conformational changes that synthesise ATP from ADP and Pi. The chemiosmotic theory (Peter Mitchell, 1978 Nobel Prize) explains how the proton motive force (proton gradient + membrane potential) couples electron transport to ATP synthesis. Uncouplers (e.g., DNP) dissipate the proton

gradient, generating heat instead of ATP.

Oxygen Consumption

– The volume of oxygen consumed by the body per unit time, reflecting overall metabolic rate. Resting oxygen consumption (VO_2) in a normal adult is approximately 250 mL/min (about 3.5 mL/kg/min, 1 MET). It is calculated as cardiac output $\times$ (arterial O₂ content - venous O₂ content) by the Fick principle. Oxygen consumption increases with exercise, fever, and hyperthyroidism, and decreases with hypothermia, hypothyroidism, and anesthesia. Maximum oxygen consumption ($\text{VO}_2 \text{ max}$) measures aerobic capacity and is used in cardiopulmonary exercise testing and heart failure prognosis.

Oxygen Delivery

– The rate at which oxygen is transported from the lungs to the tissues, equal to cardiac output multiplied by arterial oxygen content: $\text{DO}_2 = \text{CO} \times \text{CaO}_2$. Arterial oxygen content = $(1.34 \times \text{hemoglobin} \times \text{SaO}_2) + (0.003 \times \text{PaO}_2)$. Normal oxygen delivery is approximately 1000 mL/min. Determinants include cardiac output, hemoglobin concentration, and oxygen saturation. Oxygen delivery declines with anemia, hypoxemia, reduced cardiac output, or carbon monoxide poisoning. The balance between delivery and consumption determines tissue oxygenation; a critical DO_2 threshold leads to anaerobic metabolism and lactate production.

Oxygen-Hemoglobin Dissociation Curve

– The sigmoidal relationship between partial pressure of oxygen (PO_2) and hemoglobin oxygen saturation (SO_2). The curve reflects hemoglobin's cooperative binding: oxygen binding to one subunit increases affinity for subsequent oxygen molecules. At PO_2 of 100 mmHg (alveolar), hemoglobin is approximately 98 percent saturated. At PO_2 of 40 mmHg (mixed venous), saturation is approximately 75 percent. The steep portion of the curve (PO_2 20-60 mmHg) allows large oxygen unloading with small PO_2 decreases in tissue capillaries. The curve is shifted rightward (decreased affinity) by increased temperature, decreased pH (Bohr effect), increased PCO_2 , and increased 2,3-BPG, enhancing oxygen unloading. Leftward shifts (increased affinity) occur with decreased temperature, increased pH, and decreased 2,3-BPG (e.g., stored blood), reducing

oxygen unloading. fetal hemoglobin (HbF) has a left-shifted curve for placental oxygen transfer.

Pancreatic Enzyme

– Digestive enzymes secreted by pancreatic acinar cells into the duodenum, including proteases (trypsinogen, chymotrypsinogen, proelastase, procarboxypeptidases), amylase (starch digestion), and lipase (triglyceride digestion), along with bicarbonate from ductal cells to neutralize gastric acid. Enzymes are secreted in inactive zymogen form and activated in the duodenum (trypsinogen to trypsin by enterokinase; trypsin then activates the others) to prevent autodigestion. Lipase requires bile salts and colipase for efficient fat digestion. Deficiency (chronic pancreatitis, cystic fibrosis) causes malabsorption, steatorrhea, and protein-energy malnutrition.

Pentose Phosphate Pathway

– A cytoplasmic glucose oxidation pathway running parallel to glycolysis, primarily in the liver, adipose tissue, adrenal cortex, and red blood cells. It has two phases: the oxidative phase (producing NADPH and ribose-5-phosphate) and the non-oxidative phase (interconverting sugar phosphates). Key enzyme: glucose-6-phosphate dehydrogenase (G6PD), the rate-limiting enzyme, producing NADPH. NADPH is essential for: fatty acid and steroid biosynthesis, maintaining reduced glutathione (protecting red blood cells from oxidative damage and preventing haemolysis), and cytochrome P450 detoxification. The non-oxidative phase recycles ribose-5-phosphate to glycolytic intermediates. G6PD deficiency (X-linked, common in Mediterranean, African, and Asian populations) causes hemolytic anemia triggered by oxidative stress from drugs (primaguine, sulphonamides) or fava beans.

Peristalsis

– Rhythmic sequential contractions of longitudinal and circular smooth muscle that propel gastrointestinal contents in an aboral (oral to anal) direction. The peristaltic reflex involves stretch activation of the intestinal wall: proximal to the stretch, longitudinal muscle contracts and circular muscle relaxes (ascending contraction); distally, circular muscle contracts and longitudinal muscle relaxes (descending relaxation). This is mediated by the myenteric (Auerbach's) plexus: excitatory neurotransmitters

(acetylcholine, substance P) cause proximal contraction, and inhibitory neurotransmitters (VIP, nitric oxide) cause distal relaxation. Peristalsis propels chyme at a rate of approximately 1 cm/min in the small intestine, 5-10 cm/min in the esophagus, and is slower in the colon. Disorders include achalasia (failure of LES relaxation), intestinal pseudo-obstruction, and Hirschsprung disease.

Peroxisome

– Single-membrane organelles containing oxidative enzymes (catalase, urate oxidase, D-amino acid oxidase) that produce and degrade hydrogen peroxide (H_2O_2). Functions: very-long-chain fatty acid beta-oxidation, plasmalogen synthesis (ether phospholipids for myelin), bile acid synthesis, cholesterol synthesis (initial steps), amino acid catabolism, ROS detoxification. Peroxisomes import proteins post-translationally via PTS1/PTS2 signals. Disorders: Zellweger syndrome (peroxisome biogenesis), X-linked adrenoleukodystrophy (VLCFA accumulation), Refsum disease (phytanic acid).

Phenylketonuria

– The most common inborn error of amino acid metabolism, caused by deficiency of phenylalanine hydroxylase (PAH, autosomal recessive), which converts phenylalanine to tyrosine. The deficiency leads to accumulation of phenylalanine and its transamination product phenylpyruvate in the blood and brain. Newborn screening (Guthrie test or tandem mass spectrometry) detects elevated phenylalanine levels (greater than 120 micromol/L). Untreated PKU causes severe intellectual disability, seizures, behavioural problems, eczema, microcephaly, and a musty odour. Newborn screening and early dietary restriction (low phenylalanine diet with special formula) prevents neurological damage. Maternal PKU (uncontrolled hyperphenylalaninaemia during pregnancy) causes fetal intellectual disability, microcephaly, and congenital heart defects.

Phospholipase C Pathway

– A GPCR signaling pathway activated primarily by Gq-protein coupled receptors (e.g., alpha-1 adrenergic, muscarinic M1/M3, vasopressin V1, angiotensin II AT1 receptors). When the Gq-alpha subunit is activated, it stimulates phospholipase C-beta (PLC-beta), which cleaves the membrane phospholipid phosphatidylinositol 4,5-bisphosphate (PIP2) into

two second messengers: inositol 1,4,5-trisphosphate (IP3) and diacylglycerol (DAG). IP3 is a water-soluble molecule that diffuses through the cytoplasm and binds to IP3 receptors on the endoplasmic reticulum, triggering Ca^{2+} release into the cytoplasm. DAG remains in the membrane and activates protein kinase C (PKC), which phosphorylates downstream target proteins. The Ca^{2+} signal activates calmodulin-dependent kinases (CaMK), and the pathway mediates smooth muscle contraction, neurotransmitter release, hormone secretion, and cell proliferation.

Phytomenadione

- See Vitamin K: Phylloquinone.

Platelet Aggregation

- The adhesion and clumping of platelets to form a hemostatic plug at sites of vascular injury. Following exposure of subendothelial collagen, platelets adhere via von Willebrand factor and GPIb receptors, become activated (shape change, granule release of ADP, thromboxane A2, serotonin), and aggregate by linking activated GPIIb/IIIa receptors with fibrinogen. Aggregation amplifies primary hemostasis and is essential for clot formation. Inhibited therapeutically by aspirin (irreversible COX-1 inhibition), clopidogrel and ticagrelor (P2Y12 ADP receptor blockade), and GPIIb/IIIa antagonists. Platelet aggregation testing (e.g., aggregometry) evaluates platelet function.

Positive Feedback

- A regulatory mechanism in which an output amplifies the initiating stimulus, producing an accelerating or self-reinforcing response that drives the system away from equilibrium and toward completion of an event. Examples: the oxytocin-induced uterine contractions of labor strengthen until delivery; sodium channel opening during an action potential causes further depolarization; platelet activation promotes further activation during hemostasis; the LH surge of ovulation. Positive feedback loops are inherently unstable and are typically terminated by an external event.

Proprioception

- The sense of body position, movement, and joint position arising from mechanoreceptors in muscles (muscle spindles), tendons (Golgi tendon organs), and joints, as well as skin receptors. Signals ascend

via the dorsal column-medial lemniscal pathway (conscious proprioception) and the spinocerebellar tract (unconscious). Proprioception is essential for coordinated movement, posture, balance, and motor learning. Loss (peripheral neuropathy, dorsal column disease such as tabes dorsalis) produces ataxia, unsteadiness with eyes closed (positive Romberg sign), and impaired fine motor control. Tested by joint position sense and vibration sense.

Protein

- Polymers of amino acids linked by peptide bonds, performing virtually all cellular functions. Four structural levels: primary (amino acid sequence), secondary (alpha helix, beta sheet), tertiary (3D fold of single polypeptide), quaternary (multiple subunits). Functions: enzymes (catalysis), structural (cytoskeleton, collagen), transport (hemoglobin, membrane transporters), signaling (hormones, receptors), defense (antibodies), storage, movement (myosin, kinesin). Protein folding: chaperones assist; misfolding causes diseases (Alzheimer, Parkinson, prion). Degradation: ubiquitin-proteasome system, lysosomal.

Protein Folding

- The process by which newly synthesized polypeptide chains acquire their functional three-dimensional structures. The amino acid sequence (primary structure) determines the folding pathway. Key structural levels: primary (amino acid sequence), secondary (alpha-helices and beta-sheets formed by hydrogen bonding), tertiary (overall 3D fold of a single polypeptide), and quaternary (arrangement of multiple subunits). Chaperone proteins assist proper folding: Hsp70 (heat shock protein 70) binds exposed hydrophobic regions of nascent polypeptides; Hsp60 (chaperonin, GroEL/GroES in bacteria) provides an isolated compartment for folding. Misfolded proteins are targeted for degradation by the ubiquitin-proteasome system. Protein misfolding causes conformational diseases including Alzheimer's (amyloid-beta), Parkinson's (alpha-synuclein), prion diseases (Creutzfeldt-Jakob), and cystic fibrosis (CFTR misfolding).

Proximal Tubule Reabsorption

- The proximal convoluted tubule (PCT) reabsorbs approximately 65 percent of filtered sodium, wa-

ter, glucose, amino acids, bicarbonate, and phosphate. Sodium reabsorption is the driving force for most solute and water transport: the basolateral Na^+/K^+ ATPase creates a low intracellular Na^+ concentration, allowing Na^+ entry from the tubular lumen via secondary active transporters ($\text{Na}^+/\text{glucose}$, $\text{Na}^+/\text{amino acid}$ cotransporters on the apical membrane; Na^+/H^+ exchanger). Water follows sodium osmotically via aquaporins (AQP1) in the proximal tubule. Glucose and amino acids are completely reabsorbed in the early PCT via sodium-coupled transporters (SGLT2 for glucose, SGLT1 for glucose and amino acids) until their transport maximum (T_m) is exceeded. Bicarbonate is reabsorbed via H^+ secretion (Na^+/H^+ exchanger) and carbonic anhydrase in the brush border. Phosphate reabsorption is regulated by PTH (decreases reabsorption, increases phosphate excretion).

Pulmonary Surfactant

– A phospholipid-protein mixture produced by type II alveolar pneumocytes that reduces surface tension at the air-liquid interface within alveoli. The primary component is dipalmitoylphosphatidylcholine (DPPC, lecithin), which forms a monolayer that reduces surface tension to near zero during expiration. Surfactant prevents alveolar collapse (atelectasis) at end-expiration by reducing the collapsing force, increases lung compliance, and stabilizes alveoli of different sizes (preventing small alveoli from collapsing into larger ones via the LaPlace relationship). Surfactant is produced from approximately week 24 of gestation, and its deficiency in premature infants causes respiratory distress syndrome (RDS) with atelectasis, hypoxaemia, and the need for surfactant replacement therapy and mechanical ventilation.

Pyruvate

– The three-carbon α -keto acid produced at the end of glycolysis from phosphoenolpyruvate by pyruvate kinase. Under aerobic conditions, pyruvate enters the mitochondrial matrix via the mitochondrial pyruvate carrier (MPC) and is converted to acetyl-CoA by the pyruvate dehydrogenase complex (PDC), an irreversible reaction that also produces CO_2 and NADH. The PDC requires five co-factors derived from vitamins: thiamine pyrophosphate (B1), FAD (B2), NAD^+ (B3), CoA (from pantothenic acid, B5), and lipoic acid. Under anaer-

obic conditions, pyruvate is reduced to lactate by lactate dehydrogenase, regenerating NAD^+ for continued glycolysis. Pyruvate is the branch point between aerobic (TCA cycle) and anaerobic (lactate) metabolism, and its fate is determined by oxygen availability and tissue metabolic demands.

Receptor

– A protein that binds a specific signaling molecule (ligand) and initiates a cellular response. Types: (1) Cell surface: ion channel (nicotinic AChR), G-protein coupled (GPCR: adrenergic, muscarinic, opioid), enzyme-linked (RTK: insulin receptor, cytokine receptors). (2) Intracellular: nuclear (steroid, thyroid, vitamin D), cytoplasmic (some steroid). Signal transduction: ligand binding $\rightarrow$ conformational change $\rightarrow$ second messengers (cAMP, IP_3/DAG , Ca^{2+}) or kinase cascades (MAPK, $\text{PI3K}/\text{Akt}$, JAK/STAT). Desensitization: phosphorylation, internalization, downregulation. Clinical: drug targets (agonists, antagonists, inverse agonists).

Receptor Tyrosine Kinases

– Single-pass transmembrane receptors with intrinsic tyrosine kinase activity in their intracellular domain. Ligand binding (e.g., insulin, EGF, PDGF, FGF) induces receptor dimerization and autophosphorylation of tyrosine residues. Phosphorylated tyrosines serve as docking sites for intracellular signaling proteins containing SH2 domains, activating downstream cascades: the Ras-MAP kinase pathway (cell proliferation and differentiation), the $\text{PI3K}/\text{Akt}$ pathway (cell survival and metabolism), and the PLC -gamma pathway (Ca^{2+} signalling). RTKs are frequently mutated or overexpressed in cancer (e.g., HER2 in breast cancer, EGFR in lung cancer), making them important therapeutic targets for tyrosine kinase inhibitors (imatinib, gefitinib, trastuzumab).

Refractory Period

– The period after an action potential during which a cell cannot (absolute refractory period) or can only partially (relative refractory period) generate a new action potential. The absolute refractory period results from sodium channel inactivation and ensures one-way action potential propagation and prevents summation; the relative refractory period reflects recovery of some sodium channels with continued

potassium conductance, allowing a second action potential only if stimulated more strongly. In cardiac muscle, the long refractory period prevents tetany and allows rhythmic pumping; shortened cardiac refractoriness (QT prolongation, early afterdepolarizations) predisposes to arrhythmias.

Renal Clearance

– The volume of plasma completely cleared of a substance by the kidneys per unit time, measured in mL/min. Clearance of any substance X is calculated as: $CX = (Ux \times V)/Px$, where Ux is urine concentration, V is urine flow rate, and Px is plasma concentration. Inulin clearance equals GFR (approximately 125 mL/min) because inulin is freely filtered but neither reabsorbed nor secreted. Paraaminohippuric acid (PAH) clearance approximates renal plasma flow (approximately 625 mL/min) because it is both filtered and completely secreted by the proximal tubule. Creatinine clearance is the most common clinical GFR estimate; cystatin C is a more accurate alternative unaffected by muscle mass. The concept is essential for determining drug dosing in renal impairment.

Renin-Angiotensin-Aldosterone System

– The RAAS is a hormonal cascade regulating blood pressure, fluid volume, and electrolyte balance. Stimulus: decreased renal perfusion pressure (detected by baroreceptors in the afferent arteriole), decreased sodium delivery to the macula densa, or increased sympathetic activity. Renin (from juxtaglomerular cells) cleaves angiotensinogen (from the liver) to angiotensin I. Angiotensin-converting enzyme (ACE, primarily in pulmonary endothelium) converts angiotensin I to angiotensin II. Angiotensin II is a potent vasoconstrictor, stimulates aldosterone secretion (Na^+ and water retention), increases ADH release, enhances thirst, increases sympathetic activity, and promotes cardiac and vascular remodelling. The RAAS is a target of ACE inhibitors, angiotensin receptor blockers (ARBs), direct renin inhibitors, and mineralocorticoid receptor antagonists for treating hypertension and heart failure.

Repolarization

– The return of the membrane potential toward the resting value after depolarization. In neurons

and skeletal/cardiac muscle, repolarization is primarily caused by the efflux of potassium through voltage-gated potassium channels and inactivation of sodium channels. In cardiac tissue, phase 3 repolarization is mediated by delayed rectifier potassium currents (IKr , IKs); drugs that block these currents prolong repolarization and the QT interval, predisposing to torsades de pointes. On the ECG, ventricular repolarization produces the T wave. Disturbed repolarization (ST changes, T wave abnormalities) is a key marker of ischemia and electrolyte imbalance.

Residual Volume

– The volume of air remaining in the lungs after a maximal forced expiration, approximately 1.2 L in adults. Residual volume cannot be measured by simple spirometry because it cannot be exhaled; it is measured by body plethysmography, helium dilution, or nitrogen washout. It keeps alveoli patent and prevents alveolar collapse at end expiration, maintaining continuous gas exchange. Residual volume is increased in obstructive lung disease (air trapping, COPD, emphysema) and decreased in restrictive lung disease.

Respiratory Physiology

– The study of pulmonary function encompassing ventilation (movement of air), gas exchange (diffusion of O_2 and CO_2 across the alveolar-capillary membrane), transport of gases in blood, and regulation of breathing. Key concepts include lung volumes and capacities, alveolar ventilation, dead space, ventilation-perfusion matching, the oxygen-hemoglobin dissociation curve, and the chemoreceptor-mediated control of ventilation. Understanding respiratory physiology underpins the interpretation of spirometry, blood gases, and the management of respiratory failure, hypoxemia, and hypercapnia.

Respiratory Rate

– The number of breaths per minute. Normal adult respiratory rate is 12-20 breaths/min at rest; normal newborn rate is 30-60. Tachypnea (>20 in adults) occurs with fever, hypoxia, acidosis, pain, anxiety, and lung disease; bradypnea (<12) with sedative/opioid overdose, hypothyroidism, and raised intracranial pressure; Kussmaul respirations (deep, rapid) with metabolic acidosis (DKA); Cheyne-

Stokes with heart failure and brainstem lesions. Respiratory rate is the first vital sign to change in acute illness and a key component of early warning scores.

Resting Membrane Potential

– The steady electrical potential difference across the cell membrane of an unstimulated cell, typically -70 mV in neurons, -80 to -90 mV in skeletal and cardiac muscle, and -50 to -60 mV in smooth muscle. It is generated by the differential distribution of ions established by the Na⁺/K⁺ ATPase (3 Na⁺ out, 2 K⁺ in) and maintained by selective membrane permeability—highest to potassium—so the potential approaches the potassium equilibrium potential (Nernst, -90 mV), with small contributions from sodium and chloride leak. The resting potential is the baseline from which depolarization (toward threshold) or hyperpolarization (away) occurs.

Retinol

– See Vitamin A: Retinal.

Ribosome

– Ribonucleoprotein complexes (rRNA + proteins) that synthesize proteins by translating mRNA. Two subunits: 60S (large, 28S/5.8S/5S rRNA) and 40S (small, 18S rRNA) in eukaryotes (80S complete). Prokaryotes have 50S/30S (70S complete). Free ribosomes in cytosol make cytosolic/nuclear proteins; bound ribosomes on rough ER make secretory/membrane/organelle proteins. Each ribosome has A, P, and E sites for tRNA binding. Translation: initiation (start codon recognition), elongation (codon-anticodon pairing, peptide bond formation), termination (stop codon recognition).

RNA

– Ribonucleic acid, single-stranded nucleic acid (ribose sugar, uracil instead of thymine). Types: mRNA (messenger, carries genetic code from DNA to ribosome), tRNA (transfer, brings amino acids to ribosome, anticodon-codon pairing), rRNA (ribosomal, structural/catalytic component of ribosome), snRNA (spliceosomal, intron removal), miRNA/siRNA (regulatory, post-transcriptional silencing), lncRNA (long non-coding, chromatin regulation), piRNA (transposon silencing in germline). Transcription: RNA polymerase II synthesizes pre-mRNA from DNA template.

Salivation

– The secretion of saliva by the salivary glands.

Salivation is controlled by the autonomic nervous system: parasympathetic stimulation (CN VII—submandibular and sublingual glands; CN IX—parotid gland) produces profuse, watery saliva via acetylcholine acting on muscarinic M₃ receptors; sympathetic stimulation produces scanty, viscous saliva via noradrenaline acting on β -adrenergic receptors. Salivation is triggered by: sight, smell, or thought of food (cephalic phase), mechanical stimulation of the mouth (food in the oral cavity), and the presence of acid or chemical irritants. The salivary center is located in the medulla oblongata (superior and inferior salivatory nuclei). Daily volume: 1–1.5 L. Hypersalivation (sialorrhoea) can be caused by oral inflammation, teething, pregnancy, neurological disorders (Parkinson disease, motor neuron disease, cerebral palsy, rabies), gastro-esophageal reflux, and medications (clozapine, anticholinesterases). Hyposalivation (xerostomia/dry mouth): Sjögren syndrome, radiation therapy to the head and neck, medications (anticholinergics, antidepressants, antihistamines, diuretics), diabetes, and dehydration.

Saltatory Conduction

– The rapid propagation of action potentials along myelinated nerve fibers, where the action potential appears to "jump" from one Node of Ranvier to the next. Myelin (produced by Schwann cells in the PNS and oligodendrocytes in the CNS) insulates the axon, preventing ion flow across the internodal membrane. Action potentials are generated only at the nodes (approximately 1 mm apart), where voltage-gated Na⁺ channels are concentrated. The local current from one node depolarises the next node to threshold, causing saltatory conduction at speeds up to 50 m/s in myelinated fibers (compared to approximately 0.5 m/s in unmyelinated fibers). Saltatory conduction is energy-efficient, as Na⁺/K⁺ ATPase activity is required only at the nodes. Demyelinating diseases such as multiple sclerosis (CNS) and Guillain-Barré syndrome (PNS) slow or block conduction, causing neurological deficits.

Second Messengers

– Intracellular signaling molecules generated in response to extracellular signals (first messengers like hormones or neurotransmitters). cAMP (cyclic adenosine monophosphate): produced from ATP by adenylyl cyclase, activated by Gs-protein cou-

pled receptors, activates protein kinase A (PKA); degraded by phosphodiesterase. IP₃ (inositol 1,4,5-trisphosphate): produced from PIP₂ by phospholipase C, triggers Ca²⁺ release from the endoplasmic reticulum. DAG (diacylglycerol): remains in the membrane along with IP₃, and together they activate protein kinase C (PKC). Ca²⁺ is a versatile second messenger that binds calmodulin, activating CaMKII (in neurons, critical for long-term potentiation and memory formation). The second messenger concept is central to understanding hormone action, drug effects, and intracellular communication.

Second Messenger Systems

– Intracellular signaling molecules that relay extracellular signals (first messengers: hormones, neurotransmitters, growth factors) to cellular responses. Major second messengers: cAMP (produced by adenylyl cyclase from ATP, activated by Gs-GPCRs; activates PKA; degraded by phosphodiesterase; example: epinephrine binding beta-1 receptors in the heart increasing heart rate and contractility). cGMP (produced by guanylyl cyclase; activated by nitric oxide in smooth muscle causing vasodilation; also activated by natriuretic peptides ANP/BNP). IP₃ (produced by phospholipase C from PIP₂, releases Ca²⁺ from ER). DAG (produced with IP₃, activates PKC). Ca²⁺ itself acts as a second messenger, activating calmodulin and CaMK. Second messenger systems provide signal amplification: a single activated receptor can activate many G-proteins, each activating an enzyme that produces many second messenger molecules.

Secretin

– A peptide hormone produced by S-cells in the duodenal and jejunal mucosa in response to acidic chyme (pH less than 4.5) entering the duodenum from the stomach. Secretin's primary action is to stimulate the pancreatic ductal cells to secrete a bicarbonate-rich fluid, neutralizing duodenal acid and raising the pH to approximately 7-8, which optimizes pancreatic enzyme activity. Secretin also inhibits gastric acid secretion and gastric motility (slowing gastric emptying), stimulates bile secretion and gallbladder contraction, and enhances the effects of cholecystikinin (CCK). Secretin release is inhibited by H⁺ buffering in the duodenum (negative feedback). Secretin was the first hormone

discovered (Bayliss and Starling, 1902), establishing the concept of hormonal regulation.

Segmentation

– A pattern of intestinal motility involving localized, rhythmic contractions of circular muscle that segment the intestinal contents, mixing them with digestive secretions and increasing contact with the absorptive mucosal surface. Unlike peristalsis, segmentation does not propel contents distally. It occurs predominantly in the fed state in the small intestine, at a frequency determined by the slow wave rhythm of the intestine (approximately 12 per minute in the duodenum, 8 per minute in the ileum). The contractions are mediated by the enteric nervous system and the interstitial cells of Cajal (pacemaker cells). Segmentation is essential for efficient digestion and absorption; loss of segmentation occurs in intestinal obstruction and ileus.

Sensory Nerves

– Nerves that transmit sensory information from peripheral receptors to the central nervous system. Sensory (afferent) neurons have their cell bodies in the dorsal root ganglia (spinal nerves) or cranial nerve ganglia (cranial nerves). Sensory receptors: mechanoreceptors (touch, pressure, vibration, stretch—Pacinian corpuscles, Meissner corpuscles, Merkel discs, Ruffini endings), thermoreceptors (cold—A δ fibers; warm—unmyelinated C fibers), nociceptors (pain—A δ fibers: fast, sharp, localised; C fibers: slow, dull, diffuse), chemoreceptors (taste, smell, O₂, CO₂, pH), and photoreceptors (rods and cones in the retina). Sensory pathways: spinothalamic tract (pain, temperature, crude touch—crosses in spinal cord), dorsal columns/medial lemniscus (fine touch, vibration, proprioception—crosses in medulla), and trigeminothalamic tract (facial sensation). Dermatomes: areas of skin supplied by a single spinal nerve (C4—shoulder, C6—thumb, C8—little finger, T4—nipple, T10—umbilicus, L4—medial foot, S1—lateral foot). Sensory deficits help localise neurological lesions at the level of the peripheral nerve, plexus, nerve root, spinal cord, brainstem, thalamus, or cortex.

Shivering

– Involuntary, rhythmic skeletal muscle contraction generating heat in response to cold exposure or

fever, a key thermoregulatory response under hypothalamic (preoptic area) control. Shivering can increase heat production 3-5 fold. It is triggered when core temperature falls below the set point and sympathetic activation increases muscle tone, followed by rhythmic oscillation. Shivering also occurs during fever when the set point is raised. Postoperative shivering after anesthesia is common and treated with warming. It increases metabolic rate and oxygen consumption, relevant in hypothermic or post-arrest patients.

Signal Transduction

– The process by which an extracellular signal (hormone, neurotransmitter, growth factor, drug) binding to a cell-surface or intracellular receptor is converted into a specific intracellular response. Major pathways: G protein-coupled receptors (adenylyl cyclase/cAMP, phospholipase C/IP3/DAG), receptor tyrosine kinases (Ras-MAPK, PI3K-Akt), ligand-gated ion channels, and nuclear receptors (steroid/thyroid hormones modulating gene transcription). Pathways involve second messengers (cAMP, calcium, DAG, IP3), phosphorylation cascades, and transcription factors. Dysregulated signal transduction underlies cancer, diabetes, and many endocrinopathies; many drugs target these pathways.

Sliding Filament

– The mechanism of muscle contraction in which actin filaments slide past myosin filaments, shortening the sarcomere without changing filament lengths. Myosin cross-bridges bind actin, undergo a power stroke using ATP hydrolysis, detach, and reattach to new actin sites in a cyclic manner. The extent of sliding is limited by the overlap between thin (actin) and thick (myosin) filaments. Active tension depends on sarcomere length (Frank-Starling-like length-tension relationship in muscle). Contraction stops when calcium is pumped back into the sarcoplasmic reticulum, allowing tropomyosin to block cross-bridge binding.

Stretch Reflex

– A monosynaptic spinal reflex in which stretching a muscle (e.g., a tap on the patellar tendon) excites muscle spindles, generating an afferent signal (Ia fibers) that directly excites the alpha motor neurons of the same muscle, causing contraction and

resistance to stretch. Reciprocal inhibition via Ia inhibitory interneurons relaxes antagonists. The stretch reflex maintains posture, resists gravity, and is tested by deep tendon reflexes (e.g., patellar, biceps, ankle). Reduced reflexes indicate lower motor neuron lesions; hyperactive reflexes with clonus indicate upper motor neuron lesions.

Sweating

– The secretion of sweat by eccrine glands, the primary heat-loss mechanism in humans, controlled by sympathetic cholinergic innervation (in contrast to the catecholaminergic sympathetic response elsewhere). Evaporation of sweat cools the skin; sweating is triggered by elevated core temperature (hypothalamic preoptic area), exercise, emotional stress, and fever. Sweat contains water, sodium chloride, urea, and lactate. Loss of sodium through sweat is clinically relevant in cystic fibrosis (elevated sweat chloride—the diagnostic test). Disorders include hyperhidrosis (excessive sweating) and anhidrosis (impaired sweating, predisposing to hyperthermia).

Sympathetic Nervous System

– The division of the autonomic nervous system responsible for the 'fight or flight' response, preparing the body for intense physical activity or stress. Sympathetic preganglionic neurons originate in the intermediolateral column of the spinal cord gray matter (T1–L2), making it the thoracolumbar system. Preganglionic fibers are short and synapse in the paravertebral sympathetic chain ganglia (bilaterally, 22 ganglia) or prevertebral ganglia (celiac, superior mesenteric, inferior mesenteric, aorticorenal). The neurotransmitter of preganglionic fibers is acetylcholine (nicotinic receptors); postganglionic fibers release noradrenaline (norepinephrine) at target organs (adrenergic α and β receptors), except sweat glands and some blood vessels (cholinergic). Sympathetic effects: pupil dilation (mydriasis), increased heart rate and contractility (chronotropic and inotropic— β_1), bronchodilation (β_2), vasoconstriction of skin and splanchnic vessels (α_1), vasodilation of skeletal muscle vessels (β_2), increased sweating (cholinergic), increased renin secretion (β_1), decreased GI motility and secretion (α_2 , β_2), contraction of sphincters (urinary, anal— α_1), ejaculation, and release of glucose

(glycogenolysis— β 2, gluconeogenesis). The adrenal medulla (modified sympathetic ganglion) secretes adrenaline (epinephrine, 80%) and noradrenaline (20%) into the bloodstream. The sympathetic nervous system also controls blood pressure via the baroreceptor reflex.

Synapse

– The specialized junction between a neuron and another neuron (or effector cell—muscle, gland) where information is transmitted from one cell to another. Types: (1) Chemical synapses (most common in the nervous system)—the presynaptic terminal releases neurotransmitter molecules into the synaptic cleft (20–40 nm wide) in response to an action potential. Neurotransmitters diffuse across the cleft and bind to postsynaptic receptors (ionotropic—ligand-gated ion channels, fast response; metabotropic—G-protein coupled receptors, slow, modulatory). This generates either an excitatory postsynaptic potential (EPSP—depolarisation) or inhibitory postsynaptic potential (IPSP—hyperpolarisation). Summation of many EPSPs reaching threshold generates a new action potential. (2) Electrical synapses—gap junctions (connexin proteins) allow direct flow of ions between cells, enabling very fast, bidirectional transmission (found in smooth and cardiac muscle, some CNS regions). Key neurotransmitters: glutamate (main excitatory CNS transmitter), GABA (main inhibitory CNS transmitter), acetylcholine (neuromuscular junction, autonomic ganglia), dopamine, noradrenaline, serotonin, and neuropeptides (substance P, endorphins). Synaptic plasticity: long-term potentiation (LTP) and long-term depression (LTD)—mechanisms of learning and memory. The synapse is the site of action of many drugs (anaesthetics, antidepressants, antipsychotics, anxiolytics, muscle relaxants) and toxins (botulinum toxin—blocks ACh release, tetanus toxin—blocks inhibitory interneurons).

Taste

– The sensation produced by the interaction of chemical substances with taste receptor cells (TRCs) on the tongue, palate, pharynx, epiglottis, and upper esophagus. Taste is one of the five primary senses (gustation). Five basic taste qualities: sweet (sugars, artificial sweeteners—T1R2/T1R3 receptors), sour (acids—protons, PKD2L1 receptor),

salty (sodium ions—ENaC channel), bitter (alkaloids, toxins—T2R receptor family, 25 subtypes), and umami (savory—glutamate, T1R1/T1R3 receptor). Taste buds (5,000) are housed in papillae on the tongue: fungiform (anterior), foliate (lateral), circumvallate (posterior), and filiform (no taste buds—mechanical). Each taste bud contains 50–100 TRCs with microvilli exposed to the oral cavity via a taste pore. Taste information is transmitted via cranial nerves: facial (CN VII—chorda tympani, anterior two-thirds of tongue), glossopharyngeal (CN IX—posterior one-third), and vagus (CN X—epiglottis and pharynx) to the nucleus of the solitary tract in the medulla, then to the thalamus (VPM) and primary gustatory cortex (insula and operculum). Taste disorders: ageusia (loss of taste), hypogeusia (reduced), dysgeusia (distorted), and phantom taste perception. Causes: viral infections (COVID-19—anosmia and ageusia are hallmark symptoms), medications (ACE inhibitors—metallic taste), chemotherapy, head trauma, radiation, Bell palsy, and ageing. Taste is closely linked to smell (olfaction); much of what is perceived as 'taste' is actually retronasal olfaction.

Tay-Sachs Disease

– A lysosomal storage disease caused by deficiency of hexosaminidase A (Hex A), an autosomal recessive disorder leading to accumulation of GM2 ganglioside in neurons of the central nervous system. Hex A is a heterodimer of alpha and beta subunits; mutations in the HEXA gene (encoding the alpha subunit) cause the classic infantile form. Normal carrier screening: Hex A activity is approximately 50 percent of normal. Affected infants appear normal at birth but develop progressive neurodegeneration by 3–6 months with hypotonia, loss of motor skills, exaggerated startle reflex, cherry-red macula on fundoscopy, macrocephaly, and seizures, with death typically by age 4. Carrier frequency is approximately 1 in 30 in Ashkenazi Jewish populations, and enzyme-based carrier screening has reduced the incidence through prenatal diagnosis.

TCA Cycle

– The tricarboxylic acid (Krebs) cycle occurs in the mitochondrial matrix, completing the oxidation of acetyl-CoA (from carbohydrates, fats, and proteins) to CO₂ while generating reducing equivalents

(NADH, FADH₂) for the electron transport chain. Eight steps: (1) citrate synthase (acetyl-CoA + oxaloacetate to citrate), (2) aconitase (citrate to isocitrate), (3) isocitrate dehydrogenase (rate-limiting, isocitrate to alpha-ketoglutarate, producing NADH and CO₂), (4) alpha-ketoglutarate dehydrogenase complex (alpha-ketoglutarate to succinyl-CoA, producing NADH and CO₂, requiring TPP, lipoic acid, CoA, FAD, NAD⁺), (5) succinyl-CoA synthetase (succinyl-CoA to succinate, producing GTP), (6) succinate dehydrogenase (succinate to fumarate, producing FADH₂, also Complex II of ETC), (7) fumarase (fumarate to malate), (8) malate dehydrogenase (malate to oxaloacetate, producing NADH). The cycle produces 3 NADH, 1 FADH₂, and 1 GTP per acetyl-CoA, yielding approximately 10 ATP equivalents.

Temperature (Body Temperature)

– The balance between heat production (metabolism, muscle activity) and heat loss (radiation, conduction, convection, evaporation). Normal core body temperature: 36.5–37.5°C (97.7–99.5°F), regulated by the hypothalamus (preoptic anterior hypothalamus—thermoregulatory center). Temperature is measured orally (sublingual—0.3–0.5°C below core), axillary (0.5–1.0°C below core), tympanic (close to core, infrared), rectal (closest to core), or via esophageal/pulmonary artery catheter (gold standard—core). Circadian variation: lowest at 4–6 AM, highest at 4–6 PM. Effects of exercise, digestion, menstrual cycle (0.5°C rise post-ovulation). Hyperthermia: elevated temperature due to failed thermoregulation (heat stroke, malignant hyperthermia, neuroleptic malignant syndrome)—does not respond to antipyretics. Fever (pyrexia): regulated temperature elevation driven by cytokines (IL-1, IL-6, TNF, prostaglandin E₂) in response to infection, inflammation, or tissue damage—responds to antipyretics. Hypothermia: core temperature <35°C. Fever of unknown origin (FUO): temperature >38.3°C (101°F) for ≥3 weeks with no diagnosis after 1 week of inpatient investigation.

Thermoneutral Zone

– The range of ambient temperatures over which body temperature is maintained by basal metabolic heat production alone, without additional thermoregulatory responses such as shivering or sweat-

ing. In humans the zone is approximately 27–32 degrees C for a resting nude adult. Within the zone, vasomotor tone adjusts heat loss. Below it, heat-conserving (vasoconstriction, shivering, nonshivering thermogenesis) responses begin; above it, heat-dissipating (vasodilation, sweating) responses occur. The zone narrows with age, anesthesia, and prematurity—preterm infants have a high surface-to-volume ratio and limited thermoregulation.

Thermoregulation

– The physiological maintenance of core body temperature near the set point (37 degrees C) via a balance of heat production and heat loss, controlled by the preoptic area of the hypothalamus. Heat production includes basal metabolism, muscular activity, shivering, and nonshivering thermogenesis (brown fat); heat loss occurs via radiation, conduction, convection, and evaporation (sweating). Sensors in skin and core detect temperature, and effectors adjust vasomotor tone, sweating, shivering, and behavior. Fever reflects a raised set point (pyrogens, prostaglandins). Failure causes hypo- or hyperthermia.

Tidal Volume

– The volume of air inspired or expired during each normal breath, approximately 500 mL (6–8 mL/kg) in a resting adult. Tidal volume is measured by spirometry. Minute ventilation = tidal volume × respiratory rate (6 L/min). Only a portion reaches the alveoli (alveolar ventilation) after subtracting dead space (150 mL). Low tidal volumes cause hypoventilation, atelectasis, and hypercapnia; excessive tidal volumes (lung-protective ventilation typically 6 mL/kg) cause ventilator-induced lung injury—barotrauma, volutrauma, biotrauma. Ventilation-perfusion matching depends on appropriate tidal volume distribution.

Transcription

– The synthesis of RNA from a DNA template by RNA polymerase, the first step of gene expression. In eukaryotes, RNA polymerase II transcribes protein-coding genes into pre-mRNA. Initiation: RNA polymerase binds to the promoter region (containing the TATA box approximately 25–30 base pairs upstream of the transcription start site), with the help of general transcription factors (TFIIA, TFIIB, TFIID/TBP, TFIIIE, TFIIF, TFIIF) form-

ing the pre-initiation complex. TFIID contains the TATA-binding protein (TBP) that binds the TATA box. Elongation: RNA polymerase II moves along the template strand, synthesising pre-mRNA in the 5' to 3' direction, adding ribonucleotides complementary to the DNA template. Termination: polyadenylation signal (AAUAAA) triggers cleavage and polyadenylation of the 3' end, followed by RNA polymerase dissociation. Transcription is regulated by promoter elements, enhancers, silencers, and transcription factors, allowing precise spatiotemporal gene expression.

Translation

– The synthesis of proteins from mRNA templates by ribosomes, the final step of gene expression. The genetic code is read in triplets (codons), each specifying an amino acid. Initiation: the small ribosomal subunit (40S in eukaryotes) binds the mRNA at the 5' cap, scans for the start codon (AUG), and the initiator tRNA (Met-tRNA_i) binds. The large subunit (60S) joins to form the complete ribosome (80S), with the start codon in the P site. Eukaryotic initiation factors (eIFs) facilitate this process: eIF4E binds the 5' cap, eIF2 binds Met-tRNA_i to the small subunit, and eIF5B joins the large subunit. Elongation: aminoacyl-tRNAs enter the A site via EF-Tu (eEF1A in eukaryotes), peptide bond formation occurs in the P site, and translocation moves the ribosome three nucleotides along the mRNA via EF-G (eEF2). Termination: a stop codon (UAA, UAG, UGA) in the A site is recognised by release factors, releasing the completed polypeptide.

Tubular Reabsorption

– The process by which the renal tubules return filtered water and solutes from the tubular lumen to the blood, reclaiming 99 percent of the glomerular filtrate. Proximal tubule: reabsorbs 65 percent of sodium, most glucose, amino acids, water, bicarbonate, phosphate, and urate. Loop of Henle: countercurrent multiplier concentrating the medullary interstitium; ascending limb reabsorbs NaCl but is water-impermeable. Distal convoluted tubule: sodium/chloride cotransport. Collecting duct: aldosterone-regulated sodium reabsorption, ADH-regulated water reabsorption. Impaired reabsorption causes glucosuria, aminoaciduria, phosphaturia, and renal salt/water wasting.

Tubular Secretion

– The transport of substances from the peritubular capillary blood into the tubular lumen, a second mechanism (besides filtration) by which the kidney eliminates waste and regulates ions. Organic anions (PAH, penicillins, urate) and organic cations (creatinine, histamine, many drugs) are actively secreted in the proximal tubule via OAT and OCT transporters. Potassium and hydrogen ions are secreted in the distal tubule and collecting duct (potassium-sparing diuretics block this). Secretion is important for rapid clearance of drugs and endogenous waste and explains why some substances (PAH) are cleared in one pass.

Tubuloglomerular Feedback

– A feedback mechanism at the juxtaglomerular apparatus (JGA) that adjusts GFR based on tubular fluid NaCl concentration. The macula densa cells (specialized tubular epithelial cells in the thick ascending limb) sense NaCl concentration via the NKCC2 cotransporter. When GFR is high, increased NaCl delivery to the macula densa triggers release of ATP and adenosine, causing afferent arteriole constriction and reducing GFR. When GFR is low, decreased NaCl delivery causes afferent arteriole dilation (via increased nitric oxide and prostaglandins), increasing GFR. This feedback loop maintains a relatively constant NaCl delivery to the distal tubule and stabilises GFR despite changes in blood pressure. The JGA also releases renin in response to low NaCl, activating the RAAS. Tubuloglomerular feedback is impaired in diabetic nephropathy and during ACE inhibitor therapy.

Uncompetitive Inhibition

– A type of enzyme inhibition where the inhibitor binds only to the enzyme-substrate (ES) complex at a site distinct from the active site, forming an inactive ESI complex. The inhibitor cannot bind to the free enzyme. Both V_{max} and K_m decrease: V_{max} decreases because the ESI complex is non-productive (fewer active ES complexes), and K_m decreases because the inhibitor effectively traps substrate in the ES complex (increasing apparent substrate affinity). On a Lineweaver-Burk plot: lines are parallel, with different slopes and both x- and y-intercepts changing (same slope, different y-intercept and x-intercept). Uncompetitive

inhibition is rare in single-substrate reactions but occurs in multisubstrate reactions (e.g., inhibition of lactate dehydrogenase by pyruvate at high concentrations) and is the mechanism of some drugs such as methotrexate (inhibition of dihydrofolate reductase when bound to NADPH).

Urea Cycle

– The hepatic metabolic pathway converting toxic ammonia ($\text{NH}_3/\text{NH}_4^+$) to urea for renal excretion, occurring partly in the mitochondrial matrix and partly in the cytoplasm. Five steps: (1) carbamoyl phosphate synthetase I (CPS-I, mitochondrial, rate-limiting, activated by N-acetylglutamate), combining CO_2 , NH_3 , and ATP; (2) ornithine transcarbamylase (OTC, mitochondrial), combining carbamoyl phosphate with ornithine to form citrulline; (3) argininosuccinate synthetase (cytoplasmic), combining citrulline with aspartate to form argininosuccinate; (4) argininosuccinate lyase (cytoplasmic), cleaving argininosuccinate to arginine and fumarate; (5) arginase (cytoplasmic), hydrolysing arginine to ornithine and urea. Urea is the non-toxic nitrogenous waste product excreted by the kidneys. Deficiencies cause hyperammonaemia (ammonia intoxication), with symptoms including lethargy, vomiting, cerebral edema, and coma.

Urine Formation

– The process by which the kidney produces urine through three steps: glomerular filtration (formation of 180 L/day ultrafiltrate), tubular reabsorption (return of 99 percent of water and most solutes), and tubular secretion (active addition of waste and ions). Net result: 1-2 L/day of urine containing urea, creatinine, and excess electrolytes. Regulated by hormones: ADH (water reabsorption), aldosterone (sodium reabsorption, potassium secretion), atrial natriuretic peptide (natriuresis), and parathyroid hormone (calcium/phosphate). Urinalysis and the composition of urine reflect filtration, reabsorption, and secretion functions.

Vitamin A: Retinal

– Vitamin A (retinol) is a fat-soluble vitamin essential for vision, immune function, cell differentiation, and reproduction. In the eye, retinol is oxidized to retinal (retinaldehyde), which binds to opsin in the photoreceptor outer segments forming rhodopsin (in rods) and photopsins (in cones). Light absorption

by 11-cis-retinal causes isomerization to all-trans-retinal, triggering the phototransduction cascade (G-protein transducin activation, phosphodiesterase activation, cGMP hydrolysis, Na^+ channel closure, and hyperpolarisation of the photoreceptor cell). Vitamin A deficiency causes night blindness (nyctalopia), xerophthalmia (dry cornea), Bitot spots, keratomalacia, and increased infection risk. Excess vitamin A (hypervitaminosis A) causes hepatotoxicity, teratogenicity, and raised intracranial pressure.

Vitamin B12: Cobalamin

– Vitamin B12 (cobalamin) is a water-soluble vitamin containing cobalt, essential for two enzymatic reactions: (1) methionine synthase (cytoplasmic, requiring methylcobalamin), converting homocysteine to methionine (linking to folate metabolism), and (2) methylmalonyl-CoA mutase (mitochondrial, requiring adenosylcobalamin), converting methylmalonyl-CoA to succinyl-CoA (in odd-chain fatty acid and branched-chain amino acid metabolism). Intrinsic factor (IF, from gastric parietal cells) is essential for B12 absorption in the terminal ileum. B12 deficiency causes megaloblastic anemia (with hypersegmented neutrophils), peripheral neuropathy, subacute combined degeneration of the spinal cord (dorsal columns and corticospinal tracts), and glossitis. Pernicious anemia is an autoimmune condition causing IF deficiency.

Vitamin B1: Thiamine

– Thiamine (thiamine pyrophosphate, TPP) is a water-soluble B vitamin essential as a cofactor for several key metabolic enzymes: pyruvate dehydrogenase (linking glycolysis to the TCA cycle), alpha-ketoglutarate dehydrogenase (TCA cycle), transketolase (pentose phosphate pathway), and branched-chain alpha-ketoacid dehydrogenase (branched-chain amino acid catabolism). Thiamine deficiency causes: beriberi (dry: peripheral neuropathy and muscle wasting; wet: high-output heart failure with edema and vasodilation), and Wernicke-Korsakoff syndrome (confusion, ataxia, ophthalmoplegia, and amnesia, commonly seen in chronic alcoholism). Wernicke encephalopathy is a medical emergency treated with intravenous thiamine before glucose administration to prevent Korsakoff psychosis.

Vitamin B3: Niacin

– Niacin (nicotinic acid and nicotinamide) is a water-soluble vitamin that serves as the precursor for the coenzymes NAD⁺ (nicotinamide adenine dinucleotide) and NADP⁺ (nicotinamide adenine dinucleotide phosphate), which are essential for over 400 enzymatic reactions including glycolysis, the TCA cycle, oxidative phosphorylation, and fatty acid synthesis. NAD⁺ is a key electron carrier in catabolic reactions; NADP⁺ is important in anabolic reactions and antioxidant defense (via glutathione). Niacin deficiency causes pellagra, characterized by the 4 Ds: dermatitis (photosensitive), diarrhea, dementia, and death. Pellagra is endemic in populations consuming maize-based diets low in tryptophan (niacin precursor). Therapeutic niacin (in high doses) lowers triglycerides and LDL while raising HDL.

Vitamin B6: Pyridoxine

– Pyridoxine (pyridoxal phosphate, PLP, the active form) is a water-soluble B vitamin essential as a cofactor for over 100 enzymatic reactions, particularly in amino acid metabolism. Key reactions include transamination (ALT, AST), decarboxylation (producing neurotransmitters: serotonin from 5-HTP, dopamine/norepinephrine from L-DOPA, GABA from glutamate, histamine from histidine), and glycogen phosphorylase (glycogenolysis). PLP is also required for heme synthesis (ALA synthase step), sphingolipid synthesis, and serine racemization. PLP is also required for amino acid transport across cell membranes. Pyridoxine deficiency is rare but causes dermatitis, glossitis, microcytic anemia, peripheral neuropathy, and seizures in infants. Isoniazid (tuberculosis treatment) can cause B6 deficiency as a side effect, requiring supplementation.

Vitamin B9: Folate

– Folate (folic acid, tetrahydrofolate/THF) is a water-soluble B vitamin essential for one-carbon transfer reactions in nucleotide synthesis (thymidylate synthesis for DNA, purine synthesis), amino acid metabolism (methionine synthesis from homocysteine), and methylation reactions. THF carries one-carbon units at various oxidation states (methyl, methylene, methenyl, formyl, formimino). Key reactions: thymidylate synthase converts dUMP to dTMP (DNA synthesis, the target of 5-fluorouracil), and methionine synthase converts homocysteine to

methionine (requiring methylcobalamin/B12). Folate deficiency causes megaloblastic anemia (identical to B12 deficiency), neural tube defects in pregnancy (spina bifida, anencephaly), and elevated homocysteine (cardiovascular risk factor). Folic acid supplementation before and during early pregnancy prevents neural tube defects.

Vitamin B Complex

– The vitamin B complex comprises eight water-soluble B vitamins that function primarily as coenzymes or cofactors in cellular metabolism: Vitamin B1 (thiamine, a cofactor in carbohydrate metabolism and nerve function), Vitamin B2 (riboflavin, precursor of FAD/FMN in oxidation-reduction reactions), Vitamin B3 (niacin, precursor of NAD⁺/NADP⁺), Vitamin B5 (pantothenic acid, component of coenzyme A), Vitamin B6 (pyridoxine, cofactor in amino acid metabolism and neurotransmitter synthesis), Vitamin B7 (biotin, cofactor in carboxylation reactions), Vitamin B9 (folate/folic acid, essential for one-carbon transfer in nucleotide synthesis), and Vitamin B12 (cobalamin, cofactor for methionine synthase and methylmalonyl-CoA mutase). B vitamins are obtained from a wide variety of foods (meat, eggs, dairy, legumes, leafy greens, whole grains) and are generally not stored in large quantities, requiring regular dietary intake. Deficiencies cause specific syndromes (beriberi for B1, pellagra for B3, megaloblastic anemia for B9/B12, see individual entries).

Vitamin C (Ascorbic Acid)

– A water-soluble vitamin and a powerful antioxidant, essential for collagen synthesis (required for proline and lysine hydroxylation in collagen triple helix formation), carnitine synthesis, neurotransmitter synthesis (dopamine to norepinephrine), and iron absorption (reduces ferric to ferrous iron in the gut). Humans lack L-gulonolactone oxidase and cannot synthesise vitamin C, requiring dietary intake (citrus fruits, berries, kiwi, tomatoes, peppers, broccoli). Vitamin C deficiency causes scurvy: impaired wound healing, gingival hyperplasia and bleeding (swollen, bleeding gums), perifollicular haemorrhages, ecchymoses, coiled hairs, joint pain, fatigue, and anemia. In severe cases, scurvy causes haemarthrosis, intraosseous bleeding, and death. Vitamin C is also a cofactor for dopamine beta-

hydroxylase (norepinephrine synthesis). High-dose vitamin C has been used as an unproven treatment for the common cold and has been investigated in sepsis and cancer (intravenous high-dose as adjunctive therapy, limited evidence).

Vitamin D: Calcitriol

– Vitamin D is a fat-soluble vitamin (actually a prohormone) essential for calcium and phosphorus homeostasis and bone health. Cholecalciferol (D3) is synthesized in the skin from 7-dehydrocholesterol by UVB radiation, or obtained from diet (ergocalciferol/D2 from plants, D3 from animal sources). It is hydroxylated in the liver to 25-hydroxyvitamin D (calcidiol), then in the kidney to the active form 1,25-dihydroxyvitamin D (calcitriol) by 1- α -hydroxylase (regulated by PTH, low calcium, and low phosphate; inhibited by FGF23 and high phosphate). Calcitriol increases intestinal calcium and phosphate absorption, promotes renal calcium reabsorption, and mobilises calcium from bone. Vitamin D deficiency causes rickets in children (soft, deformed bones) and osteomalacia in adults (bone pain, weakness, fractures).

Vitamin E: Tocopherol

– Vitamin E (alpha-tocopherol) is a fat-soluble vitamin and the body's primary lipid-soluble antioxidant, protecting polyunsaturated fatty acids in cell membranes from lipid peroxidation by free radicals (reactive oxygen species). It donates a hydrogen atom to lipid peroxy radicals, breaking the chain reaction of lipid peroxidation. Vitamin E works synergistically with vitamin C (which regenerates reduced vitamin E at the membrane-cytosol interface) and selenium (as a cofactor for glutathione peroxidase) in protecting against oxidative damage. Vitamin E deficiency is rare but occurs in fat malabsorption syndromes (cystic fibrosis, abetalipoproteinaemia) and causes peripheral neuropathy, spinocerebellar ataxia, retinopathy, and haemolysis (due to red blood cell membrane lipid peroxidation).

Vitamin K: Phyloquinone

– Vitamin K is a fat-soluble vitamin essential for the post-translational gamma-carboxylation of glutamate residues to gamma-carboxyglutamate (Gla) in specific clotting factors (II, VII, IX, X, protein C, protein S) and anticoagulant proteins (protein C, protein S, protein Z). The gamma-carboxylation

reaction, catalyzed by gamma-glutamyl carboxylase, requires reduced vitamin K (vitamin K hydroquinone) as a cofactor and is essential for the calcium-binding function of these proteins, allowing them to bind calcium and phospholipid membranes. Vitamin K deficiency causes bleeding (elevated PT/INR), most commonly in newborns (given prophylactic vitamin K at birth), patients with fat malabsorption, or those on warfarin therapy (which inhibits vitamin K epoxide reductase, preventing recycling of vitamin K). The antidote is vitamin K administration.

Withdrawal Reflex

– A protective polysynaptic spinal reflex in which a painful stimulus causes flexion (withdrawal) of the stimulated limb, removing it from the source of injury, with reciprocal extension of the contralateral limb (crossed extensor reflex) to maintain posture. The reflex arc: nociceptors $\rightarrow$ afferent fibers $\rightarrow$ spinal interneurons $\rightarrow$ flexor motor neurons. It is involuntary, rapid, and mediated at the spinal level, though modulated by descending pathways. Absent with lower motor neuron lesions and spinal shock; exaggerated with upper motor neuron lesions. Evaluated as part of the neurologic examination.

Zymogen (Proenzyme)

– An inactive precursor of an enzyme that requires proteolytic cleavage to become catalytically active. Zymogens are synthesised and stored in cells (typically in secretory vesicles or zymogen granules) and are activated at the appropriate site and time by specific proteases, preventing premature or inappropriate enzymatic activity that could damage the cell of origin or surrounding tissues. The conversion of a zymogen to an active enzyme involves the cleavage of one or more specific peptide bonds, which induces a conformational change that exposes the active site. Major zymogen systems in human physiology: digestive zymogens (secreted by the exocrine pancreas and gastric chief cells as inactive precursors to prevent autodigestion — trypsinogen $\rightarrow$ trypsin, chymotrypsinogen $\rightarrow$ chymotrypsin, proelastase $\rightarrow$ elastase, procarboxypeptidase $\rightarrow$ carboxypeptidase, pepsinogen $\rightarrow$ pepsin in the stomach, activated by gastric acid), clotting cascade (coagulation factors circulate as inactive zymogens — prothrombin $\rightarrow$ thrombin, fibrinogen $\rightarrow$ fibrin, factor X $\rightarrow$ Xa, etc.

— activated sequentially in the coagulation cascade), fibrinolytic system (plasminogen $\rightarrow$ plasmin), complement system (complement proteins C1-C9 circulate as inactive zymogens, activated by classical, lectin, or alternative pathways), and procollagen (procollagen $\rightarrow$ collagen by procollagen peptidases). The pancreas is particularly dependent on zymogen physiology: the pancreatic acinar cells synthesise and package digestive enzymes as zymogens in zymogen granules, which are secreted into the pancreatic duct and activated in the duodenum by enteropeptidase (enterokinase). Premature activation of trypsinogen to trypsin within the pancreas causes acute pancreatitis (autodigestion of pancreatic tissue).

Chapter 33

Psychiatry

Addiction

- A chronic, relapsing brain disorder characterized by compulsive substance use or behavior despite harmful consequences. It involves changes in brain reward, motivation, and memory circuits, leading to impaired control over the behavior. Treatment often combines medication, behavioral therapy, and social support.

Adjustment Disorder

- Emotional or behavioral symptoms in response to an identifiable stressor occurring within three months of the onset of the stressor. The symptoms are disproportionate to the severity of the stressor and cause significant distress or impairment. It resolves within six months of the termination of the stressor. Subtypes include with depressed mood, with anxiety, with mixed anxiety and depressed mood, with disturbance of conduct, with mixed disturbance of emotions, and unspecified.

Affective Flattening

- A significant reduction in the range and intensity of emotional expression. It is a negative symptom of schizophrenia characterized by reduced facial expression, monotonous voice, and decreased body language. It is distinct from blunted affect (reduced range) and constricted affect (narrowed range). It is less responsive to antipsychotics.

Agitation

- A state of excessive motor activity, emotional excitement, and restlessness. In psychiatric settings, it may be a symptom of mania, psychosis, delirium, substance intoxication, or withdrawal. Acute agitation is managed with de-escalation techniques first, then pharmacological management with benzodiazepines (lorazepam), antipsychotics (haloperidol, olanzapine IM), or combination (B52: diphenhy-

dramine + haloperidol + lorazepam). Physical restraints are used as a last resort.

Agoraphobia

- Marked fear or anxiety about two or more of five situations: using public transportation, being in open spaces, being in enclosed places, standing in line or being in a crowd, and being outside the home alone. The individual fears or avoids these situations because escape might be difficult or help unavailable if panic-like symptoms develop. The fear is out of proportion, persists for six months, and causes significant impairment.

Alcohol Use Disorder

- A problematic pattern of alcohol use leading to significant impairment or distress. Severity is classified as mild (2–3 criteria), moderate (4–5 criteria), or severe (6 or more criteria). Criteria include drinking more or longer than intended, persistent desire to cut down, spending excessive time with alcohol, craving, failure to fulfill obligations, continued use despite social or interpersonal problems, and tolerance and withdrawal. Withdrawal can include seizures, delirium tremens, and autonomic hyperactivity. Severe alcohol withdrawal can progress to delirium tremens, a life-threatening condition with a mortality rate of 5–15 percent if untreated. Management of alcohol withdrawal involves the CIWA-Ar (Clinical Institute Withdrawal Assessment for Alcohol, revised) scale to guide benzodiazepine administration. First-line treatment is symptom-triggered benzodiazepine therapy (lorazepam, diazepam, or chlordiazepoxide). Supportive care includes intravenous fluids, thiamine supplementation to prevent Wernicke-Korsakoff syndrome (100 mg IV or IM daily), correction of electrolyte disturbances (hypokalaemia, hypomagne-

saemia, hypophosphataemia), and multivitamins. Carbamazepine and gabapentin are alternative treatments for mild-to-moderate withdrawal. Severe withdrawal may require ICU admission and management of delirium tremens.

Alcohol Withdrawal

– Symptoms occurring after cessation or reduction of prolonged heavy drinking. Timeline includes: tremor and anxiety at 6–12 hours, perceptual disturbances at 12–24 hours, withdrawal seizures at 24–48 hours, and delirium tremens at 48–96 hours. Delirium tremens includes autonomic hyperactivity, tremor, hallucinations, and confusion with a mortality rate of 5–15% if untreated. CIWA-Ar scale guides management. Benzodiazepines are first-line treatment.

Alcoholism

– See Alcohol Use Disorder. The traditional term for chronic dependent alcohol use, now subsumed under alcohol use disorder in DSM-5-TR.

Allogia

– Poverty of speech or poverty of content of speech, a negative symptom of schizophrenia. It manifests as brief, empty replies to questions, reduced spontaneous speech, and lack of elaboration. It reflects dysfunction in the mesocortical dopamine pathway and is less responsive to antipsychotic medications than positive symptoms.

Anhedonia

– The inability to experience pleasure from activities that were previously enjoyable. It is a core symptom of major depressive disorder and a negative symptom of schizophrenia. It is mediated by dysfunction in the brain's reward circuitry, particularly the mesolimbic dopamine system.

Anorexia Nervosa

– A severe eating disorder characterized by restriction of energy intake relative to requirements leading to significantly low body weight ($\text{BMI} < 18.5 \text{ kg/m}^2$ in adults), intense fear of gaining weight or becoming fat, and disturbance in the way one's body weight or shape is experienced. Subtypes: Restricting type (weight loss achieved via dieting, fasting, excessive exercise) and Binge-eating/purging type (recurrent episodes of binge eating or purging via self-induced vomiting, laxatives, diuretics). Physical exam findings: lanugo hair, emaciation, bradycardia, hy-

potension, hypothermia, dry skin, amenorrhea (not required for DSM-5-TR). Complications: osteopenia/osteoporosis, cardiac arrhythmias (QT prolongation, sudden cardiac death from severe electrolyte disturbances), pancytopenia, structural brain atrophy. Laboratory abnormalities: hypokalemia, hyponatremia, leukopenia, elevated BUN, euthyroid sick syndrome. Management: nutritional rehabilitation (primary goal; monitor for Refeeding Syndrome: hypophosphatemia, hypokalemia, hypomagnesemia leading to cardiac failure), Family-Based Treatment (Maudsley approach) for adolescents, CBT. Medications: olanzapine (promotes weight gain and reduces obsessive thoughts), SSRIs (ineffective for weight gain while severely underweight, but useful for comorbid anxiety/depression after weight restoration). Highest mortality rate of any psychiatric illness.

Anorgasmia

– Persistent or recurrent delay in, or absence of, orgasm following a normal sexual excitement phase. Causes: antidepressants (especially SSRIs, the most common iatrogenic cause), psychosocial factors (anxiety, relationship issues, past trauma), neurological disorders (spinal cord injury, multiple sclerosis, diabetic neuropathy), hormonal abnormalities (low testosterone, hypothyroidism), and pelvic surgery. Management: for SSRI-induced anorgasmia, strategies include dose reduction, drug holiday, switching to bupropion or mirtazapine, or augmentation with buspirone, cyproheptadine, or sildenafil. Psychosexual therapy and behavioural techniques are effective for psychogenic causes. Prognosis depends on etiology; medication-induced anorgasmia is usually reversible.

Anticholinergic Burden

– The cumulative effect of taking multiple medications with anticholinergic properties. It can cause dry mouth, constipation, urinary retention, blurred vision, confusion, and delirium, especially in elderly patients. Many psychiatric medications (TCAs, first-generation antipsychotics, some antihistamines) have anticholinergic effects.

Anticonvulsant Mood Stabilizers

– Antiepileptic drugs used as mood stabilizers in bipolar disorder. Valproate (divalproex) is effective for acute mania and rapid cycling. Carbamazepine is effective for acute mania but has numerous drug

interactions via CYP3A4 induction. Lamotrigine is effective for bipolar depression prevention but not acute mania. All require monitoring for side effects and drug levels (except lamotrigine, which is dose-titrated).

Antisocial Personality Disorder

– A pattern of disregard for and violation of the rights of others occurring since age 15 years. At least three of seven criteria: failure to conform to social norms, deceitfulness, impulsivity, irritability and aggressiveness, reckless disregard for safety, consistent irresponsibility, and lack of remorse. Diagnosis requires evidence of conduct disorder before age 15. Associated with psychopathy, which includes affective and interpersonal features beyond the DSM criteria.

Anxiety

– A normal emotional response to perceived danger, but anxiety disorders involve excessive, persistent worry that interferes with daily life. Symptoms can include restlessness, rapid heart rate, muscle tension, and avoidance behaviors. Common types include generalized anxiety disorder, panic disorder, social anxiety, and phobias, all of which are treatable with therapy and medication.

Anxiety Disorder

– A group of psychiatric conditions characterized by excessive fear, anxiety, and related behavioral disturbances. Includes generalized anxiety disorder (GAD), panic disorder, social anxiety disorder, specific phobias, and agoraphobia. GAD: persistent, excessive worry about multiple domains for ≥ 6 months, with restlessness, fatigue, difficulty concentrating, irritability, muscle tension, and sleep disturbance. Treatment: SSRIs/SNRIs (sertraline, escitalopram, venlafaxine), buspirone, benzodiazepines for short-term use, and cognitive-behavioral therapy (CBT).

Applied Behavior Analysis

– A behavioral intervention based on learning theory principles that uses systematic reinforcement to shape desired behaviors and reduce problematic behaviors. It is the primary evidence-based intervention for autism spectrum disorder, particularly in young children. Core components include positive reinforcement, prompting, fading, chaining, and generalization. It requires intensive, structured sessions.

Attention Deficit Disorder

– Historical DSM-IV label for the predominantly inattentive presentation of attention-deficit/hyperactivity disorder. DSM-5 unifies prior ADD and ADHD subtypes within attention-deficit/hyperactivity disorder, with specifiers for predominantly inattentive, predominantly hyperactive-impulsive, or combined presentation. The acronym persists in clinical shorthand for the inattentive phenotype lacking overt hyperactivity. See Attention-Deficit/Hyperactivity Disorder.

Attention-Deficit/Hyperactivity Disorder

– A neurodevelopmental disorder characterized by persistent patterns of inattention, hyperactivity, and impulsivity that interfere with functioning or development. Three presentations: predominantly inattentive, predominantly hyperactive-impulsive, and combined. Inattention symptoms include difficulty sustaining attention, poor organization, forgetfulness, and distractibility. Hyperactivity-impulsive symptoms include fidgeting, excessive talking, difficulty waiting turns, and interrupting. Must have symptoms present before age 12. Diagnosis is clinical, using DSM-5 criteria, supported by rating scales (Conners Rating Scales, SNAP-IV, Vanderbilt Assessment Scale), collateral history from parents and teachers, and neuropsychological testing to evaluate attention and executive function. Management includes pharmacological treatment with psychostimulants (methylphenidate, dexamphetamine, lisdexamfetamine) as first-line, non-stimulant options (atomoxetine, guanfacine, clonidine), and behavioural interventions (parent training, behavioural classroom management, organisational skills training). Prognosis with treatment is good; untreated ADHD is associated with academic underachievement, social difficulties, substance misuse, and occupational impairment in adulthood.

Attention-Deficit/Hyperactivity Disorder (ADHD)

– A neurodevelopmental condition marked by persistent inattention, hyperactivity, and impulsivity that interferes with daily functioning. In children, symptoms often include difficulty staying seated, frequent interrupting, and trouble sustaining

attention. Adults may experience restlessness, poor time management, and difficulty concentrating, though hyperactivity often diminishes with age.

Atypical Features

- A specifier for depressive episodes characterized by mood reactivity, significant weight gain or increased appetite, hypersomnia, leaden paralysis, and a long-standing pattern of interpersonal rejection sensitivity. Atypical depression often presents in younger patients and may respond preferentially to MAOIs or SSRIs rather than TCAs.

Autism Spectrum Disorder

- A neurodevelopmental disorder characterized by persistent deficits in social communication and social interaction across multiple contexts, and restricted, repetitive patterns of behavior, interests, or activities. Social deficits include difficulty with social-emotional reciprocity, nonverbal communicative behaviors, and developing/maintaining relationships. Restricted behaviors include stereotyped movements, insistence on sameness, and restricted interests. Severity is specified both domains. Diagnosis is based on DSM-5 criteria. Management includes early intensive behavioural intervention (applied behaviour analysis), speech and language therapy, social skills training, occupational therapy, and pharmacological treatment of associated conditions such as SSRIs for anxiety and antipsychotics for irritability. Prognosis is variable, with early intervention improving outcomes.

Avoidant Personality Disorder

- A pattern of social inhibition, feelings of inadequacy, and hypersensitivity to negative evaluation. At least four of seven criteria: avoids occupational activities involving interpersonal contact, unwilling to get involved unless certain of being liked, shows restraint within intimate relationships due to fear of shame, preoccupied with being criticized or rejected in social situations, inhibited in new interpersonal situations due to feelings of inadequacy, views self as socially inept, and is unwilling to get involved unless certain of being liked. Diagnosis is clinical using DSM-5 criteria. Treatment includes psychodynamic therapy and CBT focusing on social skills training and graded exposure to feared social situations. Pharmacotherapy with SSRIs may help with comorbid social anxiety. Prognosis is guarded, as

the disorder is typically lifelong, though symptoms may improve with treatment.

Avolition

- A severe lack of motivation to initiate and perform self-directed, purposeful activities. It is a negative symptom of schizophrenia and is seen in severe depression. It manifests as neglect of personal hygiene, inability to complete tasks, and social withdrawal. It is mediated by dysfunction in the prefrontal cortex and dopamine reward pathways.

Benzodiazepine Use Disorder

- A problematic pattern of benzodiazepine use leading to significant impairment. Benzodiazepines include alprazolam, clonazepam, diazepam, and lorazepam. Dependence can develop rapidly with regular use. Withdrawal can be life-threatening, presenting with anxiety, insomnia, tremor, seizures, and psychosis. Cross-tolerance with alcohol exists. Abrupt discontinuation should be avoided; gradual taper is essential.

Benzodiazepine Withdrawal

- Symptoms from cessation or reduction of prolonged benzodiazepine use. Early symptoms include anxiety, insomnia, tremor, and diaphoresis. Severe withdrawal can include seizures, psychosis, and delirium. Withdrawal severity depends on the half-life of the benzodiazepine, duration of use, and dose. Abrupt discontinuation after chronic use can be fatal. A slow taper, often switching to a long-acting benzodiazepine, is the standard approach.

Bereavement

- Natural grief response to the death of a loved one, marked by sadness, yearning, and preoccupation with the deceased, experienced in waves that diminish over weeks to months with preserved self-esteem. Distinct from major depression by its wave-like quality and preserved self-worth. Persistence beyond twelve months with marked impairment may indicate prolonged grief disorder. See Prolonged Grief Disorder.

Bipolar Disorder

- A mood disorder characterized by episodes of mania/hypomania and depression. Bipolar I: at least one manic episode (elevated mood, grandiosity, decreased need for sleep, pressured speech, increased goal-directed activity, risky behavior) lasting ≥ 1 week or requiring hospitalization. Bipolar II: hy-

pomanic episodes and major depressive episodes without full mania. Treatment: mood stabilizers (lithium, valproate, lamotrigine), atypical antipsychotics, and psychotherapy. Antidepressants used cautiously due to risk of mood switching.

Bipolar I Disorder

– A mood disorder defined by at least one manic episode lasting at least seven days or requiring hospitalization. A manic episode is a distinct period of abnormally elevated, expansive, or irritable mood and increased goal-directed activity or energy. Associated symptoms include inflated self-esteem, decreased need for sleep, pressured speech, flight of ideas, distractibility, increased activity, and risky behavior. Major depressive episodes may occur but are not required for diagnosis.

Bipolar II Disorder

– A mood disorder characterized by at least one hypomanic episode and at least one major depressive episode, with no history of a full manic episode. The depressive episodes in bipolar II tend to be more frequent and longer-lasting than in bipolar I, leading to greater cumulative disability. Patients may be misdiagnosed with unipolar depression if the hypomanic episodes are not identified.

Body Dysmorphic Disorder

– Preoccupation with one or more perceived defects or flaws in physical appearance that are not observable or appear slight to others. The individual performs repetitive behaviors in response to appearance concerns such as mirror checking, excessive grooming, skin picking, reassurance seeking, and comparing. The preoccupation causes clinically significant distress or impairment. Insight is often poor, and patients may seek cosmetic procedures that do not resolve the concern.

Borderline Personality Disorder

– A pattern of instability in interpersonal relationships, self-image, and affects, with marked impulsivity. At least five of nine criteria: frantic efforts to avoid abandonment, unstable and intense relationships, identity disturbance, impulsivity, recurrent suicidal behavior, affective instability, chronic feelings of emptiness, inappropriate intense anger, and transient paranoid ideation or dissociation. Strongly associated with childhood trauma, especially sexual abuse. DBT is the evidence-based treatment of

choice. Other treatments include mentalisation-based therapy (MBT), transference-focused psychotherapy (TFP), and general psychiatric management (GPM). Pharmacotherapy targets specific symptoms: SSRIs for mood instability, low-dose antipsychotics for cognitive-perceptual symptoms, and mood stabilizers for affective dysregulation. Prognosis is guarded; symptoms typically improve with age and treatment, but functional impairment often persists.

Brief Psychotic Disorder

– A disturbance characterized by the sudden onset of at least one psychotic symptom: delusions, hallucinations, disorganized speech, or grossly disorganized or catatonic behavior. The disturbance lasts at least one day but less than one month, after which the individual fully returns to premorbid functioning. It may occur in response to a very stressful event and is diagnosed only when the disturbance is not better explained by another psychotic disorder, mood disorder, or substance use.

Bulimia Nervosa

– An eating disorder characterized by recurrent episodes of binge eating (consuming an abnormally large amount of food within a discrete 2-hour period with a sense of lack of control) accompanied by recurrent inappropriate compensatory behaviors to prevent weight gain (self-induced vomiting, misuse of laxatives/diuretics, fasting, or excessive exercise). Duration criterion: episodes occur at least once weekly for at least 3 months. Unlike anorexia nervosa, patients typically maintain a normal body weight (BMI 18.5–30 kg/m²) or are slightly overweight. Physical exam signs: Russell sign (calluses/abrasions on dorsal hand/knuckles from self-induced vomiting), sialadenitis (painless bilateral enlargement of parotid glands due to hypersecretion), dental enamel erosion (lingual surface of maxillary anterior teeth from gastric acid exposure), Mallory-Weiss tears, Boerhaave syndrome. Laboratory findings: hypokalemia, hypochloremic metabolic alkalosis (from vomiting) or metabolic acidosis (from laxative abuse). Treatment: Cognitive Behavioral Therapy (CBT-E, first-line psychotherapy), Nutritional counseling. Pharmacotherapy: Fluoxetine (60 mg/day, only FDA-approved medication for bulimia; reduces binge-purge frequency).

Contraindication: Bupropion is strictly contraindicated due to increased risk of epileptic seizures in patients with eating disorders.

Caffeine Withdrawal

- A syndrome occurring after abrupt cessation or reduction of caffeine use. Symptoms include headache, fatigue, depressed mood, difficulty concentrating, and flu-like symptoms. Onset is typically 12–24 hours after last caffeine intake, peak at 20–51 hours, and duration of 2–9 days. It is one of the most commonly experienced withdrawal syndromes.

Cannabis Use Disorder

- A problematic pattern of cannabis use leading to significant impairment. Criteria include tolerance and withdrawal (irritability, anger, decreased appetite, restlessness, anxiety, sleep disturbance). Cannabis intoxication includes euphoria, impaired judgment, and time distortion. High-potency concentrates (dabbing) increase the risk of dependence. Cannabinoid hyperemesis syndrome presents with cyclic vomiting in heavy users.

Catatonia

- A neuropsychiatric syndrome characterized by motor abnormalities including immobility, mutism, posturing, waxy flexibility, stereotypy, mannerisms, grimacing, echolalia, and echopraxia. It can occur in mood disorders, psychotic disorders, medical conditions, or as catatonia due to another medical condition. Lorazepam challenge and ECT are first-line treatments. Immobility and autonomic instability suggest malignant catatonia.

Claustrophobia

- An anxiety disorder characterized by an intense, irrational fear of enclosed or confined spaces (e.g., lifts, tunnels, MRI scanners, windowless rooms). Individuals experience marked anxiety, panic attacks, and avoidance behaviour. Prevalence: approximately 5–10% of the general population. Claustrophobia is classified as a specific phobia (situational type) in DSM-5. The fear is out of proportion to the actual danger and causes significant distress or functional impairment. Pathophysiology involves conditioned fear responses, catastrophic misinterpretation of bodily sensations, and possibly a heightened sensitivity to suffocation cues. Management: CBT with graded in vivo exposure is the most effective treatment; virtual reality exposure therapy is an emerg-

ing alternative. Pharmacotherapy (SSRIs, benzodiazepines) may be used adjunctively. Prognosis is excellent with treatment; most patients achieve significant symptom reduction.

Cognitive Behavioral Therapy

- A structured, time-limited psychotherapy that identifies and modifies maladaptive thought patterns (cognitive distortions) and behaviors. It is based on the cognitive model that thoughts, feelings, and behaviors are interconnected. CBT uses techniques including cognitive restructuring, behavioral activation, exposure, and skills training. It is the most evidence-based psychotherapy for depression, anxiety disorders, OCD, PTSD, and eating disorders.

Cognitive Behavioral Therapy for Insomnia (CBT-I)

- Cognitive behavioral therapy for insomnia is a structured, evidence-based program that targets the thoughts and behaviors perpetuating poor sleep. Components include sleep restriction, stimulus control, cognitive restructuring, and sleep hygiene education. CBT-I is recommended as first-line treatment for chronic insomnia and yields durable improvements without the risks of sleep medications.

Cognitive Distortions

- Systematic errors in thinking that perpetuate negative emotional states and maladaptive behaviors. Common distortions include all-or-nothing thinking, catastrophizing, mind reading, overgeneralization, emotional reasoning, and should statements. CBT focuses on identifying and modifying these patterns.

Comorbidity

- The co-occurrence of two or more psychiatric disorders in a single patient. Psychiatric comorbidity is the rule rather than the exception. For example, depression commonly co-occurs with anxiety disorders, substance use disorders, and personality disorders. Comorbidity complicates treatment and worsens prognosis.

Compulsions

- Repetitive behaviors or mental acts that the individual feels driven to perform in response to an obsession or according to rigid rules. They are aimed at preventing or reducing anxiety or preventing some dreaded event, but are not connected in a realistic way with what they are designed to neutralize. Common compulsions include washing,

checking, counting, ordering, arranging, and mental rituals. Time-consuming compulsions (more than one hour daily) are associated with greater severity.

Conduct Disorder

– A childhood/adolescent disorder characterized by a persistent pattern of violating others' basic rights or major age-appropriate norms. Behaviors: aggression to people/animals, destruction of property, deceitfulness/theft, and serious rule violations. Diagnosis requires ≥ 3 criteria in the past 12 months with functional impairment. Risk factors: abuse, neglect, parental substance use, and genetic predisposition. Treatment: parent management training, multisystemic therapy, and CBT; limited pharmacotherapy for comorbid conditions.

Consultation-Liaison Psychiatry

– The subspecialty of psychiatry focused on the interface between psychiatry and general medical illness. Psychiatrists provide consultation on medical-surgical wards for patients with psychiatric symptoms arising from or coexisting with medical conditions. Common issues include delirium, depression in medically ill patients, factitious disorder, adjustment reactions, and capacity assessments. It requires expertise in both psychiatric and medical conditions.

Conversion Disorder

– A condition in which patients present with neurological symptoms (weakness, paralysis, non-epileptic seizures, sensory loss, gait abnormalities, dystonia, speech difficulties) that cannot be explained by organic disease. Previously known as hysteria. The symptoms are not intentionally produced (unlike malingering or factitious disorder). Associated with psychological stressors and trauma. Most common in young women. Diagnosis: positive signs on neurological exam (Hoover sign for weakness, variability in dystonia), inconsistency with known neurological disease. Treatment: psychoeducation, physical therapy, CBT, and treatment of comorbid psychiatric conditions. Prognosis: variable; acute onset has better outcomes.

Conversion Disorder (formerly Hysteria)

– A historical psychiatric term that has been discarded from modern diagnostic classifications (DSM-5, ICD-11). Originally derived from the Greek

word for uterus (hystera), reflecting the ancient belief that symptoms originated from a 'wandering uterus'. Previously used to describe a range of symptoms: (1) Motor: paralysis, seizures, pseudoseizures (psychogenic non-epileptic seizures), mutism, aphonia; (2) Sensory: anesthesia, paraesthesia, blindness, deafness; (3) Dissociative: amnesia, fugue, depersonalisation, multiple personality; (4) Somatic: chronic pain, globus hystericus, hyperventilation. The term hysteria was replaced by more specific diagnostic categories: conversion disorder (functional neurological symptom disorder—motor/sensory symptoms without organic cause), somatisation disorder (now somatic symptom disorder, multiple physical complaints), dissociative disorders (dissociative identity disorder, dissociative amnesia). Freud redefined hysteria as resulting from repressed psychological trauma (especially sexual abuse) with unconscious conversion into physical symptoms. Pierre Janet proposed dissociation as the core mechanism. Current understanding integrates psychodynamic, behavioural, cognitive, and neurobiological factors, and does not attribute to the uterus.

Countertransference

– The therapist's emotional reactions to the patient, which may be influenced by the therapist's own unresolved conflicts or may be a response to the patient's transference. Awareness of countertransference is essential for effective therapy and can provide valuable clinical information about the patient's interpersonal style.

Cross-Tolerance

– Tolerance to one substance that extends to another substance with a similar mechanism of action. For example, tolerance to one benzodiazepine extends to all benzodiazepines, and tolerance to alcohol extends partially to benzodiazepines due to shared GABA-A receptor mechanisms. Cross-tolerance is clinically relevant when switching between substances of the same class.

Cultural Psychiatry

– The study and clinical practice of how cultural factors influence mental health, illness expression, diagnosis, and treatment. Cultural concepts of distress, idioms of distress, and cultural syndromes must be considered. The DSM-5 includes a Cultural Formulation Interview. Culture influences

symptom presentation, help-seeking behavior, treatment adherence, and the therapeutic relationship.

Cyclothymic Disorder

- A chronic mood disorder characterized by numerous periods of hypomanic symptoms and periods of depressive symptoms over at least two years (one year in children and adolescents). The hypomanic and depressive symptoms do not meet criteria for a hypomanic or major depressive episode. The patient is never symptom-free for more than two months at a time. It carries a 15–50% risk of developing bipolar I or II disorder.

Defense Mechanisms

- Unconscious psychological strategies used to manage anxiety and protect the ego from distressing thoughts or feelings. Mature defenses include sublimation, humor, and altruism. Immature defenses include projection, denial, splitting, and acting out. Understanding defense mechanisms helps clinicians conceptualize personality organization.

Delayed Ejaculation

- A sexual dysfunction characterized by a persistent or recurrent delay in, infrequency of, or absence of ejaculation during partnered sexual activity, lasting ≥ 6 months and causing marked distress. Prevalence: 1–5% of men. Lifelong vs. acquired. Causes: psychosocial (masturbatory style discrepancy, relationship issues, performance pressure, religious upbringing), medication-induced (SSRIs, antipsychotics, alpha-blockers, thiazide diuretics), neurological (spinal cord injury, multiple sclerosis, diabetic neuropathy), surgical (radical prostatectomy, retroperitoneal lymph node dissection), and hormonal (low testosterone, hyperprolactinemia). Diagnosis: clinical interview distinguishing anejaculation from retrograde ejaculation (post-orgasmic urine analysis). Treatment: address underlying cause, switch/reduce offending medications, vibratory stimulation (for neurogenic), electroejaculation (for fertility), psychotherapy, and off-label cabergoline or oxytocin (limited evidence).

Delirium

- An acute, fluctuating disturbance of attention and awareness with an underlying medical cause. It is characterized by disorganized thinking, altered level of consciousness, and perceptual disturbances. Risk factors include advanced age, dementia, in-

fection, medications, and metabolic derangements. Prevention through hydration, sleep promotion, and minimizing restraints is essential.

Delirium Tremens

- The most severe form of alcohol withdrawal syndrome, a medical emergency with mortality of 5–15% if untreated. Typically occurs 48–96 hours after the last drink in individuals with chronic heavy alcohol use. Characterized by: altered mental status (confusion, disorientation), profound autonomic hyperactivity (tachycardia, hypertension, hyperthermia, diaphoresis), tremor, hallucinations (visual, tactile, auditory), agitation, and seizures. Risk factors: prior DTs, concurrent infection or illness, electrolyte abnormalities. Management: ICU admission, benzodiazepines (diazepam or lorazepam, high-dose titrated to symptom control), thiamine, correction of electrolyte disturbances, and supportive care (hydration, nutrition, monitoring).

Delusional Disorder

- A disorder characterized by the presence of one or more delusions lasting one month or more in the context of relatively preserved functioning. The delusions are non-bizarre (involving real-life situations that could conceivably occur, such as being followed, infected, loved from afar, or conspired against). If hallucinations are present, they are not prominent and are related to the delusional theme. The behavior is not clearly bizarre or odd beyond the impact of the delusion.

Denial

- A defense mechanism in which a person refuses to accept an unpleasant reality. It is a common initial response to traumatic events and terminal illness diagnoses. While adaptive in the short term, chronic denial can prevent appropriate medical treatment and psychological processing.

Dependent Personality Disorder

- A pattern of submissive and clinging behavior related to an excessive need to be taken care of. At least five of eight criteria: difficulty making everyday decisions without excessive advice, needing others to assume responsibility, difficulty expressing disagreement due to fear of loss of support, difficulty initiating projects, going to excessive lengths to obtain nurturance, feeling uncomfortable or helpless when alone, urgently seeking another relationship

when one ends, and unrealistically preoccupied with fears of being left to care for self. Diagnosis is clinical using DSM-5 criteria. Treatment includes psychodynamic psychotherapy and CBT focusing on building autonomy and assertiveness. Pharmacotherapy is used for comorbid depression or anxiety. Prognosis is variable, with some improvement possible with long-term therapy.

Depersonalization-Derealization Disorder

– Persistent or recurrent experiences of depersonalization, derealization, or both. Depersonalization includes experiences of unreality, detachment, or being an outside observer with respect to one's thoughts, feelings, sensations, body, or actions. Derealization includes experiences of unreality or detachment with respect to surroundings. The individual maintains intact reality testing, meaning they recognize the experiences as subjective and not objectively real.

Depression

– Major depressive disorder is a common, disabling mood disorder characterized by persistent sadness and loss of interest or pleasure in activities, affecting approximately 7 percent of adults worldwide annually. According to DSM-5 criteria, diagnosis requires five or more of the following symptoms present during the same 2-week period representing a change from previous functioning, with at least one being either depressed mood or anhedonia: depressed mood most of the day nearly every day, marked diminished interest or pleasure in all or almost all activities most of the day nearly every day, significant weight loss or gain, insomnia or hypersomnia, psychomotor agitation or retardation, fatigue or loss of energy, feelings of worthlessness or excessive or inappropriate guilt, diminished ability to think or concentrate, and recurrent thoughts of death or suicidal ideation. The episode causes clinically significant distress or impairment. Depression is the leading cause of disability worldwide and is a major risk factor for suicide. Treatment includes antidepressants (SSRIs, SNRIs, bupropion, mirtazapine as first-line), psychotherapy (CBT, interpersonal therapy, behavioural activation), and combination therapy for moderate-to-severe depression. Electroconvulsive therapy (ECT) is the most

effective treatment for severe depression with psychotic features or treatment resistance. Prognosis is variable; many patients achieve remission, but recurrence rates are high, particularly without maintenance treatment. Management of suicide risk is a priority.

Dialectical Behavior Therapy

– A comprehensive cognitive-behavioral treatment originally developed for borderline personality disorder. It combines cognitive-behavioral techniques with mindfulness and acceptance strategies. Core modules include mindfulness, distress tolerance, emotion regulation, and interpersonal effectiveness. DBT is the treatment of choice for borderline personality disorder and has been adapted for substance use disorders, eating disorders, and PTSD.

Dissociation

– A disruption in the normal integration of consciousness, memory, identity, emotion, perception, behavior, and sense of self. It exists on a spectrum from normal (daydreaming) to pathological (DID, depersonalization-derealization). It is strongly associated with childhood trauma and can be triggered by stress, sleep deprivation, and certain substances.

Dissociative Amnesia

– Inability to recall important autobiographical information, usually of a traumatic or stressful nature, that is inconsistent with ordinary forgetting. The amnesia may be localized, selective, generalized, or continuous. In dissociative amnesia with dissociative fugue, there is purposeful travel or bewildered wandering associated with amnesia for identity or other important autobiographical information.

Dissociative Disorder

– DSM-5 category comprising disruption of the normally integrated functions of consciousness, memory, identity, perception, and behaviour, including dissociative amnesia, dissociative identity disorder, and depersonalization-derealization disorder. Strongly associated with severe early-life trauma. Diagnosis is clinical, after exclusion of organic causes. Treatment is trauma-informed phased psychotherapy with pharmacotherapy for comorbid conditions.

Dissociative Identity Disorder

– The presence of two or more distinct personality states or an experience of possession involving marked discontinuity in sense of self, agency, affect,

behavior, memory, perception, cognition, and/or sensory-motor functioning. Identity disruption is accompanied by gaps in recall of everyday events, personal information, and/or traumatic events that are inconsistent with ordinary forgetting. The disturbance causes clinically significant distress or impairment and is not part of a broadly accepted cultural or religious practice. Caused by severe childhood trauma, particularly prolonged and severe abuse in early childhood. The presentation is often misunderstood and can be confused with malingering. Diagnosis requires careful clinical assessment using structured interviews (SCID-D). Treatment focuses on trauma-informed psychotherapy, with phases of stabilisation, trauma processing, and integration. Medications treat comorbid symptoms. Prognosis is guarded.

Dysthymia (Persistent Depressive Disorder)

– A chronic form of depression with depressed mood for most of the day, more days than not, for ≥ 2 years (≥ 1 year in children/adolescents). Symptoms: poor appetite or overeating, insomnia or hypersomnia, low energy, low self-esteem, poor concentration, and hopelessness. Does not meet full criteria for major depressive episode continuously. Double depression: MDE superimposed on dysthymia. Treatment: SSRIs/SNRIs and psychotherapy (CBT, interpersonal therapy).

Eating Disorder

– A group of conditions characterized by abnormal eating habits and distorted body image, including anorexia nervosa, bulimia nervosa, binge eating disorder, and avoidant/restrictive food intake disorder (ARFID). Anorexia: severe calorie restriction, intense fear of weight gain, and body image disturbance with dangerously low weight. Bulimia: binge eating followed by purging behaviors. Binge eating: recurrent binge eating without purging. Treatment: nutritional rehabilitation, CBT, family-based therapy for adolescents, and fluoxetine for bulimia. Medical complications require monitoring.

Electroconvulsive Therapy

– A neuromodulation treatment involving the induction of a generalized seizure under general anesthesia using electrical current applied to the scalp. It is the most effective treatment for severe depression, espe-

cially with psychotic features, catatonia, or suicidal ideation. It is also effective for severe mania and treatment-resistant schizophrenia. Cognitive side effects include transient memory impairment. Bilateral electrode placement is more effective but has more cognitive side effects than unilateral placement. ECT is highly effective, with response rates of 70-90 percent for severe depression. The mechanism of action is not fully understood but involves modulation of neurotransmitter systems, neuroplasticity, and increased hippocampal neurogenesis. Modern ECT is performed under general anesthesia with muscle relaxation, using brief electrical pulses to induce a generalised seizure lasting approximately 20-60 seconds. Contraindications include raised intracranial pressure, recent myocardial infarction, and unstable vascular aneurysms. Memory loss (both retrograde and anterograde) is the most significant side effect and is usually transient. Maintenance ECT is sometimes used to prevent relapse.

Erectile Disorder

– A sexual dysfunction characterized by persistent or recurrent difficulty achieving or maintaining an erection sufficient for sexual activity, or a marked decrease in erectile rigidity, lasting ≥ 6 months and causing marked distress. Prevalence: 10-20% of men under 60, rising to 40-70% over age 70. Etiology: organic (vascular disease, diabetes, hypertension, hyperlipidemia, obesity, smoking, hypogonadism, neurological conditions, postsurgical) and psychogenic (performance anxiety, depression, relationship conflict). Diagnosis: clinical history, IIEF-5 questionnaire, nocturnal penile tumescence testing, penile duplex Doppler ultrasound, and hormonal profile. First-line treatment: PDE5 inhibitors (sildenafil, tadalafil, vardenafil, avanafil). Second-line: intracavernosal injections (alprostadil, papaverine, phentolamine), vacuum erection devices, and low-intensity shockwave therapy. Third-line: penile prosthesis surgery. Treat underlying medical conditions and offer psychotherapy for psychogenic factors.

Euphoria

– An intense feeling of well-being, elation, or happiness, which can be a normal emotional response or a pathologic symptom. In medical contexts, euphoria is most commonly associated with: substance

use (opioids, stimulants–cocaine, amphetamines, MDMA, cannabis, alcohol), psychiatric disorders (mania in bipolar I disorder–elevated, expansive, or irritable mood with increased energy), neurologic conditions (multiple sclerosis–lesional euphoria, frontal lobe syndromes), and endocrine disorders (Cushing syndrome, hyperthyroidism). Euphoric mood is distinguished from euthymia (normal mood) and from the emotional lability of pseudobulbar affect. Pathologic euphoria may impair judgment and lead to risky behavior.

Excoriation Disorder

– Recurrent skin picking resulting in skin lesions. The individual has made repeated attempts to decrease or stop the skin picking. The skin picking causes clinically significant distress or impairment. It is not attributable to a medical condition or substance. Common sites include face, arms, and hands. The picking may be automatic or focused and is often preceded by tension and followed by relief.

Exhibitionistic Disorder

– A paraphilic disorder involving recurrent, intense sexual arousal from exposing one’s genitals to an unsuspecting person. The individual has acted on these urges or they cause marked distress or interpersonal difficulty. Duration ≥ 6 months. Onset typically before age 18. Treatment: CBT and SSRIs.

Extrapyramidal Symptoms

– Drug-induced movement disorders caused by D2 receptor blockade in the nigrostriatal pathway. They include acute dystonia (muscle spasm, typically within hours of starting), akathisia (inner restlessness), drug-induced parkinsonism (tremor, rigidity, bradykinesia after weeks of use), and tardive dyskinesia (involuntary movements after months to years). EPS is more common with high-potency typical antipsychotics. Anticholinergic agents (benztropine, diphenhydramine) treat acute dystonia and parkinsonism, and beta-blockers (propranolol) treat akathisia. Tardive dyskinesia is managed by switching to a second-generation antipsychotic with lower D2 potency (clozapine, quetiapine) and adding VMAT2 inhibitors (valbenazine, deutetrabenazine). Prevention involves using the lowest effective dose of antipsychotic and regular monitoring using the Abnormal Involuntary Movement Scale (AIMS).

Factitious Disorder

– Presentation of physical or psychological symptoms or imposing injury or disease on another, with the deceptive intention of assuming the sick role. In factitious disorder imposed on self, the individual falsifies signs or symptoms, induces injury or disease, and presents to medical providers. In factitious disorder imposed on another, the individual falsifies symptoms in another person. The deceptive behavior occurs even in the absence of obvious external rewards.

Female Orgasmic Disorder (Anorgasmia)

– A sexual dysfunction characterized by a persistent or recurrent delay in, infrequency of, or absence of orgasm, or markedly reduced intensity of orgasmic sensation, in $\geq 75\%$ of sexual encounters, lasting ≥ 6 months and causing marked distress. Lifelong (primary, never achieved orgasm by any means) vs. acquired (previously able) vs. situational (only with certain partners or activities). Prevalence: 10-15% of women. Causes: psychosocial (anxiety, distraction, lack of knowledge, relationship issues, negative attitudes toward sex), medication-induced (SSRIs—most common, antipsychotics), medical (spinal cord injury, multiple sclerosis, diabetes, pelvic surgery), and partner factors. Diagnosis: clinical DSM-5 criteria. Treatment: education, directed masturbation, CBT, mindfulness-based sex therapy, sensate focus, and vibratory stimulation. Switching to bupropion or adding buspirone may help with SSRI-induced anorgasmia. Filbanserin and bremelanotide are approved for HSDD not anorgasmia specifically.

Female Sexual Interest/Arousal Disorder

– A sexual dysfunction in women characterized by absent or reduced sexual interest, thoughts, or receptivity, and/or absent or reduced sexual arousal (genital or nongenital), persisting for ≥ 6 months and causing marked distress. Combines the former DSM-IV diagnoses of hypoactive sexual desire disorder and female sexual arousal disorder. Prevalence: 10-20% of women. Etiology: multifactorial (relationship factors, partner factors, individual vulnerability, medical/psychiatric comorbidities, medication effects). Diagnosis: clinical DSM-5 criteria. Treatment: psychotherapy (CBT, mindfulness-based sex

therapy), sensate focus exercises, education, addressing relationship factors, and pharmacotherapy (flibanserin, bremelanotide, off-label testosterone therapy). Lubricants and vaginal moisturizers for arousal complaints.

Fetishistic Disorder

– A paraphilic disorder characterized by recurrent, intense sexual arousal from either the use of nonliving objects (fetish) or a highly specific focus on nongenital body parts (partialism), lasting ≥ 6 months and causing distress or impairment or involving acting on these urges. Common fetishes: shoes, feet, footwear, leather, lingerie, and rubber. Fetishism is common in the general population (up to 30% report some fetish interest) and typically only becomes a disorder when it causes significant distress, impairment, or involves nonconsenting individuals or causes harm. Most common in males. Treatment: CBT, aversion therapy (historical, controversial), and SSRIs.

Frotteuristic Disorder

– A paraphilic disorder involving recurrent, intense sexual arousal from touching or rubbing against a nonconsenting person, lasting ≥ 6 months and causing distress or impairment or involving acting on these urges. Typically occurs in crowded public places (subways, buses, concerts). The individual rubs their genitals against the victim's buttocks or thighs. Onset: adolescence, almost exclusively male. Typically decreasing with age. Legal consequences: sexual offense charges. Treatment: CBT, relapse prevention, and SSRIs.

Gender Dysphoria

– Psychological distress resulting from incongruence between one's experienced gender and assigned gender at birth. Persists for ≥ 6 months and causes significant impairment. Onset in childhood (may resolve) or adolescence/adulthood (persistent). Diagnosis: DSM-5 requires marked incongruence between experienced/expressed gender and primary/secondary sex characteristics, with strong desire to be rid of them or to have opposite sex characteristics. Treatment: gender-affirming care including hormone therapy (testosterone/estrogen), puberty blockers for adolescents, and surgical interventions. Access to affirming care improves mental health outcomes.

Generalized Anxiety Disorder

– Characterized by excessive, difficult-to-control anxiety and worry about multiple events or activities occurring more days than not for at least six months. Associated symptoms include restlessness, being easily fatigued, difficulty concentrating, irritability, muscle tension, and sleep disturbance. The anxiety causes significant distress or impairment. It is often comorbid with depression and other anxiety disorders.

Genito-Pelvic Pain/Penetration Disorder

– A sexual dysfunction characterized by persistent or recurrent difficulties with vaginal penetration, marked vulvovaginal or pelvic pain during intercourse, fear or anxiety about penetration, and/or tensing of the pelvic floor muscles, lasting ≥ 6 months and causing marked distress. Combines the former DSM-IV diagnoses of vaginismus and dyspareunia. Prevalence: 3-15% of women. Etiology: multifactorial (pelvic floor hypertonicity, history of sexual trauma, anxiety, endometriosis, vulvodynia, interstitial cystitis, postpartum/perimenopausal changes, inadequate lubrication). Diagnosis: clinical interview, pelvic exam, and exclusion of organic causes (infection, endometriosis, adhesions). Treatment: multimodal — pelvic floor physical therapy, dilator therapy, CBT/sex therapy, lubricants, topical lidocaine, vaginal estrogen (if atrophic), trigger point injections, and treatment of underlying medical conditions. Graded exposure to penetration is key.

Grief

– A natural emotional response to loss, particularly the death of a loved one, but also following other significant losses such as divorce, job loss, or declining health. It encompasses a range of feelings including sadness, anger, guilt, and numbness, often occurring in waves rather than linear stages. While grief is not a mental disorder, prolonged or disabling grief may be diagnosed as prolonged grief disorder and benefit from specialized therapy.

Hallucination

– A perception in the absence of an external stimulus, experienced as real and occurring in objective space. Hallucinations can involve any sensory modality: auditory (most common, voices commenting or conversing—characteristic of schizophrenia, also in

bipolar mania, psychotic depression), visual (formed or unformed–delirium, dementia, Charles Bonnet syndrome in visually impaired with preserved cognition, Lewy body dementia), olfactory (unusual odours–temporal lobe epilepsy, olfactory reference syndrome), gustatory (tastes–seizures, psychosis), tactile (formication–cocaine/amphetamine use, alcohol withdrawal, delusional infestation), and somatic (sensations within the body). Hallucinations are distinct from: illusions (distortions of real external stimuli), hallucinations in sleep (hypnagogic at sleep onset, hypnopompic on waking–normal if not distressing), and pseudohallucinations (experienced as lacking objective reality, located inside the head, often in PTSD). Hallucinations in the context of psychiatric illness must be differentiated from those due to: delirium (acute, fluctuating, medical cause), dementia (chronic, progressive), epilepsy (ictal/postictal, especially temporal lobe), drugs (stimulants, hallucinogens like LSD, psilocybin, ketamine, withdrawal from alcohol/benzodiazepines), sensory deprivation, and migraine (visual aura). Management: treat underlying cause; antipsychotics for psychiatric disorders (olanzapine, risperidone, clozapine for refractory auditory hallucinations); ECT for severe psychotic depression.

Histrionic Personality Disorder

– A pattern of excessive emotionality and attention-seeking. At least five of eight criteria: discomfort when not the center of attention, inappropriate sexually seductive behavior, displays rapidly shifting and shallow emotions, uses physical appearance for attention, speaks in an impressionistic and vague manner, shows self-dramatization and theatricality, is suggestible, and considers relationships more intimate than they actually are.

Hoarding Disorder

– Persistent difficulty discarding or parting with possessions, regardless of their actual value. The individual perceives a need to save items and experiences distress at the thought of discarding them. This results in accumulation of possessions that congest and clutter active living areas. The hoarding is not attributable to another medical condition and causes significant distress or impairment. It is distinct from collecting, which is organized and purposeful.

Hypnosis

– A state of focused attention, reduced peripheral awareness, and heightened suggestibility, resembling a trance-like state but distinct from sleep. Hypnosis is induced by a procedure (hypnotic induction) involving focused concentration, relaxation, and guided imagery. Characteristics: absorption (deep involvement in the experience, narrowed attention), dissociation (automaticity, detachment from immediate environment), suggestibility (heightened responsiveness to suggestions, both verbal and non-verbal). The subject remains aware, oriented, and able to resist suggestions. Clinical applications: (1) Pain management (acute and chronic pain, labour, dental procedures, cancer-related pain), (2) Anxiety and stress reduction (medical procedures, phobias, performance anxiety), (3) Irritable bowel syndrome (good evidence, NICE recommended), (4) Smoking cessation and habit modification (moderate evidence), (5) Post-traumatic stress disorder (as adjunctive therapy), (6) Nausea and vomiting (chemotherapy-related). Hypnotherapy is a regulated profession in many countries; clinical hypnosis should only be practiced by appropriately trained healthcare professionals. Contraindications: severe mental illness with psychotic features (delusions, hallucinations–hypnosis may worsen), dissociative identity disorder, epilepsy (rarely, may trigger seizure). Theories of mechanism: involvement of prefrontal cortex deactivation (reduced executive function and reality testing) and enhanced connectivity between the prefrontal cortex and insula (increased body awareness and interoception).

Hypoactive Sexual Desire Disorder (HSDD)

– A sexual dysfunction characterized by persistently or recurrently deficient or absent sexual thoughts, fantasies, and desire for sexual activity, causing marked distress or interpersonal difficulty. In DSM-5, HSDD in women is merged with female sexual arousal disorder into female sexual interest/arousal disorder. In men, it remains a separate diagnosis. Prevalence: 10-15% of men, 20-30% of women. Causes: psychosocial (relationship conflict, stress, depression, anxiety), hormonal (low testosterone, hyperprolactinemia, menopause), medication-induced (SSRIs, antipsy-

chotics, hormonal contraceptives), and medical (diabetes, thyroid disease, chronic illness). Diagnosis: clinical interview ruling out other psychiatric disorders, medication effects, and medical conditions. Lab work: testosterone (total and free), prolactin, TSH. Treatment: treat underlying cause, modify offending medications, psychotherapy (CBT, sensate focus), and for women: flibanserin (Addyi) or bremelanotide (Vyleesi); for men with low testosterone: testosterone replacement therapy.

Hypochondriasis

- Historical DSM-IV diagnosis denoting persistent preoccupation with having a serious illness based on misinterpretation of bodily symptoms despite appropriate reassurance. Reclassified in DSM-5 into somatic symptom disorder, when somatic symptoms are prominent, and illness anxiety disorder, when symptoms are mild or absent. Retained in ICD-11. See Illness Anxiety Disorder and Somatic Symptom Disorder.

Hypomania

- Distinct period of abnormally elevated, expansive, or irritable mood with increased energy lasting at least four consecutive days, observable by others but without marked functional impairment, hospitalisation, or psychotic features. The defining feature of bipolar II disorder, distinguished from mania by duration, severity, and absence of psychosis. Management uses mood stabilisers and atypical antipsychotics. See Hypomanic Episode.

Hypomanic Episode

- A distinct period of abnormally elevated, expansive, or irritable mood with increased energy lasting at least four consecutive days. The episode is not severe enough to cause marked impairment in functioning or necessitate hospitalization, and there are no psychotic features. The change in functioning is observable by others. Hypomanic episodes are the defining feature of bipolar II disorder and may transition to full mania or major depression.

Ideas of Reference

- The false belief that unrelated events, objects, or people have a particular and unusual significance specifically for the patient. For example, believing that TV newscasters are sending personal messages or that strangers are conspiring against them. While common in schizotypal personality disorder, they

can also occur in schizophrenia and bipolar disorder.

Illness Anxiety Disorder

- Preoccupation with having or acquiring a serious illness, with minimal or no somatic symptoms present. The individual has a high level of anxiety about health, performs excessive health-related behaviors, and experiences maladaptive avoidance. Symptoms persist for at least six months. The individual is not delusional and insight may vary. Previously known as hypochondriasis.

Improving Sleep

- Adopting habits and environmental modifications to enhance the quality and duration of restorative sleep. Core strategies include maintaining a consistent sleep schedule, creating a dark and cool sleep environment, reducing screen exposure before bed, and avoiding caffeine and alcohol in the evening. Cognitive behavioral therapy for insomnia (CBT-I) is the first-line treatment for chronic sleep difficulties.

Insomnia Disorder

- Difficulty initiating or maintaining sleep, or early-morning awakening with inability to return to sleep, at least three nights per week for at least three months. The individual experiences clinically significant distress or impairment in functioning. Despite adequate opportunity for sleep, the individual is unable to obtain sufficient sleep. It is not better explained by another sleep disorder, substance use, or medical condition. Cognitive behavioral therapy for insomnia (CBT-I) is first-line treatment. Pharmacological options include benzodiazepine receptor agonists (zolpidem, zaleplon, eszopiclone), melatonin receptor agonists (ramelteon), orexin receptor antagonists (suvorexant, lemborexant), and sedating antidepressants (trazodone, doxepin, mirtazapine). Benzodiazepines are generally avoided due to tolerance and dependence risks. Sleep hygiene measures and stimulus control are essential components of management.

Intellectual Disability

- Neurodevelopmental disorder with onset in the developmental period, characterised by deficits in intellectual and adaptive functioning across conceptual, social, and practical domains. DSM-5 grades severity by adaptive functioning: mild, moderate, severe, profound. Etiology is heterogeneous—genetic,

prenatal, perinatal, postnatal, or idiopathic. Management is multidisciplinary, emphasising early intervention, education, behavioural supports, and treatment of comorbidities.

Intermittent Explosive Disorder

– A disorder characterized by recurrent, impulsive, problematic outbursts of verbal or physical aggression that are grossly disproportionate to the provocation. The outbursts are not premeditated and cause marked distress or functional impairment. Age >6 years. Not better explained by another disorder (ADHD, conduct disorder, PTSD, ASD) or substance intoxication. Diagnosis: DSM-5 criteria including aggressive outbursts occurring twice weekly for 3 months (verbal/non-destructive) or 3 outbursts involving damage/injury in the past year. Treatment: CBT (anger management, relaxation), SSRIs (fluoxetine), and mood stabilizers.

Interpersonal Psychotherapy

– A time-limited, evidence-based psychotherapy for depression that focuses on the interpersonal context of mood symptoms. It identifies four problem areas: grief, role disputes, role transitions, and interpersonal deficits. IPT helps patients improve interpersonal functioning and social support. It is an alternative to CBT for depression and has been adapted for eating disorders, postpartum depression, and adolescent depression.

Leukotomy

– A neurosurgical procedure involving the cutting of white matter fibers in the prefrontal cortex, also known as frontal lobotomy or prefrontal leukotomy. Developed by Egas Moniz (Nobel Prize 1949) and Walter Freeman. leukotomy was used for severe psychiatric disorders (schizophrenia, severe depression, OCD) from the 1930s to 1950s, before the advent of effective psychopharmacology. The transorbital lobotomy (Freeman, using an ice pick-like instrument through the orbit) was a simplified outpatient procedure. Use declined dramatically in the 1950s with the introduction of antipsychotics (chlorpromazine) and antidepressants, and due to severe lasting side effects. Side effects of leukotomy: apathy, emotional blunting, inattention, executive dysfunction, cognitive impairment, seizures (5-10%), and death. leukotomy is rarely performed today, but modern stereotactic procedures (anterior cap-

sulotomy, cingulotomy, subcaudate tractotomy) are used in extremely severe, treatment-refractory cases of OCD and depression.

Lithium

– A mood-stabilising medication used primarily for bipolar disorder (mania, hypomania, and prophylaxis of recurrent episodes). See Lithium Toxicity and Bipolar Disorder.

Lithium Toxicity

– Occurs when lithium levels exceed the therapeutic range. Mild toxicity (1.5–2.0 mEq/L): nausea, vomiting, diarrhea, coarse tremor, muscle weakness. Moderate toxicity (2.0–2.5 mEq/L): confusion, ataxia, blurred vision, dysarthria. Severe toxicity (above 2.5 mEq/L): seizures, coma, cardiac arrhythmias, renal failure, and potentially death. Treatment includes stopping lithium, IV fluids, and hemodialysis for severe cases. NSAIDs, ACE inhibitors, and thiazide diuretics increase lithium levels.

Lysergic Acid Diethylamide (LSD)

– A potent hallucinogenic drug (psychedelic) classified as a Schedule 1 controlled substance (high abuse potential, no accepted medical use). LSD acts as a partial agonist at serotonin 5-HT_{2A} receptors in the prefrontal cortex, leading to altered sensory perception, mood, and cognition. Effects: visual hallucinations (geometric patterns, intensified colours, trails), synaesthesia (cross-modal sensory experience, e.g., hearing colours), profound introspection, euphoria/dysphoria, altered sense of time, depersonalization, and mystical experiences. Onset: 30-60 minutes after oral ingestion. Peak: 2-4 hours. Duration: 8-12 hours. Dose: typical 50-200 microgram. Adverse effects: 'bad trip' (anxiety, panic, paranoia, fear of losing control), flashbacks (recurrence of drug effect weeks to months later, Hallucinogen Persisting Perception Disorder–HPPD), exacerbation of pre-existing psychiatric illness (psychosis, bipolar disorder), and acute toxicity (hyperthermia, hypertension, tachycardia, seizures, serotonin syndrome). LSD is not considered physically addictive (does not produce withdrawal or compulsive drug-seeking behaviour), but tolerance develops rapidly (cross-tolerance with other 5-HT_{2A} agonists like psilocybin and mescaline). Medical research: renewed interest in using LSD and other psychedelics (psilo-

cybin, MDMA, ayahuasca) for treatment-resistant depression, anxiety in terminal illness, PTSD, and substance use disorders in controlled clinical settings.

Major Depressive Disorder

– A mood disorder characterized by at least one major depressive episode consisting of five or more symptoms during the same two-week period. At least one symptom must be either depressed mood or loss of interest or pleasure (anhedonia). Symptoms include significant weight change, insomnia or hypersomnia, psychomotor agitation or retardation, fatigue, feelings of worthlessness or excessive guilt, diminished concentration, and recurrent thoughts of death or suicidal ideation. The episode causes clinically significant distress or impairment. MDD is the leading cause of disability worldwide, affecting approximately 7 percent of adults annually. Treatment involves antidepressants (SSRIs, SNRIs, bupropion, mirtazapine), psychotherapy (CBT, interpersonal therapy, behavioural activation), and combination therapy for moderate-to-severe episodes. ECT is reserved for severe, psychotic, or treatment-resistant depression. Prognosis is variable; recurrence is common, and maintenance treatment is recommended.

Male Hypoactive Sexual Desire Disorder

– A sexual dysfunction in men characterized by persistently deficient or absent sexual/erotic thoughts or desire for sexual activity, causing marked distress. Prevalence: 5-15% of men. Distinguish from erectile disorder (men may have ED but intact desire). Causes: low testosterone (primary or secondary hypogonadism), hyperprolactinemia, depression, relationship conflict, medication side effects (SSRIs, antipsychotics, beta-blockers, spironolactone), chronic illness (diabetes, CKD, COPD), and aging. Diagnosis: total and free testosterone, prolactin, TSH, and clinical interview. Treatment: testosterone replacement (if confirmed hypogonadal), treat hyperprolactinemia, switch offending medications, CBT, and sex therapy. Testosterone is not recommended for age-related low T without clear hypogonadism.

Malingering

– The intentional fabrication or exaggeration of physical or psychological symptoms for external incentives (avoiding work, obtaining financial compensa-

tion, evading criminal prosecution, obtaining drugs). Not a psychiatric illness (coded as a V-code/Z-code). Suspicion raised by: non-compliance with treatment, antisocial personality disorder, discrepancies between reported symptoms and objective findings, and symptoms that emerge in specific contexts (legal, military, disability evaluation). Diagnosis: collateral information, psychological testing (MMPI-2 validity scales). No psychiatric treatment; management involves confrontation and documentation.

Mania

– A distinct period of abnormally elevated, expansive, or irritable mood with increased goal-directed activity or energy, lasting ≥ 1 week (or any duration if hospitalization required). Requires ≥ 3 of: inflated self-esteem, decreased need for sleep, pressured speech, flight of ideas, distractibility, increased goal-directed activity, and excessive involvement in risky activities. Causes significant functional impairment or psychosis. Core feature of bipolar I disorder. Treatment: mood stabilizers (lithium, valproate) and atypical antipsychotics.

Manic Episode

– A distinct period lasting at least seven days (or any duration if hospitalization is required) of abnormally elevated, expansive, or irritable mood with increased energy or activity. At least three symptoms must be present: inflated self-esteem or grandiosity, decreased need for sleep, pressured speech, flight of ideas or racing thoughts, distractibility, increased goal-directed activity or psychomotor agitation, and excessive involvement in pleasurable activities with high potential for painful consequences (e.g., buying sprees, sexual indiscretions, risky investments). The mood disturbance is severe enough to cause marked impairment in social or occupational functioning, requires hospitalisation to prevent harm to self or others, or includes psychotic features. First-line treatment is lithium or valproate, with atypical antipsychotics (olanzapine, quetiapine, risperidone, aripiprazole, and asenapine) as effective alternatives. Benzodiazepines are used as adjunctive therapy for acute agitation. ECT is highly effective for severe or refractory mania.

Melancholic Features

– A specifier for major depressive episodes characterized by a loss of interest or pleasure in all or almost

all activities, a depressed mood that is qualitatively distinct from grief, prominent psychomotor retardation or agitation, significant anorexia or weight loss, excessive guilt, and worsening of mood in the morning. It suggests a more severe, biologically driven depression with better response to antidepressants or ECT.

Melatonin Receptor Agonists

– Medications that act on MT1 and MT2 receptors in the suprachiasmatic nucleus to regulate circadian rhythms. Ramelteon is approved for insomnia with sleep onset difficulty. It has no abuse potential and does not cause dependence. It is a useful alternative to benzodiazepines for sleep initiation problems.

Mental Health

– Mental health encompasses emotional, psychological, and social well-being, affecting how individuals think, feel, behave, and handle stress, relationships, and decision-making. Common mental disorders: anxiety disorders (generalized anxiety, panic, phobias, social anxiety—lifetime prevalence 29%), depressive disorders (major depressive disorder, persistent depressive disorder—lifetime prevalence 21%), bipolar disorder (manic-depressive illness), schizophrenia and other psychotic disorders, and trauma/stressor-related disorders (PTSD, adjustment disorder). The biopsychosocial model recognizes genetic vulnerability (heritability 30–50% for major depression), neurobiologic factors (neurotransmitter dysregulation, HPA-axis abnormalities), psychological factors (maladaptive cognitions, coping deficits), and social determinants (childhood adversity, poverty, discrimination, isolation). Treatment: psychotherapy (CBT, DBT, psychodynamic, interpersonal therapy), pharmacotherapy (antidepressants, mood stabilizers, antipsychotics, anxiolytics), neuromodulation (ECT, TMS, ketamine/esketamine for treatment-resistant depression), and social support interventions. Screening (PHQ-9, GAD-7, AUDIT-C) in primary care improves detection and outcomes.

Mental Status Examination

– A structured assessment of the patient's current psychological functioning performed during the clinical interview. It evaluates appearance, behaviour, speech, mood, affect, thought process, thought content, perceptions, cognition, insight, and judgment.

It provides a snapshot of the patient's mental state at the time of evaluation and is documented in the psychiatric note.

Methylphenidate

– See Methylphenidate in Pharmacology.

Mindfulness and Meditation

– Mindfulness is the practice of nonjudgmental, present-moment awareness cultivated through meditation techniques, including focused attention (breath, body scan), open monitoring (observing thoughts/emotions without attachment), and loving-kindness meditation. Neurobiologic correlates include decreased default mode network activity (reduced rumination), increased prefrontal cortex activation (enhanced executive control), and reduced amygdala reactivity (stress regulation). Meta-analyses demonstrate moderate-to-strong effects in reducing anxiety, depression, stress, and pain severity; mindfulness-based stress reduction (MBSR) and mindfulness-based cognitive therapy (MBCT) are evidence-based programs with efficacy equivalent to antidepressants for preventing depression relapse. Typical training: 8-week program with 2–3 hours/week group sessions plus 45 minutes daily home practice. Benefits accumulate with consistent practice; smartphone-based apps (Headspace, Calm) improve accessibility but produce smaller effects than instructor-led programs.

Monoamine Oxidase Inhibitors

– Antidepressants that inhibit monoamine oxidase, the enzyme responsible for breaking down serotonin, norepinephrine, and dopamine. MAOIs include phenelzine, tranylcypromine, isocarboxazid, and selegiline (transdermal). They are effective for atypical depression and treatment-resistant depression. The major risk is hypertensive crisis from tyramine-rich foods (“cheese reaction”). They are contraindicated with sympathomimetics, meperidine, and other serotonergic agents due to risk of serotonin syndrome. Dietary restrictions require avoidance of aged cheeses, cured meats, fermented foods, and certain alcoholic beverages (tyramine-rich foods). The transdermal selegiline patch bypasses gastrointestinal MAO and does not require dietary restrictions at the lowest dose. MAOIs are reserved for treatment-resistant cases due to their side effect profile and drug interactions.

Mood Stabilizers

- Medications used to treat mood episodes in bipolar disorder and prevent recurrence. The primary mood stabilizers are lithium, valproate, carbamazepine, and lamotrigine. Each has a different mechanism and side effect profile. Lithium is the only agent with demonstrated anti-suicide properties. Valproate is particularly effective for rapid-cycling bipolar disorder. Lamotrigine is more effective for bipolar depression than mania.

Motivational Interviewing

- A client-centered, directive counseling method for enhancing intrinsic motivation to change by exploring and resolving ambivalence. Developed by Miller and Rollnick, it uses the spirit of partnership, acceptance, compassion, and evocation. Core skills include open-ended questions, affirmations, reflections, and summaries. It is particularly effective for substance use disorders and health behavior change.

Munchausen Syndrome

- The severe form of factitious disorder imposed on self, named after Baron von Munchausen, in which the patient repeatedly feigns or self-induces illness to assume the sick role. Patients migrate between hospitals and submit to invasive procedures. Management is harm-reduction, not cure.

Narcissistic Personality Disorder

- A pattern of grandiosity, need for admiration, and lack of empathy. At least five of nine criteria: grandiose sense of self-importance, preoccupation with fantasies of unlimited success, belief of being “special,” requires excessive admiration, sense of entitlement, interpersonally exploitative, lacks empathy, envious of others or believes others are envious, and shows arrogant, haughty behaviors. May present as grandiose or vulnerable (covert) narcissism.

Narcolepsy

- A chronic sleep disorder characterized by excessive daytime sleepiness and irresistible sleep attacks, with or without cataplexy (sudden bilateral loss of muscle tone triggered by strong emotions). Narcolepsy type 1: with cataplexy, caused by loss of hypocretin/orexin neurons in the hypothalamus. Other features: sleep paralysis (inability to move upon falling asleep or waking), hypnagogic/hypnopompic hallucinations, and disrupted nighttime sleep. Diagnosis: polysomnography followed by MSLT (mean sleep latency <8 minutes, ≥ 2 SOREM periods). Treatment: wake-promoting agents (modafinil, armodafinil, solriamfetol), sodium oxybate for cataplexy/EDS, and SSRIs/SNRIs for cataplexy.

Neuroleptic

- An older term for antipsychotic medications, derived from their ability to produce a state of mental indifference and motor slowing. The term is now largely replaced by “antipsychotic,” though it is still used in specific contexts such as neuroleptic malignant syndrome. Typical neuroleptics are first-generation antipsychotics.

Neuroplasticity

- The brain’s ability to reorganize its structure, function, and connections in response to experience, learning, and injury. It is relevant to psychiatric treatment because antidepressants, psychotherapy, and ECT are thought to promote neuroplastic changes including neurogenesis in the hippocampus and synaptic remodeling.

Obsessions

- Recurrent, persistent, intrusive, and unwanted thoughts, urges, or images that are experienced as intrusive and cause marked anxiety or distress. Common obsessions include contamination fears, fears of harming oneself or others, need for symmetry, taboo thoughts (sexual, religious, or aggressive), and doubt. The individual recognizes the obsessions as excessive or irrational in many cases (good insight).

Obsessive-Compulsive Disorder

- Characterized by the presence of obsessions, compulsions, or both. Obsessions are recurrent, persistent, intrusive, and unwanted thoughts, urges, or images that cause marked anxiety or distress. The individual attempts to ignore or suppress them or neutralize them with some other thought or action. Compulsions are repetitive behaviors or mental acts that the individual feels driven to perform in response to an obsession or according to rigid rules. They are aimed at preventing or reducing anxiety or preventing a dreaded event, but are not connected in a realistic way with what they are designed to neutralize. Compulsions are time-consuming (taking more than one hour per day) and cause significant distress or impairment. Insight varies: good or fair

insight (the individual recognises the beliefs are probably not true), poor insight, or absent insight (delusional beliefs). First-line treatment is CBT with exposure and response prevention (ERP) and SSRIs (fluoxetine, fluvoxamine, sertraline, paroxetine, or escitalopram) at higher doses than used for depression. The combination of CBT and SSRI is superior to either alone. Prognosis is variable; symptoms may be chronic but are usually responsive to treatment.

Obsessive-Compulsive Personality Disorder

– A pattern of preoccupation with orderliness, perfectionism, and mental and interpersonal control, at the expense of flexibility and efficiency. At least four of eight criteria: preoccupied with details, rules, lists, organization, or schedules to the extent that the major point of the activity is lost; shows perfectionism that interferes with task completion; excessively devoted to work; overconscientious and inflexible about morality; unable to discard worn-out objects; reluctant to delegate tasks unless others submit to their way of doing things. Diagnosis is clinical using DSM-5 criteria. Treatment is challenging as patients rarely seek help voluntarily. Psychodynamic therapy and CBT may help address perfectionism and control. Pharmacotherapy targets comorbid depression or anxiety. Prognosis is guarded, as the personality traits are ego-syntonic and resistant to change.

OCD

– See Obsessive-Compulsive Disorder.

Opioid Overdose

– A medical emergency characterized by the classic triad of respiratory depression, miosis (pinpoint pupils), and decreased level of consciousness. It can progress to respiratory arrest, cardiovascular collapse, and death. Treatment involves airway management, naloxone administration (0.4–2 mg IV/IM, may repeat), and monitoring for re-narcotization as naloxone wears off. Fentanyl and its analogs require higher and repeated naloxone doses.

Opioid Use Disorder

– A problematic pattern of opioid use leading to significant impairment or distress. Opioids include heroin, fentanyl, morphine, oxycodone, and hydrocodone. Criteria are the same eleven as for sub-

stance use disorders generally. Overdose presents with respiratory depression, miosis, and decreased level of consciousness. Naloxone is the antidote. Treatment includes methadone, buprenorphine, and naltrexone.

Oppositional Defiant Disorder

– A childhood/adolescent disorder characterized by a persistent pattern (≥ 6 months) of angry/irritable mood, argumentative/defiant behavior, and vindictiveness. Symptoms: often loses temper, is touchy/easily annoyed, angry/resentful, argues with authority figures, actively defies rules, deliberately annoys others, blames others for mistakes, and has been spiteful/vindictive at least twice in the past 6 months. Milder than conduct disorder (no aggression toward people/animals, no destruction of property). Risk factor for development of conduct disorder. Treatment: parent management training, CBT, and school-based interventions.

Orexin Receptor Antagonists

– Medications that block orexin (hypocretin) receptors to promote sleep. Suvorexant and lemborexant are approved for insomnia. They reduce wakefulness by blocking the arousal system. They have lower abuse potential than benzodiazepines and do not cause respiratory depression.

OSFED

– Other Specified Feeding or Eating Disorder, used when the clinical presentation causes significant distress or impairment but does not meet full criteria for any of the specific eating disorders. Examples include atypical anorexia nervosa (all criteria met except weight is within or above normal range), sub-threshold bulimia nervosa or binge eating disorder, purging disorder, and night eating syndrome.

Other Mental Health Disorders

– conditions beyond depression and anxiety, such as bipolar disorder (manic-depressive illness cycling between mania/hypomania and depression; lithium is cornerstone therapy), schizophrenia and psychotic disorders (hallucinations, delusions, disorganized thinking; dopamine hypothesis; antipsychotic treatment), obsessive-compulsive disorder (OCD; intrusive thoughts and repetitive rituals; CBT/ERP and SSRIs), post-traumatic stress disorder (PTSD; re-experiencing, avoidance, hyperarousal after trauma; trauma-focused therapy, SSRIs, prazosin for night-

mares), eating disorders (anorexia nervosa, bulimia nervosa, binge-eating disorder; requiring medical monitoring for refeeding syndrome), personality disorders (borderline, antisocial, avoidant; dialectical behavior therapy for BPD), and substance use disorders (alcohol, opioids, stimulants; pharmacotherapy—naltrexone, buprenorphine—and psychosocial support). Multidisciplinary treatment: psychotherapy, pharmacotherapy, social support, and coordinated care with medical providers for substance-related and other medical complications.

Other Specified Sexual Dysfunction

– A category for sexual dysfunction symptoms that cause distress but do not meet full criteria for any specific sexual dysfunction. Examples: sexual aversion (extreme avoidance of or aversion to genital sexual contact), inadequate vaginal lubrication without pain, persistent genital arousal disorder (unwanted genital arousal without sexual desire, PGAD), and sexual dysfunction due to medical conditions not otherwise covered. Management is tailored to the specific presentation.

Panic Attack

– An abrupt surge of intense fear or discomfort reaching a peak within minutes. The individual experiences at least four of thirteen symptoms: palpitations, sweating, trembling, shortness of breath, feelings of choking, chest pain, nausea, dizziness, chills or heat, paresthesias, derealization or depersonalization, fear of losing control, and fear of dying. Panic attacks are not limited to panic disorder and occur in many psychiatric and medical conditions.

Panic Disorder

– Recurrent unexpected panic attacks, which are abrupt surges of intense fear or discomfort peaking within minutes. During attacks, individuals experience at least four of thirteen symptoms: palpitations, sweating, trembling, shortness of breath, feelings of choking, chest pain, nausea, dizziness, chills or heat sensations, paresthesias, derealization, fear of losing control, and fear of dying. At least one attack is followed by persistent worry about additional attacks or maladaptive behavioral changes aimed at avoiding future attacks. Panic disorder is a chronic condition with a relapsing-remitting course. The lifetime prevalence is approximately 3-5 per-

cent, with onset typically in late adolescence or early adulthood. The fear of having another panic attack leads to a cycle of escalating anxiety and avoidance. Agoraphobia frequently co-occurs. Diagnosis is clinical using DSM-5 criteria. First-line treatment includes CBT with interoceptive exposure and SSRIs (sertraline, paroxetine, fluoxetine, escitalopram) or SNRIs (venlafaxine). Benzodiazepines (alprazolam, clonazepam) are effective acutely but avoided as first-line due to tolerance and dependence. Prognosis is good with treatment; most patients achieve significant symptom reduction.

Paraphilia

– A condition characterized by intense and persistent sexual interest in atypical objects, situations, or individuals. Examples: exhibitionism, fetishism, frotteurism, pedophilic disorder, sexual masochism, sexual sadism, transvestic disorder, voyeurism, and paraphilia not otherwise specified. Diagnosis requires that the paraphilia causes distress or impairment or involves harm to others. Treatment: CBT, SSRI medications, and antiandrogens in selected cases.

Pedophilic Disorder

– A paraphilic disorder characterized by intense and recurrent sexual attraction to prepubescent children (generally age ≤ 13), lasting ≥ 6 months, and causing distress or impairment or involving acting on these urges. Diagnosis requires the individual is ≥ 16 years old and ≥ 5 years older than the child. Assessment: clinical interview, phallometric testing. Treatment: CBT focusing on relapse prevention and cognitive distortions; pharmacotherapy (SSRIs, antiandrogens — medroxyprogesterone acetate, cyproterone acetate, GnRH agonists like leuprolide) to reduce libido. Ethical and legal considerations are paramount.

Perinatal Psychiatry

– The subspecialty focused on psychiatric disorders during pregnancy and the postpartum period. Common conditions include perinatal depression, perinatal anxiety, perinatal OCD, and postpartum psychosis. Medication selection must balance maternal mental health with fetal or neonatal exposure risks. SSRIs are generally considered safe, while lithium and valproate carry teratogenic risks. Breastfeeding considerations influence medication choice.

Persistent Depressive Disorder

– formerly called dysthymia, a chronic depressive mood lasting at least two years in adults (one year in children and adolescents). Patients experience depressed mood for more days than not, along with at least two additional symptoms: poor appetite or overeating, insomnia or hypersomnia, low energy, low self-esteem, poor concentration, or feelings of hopelessness. During a two-year period, the patient has never been symptom-free for more than two months.

Personality Disorder

– A group of mental disorders characterized by enduring maladaptive patterns of thinking, feeling, and behaving that deviate from cultural expectations and cause functional impairment. Cluster A (odd/eccentric): paranoid, schizoid, schizotypal. Cluster B (dramatic/erratic): antisocial, borderline, histrionic, narcissistic. Cluster C (anxious/fearful): avoidant, dependent, obsessive-compulsive. Diagnosis requires onset in adolescence or early adulthood and stability over time. Treatment: psychotherapy (DBT for borderline, CBT, psychodynamic); limited pharmacotherapy for specific symptoms.

Postpartum Depression

– Major depressive or manic episodes occurring during pregnancy or within four weeks of delivery (DSM-5). The term is often used more broadly to cover depressive episodes up to one year postpartum. Risk factors include prior depression, lack of social support, stressful life events, and hormonal fluctuations. Postpartum psychosis is a distinct, more severe entity requiring immediate psychiatric hospitalization.

Postpartum Psychosis

– A psychiatric emergency occurring within the first two weeks postpartum, characterized by rapid onset of psychotic symptoms including confusion, disorientation, hallucinations, and delusions. It occurs in approximately 1–2 per 1000 deliveries and is associated with bipolar disorder. Risk of infanticide and suicide is elevated. Requires immediate psychiatric hospitalization and treatment with mood stabilizers and antipsychotics.

Posttraumatic Stress Disorder (PTSD)

– A psychiatric disorder that develops after exposure

to a traumatic event (death, serious injury, sexual violence). Presents with 4 symptom clusters: re-experiencing (intrusive memories, flashbacks, nightmares), avoidance (of trauma reminders), negative alterations in cognition and mood, and hyperarousal (hypervigilance, exaggerated startle, irritability). Duration >1 month with functional impairment. Risk factors: prior trauma, lack of social support, female sex, and peritraumatic dissociation. Diagnosis: DSM-5 criteria. Treatment: trauma-focused CBT (prolonged exposure, cognitive processing therapy), EMDR, and SSRIs (sertraline, paroxetine). Prognosis: chronic without treatment.

Premature (Early) Ejaculation

– A sexual dysfunction characterized by a persistent or recurrent pattern of ejaculation occurring within approximately 1 minute of vaginal penetration and before the individual wishes it, occurring in $\geq 75\%$ of sexual encounters, lasting ≥ 6 months, and causing marked distress. Prevalence: 20–30% of men, the most common male sexual dysfunction. Lifelong (primary) vs. acquired (secondary to ED, prostatitis, hyperthyroidism, anxiety, or relationship issues). Diagnosis: clinical DSM-5 criteria (IELT, perceived control, distress). Treatment: first-line — behavioral techniques (stop-start, squeeze technique), topical anesthetics (lidocaine-prilocaine cream). Pharmacotherapy: dapoxetine (short-acting SSRI, on-demand, approved in many countries outside the US), off-label SSRIs (paroxetine 10–40 mg, sertraline 50–200 mg) daily or on-demand, and clomipramine. Treat underlying ED if present.

Premenstrual Dysphoric Disorder

– A severe, debilitating form of premenstrual syndrome characterized by marked mood symptoms (depression, anxiety, irritability, mood swings), physical symptoms (breast tenderness, bloating, fatigue), and functional impairment that occur during the luteal phase and remit within days of menses onset. Symptoms must occur in most menstrual cycles for the past year and cause significant distress. Distinguishing from PMS: greater severity and predominance of affective symptoms. Diagnosis: prospective daily symptom charting for ≥ 2 cycles. Treatment: SSRIs (intermittent luteal phase or continuous), combined oral contraceptives (drospirenone-

containing), CBT, and GnRH agonists in refractory cases.

Projection

- A defense mechanism in which unacceptable thoughts, feelings, or impulses are attributed to others. For example, a patient who is angry at the therapist may accuse the therapist of being angry at them. It is common in paranoid thinking, delusional disorders, and personality disorders.

Psychodynamic Therapy

- A form of depth psychology that explores how unconscious processes, early life experiences, and internal conflicts influence current thoughts, feelings, and behaviors. It involves exploration of transference and countertransference, defense mechanisms, and the therapeutic relationship as a vehicle for change. Brief psychodynamic therapy is time-limited and focused on specific conflicts. It is effective for depression, anxiety, personality disorders, and somatic symptom disorders.

Psychogenic Seizures

- Seizure-like episodes that are not caused by abnormal electrical activity in the brain. They are a form of conversion disorder with attacks or seizures. Events may include shaking, stiffening, unresponsiveness, and other movements. Diagnosis requires clinical evidence of incompatibility with epilepsy and can be confirmed by video-EEG monitoring showing normal EEG during an event. Treatment includes psychotherapy and education about the diagnosis.

Psychopharmacology

- The study and clinical application of medications used to treat psychiatric disorders. It involves understanding drug mechanisms, pharmacokinetics, drug interactions, and side effect profiles. It is the foundation of biological psychiatry and enables evidence-based medication management for mood, anxiety, psychotic, and cognitive disorders.

PTSD

- See Post-Traumatic Stress Disorder.

Purging Disorder

- Recurrent purging behavior to influence weight or shape in the absence of binge eating. Self-induced vomiting, misuse of laxatives, diuretics, or other medications. It is classified under Other Specified

Feeding or Eating Disorder (OSFED). It can lead to electrolyte imbalances, dental erosion, Russell's sign, and esophageal tears.

Reactive Attachment Disorder

- A pattern of inhibited, emotionally withdrawn behavior toward adult caregivers. The child rarely or minimally seeks comfort when distressed and rarely or minimally responds to comfort when distressed. The child shows a pattern of persistently irritable and sad mood that is not limited to interactions with caregivers. It results from a pattern of insufficient care including social neglect, repeated changes of primary caregivers, or rearing in unusual settings.

Restless Legs Syndrome

- An urge to move the legs, usually accompanied by uncomfortable sensations, that begins or worsens during rest, is relieved by movement, and occurs predominantly in the evening or night. The condition causes significant distress or impairment. It is associated with iron deficiency, renal failure, pregnancy, and peripheral neuropathy. Ferritin levels below 50 ng/mL should be supplemented. Dopaminergic agents and alpha-2-delta ligands (gabapentin, enacarbil) are used for treatment.

Schizoaffective Disorder

- A disorder characterized by an uninterrupted period of illness during which there is a major mood episode concurrent with criterion A of schizophrenia (delusions, hallucinations, disorganized speech, grossly disorganized or catatonic behavior, or negative symptoms). The individual must also have delusions or hallucinations for at least two weeks in the absence of a major mood episode. The mood episodes are present for the majority of the total duration of the illness.

Schizoid Personality Disorder

- A pattern of detachment from social relationships with a restricted range of emotional expression. At least four of seven criteria: neither desires nor enjoys close relationships, almost always chooses solitary activities, has little interest in sexual experiences, takes pleasure in few activities, lacks close friends, appears indifferent to praise or criticism, and shows emotional coldness, detachment, or flattened affect.

Schizophrenia

- A severe chronic mental illness characterized by psychotic symptoms (hallucinations, delusions, dis-

organized thinking) and negative symptoms (avolition, alogia, anhedonia, blunted affect), with cognitive impairment and functional decline. Diagnosis: ≥ 2 core symptoms for ≥ 1 month with continuous signs for ≥ 6 months. Onset typically in late adolescence/early adulthood. Treatment: antipsychotic medications (first-generation: haloperidol; second-generation: risperidone, olanzapine, clozapine for refractory), psychosocial interventions, and family education.

Schizotypal Personality Disorder

– A pattern of social and interpersonal deficits marked by acute discomfort with and reduced capacity for close relationships, cognitive or perceptual distortions, and eccentricities of behavior. Features include ideas of reference, odd beliefs or magical thinking, unusual perceptual experiences, odd thinking and speech, suspiciousness, inappropriate affect, and constricted affect. It shares genetic and phenomenological features with schizophrenia.

Seasonal Affective Disorder

– A specifier of recurrent major depressive episodes that occur at a specific time of year, most commonly winter (with remission in spring/summer). Symptoms: hypersomnia, hyperphagia with carbohydrate craving, weight gain, fatigue, and low energy. Associated with reduced sunlight exposure disrupting circadian rhythms and serotonin regulation. Treatment: light therapy (10,000 lux, 30 minutes upon waking), CBT-SAD, SSRIs/bupropion, and agomelatine. Dawn simulation and vitamin D supplementation may help.

Sedatives

– See Sedatives in Pharmacology.

Selective Mutism

– Consistent failure to speak in specific social situations where speaking is expected despite speaking in other situations. The disturbance interferes with educational or occupational achievement or social communication. Must last for at least one month and is not attributable to lack of knowledge of or comfort with the spoken language. Most commonly seen in children and often co-occurs with social anxiety disorder.

Self-Harm

– Intentional self-inflicted injury without suicidal intent, also termed non-suicidal self-injury; common

methods include cutting, burning, and self-hitting. Prevalent in adolescents and in borderline personality disorder, depression, eating disorders, and trauma, serving affect regulation or self-punishment. Associated with increased subsequent suicide risk. Management centres on dialectical behaviour therapy and treatment of underlying disorders.

Separation Anxiety Disorder

– Developmentally inappropriate and excessive fear or anxiety concerning separation from attachment figures. The individual may have recurrent excessive distress when anticipating or experiencing separation from home or major attachment figures. Symptoms may include worry about harm befalling attachment figures, worry about experiencing an event causing separation, reluctance to leave home or go out alone, and nightmares involving separation. Must persist for four weeks in children and six months in adults. Diagnosis is clinical using DSM-5 criteria. Treatment includes CBT with graded exposure to separation situations and SSRIs (fluoxetine, sertraline, fluvoxamine) for moderate-to-severe cases. Involving parents in treatment is essential. Prognosis is good with treatment; untreated separation anxiety may persist and predispose to other anxiety disorders in adulthood.

Serotonin-Norepinephrine-Dopamine Reuptake Inhibitors

– A class of antidepressants that inhibit reuptake of serotonin, norepinephrine, and dopamine. The primary agent is bupropion, which also acts as a norepinephrine-dopamine reuptake inhibitor. It is used for depression, smoking cessation, and as augmentation. It lacks sexual side effects and weight gain associated with SSRIs.

Serotonin-Norepinephrine Reuptake Inhibitors

– Antidepressants that block the reuptake of both serotonin and norepinephrine. They include venlafaxine, duloxetine, desvenlafaxine, and levomilnacipran. SNRIs are used for major depressive disorder, generalized anxiety disorder, diabetic neuropathy, fibromyalgia, and chronic pain. They are particularly useful in patients with fatigue and poor concentration. Side effects include those of SSRIs plus hypertension (especially at higher doses).

Sexual Masochism Disorder

– A paraphilic disorder characterized by recurrent, intense sexual arousal from the act of being humiliated, beaten, bound, or otherwise made to suffer, lasting ≥ 6 months and causing distress or impairment or involving acting on these urges. Asphyxiophilia (sexual arousal from oxygen restriction): the most dangerous form, associated with accidental death during solo practice. Hypoxyphilia: arousal from oxygen deprivation. Consensual BDSM activities are not considered pathological. Disorder is diagnosed when the behavior causes clinically significant distress, impairment, or risk of harm. Treatment: CBT and SSRIs.

Sexual Sadism Disorder

– A paraphilic disorder characterized by recurrent, intense sexual arousal from the physical or psychological suffering of another person, lasting ≥ 6 months and causing distress or impairment or involving acting on these urges with a nonconsenting person. In the context of BDSM with consenting adults, sadistic acts alone do not constitute a disorder. Diagnosis requires that the individual has acted on these urges with a nonconsenting person or the urges cause significant distress or interpersonal difficulty. The most severe form is associated with serial sexual homicide. Treatment: CBT, SSRIs, antiandrogens, and GnRH agonists for severe cases.

Sleep Hygiene

– A set of behavioral and environmental practices designed to promote consistent, uninterrupted, and restorative sleep. Key elements include maintaining a regular sleep schedule, creating a cool, dark, and quiet sleep environment, avoiding caffeine and electronic screens before bedtime, and engaging in relaxing pre-sleep routines. Poor sleep hygiene is a common contributor to insomnia, and adopting these habits is often the first-line recommendation for improving sleep quality without medication.

Social Anxiety Disorder

– Marked fear or anxiety about one or more social situations in which the individual may be scrutinized by others. The individual fears acting in a way or showing anxiety symptoms that will be negatively evaluated. The social situations almost always provoke fear or anxiety, are avoided or endured with intense anxiety, and are disproportionate to the actual threat. The fear, anxiety, or avoidance is

persistent, typically lasting six months or more.

Somatic Symptom Disorder

– Characterized by one or more somatic symptoms that are distressing or result in significant disruption of daily life, accompanied by excessive thoughts, feelings, or behaviors related to the somatic symptoms. The individual experiences persistent high levels of worry about the seriousness of symptoms, an excessive amount of time and energy devoted to health concerns, or disproportionate and persistent concern about the medical implications of symptoms. The problematic symptoms are not better explained by another medical or psychiatric condition. Somatic symptom disorder is common, with prevalence of approximately 5-7 percent in the general population. It is associated with high healthcare utilisation and functional impairment. Diagnosis is clinical using DSM-5 criteria, after appropriate medical evaluation to exclude underlying organic pathology. Treatment includes establishing a consistent therapeutic relationship with a single primary care provider, CBT, graded exercise, and antidepressants (SSRIs, TCAs) for comorbid depression or pain. Prognosis is variable, but most patients improve with appropriate management that avoids unnecessary investigations and procedures.

Somatization

– Process by which psychological distress is expressed as bodily symptoms without identifiable organic cause. The historical DSM-IV somatization disorder is subsumed in DSM-5 by somatic symptom disorder, which emphasises disproportionate thoughts and behaviours related to somatic symptoms. Management is collaborative and longitudinal, with a single clinician, regular visits, and cognitive behavioural therapy. See Somatic Symptom Disorder.

Specific Learning Disorder

– Persistent difficulties in reading, written expression, or mathematics, despite adequate intelligence and educational opportunity. Diagnosis requires academic skills significantly below expected for age, difficulties for at least six months, and no better explained by intellectual disability, sensory impairment, or neurological condition. Subtypes include dyslexia (reading), dysgraphia (writing), and dyscalculia (mathematics).

Specific Phobia

- Marked fear or anxiety about a specific object or situation that is out of proportion to the actual danger posed. Exposure to the phobic stimulus almost invariably provokes an immediate anxiety response. The object or situation is actively avoided or endured with intense anxiety. The fear, anxiety, or avoidance persists for six months or more. Subtypes include animal, natural environment, blood-injection-injury, situational, and other.

Splitting

- A primitive defense mechanism in which objects or self-representations are viewed as entirely good or entirely bad, with no integration of positive and negative qualities. It is a core feature of borderline personality disorder and contributes to idealization-devaluation patterns in relationships. It reflects impaired object relations.

Stimulant Use Disorder

- A problematic pattern of stimulant use (cocaine, amphetamines, methamphetamine, MDMA) leading to significant impairment. Stimulants increase dopamine and norepinephrine activity. Withdrawal is characterized by fatigue, depression, increased appetite, hypersomnia, psychomotor retardation, and vivid unpleasant dreams. Methamphetamine use is associated with severe dental disease, paranoia, and hallucinations. Treatment is primarily behavioral as no FDA-approved medications exist.

Stress

- A physiological and psychological response to perceived threats or demands that activates the sympathetic nervous system and the hypothalamic-pituitary-adrenal axis. Acute stress can enhance focus and performance in challenging situations, but chronic stress contributes to the development or exacerbation of numerous health conditions, including hypertension, anxiety disorders, depression, gastrointestinal problems, and immunosuppression. Effective stress management techniques include regular physical activity, mindfulness meditation, adequate sleep, social support, and professional counseling when needed.

Substance Abuse Psychiatry

- The subspecialty focused on the evaluation and treatment of substance use disorders and co-occurring psychiatric conditions. Dual diagnosis patients require integrated treatment addressing both

disorders simultaneously. Psychopharmacology includes medication-assisted treatment (methadone, buprenorphine, naltrexone for opioid use disorder; acamprosate, disulfiram, naltrexone for alcohol use disorder) alongside psychotherapy including motivational interviewing and CBT.

Substance/Medication-Induced Sexual Dysfunction

- Sexual dysfunction directly caused by substance use or medication effects. Common culprits: SSRIs/SNRIs (decreased desire, delayed ejaculation/anorgasmia, erectile dysfunction — most common cause of drug-induced sexual dysfunction), antipsychotics (hyperprolactinemia causing decreased desire and ED), antihypertensives (beta-blockers, thiazides, alpha-blockers), hormonal contraceptives (decreased desire, vaginal dryness), antiandrogens (spironolactone, finasteride), opioids (decreased desire, ED, delayed ejaculation), and alcohol (acute: erectile difficulty; chronic: decreased desire and testicular atrophy). Management: identify the culprit, dose reduction, drug holiday, switch to alternative (bupropion, mirtazapine for depression; PDE5 inhibitors for ED), and add-on therapy (buspirone for SSRI-induced sexual dysfunction). Bupropion has the lowest rate of sexual side effects among antidepressants.

Substance Use Disorder

- A problematic pattern of substance use leading to clinically significant impairment or distress, manifested by at least two of eleven criteria within a twelve-month period. Criteria include taking the substance in larger amounts or over a longer period than intended, persistent desire or unsuccessful efforts to cut down, great deal of time spent obtaining or recovering from the substance, craving, failure to fulfill obligations, continued use despite social problems, giving up activities, recurrent use in hazardous situations, continued use despite physical or psychological problems, tolerance, and withdrawal. Severity is graded as mild (2-3 criteria), moderate (4-5), or severe (6 or more). Diagnosis is clinical using DSM-5 criteria. Treatment involves motivational interviewing to enhance motivation for change, CBT, contingency management, 12-step facilitation, and medication-assisted treatment where available (methadone, buprenorphine, naltrexone

for opioid use disorder; acamprosate, disulfiram, naltrexone for alcohol use disorder). Relapse rates are high, and recovery often requires multiple treatment episodes and long-term support.

Suicidal Ideation

– Thoughts about killing oneself, ranging from passive (wish to be dead, wishes to fall asleep and not wake) to active (thoughts of killing oneself with varying degrees of intent, plan, and means). The C-SSRS grades severity from 1 (wish to be dead) to 5 (active suicidal ideation with specific plan and intent). Assessment of suicidal ideation must include questions about plan, intent, means, and history of attempts.

Suicide

– The intentional act of taking one's own life. Suicide is a major public health problem worldwide, causing 700,000 deaths annually. Risk factors: psychiatric disorders (major depression—most common contributor, bipolar disorder, schizophrenia, borderline personality disorder, PTSD, substance use disorders—especially alcohol), previous suicide attempt (strongest predictor), family history of suicide, access to means (firearms—most common method in the US; hanging, pesticide poisoning—common globally), male sex (3–4:1 ratio of completed suicide vs attempts), older age (peaks in middle-aged and older adults), chronic physical illness, social isolation, unemployment, financial stress, history of childhood abuse/trauma, and LGBTQ+ identity (increased risk in the context of minority stress). Assessment: direct questioning about suicidal thoughts, plans, intent, and means (does not increase risk—contrary to myth). The SAFE-T (Suicide Assessment Five-step Evaluation and Triage) framework. Acute management: ensure safety—remove means, hospitalisation (voluntary or involuntary if imminent risk), suicide watch (1:1 observation), and pharmacological treatment of underlying psychiatric condition. Long-term management: psychotherapy (CBT, dialectical behaviour therapy—DBT for borderline personality disorder), pharmacotherapy (antidepressants—SSRIs, lithium—reduces suicide risk in mood disorders, clozapine—for schizophrenia), and psychosocial interventions (safety planning, crisis hotlines—988 in the US, 111 option 2 in the UK). Postvention: support for bereaved family and

friends (suicide bereavement). Prevention: restricting access to means, responsible media reporting, school-based programmes, and gatekeeper training (GPs, teachers, police).

Tardive Dyskinesia

– Involuntary, repetitive, purposeless movements caused by prolonged use of antipsychotic medications, typically developing after months to years of exposure. Movements include choreoathetoid movements of the tongue, face, and extremities (lip smacking, tongue protrusion, grimacing, choreiform movements of limbs). It is caused by dopamine receptor supersensitivity. It may be irreversible. VMAT2 inhibitors (valbenazine, deutetrabenazine) are FDA-approved treatments. Risk is lower with atypical antipsychotics (especially clozapine and quetiapine) compared to typical antipsychotics. Prevention involves using the lowest effective dose, regular screening using the Abnormal Involuntary Movement Scale (AIMS) every 6–12 months, and switching to an atypical antipsychotic with lower D2 affinity if emerging dyskinesia is detected. Patients should be warned about the risk prior to starting antipsychotic treatment.

Therapeutic Alliance

– The collaborative, trusting relationship between therapist and patient that is foundational to effective psychotherapy. It includes agreement on goals, tasks, and the bond between therapist and patient. It is the strongest predictor of psychotherapy outcome across all therapeutic modalities.

Therapeutic Drug Monitoring

– The clinical practice of measuring drug levels in blood to ensure therapeutic concentrations while avoiding toxicity. It is particularly important for medications with narrow therapeutic windows including lithium (0.6–1.2 mEq/L), valproate (50–125 mcg/mL), carbamazepine (4–12 mcg/mL), and clozapine (350–600 ng/mL).

Therapeutic Hypothermia

– Controlled cooling of the body temperature used in psychiatric practice for severe catatonia and neuroleptic malignant syndrome. In NMS, cooling is a key treatment alongside discontinuation of the offending agent and dantrolene administration. Body temperature is reduced to below 38 degrees Celsius using cooling blankets, ice packs, or intravascular

cooling catheters.

Thought Blocking

- An abrupt interruption in the train of thought before it is completed, as if the thought was removed or pushed out of the patient's mind. The patient may pause mid-sentence, appear confused, and report that the thought was "taken out" or "blocked." It is a formal thought disorder seen in schizophrenia.

Tourette Disorder

- A neurodevelopmental disorder characterized by multiple motor tics and one or more vocal tics lasting >1 year, with onset before age 18. Motor tics: eye blinking, head jerking, shoulder shrugging, facial grimacing. Vocal tics: throat clearing, sniffing, grunting, barking, coprolalia (obscene words, occurs in <10%). Premonitory urge precedes tics. Comorbidities: ADHD (60%), OCD (30-50%), anxiety. Course: waxing and waning severity; most improve by late adolescence. Diagnosis: clinical DSM-5 criteria. Treatment: CBIT (habit reversal training), alpha-2 agonists (clonidine, guanfacine), antipsychotics (haloperidol, pimozide) for severe tics.

Tourette Syndrome

- A neurodevelopmental disorder characterized by multiple motor tics and at least one vocal tic occurring over at least one year. Tics are sudden, rapid, recurrent, stereotyped movements or vocalizations. They are often preceded by premonitory urges. Tics typically worsen in adolescence and may improve in adulthood. Comorbidities include ADHD, OCD, and anxiety disorders. Treatments include behavioral therapy and antipsychotics for severe tics.

Tranquillisers

- See Tranquillisers in Pharmacology.

Transference

- A psychoanalytic concept in which feelings, attitudes, and expectations originally directed toward a significant figure from childhood are unconsciously redirected onto the therapist. In psychodynamic therapy, transference is a therapeutic tool for understanding the patient's relational patterns and resolving conflicts.

Transvestic Disorder

- A paraphilic disorder characterized by recurrent, intense sexual arousal from cross-dressing, lasting ≥6 months and causing marked distress or impair-

ment. Almost exclusively in heterosexual males. Transvestic disorder is distinguished from gender dysphoria by the primary motivation: sexual arousal (transvestic) vs. identity incongruence (gender dysphoria). Many cross-dressers do not experience distress and therefore do not meet disorder criteria. Treatment: CBT for distress or guilt, and SSRIs for compulsive behavior. No treatment is indicated for cross-dressing without distress.

Trichotillomania

- Recurrent pulling out of one's hair, resulting in hair loss. The individual has made repeated attempts to decrease or stop hair pulling. The hair pulling causes clinically significant distress or impairment. It is not attributable to another medical condition. The pulling can occur from any body region and may be focused or focused-pulling. It is classified under obsessive-compulsive and related disorders.

Tricyclic Antidepressants

- Older antidepressants that non-selectively inhibit the reuptake of serotonin and norepinephrine. They include amitriptyline, nortriptyline, imipramine, clomipramine, and desipramine. TCAs are effective but have more side effects than SSRIs, including anticholinergic effects (dry mouth, urinary retention, constipation), orthostatic hypotension, weight gain, and cardiac conduction delays. Lethal in overdose due to cardiac arrhythmias. They are used for depression, neuropathic pain, migraine prophylaxis, and off-label for insomnia and anxiety. TCAs have significant anticholinergic, antihistaminergic, and alpha-adrenergic blocking properties. Nortriptyline has the least anticholinergic side effects and is preferred in elderly patients. Due to their narrow therapeutic index and cardiotoxicity in overdose, TCAs are used less frequently than SSRIs but remain important for treatment-resistant depression. Monitoring of ECG and serum drug levels is recommended.

Uranism

- An archaic and now obsolete term for male homosexuality, derived from the Greek goddess Aphrodite Urania (heavenly Aphrodite), used historically in 19th-century sexology literature (Karl Heinrich Ulrichs, Magnus Hirschfeld). The term is no longer used in modern medical or psychiatric practice; the preferred terminology is homosexuality or same-sex

attraction.

Vagus Nerve Stimulation

- A neuromodulation treatment involving electrical stimulation of the left vagus nerve via an implanted device. It is FDA-approved for treatment-resistant depression and epilepsy. It requires surgical implantation and delivers intermittent stimulation. Improvement may take months to develop. Non-invasive transcutaneous vagus nerve stimulation is being investigated.

Voyeuristic Disorder

- A paraphilic disorder involving recurrent, intense sexual arousal from observing an unsuspecting person who is naked, disrobing, or engaging in sexual activity. The individual has acted on these urges or they cause marked distress or interpersonal difficulty. Duration ≥ 6 months. Most common in males with onset in adolescence. Treatment: CBT and SSRIs.

Word Salad

- Severe disorganized speech consisting of a jumble of words and phrases that lack meaning or logical connection. It is a hallmark of formal thought disorder in schizophrenia and represents the most severe form of disorganized speech. It reflects profound disruption of language processing.

Chapter 34

Public Health and Preventive Medicine

Antimicrobial Resistance

- Development of resistance to antimicrobial agents. Occurs when microorganisms evolve mechanisms to survive exposure to drugs that previously killed or inhibited them. Driven by overuse and misuse of antibiotics in humans, agriculture, and animal husbandry. Results in treatment failure, prolonged illness, increased healthcare costs, and higher mortality. Major global health threat requiring antimicrobial stewardship, surveillance, and development of new agents.

Asbestosis

- Occupational lung disease caused by inhalation of asbestos fibers. Characterized by diffuse interstitial pulmonary fibrosis. Long latency period of 10 to 20 years. Associated with increased risk of mesothelioma and lung cancer.

Body Mass Index (BMI)

- A measurement that estimates body fat based on weight and height, calculated as weight in kilograms divided by height in meters squared (kg/m^2). WHO classification: underweight <18.5 , normal 18.5 - 24.9 , overweight 25 - 29.9 , obese class I 30 - 34.9 , class II 35 - 39.9 , class III (morbid obesity) ≥ 40 . BMI is a screening tool, not a diagnostic test for body fatness, and does not account for muscle mass, bone density, body composition, or fat distribution. Limitations: overestimates body fat in athletes (high muscle mass), underestimates in older adults (low muscle mass), and does not reflect visceral adipose tissue (the most metabolically harmful fat). Waist circumference is a better predictor of cardiovascular risk than BMI alone. Clinically, BMI is used to stratify risk for obesity-related conditions (diabetes, hypertension, CVD, sleep apnea, certain cancers) and guide treatment decisions (bariatric surgery eligibility typically requires BMI ≥ 40 or ≥ 35 with

comorbidities).

Booster Dose

- Additional dose of a vaccine given after the primary series to re-stimulate the immune response and maintain protection. Required for vaccines where immunity wanes over time such as tetanus and pertussis.

Burden of Disease

- Measure of the gap between current health status and an ideal health situation where everyone lives to old age free of disease and disability. Measured in DALYs. Used to set health priorities and allocate resources.

Burden of Illness

- Total impact of a disease on a population measured in terms of mortality, morbidity, disability, and economic costs. Used to set health priorities and allocate research funding.

Byssinosis

- Occupational lung disease caused by inhalation of cotton, flax, or hemp dust. Characterized by chest tightness and wheezing that improves away from work. Also known as brown lung disease.

Contraindication to Vaccination

- Condition or factor that increases the risk of a serious adverse reaction to a vaccine. Absolute contraindications include severe allergic reaction to a previous dose. Relative contraindications include immunosuppression for live vaccines.

Crossover Trial

- Study design where participants receive both treatments in a random sequence with a washout period between. Each participant serves as their own control. Increases statistical power but requires a washout period to avoid carryover effects.

Disease Prevention

- Actions taken to prevent disease or detect it early before symptoms develop. Includes immunization, screening, and chemoprophylaxis. Distinguished from treatment which occurs after disease has manifested.

Disease Surveillance

- Continuous systematic collection, analysis, interpretation, and dissemination of health data for disease prevention and control. Essential for early detection of outbreaks and monitoring disease trends.

Effect Modification

- Situation where the magnitude of the association between exposure and outcome differs across levels of another variable. Also called interaction. Unlike confounding, effect modification is a real biological phenomenon that should be reported.

Effect Size

- Quantitative measure of the magnitude of an observed effect. Common measures include Cohen's *d* for mean differences and odds ratios for binary outcomes. Important for assessing clinical significance beyond statistical significance.

Epidemic Curve

- Graphical representation of the number of cases of disease over time during an outbreak. Can be point source, propagated, or intermittent. Provides information about the outbreak pattern, incubation period, and potential source.

Epidemics

- The occurrence of cases of a disease or health-related event in a community or region at a rate clearly in excess of normal expectancy. Epidemics arise from point sources (single exposure, e.g., contaminated food at an event), propagated spread (person-to-person transmission, e.g., influenza, measles), or mixed patterns. Investigation steps: confirm diagnosis, establish case definition, verify cases, plot epidemic curve (cases over time), calculate attack rates, generate hypotheses about source and mode of transmission, implement control measures (isolation, quarantine, vaccination, treatment, sanitation), and communicate findings. A pandemic is an epidemic that has spread across multiple continents. Epidemiology is the scientific discipline that studies the distribution and determinants of health-related states in populations.

Epidemiological study

- An investigation of the links between certain behaviors or risk factors and the occurrence of disease or good health in a population.

Epidemiologic Transition

- Theory describing the shift in patterns of mortality and disease from infectious to chronic noncommunicable diseases as countries develop. Characterized by changing age distributions and life expectancies.

Essential Fatty Acid

- Fatty acids that cannot be synthesized by the body and must be obtained from the diet. Include omega-3 and omega-6 fatty acids. Important for brain development, inflammation regulation, and cardiovascular health.

Folate Deficiency

- Causes megaloblastic anemia and neural tube defects in developing fetuses. Prevention through folic acid supplementation before and during pregnancy. Found in leafy greens, legumes, and fortified grains.

General Practitioner (GP)

- A physician providing comprehensive primary medical care to individuals and families in the community. GPs practice general practice/family medicine, managing undifferentiated presentations, chronic disease, prevention, and coordinating specialist referrals. Training: 4-6 years medical school + 2 years foundation training + 3 years GP specialty training. Gatekeeper role: GPs triage and refer to specialist care, reducing healthcare costs. The role includes continuity of care, home visits, palliative care, and holistic biopsychosocial management. UK: approximately 1 GP per 1,800 patients.

Genetic Epidemiology

- Study of the role of genetic factors in determining health and disease in populations. Includes twin studies, family studies, and genome-wide association studies.

Hazard Ratio

- Ratio of hazard rates between two groups at any point in time. Used in survival analysis to compare the rate of events between treatment and control groups. Similar to relative risk but accounts for time-to-event data.

Health Equity

- Attainment of the highest level of health for all people. Involves addressing social determinants such

as income, education, housing, and access to health-care that produce systematic disparities between population groups. Requires targeted policies and interventions to eliminate avoidable and unfair differences in health outcomes. Distinct from health equality in that equity allocates resources according to need.

Health Inequality

- Differences in health status between different population groups that are avoidable and unfair. Includes inequalities in access to healthcare, healthy food, safe housing, and education.

Herd Immunity

- Protection of a population against an infectious disease when a sufficient proportion is immune either through vaccination or prior infection. The threshold varies by disease. Reduces the risk of infection for susceptible individuals.

Hospice

- A philosophy and model of care that focuses on providing comfort, dignity, and quality of life for patients with terminal illness and their families when curative treatment is no longer the goal. Hospice care is multidisciplinary: medical (pain and symptom management, palliative medicine specialist), nursing (24/7 availability, symptom monitoring), social work (emotional support, practical assistance, advance care planning, referral to financial/legal services), chaplaincy/spiritual care, bereavement support (for family for up to 13 months after death), physiotherapy, occupational therapy, dietitian, and trained volunteers. Settings: inpatient hospice units (free-standing, NHS-funded or charitable), home hospice care (most preferred, enabling patients to die at home if desired), hospital palliative care teams, and day hospice. Admission criteria: life expectancy of 6 months or less (though many have longer trajectories), patient and family agree to focus on comfort rather than life-prolonging treatment. The modern hospice movement began with St. Christopher's Hospice in London (1967, founded by Dame Cicely Saunders), emphasising total pain (physical, psychological, social, spiritual). Over 200 hospices operate in the UK (mostly charitable) and over 5,000 in the US.

Inactivated Vaccine

- Vaccine containing killed pathogens that cannot

replicate. Safer than live-attenuated vaccines but require multiple doses and booster shots to maintain protection. Induce humoral immune responses primarily. Examples: influenza (injectable), polio (IPV), hepatitis A, rabies. More stable for storage and transport than live vaccines.

Iodine Deficiency

- Leading cause of preventable intellectual disability worldwide. Causes goiter, hypothyroidism, and cretinism in severe cases. Prevented through iodised salt supplementation programs. Universal salt iodisation is the recommended strategy endorsed by WHO and UNICEF. Pregnant women and young children are most vulnerable to the effects of deficiency.

Iron Deficiency

- Most common nutritional deficiency worldwide. Causes microcytic hypochromic anemia, fatigue, and impaired cognitive development. Risk factors include menstruation, pregnancy, and inadequate dietary intake.

Isolation

- Separation of individuals with a confirmed communicable disease from healthy individuals. Aims to prevent transmission to others. Required for diseases such as tuberculosis, measles, and COVID-19.

Junk Food (see Nutrition)

- See Nutrition.

Lead Exposure

- Environmental health hazard from lead in paint, water, soil, and dust. Particularly harmful to children causing developmental delays and behavioral problems. Primary prevention through lead abatement and water pipe replacement.

Lead Time

- Period between detection of disease through screening and the time it would have been diagnosed clinically. Longer lead time does not necessarily mean better prognosis. Used to calculate apparent survival benefit from screening.

Live-Attenuated Vaccine

- Vaccine containing weakened forms of the pathogen that can still replicate but do not cause disease in immunocompetent individuals. Provides strong and long-lasting immunity. Contraindicated in immunocompromised patients.

Low-calorie diet

- A weight-loss plan that limits calories to 800–1,500 a day.

Mediterranean Diet

- The Mediterranean diet is a plant-forward eating pattern inspired by traditional cuisines of Greece, Italy, and Spain, characterized by high consumption of olive oil (primary fat), vegetables, fruits, legumes, whole grains, nuts, and seeds; moderate intake of fish and seafood, poultry, dairy (yogurt, cheese), and red wine; and limited red meat, processed meats, and sweets. Rich in monounsaturated fats, polyphenols, omega-3 fatty acids, and fiber, it exerts anti-inflammatory and antioxidant effects. Robust evidence demonstrates reduction in cardiovascular events (PREDIMED trial—30% relative risk reduction), improved glycemic control, lower LDL cholesterol, reduced blood pressure, decreased cancer incidence, and slower cognitive decline. It is the recommended dietary pattern for cardiovascular disease prevention by AHA/ACC guidelines and is associated with longevity in observational studies.

Mercury Exposure

- Environmental health hazard from mercury in fish, industrial emissions, and dental amalgams.

Mesothelioma

- Rare cancer of the mesothelial lining strongly associated with asbestos exposure. Latency period of 20 to 40 years. Poor prognosis with median survival less than one year. Mostly affects the pleura.

Meta-Analysis

- A statistical technique that combines and analyzes the results of multiple independent studies on the same topic to produce a single, more precise estimate of the treatment effect or association. Meta-analysis increases statistical power, improves precision, resolves uncertainty from conflicting studies, and can identify subgroup effects. Key components: systematic literature search, quality assessment of included studies, extraction of effect estimates, calculation of a weighted pooled effect (fixed-effect or random-effects model), assessment of heterogeneity (I^2 statistic, Cochrane Q test), and publication bias assessment (funnel plot, Egger's test). Forest plot: graphical display showing individual study results and the pooled estimate. Limitations: garbage in, garbage out (quality depends on quality of in-

cluded studies), publication bias (positive results more likely to be published), and heterogeneity (clinical and methodological diversity). Meta-analysis is a key tool in evidence-based medicine and forms the highest level of evidence (systematic reviews/meta-analyses on top of the evidence pyramid).

Multimorbidity

- Co-occurrence of two or more chronic conditions in an individual. Increasingly common with aging populations. Affects quality of life, healthcare utilization, and treatment complexity.

Natural Experiment

- Observational study in which the exposure of interest is not assigned by the researcher but occurs naturally due to external factors such as policy changes, natural disasters, or geographical variation. The researcher leverages this natural variation to estimate causal effects. Strength: allows study of exposures that cannot be randomised for ethical or practical reasons. Limitation: lacks the randomisation of controlled trials, making confounding and bias more difficult to control. Techniques such as difference-in-differences, instrumental variables, and regression discontinuity are used to strengthen causal inference.

Negative Predictive Value

- Proportion of negative test results that are true negatives. Depends on disease prevalence in the tested population. Higher prevalence decreases NPV. Important for ruling out disease.

Neglected Tropical Diseases

- Group of communicable diseases that prevail in tropical and subtropical conditions affecting the poorest populations. Include Chagas disease, dengue, leishmaniasis, and schistosomiasis. Targeted for control and elimination.

Neyman Bias

- Type of selection bias where cases with rapid onset or fatal outcome are missed because they occur and resolve between screening intervals. Also called prevalence-incidence bias. Affects estimates of disease severity from screening studies.

Noise-Induced Hearing Loss

- Permanent sensorineural hearing loss caused by prolonged exposure to loud noise. Most common occupational disease worldwide. Preventable through engineering controls, administrative controls, and

hearing protection.

Notifiable Diseases

- Diseases required by law to be reported to public health authorities. Reporting enables tracking of disease trends and outbreak detection. Examples include tuberculosis, measles, and sexually transmitted infections, foodborne illnesses. Reporting enables public health surveillance, outbreak detection, and implementation of control measures. Lists vary by jurisdiction.

Nutrition

- The science of food intake, digestion, absorption, metabolism, and utilization of nutrients essential for health, growth, and disease prevention. Macronutrients: carbohydrates (primary energy source, 45–65% of total calories, emphasizing whole grains and fiber $\geq 25\text{--}38$ g/day), proteins (0.8 g/kg body weight/day, higher for athletes, illness, and older adults), and fats (20–35% of calories, prioritizing unsaturated—olive oil, avocado, nuts, fatty fish—limiting saturated $<10\%$ and trans fats). Micronutrients: vitamins (A, D, E, K, C, B-complex) and minerals (calcium, iron, zinc, magnesium, potassium, iodine) with specific RDIs; deficiencies occur in restrictive diets, malabsorption, pregnancy, and chronic disease. Dietary patterns (Mediterranean, DASH, MIND, plant-based) reduce cardiovascular disease, diabetes, cancer, and all-cause mortality, whereas high intake of ultra-processed foods, added sugars, sodium, and red/processed meats increases chronic disease risk. Screening (MNA-SF for malnutrition risk) and counseling are essential components of primary care and chronic disease management, ideally delivered by registered dietitians.

Occupational Carcinogen

- Agent in the workplace that increases the risk of cancer. IARC classifies carcinogens into groups from 1 (definitely carcinogenic) to 3 (not classifiable). Includes asbestos, benzene, chromium VI, and formaldehyde.

Occupational Health

- Branch of public health concerned with the health and safety of workers. Includes prevention and management of workplace injuries and illnesses, ergonomic assessment, and promotion of worker well-being.

Odds Ratio

- Ratio of the odds of exposure among cases to the odds of exposure among controls. Approximates relative risk when disease is rare. Widely used in case-control studies where direct incidence cannot be calculated.

Opportunity Cost

- Value of the next best alternative foregone when making a choice. In healthcare, represents the benefits that could have been gained from investing resources in a different intervention. Important concept in health economics. When choosing between healthcare interventions, the opportunity cost is the health benefits foregone from not funding the next best alternative. Used in cost-effectiveness analysis and health technology assessment to inform resource allocation decisions.

Outbreak Investigation

- Systematic process to identify the source, mode of transmission, and factors contributing to an epidemic. Aims to implement control measures and prevent future outbreaks. Follows a standard series of steps.

Overdiagnosis

- Detection of disease through screening that would never have caused symptoms or death during the patient's lifetime. Results in unnecessary treatment and associated harms. Particularly problematic in cancer screening.

Overtreatment

- Treatment of conditions detected through screening that would not have caused harm if left undetected.

Pandemic Preparedness

- Planning and capacity building to respond to pandemic threats. Includes surveillance, laboratory capacity, vaccine development, and healthcare system resilience. Guided by the International Health Regulations (IHR 2005). Includes early warning systems, stockpiling of vaccines and antivirals, surge capacity planning, and coordination mechanisms. Lessons from COVID-19, influenza pandemics, and emerging infectious disease threats inform ongoing preparedness efforts.

Patient-Centered Care

- Approach to healthcare that is respectful of and responsive to individual patient preferences, needs, and values. Ensures patient values guide all clinical decisions. Includes shared decision-making, commu-

nication, and care coordination. Improves patient satisfaction, treatment adherence, and health outcomes.

Peer Review

- The process by which research submitted for publication or presentation is evaluated by independent experts (peers) in the same field to assess its quality, validity, originality, and significance before acceptance. Types: single-blind (reviewers know authors, but not vice versa), double-blind (neither knows the other), open (both identities are known), and post-publication review. In healthcare, peer review also applies to clinical practice: regular review of doctors' performance by colleagues to maintain and improve standards of care (including case note review, morbidity and mortality meetings, and clinical audit). Peer review is the cornerstone of scientific quality control but is not infallible — it can be subject to bias, delay, and failure to detect major errors or fraud.

Personal Protective Equipment

- Equipment worn to minimize exposure to workplace hazards. Includes respirators, gloves, eye protection, and hearing protection. Last line of defense in the hierarchy of controls.

Primary Prevention

- Prevention of disease before it occurs. Includes health promotion and specific protection measures such as vaccination, health education, and environmental modifications. Aims to reduce the incidence of disease.

Primordial Prevention

- Prevention of the development of risk factors in populations through environmental, economic, social, and behavioural interventions before risk factors emerge. Targets upstream determinants such as poverty, education, and urban planning. Example: policies to reduce air pollution to prevent cardiovascular and respiratory disease. Distinct from primary prevention which targets established risk factors.

Propagated Outbreak

- Outbreak where disease spreads from person to person. Characterized by successive waves of cases corresponding to generations of transmission. The epidemic curve shows multiple peaks.

Proportional Mortality Ratio

- Proportion of deaths due to a specific cause relative

to all deaths in a population. Useful for comparing the contribution of different causes of death.

Prospective Cohort Study

- Observational study following a group of individuals over time to determine who develops the outcome of interest. Measures incidence and relative risk. Strong for studying rare exposures. Expensive and time-consuming.

Publication Bias

- Tendency for studies with positive or significant results to be published more readily than those with negative or null results. Can distort meta-analyses and systematic reviews. Addressed through trial registration and comprehensive literature searching.

Quarantine

- Separation and restriction of movement of healthy individuals who may have been exposed to a communicable disease. Aims to prevent disease transmission. Applied during the incubation period to monitor for symptom development. Historically used for plague, cholera, and yellow fever. Legal authority for quarantine varies by jurisdiction. Distinguished from isolation (separation of those already confirmed ill).

Quasi-Experimental Design

- Study design that lacks randomization but includes an intervention. Uses comparison groups that are not randomly assigned. Susceptible to confounding but can be strengthened by techniques such as difference-in-differences analysis.

Radon Exposure

- Natural radioactive gas from the decay of uranium in soil and rock. Second leading cause of lung cancer after smoking. Enters buildings through cracks in foundations. Tested with radon detectors and mitigated by ventilation systems.

Relative Risk

- Ratio of the incidence rate of disease in the exposed population to the incidence rate in the unexposed population. A relative risk greater than 1 indicates increased risk with exposure; less than 1 indicates a protective effect. Used in cohort studies and clinical trials. Important for establishing causal associations. Also called risk ratio.

Relative Risk Reduction

- Proportional reduction in risk between the treat-

ment and control groups. Calculated as the difference in risk divided by the control group risk. Often used in clinical trial reporting.

Risk Communication

- Process of exchanging information about health risks between experts and the public. Includes risk assessment, risk perception, and risk management communication. Important during outbreaks and public health emergencies.

Risk Factor

- Attribute or exposure that is associated with an increased probability of disease. Does not necessarily imply causation. Can be modifiable or nonmodifiable. Important for disease prevention and health promotion.

Scientific Evidence

- Information gathered through systematic observation, experimentation, and reasoning that supports or refutes a hypothesis or theory. In medicine, scientific evidence forms the basis for clinical practice and is ranked by quality (hierarchy of evidence). Levels (from highest to lowest): systematic reviews and meta-analyses, randomized controlled trials (RCTs), cohort studies, case-control studies, cross-sectional studies, case series/case reports, expert opinion, and anecdotal evidence. Evidence-based medicine integrates the best available scientific evidence with clinical expertise and patient values and preferences. The GRADE system rates the quality of evidence as high, moderate, low, or very low based on study design, risk of bias, consistency, directness, and precision.

Sensitivity

- Proportion of individuals with disease who test positive. True positive rate. Important for screening tests where missing cases has serious consequences.

Shared Decision-Making

- Process where healthcare providers and patients collaborate to make clinical decisions. Involves providing evidence-based information about options, eliciting patient preferences, and reaching a mutually agreed plan.

Silicosis

- Occupational lung disease caused by inhalation of crystalline silica dust. Characterized by progressive fibrosis of the lungs. Increased risk of tuberculosis and lung cancer. Common in miners, sandblasters,

and stone cutters.

Subunit Vaccine

- Vaccine containing specific components of the pathogen such as proteins or polysaccharides. Cannot cause disease because they do not contain live organisms. Examples include hepatitis B and HPV vaccines.

Syndromic Surveillance

- Monitoring of health-related data that precede diagnosis and signal a potential outbreak. Includes monitoring of symptoms, school absenteeism, and over-the-counter medication sales. Provides earlier warning than traditional surveillance.

Systematic Review

- A structured, comprehensive review of the literature that uses explicit, reproducible methods to identify, select, appraise, and synthesize all available evidence on a specific research question. Key features: pre-specified protocol (PROSPERO registration), comprehensive search strategy (multiple databases: MEDLINE, EMBASE, Cochrane CENTRAL, CINAHL), clear inclusion/exclusion criteria, quality assessment of included studies (risk of bias tools: Cochrane RoB 2 for RCTs, ROBINS-I for non-randomized studies), data extraction, and synthesis (narrative or quantitative via meta-analysis). PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines standardize reporting. Systematic reviews sit at the top of the evidence pyramid and are essential for clinical guideline development and evidence-based practice.

Tertiary Prevention

- Prevention of disease progression and complications after clinical disease has been diagnosed. Includes rehabilitation, disease management, and secondary prevention of complications. Aims to reduce disability and improve quality of life.

Vaccination

- Administration of a vaccine to stimulate the immune system and provide protection against a specific infectious disease. Can be live-attenuated, inactivated, subunit, toxoid, or mRNA-based. Most cost-effective public health intervention.

Vaccine Effectiveness

- Measure of vaccine performance in real-world conditions outside clinical trials. Lower than efficacy due to factors such as vaccine storage, administra-

tion, and population heterogeneity. Important for public health decision-making.

Vaccine Efficacy

- Proportionate reduction in disease incidence among vaccinated individuals compared to unvaccinated individuals under ideal conditions. Measured in clinical trials. Different from effectiveness which measures real-world performance.

Vitamin A Deficiency

- Leading cause of preventable childhood blindness worldwide. Causes xerophthalmia, keratomalacia, and increased susceptibility to infections. Common in developing countries with limited access to animal sources and orange fruits and vegetables.

Vitamin D Deficiency

- Causes rickets in children and osteomalacia in adults. Risk factors include limited sun exposure, dark skin, and inadequate dietary intake. Prevented through sunlight exposure, dietary sources, and supplementation.

Zinc Deficiency

- Impairs immune function, growth, and wound healing. Common in developing countries. Risk factors include vegetarian diets, malabsorption, and chronic diseases. Manifests with growth retardation, diarrhea, and recurrent infections.

Chapter 35

Pulmonology

35.1 Obstructive & Restrictive Airway Diseases

Acute Cough

- Cough lasting < 3 weeks. Most common causes: URI, acute bronchitis, pneumonia. Usually self-limited.

Acute Respiratory Distress Syndrome

- ARDS: a syndrome of acute, diffuse inflammatory lung injury causing severe hypoxemic respiratory failure with bilateral infiltrates not due to cardiogenic pulmonary edema ($\text{PaO}_2/\text{FiO}_2$ ratio ≤ 300). Causes: sepsis (most common), pneumonia, trauma, aspiration, pancreatitis, massive transfusion. Pathology: endothelial/alveolar injury, protein-rich edema, surfactant dysfunction, hyaline membranes; three phases—exudative, proliferative, fibrotic. Features: severe dyspnea, hypoxemia, refractory hypoxemia; diagnosis by Berlin criteria. Management: lung-protective ventilation (low tidal volume 6 mL/kg, plateau pressure ≤ 30), PEEP, prone positioning, conservative fluids, neuromuscular blockade; steroids controversial. Mortality 30-40 percent.

Airway Clearance Techniques

- Physical therapies to mobilize and remove secretions from the airways. Techniques include postural drainage, percussion, vibration, active cycle of breathing, autogenic drainage, positive expiratory pressure, oscillating PEP, and high-frequency chest wall oscillation. They are essential in CF, bronchiectasis, and neuromuscular disease.

Allergen Immunotherapy

- Gradual desensitization to specific allergens through repeated subcutaneous or sublingual ex-

posure. It reduces allergic asthma symptoms and medication needs. Treatment requires 3–5 years for full benefit. It is indicated for allergic asthma with identified specific allergens not controlled by standard therapy.

Allergic Bronchopulmonary Aspergillosis

- A hypersensitivity reaction to *Aspergillus fumigatus* in asthma or CF patients. Causes central bronchiectasis, elevated total IgE, and eosinophilia. Treatment includes corticosteroids and itraconazole.

Alpha-1 Antitrypsin Deficiency

- An autosomal codominant genetic disorder caused by mutations in the SERPINA1 gene. It predisposes to early-onset panlobular emphysema (lower lobes), liver disease, and panniculitis. PiZZ genotype is most severe. Treatment includes AAT augmentation therapy and smoking avoidance.

Anti-IgE Therapy

- Omalizumab is a monoclonal antibody that binds free IgE, preventing it from binding to mast cells and basophils. It reduces allergic inflammation and is approved for moderate-to-severe persistent allergic asthma. It reduces exacerbations and the need for oral corticosteroids. It is administered by subcutaneous injection every 2–4 weeks.

Anti-IL4 Receptor Therapy

- Dupilumab is a monoclonal antibody blocking the IL-4 receptor alpha subunit, inhibiting both IL-4 and IL-13 signaling. It is approved for moderate-to-severe asthma with eosinophilic phenotype or oral corticosteroid dependence. It reduces exacerbations and improves lung function.

Anti-IL5 Therapy

- Monoclonal antibodies targeting interleukin-5, a key cytokine in eosinophil production and survival.

Mepolizumab, reslizumab, and benralizumab (anti-IL-5 receptor) are approved for severe eosinophilic asthma. They reduce exacerbations and oral corticosteroid requirements in patients with blood eosinophils ≥ 300 .

ARDS

– Acute respiratory distress syndrome; see Acute Respiratory Distress Syndrome. Acute diffuse inflammatory lung injury causing severe hypoxemia ($\text{PaO}_2/\text{FiO}_2 \leq 300$), bilateral infiltrates, and non-cardiogenic pulmonary edema. Common causes: sepsis, pneumonia, trauma, aspiration. Management: lung-protective ventilation (6 mL/kg tidal volume, low plateau pressure), PEEP, prone positioning, conservative fluid strategy, and treatment of the underlying cause. Complications: barotrauma, VAP, multi-organ failure; mortality 30-40 percent.

Asbestosis

– A chronic, progressive interstitial lung disease caused by inhalation of asbestos fibers, a type of pneumoconiosis with a latency period of 15-40 years from initial exposure. A group of naturally occurring silicate minerals (chrysotile, amosite, crocidolite) once widely used in construction, shipbuilding, and insulation. Chrysotile (serpentine) is the most commonly used; amphibole forms (amosite, crocidolite) are more pathogenic. Inhaled fibers deposit in the terminal bronchioles and alveolar sacs, where they cause inflammation, fibrosis, and progressive scarring of the lung parenchyma.

Aspirin-Exacerbated Respiratory Disease

– A triad of asthma, nasal polyps, and aspirin sensitivity due to COX-1 inhibition. It involves overproduction of cysteinyl leukotrienes. Leukotriene receptor antagonists are specifically effective.

Asthma

– A chronic inflammatory disorder of the airways characterized by recurrent episodes of wheezing, breathlessness, chest tightness, and cough. Airflow limitation is often reversible. It involves eosinophilic inflammation, mucus hypersecretion, and smooth muscle hypertrophy.

Asthma-COPD Overlap

– Features of both asthma and COPD in the same patient. Characterized by persistent airflow limitation with features of both diseases: airway inflammation

(eosinophilic and neutrophilic), bronchial hyperresponsiveness, and partially reversible obstruction. Treatment: inhaled corticosteroids plus long-acting bronchodilators. Distinguished from pure asthma (usually atopic, reversible) and pure COPD (smoking history, fixed obstruction).

Bagassosis

– An occupational hypersensitivity pneumonitis (extrinsic allergic alveolitis) caused by inhalation of dust from moldy bagasse—the fibrous residue of sugarcane after extraction. Caused by thermophilic actinomycetes (*Saccharopolyspora rectivirgula*) that colonize stored bagasse. Presents with fever, cough, dyspnea, and malaise 4–8 hours after exposure. Acute episodes resolve with corticosteroid treatment and avoidance; chronic exposure leads to pulmonary fibrosis.

Berylliosis

– A granulomatous lung disease from beryllium exposure. Chronic berylliosis resembles sarcoidosis. Diagnosis requires beryllium lymphocyte proliferation test.

BiPAP

– Bilevel Positive Airway Pressure, a form of non-invasive ventilation delivering two levels of pressure: IPAP (inspiratory) for ventilation and EPAP (expiratory) for alveolar recruitment. It is particularly effective for COPD exacerbations with hypercapnic respiratory failure. It reduces work of breathing and improves gas exchange.

Bird Fancier's Lung

– HP from avian proteins in bird droppings or feathers. Common among pigeon breeders. Chronic exposure leads to progressive fibrosis.

Blue Bloater

– A clinical phenotype of chronic bronchitis in COPD. Patients present with chronic cough, sputum production, cyanosis, right heart failure, and airway-centric inflammation. They tend to be younger, have more hypercapnia, and less emphysema on imaging.

Bradypnea

– Abnormally slow respiratory rate (adult <12 breaths/min). Causes: opioid/benzodiazepine/sedative overdose, central nervous system depression (stroke, trauma, increased ICP), hypothyroidism, hypothermia, and metabolic (e.g., hypokalemia). May lead

to hypoventilation, hypercapnia, and respiratory failure. Management: airway protection, ventilation support, reversal of depressants (naloxone, flumazenil), and treatment of the cause. Contrast with apneustic/Cheyne-Stokes patterns in specific CNS lesions.

Bronchial Biopsy

- Tissue sampling of the bronchial wall during bronchoscopy. It is used to diagnose inflammatory conditions (sarcoidosis, eosinophilic bronchitis), infections, and malignancy. Endobronchial biopsy of visible lesions and transbronchial biopsy of parenchymal lesions provide complementary diagnostic information.

Bronchiectasis

- Permanent, abnormal dilation of bronchi caused by destruction of the bronchial wall from chronic airway inflammation and infection. Causes include CF, immune deficiency, primary ciliary dyskinesia, and post-infectious damage. Features include chronic cough, copious purulent sputum, and recurrent hemoptysis.

Bronchitis

- Inflammation of the bronchial mucosa. Acute bronchitis is typically viral, presents with cough (often productive), and resolves spontaneously. Cough with sputum production for at least 3 months in 2 consecutive years, often due to smoking. Treatment: supportive for acute; bronchodilators, smoking cessation, and pulmonary rehabilitation for chronic.

Bronchoalveolar Lavage

- Diagnostic procedure during bronchoscopy where saline is instilled and aspirated. Analyzed for cell counts, microbiology, and cytology. Useful for *Pneumocystis pneumonia*, pulmonary alveolar proteinosis, and sarcoidosis diagnosis.

Bronchodilator Reversibility

- Improvement in FEV1 $> 12\%$ and > 200 mL after short-acting bronchodilator. Supports asthma diagnosis. Some COPD patients show partial reversibility.

Bronchopleural Fistula

- An abnormal communication between the bronchial tree and pleural space. It is a complication of pneumonectomy, lung surgery, or empyema. It causes persistent air leak, subcutaneous emphysema, and respiratory compromise. Treatment includes chest

tube drainage, bronchoscopic intervention, and surgical repair.

Centriacinar Emphysema

- A subtype of emphysema in which destruction begins in the respiratory bronchioles and extends peripherally. It predominantly affects the upper lobes and is strongly associated with cigarette smoking. It is the most common form of emphysema and often coexists with chronic bronchitis.

Chest Physiotherapy

- Techniques to mobilize and clear secretions from the lungs, including postural drainage, percussion, vibration, and huffing. It is used in bronchiectasis, CF, and post-operative patients. Positive expiratory pressure devices and oscillating PEP devices are also used.

Chronic Bronchitis

- Defined clinically as a productive cough for at least three months in each of two consecutive years, after excluding other causes. It is characterized by hypertrophy of mucus-secreting glands in the bronchi (Reid index > 0.5), goblet cell hyperplasia, and chronic airway inflammation.

Chronic Cough

- Cough lasting > 8 weeks. Top 3 causes in non-smokers with normal CXR: upper airway cough syndrome, asthma, GERD. ACE inhibitor use is another common cause.

Chronic Obstructive Pulmonary Disease

- COPD is a preventable lung disease characterized by persistent respiratory symptoms and airflow limitation due to airway and/or alveolar abnormalities, usually caused by significant exposure to noxious particles or gases (primarily tobacco smoke). Includes emphysema and chronic bronchitis. Diagnosis: spirometry with post-bronchodilator FEV1/FVC < 0.70 . Management: smoking cessation, bronchodilators, inhaled corticosteroids, pulmonary rehabilitation, oxygen therapy, and lung volume reduction.

Chronic Obstructive Pulmonary Disease (COPD)

- COPD is a progressive lung disease characterized by persistent airflow limitation due to chronic bronchitis and emphysema, most commonly caused by cigarette smoking. Symptoms include dyspnea,

chronic cough, sputum production, and frequent respiratory infections. Treatment involves bronchodilators, inhaled corticosteroids, pulmonary rehabilitation, supplemental oxygen, and smoking cessation to reduce exacerbations and improve quality of life.

Coal Worker's Pneumoconiosis

- Pneumoconiosis from coal dust. Simple CWP shows upper lobe macules. Complicated CWP (progressive massive fibrosis) involves coalescent macules. May be associated with Caplan syndrome.

Coarse Crackles

- Lower-pitched, longer-duration crackles heard throughout inspiration, caused by fluid or secretions in larger airways. They are heard in COPD, bronchiectasis, pneumonia, and pulmonary edema. They are less specific than fine crackles.

Combination Inhalers

- Inhalers containing both an inhaled corticosteroid and a long-acting beta-2 agonist. Examples include fluticasone/salmeterol (Advair), budesonide/formoterol (Symbicort), and fluticasone furoate/vilanterol (Breo Ellipta). They simplify asthma and COPD maintenance therapy and improve adherence.

Crackles (Rales)

- Discontinuous, non-musical adventitious lung sounds produced by the sudden explosive opening of collapsed small airways and alveoli during inspiration or the bubbling of air through fluid in the bronchioles. Fine crackles: high-pitched, short duration, late inspiratory; characteristic of interstitial lung disease (idiopathic pulmonary fibrosis) and early congestive heart failure. Coarse crackles: low-pitched, moist, early inspiratory/expiratory; characteristic of pulmonary edema, pneumonia, bronchitis, and bronchiectasis.

Cryobiopsy

- A bronchoscopic technique using rapid freezing to obtain larger lung tissue samples than conventional transbronchial biopsy. It provides better histopathological specimens for diagnosing interstitial lung diseases. It requires general anesthesia and bronchoscopic expertise. It is less invasive than surgical lung biopsy.

Dead Space Ventilation

- Ventilation of alveoli without perfusion ($V/Q = \text{infinity}$). Anatomic dead space is the conducting

airways (150 mL). Physiologic dead space includes alveoli without perfusion. Increased in PE, hypotension, and emphysema. Measured by the Bohr equation.

Desquamative Interstitial Pneumonia

- A rare ILD characterized by uniform filling of alveoli with macrophages containing brown pigment (hemosiderin-laden). It is strongly associated with smoking. HRCT shows bilateral ground-glass opacities with lower lobe predominance. Smoking cessation and corticosteroids are the main treatments.

Diffusing Capacity (DLCO)

- Ability of lungs to transfer gas from alveoli to blood. Reduced in emphysema, ILD, and anemia. Increased in pulmonary hemorrhage and left-to-right shunts.

Digital Clubbing

- Bulbous enlargement of distal phalanges with loss of nail-bed angle (> 180 degrees). Associated with lung cancer, ILD, bronchiectasis, and cyanotic heart disease.

Dyspnoea

- The subjective sensation of difficult or labored breathing, also known as shortness of breath (SOB). It is a symptom common to many cardiopulmonary and systemic conditions. Causes: respiratory (asthma, COPD, pneumonia, pulmonary embolism, pneumothorax, interstitial lung disease), cardiac (heart failure, myocardial ischemia, arrhythmia, valvular disease), and others (anemia, deconditioning, anxiety, metabolic acidosis, thyrotoxicosis). Assessed using the Borg Scale or modified Medical Research Council (mMRC) scale. Acute dyspnea is a medical emergency requiring rapid assessment of airway, breathing, and circulation; immediate oxygen supplementation and treatment of the underlying cause (bronchodilators, diuretics, anticoagulation, etc.). Chronic dyspnea requires systematic evaluation with pulmonary function testing, echocardiography, and imaging.

Emphysema

- A form of COPD characterized by permanent, abnormal enlargement of airspaces distal to the terminal bronchioles, accompanied by destruction of their walls. Centriacinar emphysema affects the respiratory bronchioles and is associated with smoking.

Panlobular emphysema involves the entire acinus and is associated with alpha-1 antitrypsin deficiency.

Endobronchial Foreign Body

- A foreign object lodged in a bronchus, causing partial or complete airway obstruction. It may cause localized wheezing, atelectasis, and post-obstructive pneumonia. It is most common in children and may be initially misdiagnosed as asthma. Bronchoscopy is both diagnostic and therapeutic.

Endobronchial Valve

- A one-way valve placed bronchoscopically in a target airway to achieve lobar atelectasis in emphysema. It allows air and secretions to exit but prevents air from entering. It is used for bronchoscopic lung volume reduction in selected patients with heterogeneous emphysema and intact fissures.

Exacerbation of COPD

- An acute worsening of respiratory symptoms beyond normal day-to-day variations, requiring change in medication. It is commonly triggered by respiratory infections (viral, bacterial), air pollution, or non-compliance. Treatment includes increased bronchodilators, systemic corticosteroids, antibiotics if indicated, and oxygen therapy.

Exercise-Induced Bronchoconstriction

- Airway narrowing during or after exercise, presenting with cough, wheeze, and dyspnea. It occurs in up to 90% of asthmatics and is triggered by heat and water loss from the airways. Prevention includes pre-exercise SABA.

Exhaled Nitric Oxide

- A non-invasive measure of airway eosinophilic inflammation. FeNO > 25 ppb in adults suggests eosinophilic airway inflammation and predicts response to inhaled corticosteroids. It is useful for diagnosing eosinophilic asthma, monitoring treatment response, and differentiating asthma from other causes of cough.

Expectoration

- The act of coughing up and spitting out mucus, sputum, or phlegm from the respiratory tract; sputum production. Sputum characteristics aid diagnosis: purulent (bacterial infection), frothy pink (pulmonary edema), rust-colored (pneumococcal pneumonia), green (*Pseudomonas*, COPD exacerbation), bloody (hemoptysis—TB, malignancy,

bronchiectasis), mucoid (asthma). Assessment includes quantity, color, viscosity, and microbiologic studies (Gram stain, culture). Treatment targets the underlying cause; mucolytics/expectorants and hydration may help.

FEV1/FVC Ratio

- Fraction of air exhaled in first second relative to total. < 0.70 post-bronchodilator indicates obstruction. Normal or elevated in restrictive disease.

Fine Crackles

- High-pitched, brief, discontinuous sounds heard at the end of inspiration, caused by opening of small airways. They are characteristic of ILD, pulmonary fibrosis, and heart failure. They are also called Velcro crackles due to their resemblance to the sound of Velcro being pulled apart.

Flutter Valve

- A handheld device combining PEP therapy with oscillations during exhalation. The oscillations create shear forces that loosen mucus from airway walls, while the PEP keeps airways open. It is used for airway clearance in bronchiectasis, CF, and COPD.

Forced Oscillation Technique

- Similar to impulse oscillometry, applying small pressure oscillations at various frequencies during tidal breathing to measure respiratory resistance and reactance. It provides information about airway mechanics without requiring forced expiratory maneuvers. It is useful for detecting small airway dysfunction and monitoring treatment response in asthma and COPD.

Forced Vital Capacity

- Total air exhaled after maximal inspiration. Reduced in both obstructive and restrictive disease. In restrictive disease, FVC reduced with preserved ratio.

Haemoptysis

- The expectoration of blood from the lower respiratory tract (UK spelling). Must be differentiated from hematemesis (vomiting blood of upper GI origin) and epistaxis (nasal bleeding). Causes: bronchitis (most common), pneumonia, tuberculosis, bronchiectasis, lung cancer, pulmonary embolism, and coagulopathy. Investigation: chest X-ray, CT thorax, bronchoscopy for persistent or unexplained cases. Management: treat underlying cause; massive hemoptysis (>200 mL in 24 hours) is

life-threatening and requires prompt airway protection, lateral decubitus positioning with the bleeding side down, bronchial artery embolisation or surgical resection.

Hemoptysis

- Expectoration of blood from the lower respiratory tract. Must be differentiated from hematemesis and epistaxis. Causes: bronchitis, pneumonia, TB, bronchiectasis, lung cancer, PE.

Hypersensitivity Pneumonitis

- An immune-mediated lung disease from environmental antigen inhalation (molds, bird proteins). Acute, subacute, and chronic forms exist. HRCT shows ground-glass opacities, air trapping, and centrilobular nodules. Chronic HP progresses to fibrosis.

Hypertonic Saline Inhalation

- Nebulized 3–7% sodium chloride solution that draws water into the airway surface liquid by osmosis, improving mucociliary clearance. It is used in CF and bronchiectasis. It may cause bronchospasm and should be preceded by a bronchodilator. It reduces exacerbations in CF.

Hypoxia

- Reduced oxygen availability at the tissue level, defined as arterial partial pressure of oxygen (PaO_2) < 60 mmHg or arterial oxygen saturation (SpO_2) $< 90\%$ on room air. Five types: (1) Hypoxic hypoxia (low arterial PO_2)—caused by low inspired oxygen (high altitude), hypoventilation, V/Q mismatch, shunt, or diffusion impairment (pneumonia, COPD, pulmonary edema, ARDS). (2) Anaemic hypoxia (reduced oxygen-carrying capacity)—anemia, carbon monoxide poisoning, methaemoglobinemia. (3) Stagnant/hypoperfusion hypoxia (reduced blood flow)—heart failure, shock, peripheral vascular disease. (4) Histotoxic hypoxia (impaired tissue utilisation)—cyanide poisoning (blocks cytochrome c oxidase), sepsis. (5) Demand hypoxia (increased O_2 requirement)—exercise, hypermetabolic states (thyrotoxicosis, malignant hyperthermia). Assessment: ABG, pulse oximetry, and calculation of alveolar-arterial (A-a) gradient. Consequences: cellular anaerobic metabolism, lactic acidosis, ATP depletion, and cell death. Treatment: supplemental oxygen (high-flow nasal cannula, non-invasive ventilation, mechanical ventilation), treat underlying

cause. The hypoxic ventilatory response is mediated by peripheral chemoreceptors (carotid and aortic bodies).

Idiopathic Pulmonary Fibrosis

- A chronic, progressive fibrosing interstitial pneumonia of unknown cause. Histopathology shows usual interstitial pneumonia (UIP). Features include exertional dyspnea, dry cough, bibasilar crackles, and digital clubbing. Median survival is 3–5 years.

Impulse Oscillometry

- A pulmonary function testing technique that measures respiratory impedance by applying small pressure oscillations during tidal breathing. It assesses large airway resistance (R_5), small airway resistance (R_5 – R_{20}), and reactance. It is more sensitive than spirometry for detecting early small airway disease and is useful in patients who cannot perform spirometry (young children, elderly).

Incentive Spirometry

- A device that encourages deep breathing to prevent atelectasis after surgery. The patient inhales slowly and deeply through the device, maintaining maximal inspiration for several seconds. It promotes alveolar recruitment and prevents mucus plugging. It is standard post-operative care.

Induced Sputum Analysis

- A non-invasive method of assessing airway inflammation by examining sputum cell counts and differentials obtained after hypertonic saline inhalation. Sputum eosinophils $> 3\%$ indicate eosinophilic airway inflammation (asthma, EGPA). Neutrophilic inflammation suggests infection, COPD, or bronchiectasis. It guides anti-inflammatory therapy decisions.

Inhaled Corticosteroids

- Anti-inflammatory medications delivered directly to the airways, reducing airway inflammation, mucus production, and bronchial hyperresponsiveness. Examples include fluticasone, budesonide, beclomethasone, and mometasone. They are the cornerstone of asthma maintenance therapy. Side effects include oral candidiasis and dysphonia.

Inspiratory Crackles

- Fine, discontinuous sounds heard during inspiration, caused by the sudden opening of collapsed airways. They are a hallmark of interstitial lung disease (bibasilar, Velcro-like crackles) and pulmonary fibrosis. They are also heard in pneumonia, atelec-

tasis, and heart failure.

Interstitial Lung Disease

- A heterogeneous group of disorders with inflammation and fibrosis of lung parenchyma, causing restrictive physiology (reduced FVC and TLC with normal or elevated FEV1/FVC ratio).

Interstitial Pneumonia

- Inflammation centered on the interstitium. Caused by *Mycoplasma*, *Chlamydia*, *Legionella*, and viruses. Presents with dry cough and diffuse crackles.

Ipratropium Bromide

- An inhaled anticholinergic (antimuscarinic) bronchodilator that blocks acetylcholine at airway smooth muscle muscarinic receptors. It reduces bronchospasm and mucus secretion. It is used in COPD and acute asthma exacerbations. It is less effective than beta-2 agonists in asthma but more effective in COPD.

Kartagener Syndrome

- A subset of primary ciliary dyskinesia with situs inversus, chronic sinusitis, and bronchiectasis. Caused by dynein defects impairing both mucociliary clearance and embryonic nodal cilia rotation.

Kartagener Triad

- The classic triad of situs inversus, chronic sinusitis, and bronchiectasis, occurring in approximately 50% of patients with primary ciliary dyskinesia. It is caused by dynein defects impairing both mucociliary clearance and embryonic nodal cilia rotation.

Lfgren Syndrome

- Acute sarcoidosis with bilateral hilar lymphadenopathy, erythema nodosum, and ankle polyarthralgia. Excellent prognosis with spontaneous resolution. Associated with HLA-DR3.

Long-Acting Beta-2 Agonists

- Bronchodilators that provide sustained airway smooth muscle relaxation for 12–24 hours. Examples include salmeterol, formoterol, indacaterol, and olodaterol. They are used for maintenance therapy in asthma and COPD, always in combination with inhaled corticosteroids in asthma.

Lower Airway Obstruction

- Narrowing of airways below the carina, causing expiratory wheezing and airflow obstruction on spirometry. Causes include asthma, COPD, bronchiectasis,

and foreign body. It is characterized by scooped-out expiratory limb on flow-volume loops and reduced FEV1/FVC ratio.

Lung Disease

- Lung disease encompasses disorders affecting the airways, parenchyma, pleura, pulmonary vasculature, and chest wall. Major categories: obstructive (asthma, COPD—chronic bronchitis and emphysema), restrictive (pulmonary fibrosis, sarcoidosis, asbestosis), infectious (pneumonia, tuberculosis), pulmonary vascular (pulmonary embolism, pulmonary arterial hypertension), and neoplastic (lung cancer, the leading cause of cancer death). Common symptoms: dyspnea, cough (dry or productive), wheezing, hemoptysis, chest pain, and weight loss. Diagnosis: pulmonary function tests (spirometry, DLCO), chest imaging (X-ray, CT), bronchoscopy, and biopsy. Management: smoking cessation (most effective intervention), bronchodilators (beta-agonists, antimuscarinics), inhaled corticosteroids, oxygen therapy, pulmonary rehabilitation, antimicrobials for infection, and lung transplantation for end-stage disease.

Lung Transplant

- Surgical replacement of one or both lungs from a donor for end-stage lung disease: COPD (most common), idiopathic pulmonary fibrosis, cystic fibrosis, pulmonary hypertension, and other advanced conditions. Types: single, bilateral, heart-lung. Evaluation: multidisciplinary, age, comorbidities, functional status, infection; waiting list allocation by severity. Immunosuppression (calcineurin inhibitors, mycophenolate, steroids) prevents rejection. Complications: primary graft dysfunction, acute/chronic rejection (bronchiolitis obliterans), infection (CMV, fungal), airway anastomotic complications, and malignancy. Survival 50–90 percent at 5 years by indication.

Lung Transplantation

- Surgical replacement of a diseased lung with a healthy lung from a donor. Indications include IPF, COPD, CF, PAH, and bronchiectasis. Options include single lung transplant, double lung transplant, or heart-lung transplant. Post-transplant immunosuppression is required lifelong. Complications include rejection and infection.

Lymphocytic Interstitial Pneumo-

nia

- A rare ILD characterized by diffuse polyclonal lymphocytic infiltration of the lung parenchyma. It is strongly associated with Sjgren syndrome and HIV. HRCT shows ground-glass opacities, thin-walled cysts, and lymphadenopathy. Treatment is corticosteroids for symptomatic disease.

Metered-Dose Inhaler

- A pressurized inhaler delivering a metered dose of medication. Requires proper technique for effective delivery. Spacer devices improve drug delivery and reduce oropharyngeal deposition. Most common delivery device for asthma and COPD maintenance.

Methacholine Challenge Test

- Bronchoprovocation test for airway hyperresponsiveness. $PC_{20} < 8$ mg/mL is positive. Highly sensitive but less specific for asthma.

Middle Lobe Syndrome

- Chronic or recurrent atelectasis and infection of the right middle lobe due to bronchial obstruction. The long, narrow right middle lobe bronchus is susceptible to compression by lymph nodes, tumors, or mucous plugging. It may be caused by bronchiectasis, malignancy, or granulomatous disease. Treatment depends on the underlying cause.

Mucolytic Therapy

- Medications that reduce mucus viscosity and elasticity, facilitating clearance. N-acetylcysteine (NAC) breaks disulfide bonds in mucus glycoproteins. Dornase alfa (Pulmozyme) cleaves extracellular DNA in CF sputum. Hypertonic saline aerosol draws water into the airway surface liquid. They are used in CF, bronchiectasis, and chronic bronchitis.

Mucus Plugging

- Accumulation of thick, tenacious mucus within airways causing obstruction. It is common in asthma, CF, bronchiectasis, and chronic bronchitis. It impairs gas exchange, promotes infection, and causes atelectasis. Treatment includes airway clearance techniques, mucolytics, and bronchodilators.

Nebulizer

- A device that converts liquid medications into a mist for inhalation. Used for bronchodilators (albuterol, ipratropium) and corticosteroids in acute exacerbations. More effective than MDI in patients with severe obstruction.

Non-Asthmatic Eosinophilic Bronchitis

- Chronic cough with airway eosinophilia (induced sputum eosinophils $> 3\%$) but without bronchial hyperresponsiveness. It is a common cause of chronic cough and does not respond to bronchodilators. It responds well to inhaled corticosteroids. It is distinct from asthma in the absence of variable airflow obstruction.

Non-Invasive Ventilation

- Positive pressure ventilation delivered via a face mask or nasal mask without endotracheal intubation. BiPAP (bilevel positive airway pressure) is most commonly used for acute hypercapnic respiratory failure (COPD exacerbation) and cardiogenic pulmonary edema. It reduces the need for intubation and improves outcomes in selected patients.

Nonspecific Interstitial Pneumonia

- A pattern with uniform, temporally homogeneous inflammation and/or fibrosis. Most common ILD associated with connective tissue disease. HRCT shows bilateral ground-glass opacities with subpleural sparing.

Occupational Asthma

- Asthma from workplace exposures to sensitizers (isocyanates, flour, latex) or irritants. Improves away from work and worsens at work. Serial peak flow monitoring supports diagnosis.

Occupational COPD

- COPD from workplace dust, chemical, or fume exposure independent of smoking. Accounts for 15–20% of COPD cases. High-risk occupations: mining, construction, farming.

Orthopnoea

- Shortness of breath that occurs when lying flat and is relieved by sitting or standing upright. Orthopnoea is a classic symptom of left-sided heart failure (elevated pulmonary venous pressure worsens pulmonary congestion in the supine position). Other causes: severe COPD, asthma exacerbation, diaphragmatic paralysis, ascites, and obesity. It is quantified by the number of pillows required to sleep comfortably (e.g., two-pillow orthopnoea). Pathophysiology: supine position increases venous return (preload) and reduces lung volumes (cephalad displacement of the diaphragm and abdominal contents), worsening V/Q mismatch and in-

creasing pulmonary capillary pressure. Orthopnoea may develop acutely in pulmonary edema (cardiac asthma) or gradually in worsening chronic heart failure. Related: paroxysmal nocturnal dyspnoea (PND—sudden breathlessness during sleep, relieved by sitting up, also CHF). Management: treat the underlying cause—diuretics, vasodilators, and optimisation of heart failure therapy.

Oxygen Saturation

– The percentage of hemoglobin saturated with oxygen in arterial blood; normal 95–100 percent. Measured noninvasively by pulse oximetry (SpO₂) and invasively by co-oximetry (SaO₂). Target levels vary by context: >94 percent general; 88–92 percent in patients with hypercapnic respiratory failure (COPD); permissive targets in ARDS. Reductions indicate hypoxemia from ventilation-perfusion mismatch, shunt, hypoventilation, or reduced inspired oxygen. False readings from poor perfusion, anemia, carboxyhemoglobin. Guides oxygen therapy.

Panlobular Emphysema

– A subtype involving diffuse destruction of the entire acinus. It predominantly affects the lower lobes and is classically associated with alpha-1 antitrypsin deficiency. The destruction is more uniform compared to centriacinar emphysema.

Paraseptal Emphysema

– A form of emphysema characterized by destruction of alveoli adjacent to the pleura. It typically affects young adults and predisposes to spontaneous pneumothorax due to rupture of subpleural blebs. It may be associated with Marfan syndrome.

Peak Expiratory Flow Rate (PEFR)

– The maximum flow rate achieved during a forced expiratory manoeuvre after maximal inspiration, measured in litres per minute (L/min) using a peak flow meter. PEFR reflects the degree of airflow obstruction and is effort-dependent. Normal values are predicted based on age, sex, and height (e.g., healthy adult male 600 L/min, female 400 L/min). Uses: diagnosis and monitoring of asthma (diurnal variability >20% supports asthma diagnosis), assessment of exacerbation severity (PEFR <50% of predicted indicates severe exacerbation—NICE/BTS guidelines), and guiding asthma action plans (personal best, zone system).

PEFR <33% of predicted is life-threatening. Limitations: effort-dependent, poor technique, less reproducible than FEV₁.

Percussion Note

– The sound produced by percussing the chest wall. Normal lung produces a resonant note. Dullness suggests consolidation or fluid. Hyperresonance suggests pneumothorax or emphysema. Stony dullness suggests pleural effusion. Tympany suggests large pneumothorax.

Persistent Asthma

– Asthma requiring daily controller therapy. Mild persistent: symptoms > 2 days/week but not daily. Moderate persistent: daily symptoms, nighttime awakenings > 1/week. Severe persistent: symptoms throughout the day, frequent nighttime awakenings, SABA use several times/day, extremely limited activity.

Pink Puffer

– A clinical phenotype of emphysema in COPD. Patients present with severe dyspnea, minimal cough, thin habitus, pursed-lip breathing, accessory muscle use, and relatively normal PaO₂ with late hypercapnia. They tend to be older and have more extensive emphysema.

Pneumoconiosis

– ILDs from mineral dust inhalation (silicosis, asbestosis, coal worker's, berylliosis). They share interstitial fibrosis and risk of infection and malignancy.

Pneumomediastinum

– Air in the mediastinum, often from alveolar rupture with air tracking along bronchovascular sheaths. Causes include asthma exacerbation, trauma, Valsalva maneuver, and esophageal rupture (Boerhaave syndrome). It presents with chest pain, subcutaneous emphysema, and Hamman's crunch (mediastinal crunch synchronous with heartbeat). Usually self-limited.

Positive Pressure Ventilation

– Mechanical ventilation that delivers air/oxygen under positive pressure to support or replace spontaneous breathing. Noninvasive (NIV): CPAP (continuous) and BiPAP (two levels) via mask for obstructive sleep apnea, cardiogenic pulmonary edema, and hypercapnic COPD. Invasive: endotracheal tube/tracheostomy delivering volume-

or pressure-controlled breaths. Modes: assist-control, SIMV, pressure support, PRVC. Benefits: improved oxygenation, reduced work of breathing, alveolar recruitment. Complications: barotrauma/pneumothorax, VAP, hemodynamic compromise, hyperinflation. Requires monitoring and lung-protective settings.

Post-Operative Atelectasis

- Collapse of alveoli after surgery, the most common post-operative pulmonary complication. Risk factors include general anesthesia, abdominal surgery, obesity, smoking, and pre-existing lung disease. Prevention includes incentive spirometry, early ambulation, and adequate pain control.

Primary Ciliary Dyskinesia

- An autosomal recessive disorder of ciliary structure, most commonly caused by dynein arm defects. Leads to impaired mucociliary clearance, chronic sinopulmonary infections, bronchiectasis, and situs inversus (50% of cases).

Pulmonary Fibrosis

- Scarring replacing normal alveolar architecture. Causes: IPF, connective tissue disease, asbestos, radiation, drugs (bleomycin, methotrexate). Features: progressive dyspnea, dry cough, digital clubbing.

Pulse Oximetry

- A noninvasive method measuring oxygen saturation by spectrophotometry: light at two wavelengths (red and infrared) passes through a pulsatile vascular bed (finger, ear, toe); absorption difference estimates oxyhemoglobin fraction (SpO₂). Normal 95-100 percent. Used widely in monitoring (perioperative, emergency, sleep, home oxygen). Limitations: inaccurate with poor perfusion, motion, nail polish, anemia (despite adequate O₂ content), and elevated carboxyhemoglobin (falsely normal in CO poisoning); does not assess ventilation (PaCO₂).

Respiratory Acidosis

- Acid-base disturbance due to accumulation of CO₂ from hypoventilation, lowering pH (acidemia). Causes: respiratory depression (opioids, sedatives, CNS disease), airway obstruction, neuromuscular weakness (GBS, myasthenia), chest wall restriction, severe COPD/asthma, and ventilation-perfusion mismatch. Compensation: renal bicarbonate retention (slow, days). Diagnosis: ABG—elevated PaCO₂ (>45 mmHg), low pH, increased HCO₃ if

chronic. Management: treat cause, airway support, noninvasive/invasive ventilation; avoid over-correction; chronic compensation protects pH.

Respiratory Alkalosis

- Acid-base disturbance from excessive elimination of CO₂ by hyperventilation, raising pH (alkalemia). Causes: anxiety/hyperventilation, hypoxia, pulmonary embolism, sepsis, fever, pain, salicylate toxicity, liver failure, pregnancy, high altitude. Compensation: renal bicarbonate excretion (days). Features: paresthesias, lightheadedness, tetany, carpopedal spasm (hypocalcemia symptoms). Diagnosis: ABG—low PaCO₂ (<35 mmHg), high pH. Management: treat underlying cause, rebreathing/calming for anxiety; avoid over-sedation; check for causes like PE/ARDS which are dangerous.

Respiratory Failure

- Inadequate gas exchange resulting in hypoxemia (PaO₂ <60 mmHg), hypercapnia (PaCO₂ >50 mmHg), or both. Type 1 (hypoxemic): V/Q mismatch, shunt, diffusion impairment. Type 2 (hypercapnic): hypoventilation from neuromuscular disease, COPD exacerbation, or opioid overdose. Management: oxygen therapy, non-invasive ventilation, mechanical ventilation, and treatment of the underlying cause.

Respiratory Health

- The proper functioning of the lungs and airways, enabling efficient gas exchange and oxygen delivery to the body. Maintaining respiratory health involves avoiding tobacco smoke, minimizing exposure to air pollutants and occupational hazards, and receiving vaccinations against respiratory infections like influenza and pneumococcal disease. Regular exercise strengthens respiratory muscles and improves lung capacity, while prompt treatment of infections and management of chronic conditions such as asthma or COPD help preserve lung function over a lifetime.

Respiratory Infections

- Illnesses caused by pathogens including viruses, bacteria, and fungi that affect the airways and lungs. Common upper respiratory infections include the common cold, sinusitis, and pharyngitis, while lower respiratory infections such as bronchitis and pneumonia can be more serious, particularly in older adults and immunocompromised individuals. Treatment varies by cause, with viral infections often

managed symptomatically and bacterial infections requiring antibiotics; prevention through hand hygiene and vaccination is key.

Respiratory System

– The anatomical and physiological system responsible for gas exchange—delivering oxygen to the blood and removing carbon dioxide. Components: (1) Upper respiratory tract—nose, nasal cavity, paranasal sinuses, pharynx (nasopharynx, oropharynx, laryngopharynx). The nose warms, humidifies, and filters inspired air; the nasal mucosa contains olfactory receptors. (2) Lower respiratory tract—larynx (voice production, airway protection—epiglottis, vocal cords), trachea (C-shaped cartilage rings, 10–12 cm long), bronchi (right main bronchus—wider, shorter, more vertical—common site of aspiration), bronchioles (no cartilage, smooth muscle—asthma), alveolar ducts, and alveoli (300–500 million, total surface area 70–100 m²), where gas exchange occurs across the thin alveolar-capillary membrane (0.2–0.5 μm). (3) Lungs—right lung (three lobes: upper, middle, lower) and left lung (two lobes: upper, lower—the cardiac notch accommodates the heart). The pleura (visceral and parietal) lines the lungs and chest wall; the pleural cavity contains a thin layer of surfactant-rich fluid for lubrication. (4) Chest wall and muscles of respiration—diaphragm (primary inspiratory muscle, innervated by phrenic nerve C3–C5), intercostal muscles (external—inspiration; internal—expiration), and accessory muscles (sternocleidomastoid, scalenes—used in respiratory distress). Ventilation: the rhythmic contraction of the diaphragm and intercostal muscles creates negative intrapleural pressure, drawing air into the lungs. Control: the respiratory center in the medulla oblongata generates the breathing rhythm, modulated by chemoreceptors (central—CO₂/pH; peripheral—O₂, CO₂, pH in carotid and aortic bodies).

Respiratory Tract Infections

– Infections affecting any part of the respiratory tract, classified by anatomical location into upper respiratory tract infections (URTIs) and lower respiratory tract infections (LRTIs). URTIs: common cold (rhinovirus, coronavirus, adenovirus), pharyngitis (Group A Streptococcus—bacterial, adenovirus, EBV), tonsillitis (Streptococcus pyogenes), sinusitis (Streptococcus

pneumoniae, Haemophilus influenzae, Moraxella catarrhalis, viruses), otitis media (S. pneumoniae, H. influenzae), laryngitis (viruses, vocal strain). LRTIs: acute bronchitis (viruses—influenza, RSV; Bordetella pertussis), bronchiolitis (RSV—infants), pneumonia (community-acquired—S. pneumoniae, H. influenzae, Mycoplasma pneumoniae, Legionella, Chlamydia psittaci, viruses; hospital-acquired—Pseudomonas aeruginosa, MRSA, Enterobacteriaceae; aspiration—anaerobes). Risk factors: extremes of age, smoking, COPD, asthma, immunocompromise, cystic fibrosis, structural lung disease, and institutionalisation. Antibiotic resistance is a growing concern (MRSA, ESBL-producing Enterobacteriaceae, multidrug-resistant S. pneumoniae). Diagnosis: clinical (cough, sputum, fever, dyspnoea, chest pain), chest X-ray (consolidation in pneumonia), sputum culture, blood culture, nasopharyngeal swab (viral PCR), and urinary antigen testing (S. pneumoniae, Legionella). Prevention: hand hygiene, vaccination (influenza, pneumococcal, pertussis, RSV—maternal, palivizumab for high-risk infants), and smoking cessation.

Rhonchi

– Low-pitched, continuous adventitious sounds heard primarily during expiration, caused by secretions in the large airways. They may clear with coughing. They are heard in COPD, bronchitis, and bronchiectasis. They are different from wheezes in their lower pitch and coarser quality.

Small Airway Disease

– Disease affecting airways with diameter < 2 mm (bronchioles). It is the earliest site of damage in COPD and is often subclinical until advanced. It is characterized by narrowing, mucus plugging, and inflammation of small airways. PFTs may show air trapping (increased RV/TLC) before FEV1 decline.

Spirometry

– Most common PFT measuring air volume and flow during forced breathing. Key measurements: FVC, FEV1, FEV1/FVC ratio. Used to diagnose and classify obstructive and restrictive diseases.

Status Asthmaticus

– A severe, life-threatening asthma exacerbation unresponsive to standard bronchodilator therapy. Characterized by severe airflow obstruction, hypoxemia, and hypercapnia. Treatment includes con-

tinuous nebulized albuterol, IV magnesium sulfate, systemic corticosteroids, and possibly intubation.

Subcutaneous Emphysema

- Air in the subcutaneous tissues, often from pneumothorax, pneumomediastinum, or chest trauma. It causes a characteristic crepitus on palpation. It is usually benign and resolves when the underlying air leak is treated. Severe cases may cause skin necrosis and compartment syndrome.

Supplemental Oxygen Therapy

- Administration of oxygen above atmospheric concentration. Indicated for hypoxemia ($\text{PaO}_2 < 60$ mmHg or $\text{SpO}_2 < 90\%$). Delivered via nasal cannula (1–6 L/min), simple mask, non-rebreather mask, or mechanical ventilation. Target SpO_2 88–92% in COPD patients to avoid CO_2 retention.

Tachypnea

- Abnormally rapid respiratory rate (adult >20 breaths/min). Physiologic (exercise, anxiety) or pathologic: hypoxia, fever, sepsis, metabolic acidosis (Kussmaul), pulmonary embolism, pneumonia, heart failure, pain, and compensation for metabolic derangement. Combined with other signs aids diagnosis; persistent tachypnea with distress suggests significant illness. Neonates and infants normally breathe faster. Evaluation: oxygen saturation, ABG, imaging, and treatment of the underlying cause.

Tachypnoea

- Abnormally rapid breathing, defined as a respiratory rate >20 breaths per minute in adults (age-dependent: >60 in neonates, >40 in 1–12 months, >30 in 1–5 years, >20 in >5 years). Tachypnoea is a non-specific sign of respiratory or metabolic distress. Causes: (1) Respiratory—hypoxia (pneumonia, asthma/COPD exacerbation, pulmonary embolism, pneumothorax, pulmonary edema, ARDS, interstitial lung disease), airway obstruction, and hypercapnia (COPD, respiratory muscle weakness). (2) Cardiac—heart failure (pulmonary congestion stimulates vagal irritant receptors). (3) Metabolic—metabolic acidosis (diabetic ketoacidosis—Kussmaul breathing, uraemia, lactic acidosis, salicylate poisoning), fever (respiratory rate increases 2–4 breaths/min per 1°C rise). (4) Other—anxiety (panic attack—psychogenic hyperventilation), pain, anemia, hyperthyroidism, preg-

nancy (progesterone stimulates respiratory center), exercise, and high altitude. (5) Drugs: salicylates, theophylline, β -agonists, and other stimulants. Tachypnoea is often accompanied by shallow breathing (low tidal volume). Assessment: respiratory rate, SpO_2 , ABG, chest X-ray, ECG, and focused history. Persistent tachypnoea with hypoxia is a sign of serious illness requiring urgent investigation and treatment.

Talcosis

- Pneumoconiosis from talc dust inhalation or IV injection of crushed oral medications. Causes upper lobe nodular fibrosis. HRCT may show “galaxy sign” of calcified nodules.

Theophylline

- A methylxanthine bronchodilator that inhibits phosphodiesterase and adenosine receptors. It has a narrow therapeutic window (10–20 mcg/mL) and requires therapeutic drug monitoring. Side effects include tachyarrhythmias, seizures, nausea, and diuresis. It is used as add-on therapy for severe asthma or COPD when other treatments are insufficient.

Thermoplasty

- A bronchoscopic procedure that uses radiofrequency energy to ablate smooth muscle in the airways, reducing bronchospasm. It is approved for severe, persistent asthma in adults not controlled with ICS/LABA. It reduces exacerbations and emergency department visits but does not improve lung function.

Tiotropium Bromide

- A long-acting muscarinic antagonist (LAMA) bronchodilator used for maintenance therapy in COPD. Once-daily dosing provides sustained bronchodilation. It reduces exacerbations and improves lung function. It is often combined with a LABA for additive bronchodilation.

Tracheal Stenosis

- Narrowing of the trachea, often a complication of prolonged endotracheal intubation or tracheostomy. It presents with progressive dyspnea, stridor, and wheezing that may be mistaken for asthma. Diagnosis is by bronchoscopy or CT. Treatment is balloon dilation, stenting, or surgical resection.

Transbronchial Biopsy

- Bronchoscopic biopsy of lung parenchyma obtained through the bronchial wall. It is used to diagnose

interstitial lung diseases (sarcoidosis, HP), reject lung transplant rejection, and sample peripheral lung lesions. It carries a higher risk of pneumothorax than endobronchial biopsy.

Usual Interstitial Pneumonia

- The histopathological pattern in IPF with temporal heterogeneity, fibroblast foci, and honeycombing. HRCT shows basal-predominant, subpleural reticular opacities with traction bronchiectasis.

Ventilation-Perfusion Mismatch

- The most common cause of hypoxemia. Areas of lung are ventilated but not perfused (dead space) or perfused but not ventilated (shunt). It is the mechanism of hypoxemia in COPD, pneumonia, and PE.

Vocal Cord Dysfunction

- Abnormal adduction of the vocal cords during inspiration, causing inspiratory stridor and dyspnea. It may mimic asthma but does not respond to bronchodilators. It is often misdiagnosed as refractory asthma. Diagnosis is by laryngoscopy showing paradoxical vocal cord motion. Treatment is speech therapy and avoiding triggers.

Wheezes

- High-pitched, continuous, musical sounds heard primarily during expiration, caused by airway narrowing. They are a hallmark of asthma and COPD. Expiratory wheezing indicates intrathoracic airway obstruction; inspiratory wheezing indicates extrathoracic obstruction. A silent chest (absent wheezing) in severe asthma indicates critical obstruction.

Wheezing

- A continuous, high-pitched, musical adventitious lung sound produced by turbulent airflow through narrowed or compressed lower airways during expiration (and occasionally inspiration). Pathophysiology: bronchospasm, mucosal edema, airway inflammation, or intraluminal secretions. Most common causes: Asthma, Chronic Obstructive Pulmonary Disease (COPD), Anaphylaxis, Heart Failure ("cardiac asthma"), and foreign body aspiration (focal monophonic wheeze).

35.2 Pulmonary Vascular & Critical Care Medicine

A-a Gradient

- PAO_2 minus PaO_2 , reflecting gas transfer efficiency. Normal approximately 15 mmHg (increases with age: $< 15 + \text{age}/4$). Elevated in V/Q mismatch, shunt, and diffusion impairment. Normal gradient in hypoventilation.

Absent Breath Sounds

- Complete absence of air movement sounds in a lung field, indicating complete airway obstruction, pneumothorax, or large pleural effusion. It is a medical finding requiring urgent evaluation and intervention.

Alveolar Gas Equation

- $PAO_2 = (FiO_2 \times (P_{atm} - PH_2O)) - (PaCO_2 / R)$. $P_{atm} = 760$ mmHg, $PH_2O = 47$ mmHg, $R = 0.8$. Allows calculation of A-a gradient.

Anaphylactic Shock

- See Anaphylaxis.

Anoxia

- Complete absence of oxygen supply to tissues, distinguished from hypoxia (reduced oxygen). Anoxia causes rapid cell death, particularly in highly aerobic tissues (brain, heart, kidneys). Causes: airway obstruction (complete—foreign body, laryngeal edema, anaphylaxis), respiratory arrest, severe drowning, carbon monoxide poisoning (carboxyhaemoglobin $> 50\%$), and high-altitude exposure. Irreversible brain damage occurs within 4–6 minutes of complete anoxia (cerebral cortex most vulnerable, followed by hippocampus, basal ganglia, and cerebellum). EEG may show isoelectric activity. Hypoxic-ischemic encephalopathy (HIE) is the clinical syndrome following cardiac arrest or perinatal asphyxia. Treatment: immediate restoration of oxygenation (ABC, oxygen, ventilation), therapeutic hypothermia for HIE (reduces neurological injury), and supportive care.

Apnea-Hypopnea Index

- Number of apneas plus hypopneas per hour of sleep. Apnea = airflow cessation > 10 seconds. Hypopnea = partial obstruction with desaturation or arousal. AHI < 5 normal, 5–14 mild, 15–29 moderate, ≥ 30 severe.

Apneustic Breathing

- A breathing pattern characterized by a prolonged inspiratory pause, seen in brainstem lesions (particu-

larly the pons). It indicates damage to the apneustic center and is a poor prognostic sign in neurological injury. It may require mechanical ventilation.

Apnoea

- Temporary cessation of breathing, defined as complete cessation of airflow for ≥ 10 seconds. Obstructive apnea: airway collapse despite respiratory effort (common in obstructive sleep apnea). Central apnea: absence of respiratory effort (Cheyne–Stokes respiration in heart failure, high-altitude periodic breathing, opioid-induced central apnea, brainstem stroke). Mixed apnea: features of both. Physiologic apnea: breath-holding, voluntary apnea. Pathological apnea in infants: apnea of prematurity (seen in preterm infants <37 weeks, due to immature respiratory control, treated with caffeine), apparent life-threatening events (ALTEs, now termed brief resolved unexplained events—BRUE). Diagnosis: polysomnography (sleep study). See also Sleep apnea.

Aspiration Pneumonia

- Lung infection from aspiration of oropharyngeal or gastric contents. Risk factors include impaired consciousness and dysphagia. Right lower lobe is most commonly affected.

Assist-Control Ventilation

- Ventilator delivers a set tidal volume at a set rate. Every breath receives the full set volume. Guarantees minimum rate and minute ventilation. Risk of respiratory alkalosis and auto-PEEP.

Ataxic Breathing

- An irregular, unpredictable breathing pattern with random variations in rate and depth, seen in medullary lesions. It is the most dangerous respiratory pattern and often precedes respiratory arrest. It requires mechanical ventilation.

Atelectasis

- Complete or partial collapse of lung tissue, resulting in loss of aeration. It may be caused by airway obstruction (resorption atelectasis), pleural disease (compressive atelectasis), surfactant dysfunction (dissolution atelectasis), or scarring (cicatrization atelectasis). It impairs gas exchange and may predispose to infection.

Autogenic Drainage

- A breathing technique using controlled breathing at different lung volumes to mobilize secretions from

peripheral to central airways. It involves breathing at low lung volumes (collect), mid lung volumes (loosen), and high lung volumes (evacuate). It requires patient training and cooperation.

Azygos Vein

- A vein that drains the posterior intercostal veins and empties into the superior vena cava. It forms an important collateral pathway when the SVC is obstructed. On chest imaging, enlargement of the azygos vein may indicate SVC obstruction, heart failure, or portal hypertension.

Barotrauma

- Lung injury from excessive pressure during ventilation, causing alveolar rupture (pneumothorax, pneumomediastinum). Risk factors: high pressures, high PEEP. Prevented by lung-protective ventilation.

Biot Breathing

- An irregular breathing pattern with random periods of normal breathing interspersed with apneic episodes, seen in brainstem lesions. It is less organized than Cheyne–Stokes breathing and indicates medullary damage.

Biotrauma

- Inflammatory response to ventilator-induced lung injury with systemic cytokine release. Can lead to multi-organ dysfunction. Minimized by lung-protective ventilation strategies.

Body Plethysmography

- Technique for measuring lung volumes (TLC, RV, FRC) using a sealed chamber. Gold standard for TLC measurement. Useful for diagnosing restriction and hyperinflation.

Breath Sounds

- The sounds produced by airflow through the respiratory tract during breathing, assessed by auscultation with a stethoscope over the chest wall. Normal breath sounds are classified by location and quality: tracheal (loud, harsh, high-pitched heard over the trachea), bronchial (loud, tubular, heard over the manubrium and large airways, with a gap between inspiration and expiration), bronchovesicular (intermediate pitch and intensity, heard over the mainstem bronchi, equal inspiratory and expiratory duration,).

Breath Stacking

- A technique using a manual resuscitation bag or glossopharyngeal breathing to deliver successive breaths without exhaling, stacking tidal volumes to achieve higher lung volumes. It improves cough effectiveness and secretion clearance in patients with weak respiratory muscles.

Bronchial Stenosis

- Narrowing of a bronchus from trauma, infection, inflammation, or prior intervention. It causes localized wheezing, recurrent infections, and impaired secretion clearance. Diagnosis is by bronchoscopy. Treatment includes balloon dilation, stenting, or surgical resection.

Bronchogenic Cyst

- A congenital cyst derived from abnormal budding of the ventral foregut. It is typically found in the middle mediastinum or near the carina. It is usually asymptomatic but may cause compression of adjacent structures. Treatment is surgical resection if symptomatic.

Bronchophony

- Increased transmission of spoken sounds to the stethoscope over consolidated lung tissue. It is normally heard over the central airways. Excessive bronchophony over peripheral lung fields indicates consolidation. It is part of the constellation of physical examination findings in pneumonia.

Bronchopneumonia

- Patchy consolidation centered on bronchioles across multiple lobes. Caused by *S. aureus*, gram-negative bacteria, and *Pseudomonas*.

Bronchoscopy

- Endoscopic visualization of the lower airways using flexible or rigid bronchoscope. Indications include diagnosis of lung masses, hemoptysis evaluation, BAL, and foreign body removal. Transbronchial biopsy can sample parenchymal lesions.

Carina

- The ridge at the base of the trachea where it bifurcates into the right and left main bronchi. It is a landmark for endotracheal tube placement and bronchoscopy. The right main bronchus is wider, shorter, and more vertical than the left, making it the preferred path for aspirated foreign bodies.

Central Sleep Apnea

- Apneas from variability in respiratory effort with-

out airway obstruction. Associated with heart failure (Cheyne-Stokes respiration), high altitude, and opioid use.

CFTR Modulator Therapy

- Targeted therapies correcting the defective CFTR protein. Elexacaftor-tezacaftor-ivacaftor (Trikafta) is the most effective combination for patients with at least one F508del mutation. These therapies have dramatically changed CF prognosis.

Chest Tube Insertion

- Placement of a thoracostomy tube in the safe triangle (latissimus dorsi, pectoralis major, nipple level) to drain air, fluid, or blood from the pleural space. Connected to underwater seal drainage.

Chest Wall Deformity

- Abnormalities of the chest wall that can affect lung function. Pectus excavatum (sunken sternum) may compress the heart and lungs. Pectus carinatum (protruding sternum) is usually cosmetic. Scoliosis can cause restrictive lung disease. These may require surgical correction if severe.

Cheyne-Stokes Respiration

- Crescendo-decrescendo breathing pattern with periods of apnea, seen in heart failure and stroke. It is a form of central sleep apnea.

Chlamydophila Pneumonia

- Atypical pneumonia with mild presentation: sore throat, hoarseness, cough. Treatment is macrolides or tetracyclines.

Chylothorax

- Pleural effusion with chyle from thoracic duct disruption. Triglycerides > 110 mg/dL. Treatment includes dietary modification, octreotide, and surgical ligation if refractory.

Community-Acquired Pneumonia

- Pneumonia acquired outside healthcare settings. Common pathogens include *S. pneumoniae*, *H. influenzae*, and atypical organisms. Severity assessed by CURB-65.

Compressive Atelectasis

- Atelectasis caused by external compression of the lung by pleural fluid, air, or a mass. The lung volume is reduced by the external force. It is reversible when the compressing force is relieved (e.g., drainage of pleural effusion).

Cor Pulmonale

- Right ventricular hypertrophy and dilation from pulmonary hypertension due to lung disease. Features include peripheral edema, JVD, and hepatomegaly.

Cough

- A complex reflex arc protecting the airway by clearing secretions, irritants, and foreign material from the tracheobronchial tree. The cough reflex involves sensory receptors (rapidly adapting irritant receptors, C-fibers, and mechanoreceptors) in the larynx, trachea, and bronchi, afferent pathways (vagus nerve, superior laryngeal nerve, trigeminal nerve), the cough center in the medulla oblongata, efferent pathways (recurrent laryngeal nerve, phrenic nerve, spinal motor nerves), and effector muscles (diaphragm, abdominal wall, intercostals, and laryngeal muscles) for the coordinated cough response.

Cough Augmentation

- Techniques to improve cough effectiveness in patients with neuromuscular disease or chest wall weakness. Methods include manually assisted cough (abdominal thrust timed with cough), mechanical insufflation-exsufflation (CoughAssist device), and breath stacking with a resuscitation bag. They are essential in Duchenne muscular dystrophy and spinal cord injury.

CPAP

- Continuous Positive Airway Pressure, first-line for OSA. Delivers constant pressure through a mask to prevent airway collapse. Eliminates apneas and improves outcomes. Adherence is the main challenge.

Crazy Paving Pattern

- A HRCT finding characterized by ground-glass opacification with superimposed interlobular septal thickening and intralobular lines. It is seen in pulmonary alveolar proteinosis, lipoid pneumonia, ARDS, pulmonary hemorrhage, and Pneumocystis pneumonia. Despite its name, it is not specific to any single diagnosis.

Cryptogenic Organizing Pneumonia

- An inflammatory lung disease with granulation tissue within alveolar ducts. May be idiopathic or secondary to infection, drugs, or connective tissue disease. Responds well to corticosteroids.

CT Pulmonary Angiography

- Gold standard for PE diagnosis, showing thrombi

as filling defects. Sensitivity > 95%, specificity > 97% for central emboli.

CURB-65 Score

- One point each for: Confusion, Urea > 7 mmol/L, RR > 30, BP < 90/60, age ≥ 65. 0–1: outpatient. 2: consider hospitalization. 3–5: severe.

D-Dimer

- Fibrin degradation product elevated in PE, DVT, sepsis, and trauma. Negative result in low-probability patient excludes PE. Age-adjusted D-dimer improves specificity.

Decreased Breath Sounds

- Diminished air movement heard on auscultation, indicating decreased ventilation. Causes include pneumothorax, pleural effusion, atelectasis, and mucus plugging. Unilateral decreased breath sounds may indicate tension pneumothorax or large effusion.

Directly Observed Therapy

- Supervision of medication ingestion to ensure adherence. Standard of care for TB treatment. Ensures completion of the full treatment course and reduces development of drug resistance.

Dornase Alfa

- A recombinant human DNase that cleaves extracellular DNA in airway secretions, reducing sputum viscosity. It is used in CF to improve lung function and reduce exacerbations. It is administered as a nebulized solution once or twice daily. It has become a standard part of CF airway clearance regimens.

Dry Powder Inhaler

- A breath-actuated inhaler delivering powdered medication. Does not require hand-breath coordination. Requires adequate inspiratory flow. Examples include Advair Diskus and Spiriva HandiHaler.

Egophony

- An abnormal vocal sound heard during auscultation in which spoken “E” sounds are heard as “A” (the “E-to-A” change). It is a sign of lung consolidation, as in lobar pneumonia. The consolidated lung tissue conducts high-frequency sounds better than air-filled lung.

Electromagnetic Navigation Bronchoscopy

- A guidance system for bronchoscopy that uses electromagnetic fields to navigate to peripheral lung

lesions. It allows biopsy of lesions not visible on standard bronchoscopy. It is more accurate than conventional transbronchial biopsy for peripheral lesions. It may reduce the need for CT-guided biopsy.

Empyema

- Pus in the pleural space. CT shows peripheral enhancement (split pleura sign). Treatment requires chest tube drainage, intrapleural fibrinolytics, or VATS decortication.

Empyema Necessitans

- Extension of pleural empyema through the chest wall. Presents as a painful, fluctuant mass. Requires drainage and antibiotics.

Endobronchial Tumor

- A tumor growing within the bronchial lumen, causing obstruction, atelectasis, and post-obstructive pneumonia. It may be malignant (lung cancer, carcinoid tumor) or benign (hamartoma, papilloma). Symptoms include cough, hemoptysis, and wheezing. Treatment is bronchoscopic removal or debulking plus definitive therapy.

Endobronchial Ultrasound

- Bronchoscopy with ultrasound guidance for transbronchial needle aspiration of mediastinal and hilar lymph nodes. Essential for lung cancer staging. Less invasive than mediastinoscopy.

Endothelin Receptor Antagonists

- Medications that block endothelin-1, a potent vasoconstrictor implicated in pulmonary arterial hypertension. Bosentan (dual ERA), ambrisentan (selective ETA), and macitentan are used for PAH. Side effects include hepatotoxicity (bosentan), anemia, and teratogenicity.

Endotracheal Intubation

- Placement of a tube through the mouth into the trachea for mechanical ventilation. Gold standard for airway management. Confirmation by end-tidal CO₂ detection and bilateral breath sounds.

Ethambutol

- First-line TB drug inhibiting arabinosyl transferase. Side effects: optic neuritis (visual acuity and color vision monitoring), hyperuricemia. Dose is weight-based.

Expiratory Grunting

- A forced exhalation against a partially closed glottis, creating an audible sound. It is an end-

expiratory maneuver that generates intrinsic PEEP, helping to maintain alveolar recruitment and improve oxygenation. It is commonly seen in children with respiratory distress.

Extensively Drug-Resistant TB

- TB resistant to isoniazid, rifampin, fluoroquinolones, and at least one injectable agent. Very limited treatment options and poor outcomes.

Exudative Pleural Effusion

- From local pleural disease. Causes include pneumonia, malignancy, TB, and PE. Elevated protein, LDH, and cell count.

Farmer's Lung

- The most common HP, caused by thermophilic actinomycetes in moldy hay. Presents acutely 4–8 hours after exposure with fever, cough, and dyspnea.

Flail Chest

- A clinical condition caused by three or more consecutive ribs fractured in two or more places, creating a free-floating segment of chest wall. The segment moves paradoxically inward during inspiration and outward during expiration. It causes severe pain, impaired ventilation, and may require mechanical ventilation. It is often associated with pulmonary contusion.

Flow-Volume Loop

- Graphical representation of airflow during forced breathing. Obstructive: scooped expiratory limb. Restrictive: narrowed loop with preserved shape. Variable extrathoracic obstruction: flattening of inspiratory limb.

Foreign Body Aspiration

- Inhalation of a foreign object into the airway, most common in children (ages 1–3) and adults with impaired swallowing. It causes sudden onset choking, coughing, and unilateral wheezing. Right main bronchus is most commonly affected due to its wider, more vertical anatomy. Treatment is bronchoscopic removal.

Hamman's Sign

- A crunching or crackling sound heard on auscultation synchronized with the heartbeat, caused by air in the mediastinum (pneumomediastinum). It is a rare but specific finding. It is also described as a mediastinal crunch heard in spontaneous pneumomediastinum.

Hampton Hump

- Wedge-shaped opacification with its base abutting the pleura on chest radiography, representing pulmonary infarction secondary to Pulmonary Embolism. *See Pulmonary Embolism (PE).*

Hampton's Hump

- Wedge-shaped, pleural-based opacity on CXR representing pulmonary infarction distal to PE.

Hemothorax

- Blood in pleural space from trauma. Initial chest tube output > 1500 mL or persistent bleeding > 200 mL/hour indicates need for surgery.

Hereditary Hemorrhagic Telangiectasia

- An autosomal dominant vascular disorder (also called Osler-Weber-Rendu syndrome) characterized by telangiectasias on skin and mucous membranes, pulmonary AVMs, hepatic AVMs, and cerebral AVMs. Pulmonary AVMs can cause hypoxemia and paradoxical emboli. Treatment is embolization of pulmonary AVMs.

High-Flow Nasal Cannula

- A device delivering heated and humidified oxygen at flow rates up to 60 L/min through a nasal cannula. It provides a modest amount of PEEP, reduces dead space ventilation, and improves patient comfort compared to non-invasive ventilation. It is used for acute hypoxemic respiratory failure and post-extubation support.

Hospital-Acquired Pneumonia

- Pneumonia developing > 48 hours after hospital admission. Common pathogens include *Pseudomonas* and MRSA. Empiric treatment covers resistant organisms.

Hypercyanotic Tetralogy

- A complex congenital heart defect with four features: ventricular septal defect, overriding aorta, right ventricular outflow tract obstruction (pulmonary stenosis), and right ventricular hypertrophy. It causes right-to-left shunting and cyanosis. Treatment is surgical repair, typically in infancy.

Hyperventilation

- Breathing in excess of metabolic requirements, resulting in decreased partial pressure of arterial carbon dioxide (PaCO_2) and respiratory alkalosis. Acute hyperventilation causes: perioral and

digital paraesthesiae (numbness, tingling of lips, hands, feet), carpopedal spasm (tetany due to decreased ionised calcium from alkalosis—Chvostek and Trousseau signs), lightheadedness, dizziness, chest tightness, palpitations, anxiety, panic, and rarely loss of consciousness. Causes: anxiety and panic disorder (most common, acute or chronic hyperventilation syndrome), pain, fever, sepsis, pulmonary embolism (tachypnoea, hypoxia, hyperventilation), head injury (lesions affecting the respiratory center), metabolic acidosis (Kussmaul breathing as compensatory hyperventilation, e.g., DKA), drugs (salicylate overdose), pregnancy (progesterone stimulates the respiratory center), and neurological disorders (stroke, brainstem lesions). Diagnosis: clinical (typical symptoms, normal oxygen saturation, history of anxiety/panic), arterial blood gas (decreased PaCO_2 < 35 mmHg, elevated pH > 7.45, normal PO_2). Hyperventilation can be distinguished from pathological tachypnoea by the absence of hypoxia and underlying cause. Management: (1) Acute: reassurance, rebreathing into a paper bag (controversial and risk of hypoxia safer to use slow breathing technique), breathing retraining (5-second inhale, 5-second hold, 5-second exhale), treatment of underlying cause. (2) Chronic: cognitive behavioural therapy (CBT), breathing exercises, management of anxiety/panic disorder (SSRI, buspirone, relaxation techniques).

Hypoxemia

- PaO_2 < 80 mmHg on room air. Causes: hypoventilation, V/Q mismatch, shunt, diffusion impairment, low FiO_2 . A-a gradient helps distinguish causes.

Influenza

- A contagious respiratory illness caused by influenza A or B viruses, characterized by sudden onset of fever, myalgia, headache, malaise, nonproductive cough, sore throat, and nasal congestion. Seasonal epidemics occur annually. Complications: pneumonia (primary viral or secondary bacterial), exacerbation of underlying conditions. Diagnosis: PCR or rapid antigen testing. Treatment: supportive care, neuraminidase inhibitors (oseltamivir). Prevention: annual vaccination.

Inhaled Nitric Oxide

- A selective pulmonary vasodilator used in acute settings (acute respiratory failure, right heart fail-

ure, post-cardiac surgery). It reduces pulmonary vascular resistance and improves oxygenation by dilating well-ventilated pulmonary vessels (improving V/Q matching). It has a short half-life and requires continuous delivery.

Interferon-Gamma Release Assay

- Blood tests measuring IFN-gamma release in response to *M. tuberculosis* antigens (ESAT-6, CFP-10). More specific than PPD and unaffected by BCG. Cannot distinguish latent from active TB.

Intrapulmonary Shunt

- Perfusion of alveoli without ventilation ($V/Q = 0$). Blood passes through the pulmonary circulation without gas exchange, mixing with oxygenated blood and causing hypoxemia. It is seen in ARDS, pneumonia, and atelectasis. It is refractory to supplemental oxygen.

Isoniazid

- First-line TB drug inhibiting mycolic acid synthesis. Side effects: hepatotoxicity, peripheral neuropathy, drug-induced lupus. Most effective for latent TB treatment.

IVC Filter

- A device in the IVC to prevent DVT from reaching the lungs. Indications include recurrent PE despite anticoagulation and absolute contraindication to anticoagulation.

Klebsiella Pneumonia

- Severe, necrotizing pneumonia in alcoholic or debilitated patients. Upper lobe involvement with “bulging fissure sign” and “currant jelly” sputum.

Kussmaul Breathing

- A deep, rapid breathing pattern seen in severe metabolic acidosis (diabetic ketoacidosis, lactic acidosis, uremia). It represents the body’s attempt to compensate by blowing off CO₂. The increased respiratory rate and depth create the characteristic labored breathing.

Kyphoscoliosis

- An abnormal curvature of the spine in both the coronal (scoliosis) and sagittal (kyphosis) planes. Severe forms cause restrictive lung disease by reducing chest wall compliance and lung volumes. It can lead to chronic respiratory failure and pulmonary hypertension. Treatment includes bracing, surgical correction, and non-invasive ventilation.

Lambert-Eaton Myasthenic Syndrome

- Autoantibodies against presynaptic calcium channels at the neuromuscular junction, associated with SCLC. Proximal weakness, reduced reflexes, facilitation with exercise.

Large Airway Obstruction

- Obstruction of airways with diameter > 2 mm (trachea and main bronchi). It causes significant symptoms including stridor, dyspnea, and impaired secretion clearance. It may be fixed (stenosis, tumor) or variable (tracheomalacia, vocal cord dysfunction). Flow-volume loops show characteristic patterns.

Latent Tuberculosis Infection

- Persistent immune response to *M. tuberculosis* without active disease. Asymptomatic and non-infectious. 5–10% of immunocompetent individuals develop active TB without treatment. Treatment reduces risk by 60–90%.

Legionella Pneumonia

- From *Legionella pneumophila* in water systems. Presents with high fever, diarrhea, confusion, and hyponatremia. Diagnosis by urinary antigen test. Treatment is fluoroquinolones or macrolides.

Light’s Criteria

- An effusion is exudative if any one is met: pleural protein/serum protein > 0.5 , pleural LDH/serum LDH > 0.6 , or pleural LDH $> 2/3$ upper limit of normal serum LDH.

Lipoid Pneumonia

- Lung inflammation caused by accumulation of lipid-laden macrophages in the alveoli. Exogenous lipoid pneumonia results from aspiration of mineral oil, petroleum jelly, or oil-based nose drops. Endogenous lipoid pneumonia occurs distal to bronchial obstruction. HRCT shows ground-glass opacities with low-attenuation areas (fat density).

Lobar Pneumonia

- Consolidation involving an entire lobe. Most commonly caused by *S. pneumoniae*. Classic progression: congestion, red hepatization, gray hepatization, resolution.

Low-Dose CT Scan

- CT protocol using reduced radiation for lung cancer screening. Detects small nodules at earlier

stages. False positives require follow-up per Fleischner guidelines.

Lung Abscess

- Localized necrosis with cavitation containing purulent material. Causes include aspiration and anaerobic bacteria. CXR shows thick-walled cavity with air-fluid level.

Lung Function Tests

- A group of physiological tests that assess the function and capacity of the lungs. See Pulmonary Function Tests.

Lung Protective Ventilation

- A ventilation strategy using low tidal volumes (6 mL/kg ideal body weight), plateau pressure < 30 cmH₂O, appropriate PEEP, and permissive hypercapnia to minimize ventilator-induced lung injury. It is the standard of care for ARDS and is used in all mechanically ventilated patients to reduce barotrauma, volutrauma, and biotrauma.

Lymphangioleiomyomatosis

- A rare, progressive cystic lung disease caused by proliferation of abnormal smooth muscle-like cells (LAM cells) in the lungs, lymphatics, and kidneys. It occurs almost exclusively in women of childbearing age. HRCT shows thin-walled cysts throughout both lungs. It may be associated with tuberous sclerosis complex. Treatment includes sirolimus (mTOR inhibitor) and lung transplantation.

Massive Hemoptysis

- > 600 mL in 24 hours or causing hemodynamic compromise. Medical emergency. Treatment: airway protection, bronchial artery embolization (first-line), or surgery.

Mechanical Exsufflation

- A device that delivers positive pressure (insufflation) followed by rapid negative pressure (exsufflation) to simulate a cough. It is used in neuromuscular disease (Duchenne muscular dystrophy, spinal cord injury, ALS) to augment cough effectiveness and clear secretions.

Mediastinoscopy

- Surgical procedure to sample mediastinal lymph nodes through a small incision above the sternum. Gold standard for mediastinal lymph node staging in lung cancer. Being replaced by EBUS in many

centers.

Miliary TB

- Hematogenous dissemination of *M. tuberculosis* causing innumerable 1–3 mm granulomas throughout lungs and other organs. CXR shows “millet seed” pattern. More common in immunocompromised patients.

Minute Ventilation

- The total volume of air breathed in one minute (tidal volume x respiratory rate). Normal is 6–8 L/min. Elevated in increased metabolic demand, pain, anxiety, and sepsis. Reduced in neuromuscular disease and sedation.

Multidrug-Resistant TB

- TB resistant to at least isoniazid and rifampin. Requires second-line drugs for 18–24 months. Worse outcomes and higher mortality than drug-susceptible TB.

Mycoplasma Pneumonia

- Atypical pneumonia most common in ages 5–35. Dry cough, low-grade fever, headache. Patchy infiltrates on CXR disproportionate to symptoms (“walking pneumonia”).

Negative Pressure Ventilation

- Ventilation using negative pressure applied around the chest wall to expand the lungs, as opposed to positive pressure applied to the airway. The “iron lung” is a historical example. Modern negative pressure ventilators include the cuirass and wrap. They are rarely used today but may be useful in neuromuscular disease.

Obesity Hypoventilation Syndrome

- Chronic daytime hypercapnia in obese individuals without other causes. Reduced chest wall compliance and blunted respiratory drive. Often coexists with OSA. Treatment: weight loss and BiPAP.

Obstructive Sleep Apnea

- Repetitive upper airway obstruction during sleep. Presents with snoring, witnessed apneas, daytime sleepiness. AHI quantifies severity: 5–14 mild, 15–29 moderate, ≥ 30 severe. Treatment: CPAP, oral appliances, weight loss, surgery.

Orthopnea

- Dyspnea that occurs when lying flat and is relieved by sitting upright. It is measured by the number of pillows the patient needs to sleep (two-pillow

orthopnea). It is a hallmark of left heart failure and is caused by redistribution of fluid from the lower extremities to the lungs in the supine position.

Pancoast Tumor

- Superior sulcus tumor invading brachial plexus, subclavian vessels, and sympathetic chain. Causes Horner syndrome, shoulder/arm pain, and hand muscle atrophy. Treated with chemoradiation followed by surgery.

Parapneumonic Effusion

- Pleural effusion complicating pneumonia. Simple effusions resolve with antibiotics. Complicated effusions (pH < 7.2, glucose < 60 mg/dL) require chest tube drainage.

Paroxysmal Nocturnal Dyspnea

- Episodes of severe dyspnea that awaken the patient from sleep, typically occurring 1–2 hours after lying down. It is a classic symptom of left heart failure, caused by progressive pulmonary congestion during sleep. It is different from orthopnea in its delayed onset and nocturnal presentation.

PE Anticoagulation

- Initial heparin (LMWH or UFH), followed by warfarin (INR 2–3) for 3–6 months. DOACs are first-line for most patients. Duration depends on provoked vs. unprovoked status.

Permissive Hypercapnia

- A ventilator strategy that allows PaCO₂ to rise above normal (and pH to fall) in exchange for lung-protective ventilation with lower tidal volumes and airway pressures. It is used in severe ARDS when achieving normal PaCO₂ would require harmful ventilation parameters.

Phosphodiesterase-5 Inhibitors

- Medications that inhibit PDE-5, increasing cGMP and causing smooth muscle relaxation and vasodilation. Sildenafil and tadalafil are used for PAH and erectile dysfunction. In PAH, they reduce pulmonary vascular resistance and improve exercise capacity.

Platypnea

- Dyspnea that occurs in the upright position and is relieved by lying down. It is the opposite of orthopnea. It is rare and may be associated with hepatopulmonary syndrome, intracardiac shunting, or pulmonary arteriovenous malformations.

Pleural Effusion

- Abnormal fluid in the pleural space. Transudates result from altered pressures; exudates from inflammation, infection, or malignancy. Light's criteria differentiate the two.

Pleural Fluid Glucose

- Low pleural fluid glucose (< 60 mg/dL) suggests bacterial empyema, rheumatoid pleurisy, or tuberculosis. It indicates high metabolic activity in the pleural space consuming glucose. Very low glucose is characteristic of empyema and parapneumonic effusions requiring drainage.

Pleural Fluid pH

- Pleural fluid pH < 7.20 indicates a complicated parapneumonic effusion or empyema requiring drainage. Normal pleural fluid pH is approximately 7.60. Low pH reflects high metabolic activity and anaerobic metabolism in the pleural space. It is a key decision point in managing parapneumonic effusions.

Pleural Friction Rub

- A grating, leathery sound heard on auscultation caused by inflamed pleural surfaces rubbing against each other during breathing. It is a sign of pleurisy and may be heard in pneumonia, PE, and pleural effusion. It disappears when fluid accumulates and separates the pleural surfaces.

Pleural Plaque

- Circumscribed fibrous tissue on parietal pleura, hallmark of asbestos exposure. Bilateral, often calcified. Does not indicate asbestosis.

Pleurisy

- Pleural inflammation causing sharp, breathing-related chest pain. Causes: pneumonia, PE, autoimmune disease, malignancy. Treatment addresses the underlying cause.

Pleuritis

- Inflammation of the pleural membranes (visceral and parietal pleura). Presents with pleuritic chest pain: sharp, stabbing pain exacerbated by deep breathing, coughing, or sneezing. Common causes: viral pleurisy (most common), bacterial pneumonia with parapneumonic effusion, pulmonary embolism, tuberculosis, connective tissue diseases (SLE, rheumatoid arthritis), uremia, and malignancy. May be accompanied by pleural friction rub on auscultation. Diagnosis: clinical history, chest

X-ray (evaluate for effusion, infiltrates, or pneumothorax), ultrasound, and laboratory evaluation (CBC, CRP, D-dimer to rule out PE). Treatment: addressing the underlying cause; NSAIDs for pain relief; corticosteroids for severe inflammatory pleuritis (e.g., SLE).

Pleurodesis

- Fusion of visceral and parietal pleura to prevent recurrence of effusions or pneumothorax. Chemical pleurodesis uses talc, doxycycline, or bleomycin.

Pneumatocele

- Thin-walled, air-filled cystic spaces in the lung, often in staphylococcal pneumonia. Typically self-resolving.

Pneumocystis Pneumonia

- Opportunistic pneumonia from *P. jirovecii* in immunocompromised patients ($CD4 < 200$). Progressive dyspnea, dry cough, bilateral ground-glass opacities. Elevated LDH. Treatment is TMP-SMX.

Pneumonia

- Infection of the lung parenchyma, classified as community-acquired (CAP), hospital-acquired (HAP), or ventilator-associated (VAP). Common pathogens: *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Mycoplasma pneumoniae*, viruses. Presents with cough, fever, dyspnea, and consolidation on imaging. Severity assessment: CURB-65 or PSI. Treatment: empiric antibiotics based on setting and local resistance patterns.

Pneumothorax

- Air in the pleural space causing lung collapse. Primary spontaneous occurs in tall, thin young men. Secondary occurs with underlying lung disease. Tension is a medical emergency.

Positive End-Expiratory Pressure

- Pressure maintained at end-expiration to prevent alveolar collapse. Improves oxygenation by recruiting alveoli and increasing FRC. Balances oxygenation with hemodynamic effects.

Post-Infectious Cough

- A chronic cough persisting 3–8 weeks after a URI, caused by transient bronchial hyperresponsiveness and airway inflammation. It is self-limited and usually resolves without treatment. Inhaled corticosteroids, antitussives, and time are the mainstays of management.

Post-Obstructive Pneumonia

- Pneumonia occurring distal to a bronchial obstruction caused by tumor, foreign body, mucus plug, or stenosis. The obstruction prevents clearance of secretions, creating a favorable environment for infection. It does not resolve with antibiotics alone until the obstruction is relieved.

Post-Pneumonectomy Syndrome

- A rare complication following pneumonectomy where the remaining lung herniates across the mediastinum, causing compression of airways and vessels. It presents with dyspnea, stridor, and recurrent infections. Treatment is surgical correction with mediastinal repositioning and prosthetic implant placement.

Pott Disease

- TB of the spine involving thoracic or lumbar vertebrae. Causes vertebral destruction, kyphosis (gibbus deformity), and paravertebral abscess. May cause spinal cord compression.

Pressure Support Ventilation

- Spontaneous breathing mode with ventilator-provided pressure support above PEEP for each breath. Reduces work of breathing. Used for weaning from mechanical ventilation.

Primary Tuberculosis

- Initial *M. tuberculosis* infection causing Ghon focus in lower lobes with hilar lymph node involvement (Ghon complex). Most infections are contained, resulting in latent TB.

Prone Positioning

- Turning supine patients to prone for > 12 hours daily in severe ARDS. Improves oxygenation by recruiting dorsal lung segments. Reduces mortality when $PaO_2/FiO_2 < 150$.

Prostacyclin Analogs

- Medications that mimic prostacyclin (PGI_2), causing vasodilation and inhibiting platelet aggregation in the pulmonary vasculature. They include epoprostenol (continuous IV), treprostinil (subcutaneous, IV, inhaled, oral), and iloprost (inhaled). They are used for severe PAH.

Pulmonary Alveolar Hemorrhage

- Bleeding into the alveolar spaces from disruption of the alveolar-capillary membrane. Causes include vasculitis (GPA, MPA, Goodpasture), connective

tissue disease, medications, and coagulopathy. It presents with hemoptysis, falling hemoglobin, diffuse bilateral infiltrates, and serially bloody returns on BAL.

Pulmonary Alveolar Microlithiasis

– A rare genetic disease caused by SLC34A2 mutations, leading to accumulation of calcium phosphate microliths within the alveoli. HRCT shows diffuse bilateral calcified nodules with a “sandstorm” appearance. It is usually diagnosed in the third to fourth decade. Treatment is supportive; lung transplantation may be needed for progressive disease.

Pulmonary Alveolar Proteinosis

– A rare disease characterized by accumulation of surfactant-like material within the alveoli due to impaired clearance by alveolar macrophages. Most cases are autoimmune (anti-GM-CSF antibodies). Presents with progressive dyspnea and cough. HRCT shows bilateral ground-glass opacities with “crazy paving” pattern. Treatment is whole lung lavage.

Pulmonary Arteriovenous Malformation

– An abnormal direct communication between a pulmonary artery and vein, causing a right-to-left shunt. It may be idiopathic or associated with hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome). It can cause hypoxemia, paradoxical emboli (stroke, brain abscess), and hemoptysis. Treatment is embolization or surgical resection.

Pulmonary Artery Catheter

– A catheter inserted through the right heart into the pulmonary artery to measure hemodynamic parameters (PA pressure, PAWP, cardiac output). Used for diagnosis and management of pulmonary hypertension, heart failure, and critical illness.

Pulmonary Contusion

– Bruising of the lung parenchyma from blunt chest trauma, causing hemorrhage and edema without lung laceration. It impairs gas exchange and can progress to ARDS. It is often associated with rib fractures and flail chest. Treatment is supportive with lung-protective ventilation.

Pulmonary Edema

– Accumulation of fluid in the pulmonary interstitium and alveoli, most commonly due to left-sided heart failure (cardiogenic). Causes increased hydro-

static pressure leads to transudation. Presents with acute dyspnea, orthopnea, crackles, and S3 gallop. Non-cardiogenic causes include ARDS, renal failure, and high altitude. Treatment: diuretics, afterload reduction, oxygen, and positive pressure ventilation if severe.

Pulmonary Embolism

– The obstruction of one or more pulmonary arteries by material lodged in the bloodstream, most commonly a thrombus originating from deep vein thrombosis (DVT) in the lower extremities (90-95 percent of cases). The Virchow triad (venous stasis, hypercoagulability, endothelial injury) underlies DVT/PE pathogenesis. Major risk factors: recent surgery or trauma (especially orthopedic), prolonged immobilization, active cancer, pregnancy and postpartum state, estrogen-containing oral contraceptives and hormone replacement therapy, and inherited thrombophilias.

Pulmonary Hemosiderosis

– Iron deposition in the lungs from repeated alveolar hemorrhage. It presents with hemoptysis, anemia, and diffuse bilateral infiltrates on imaging. Causes include Goodpasture syndrome, granulomatosis with polyangiitis, and idiopathic pulmonary hemosiderosis. The classic triad is hemoptysis, anemia, and diffuse pulmonary infiltrates.

Pulmonary Infarction

– Lung necrosis from PE when bronchial supply is compromised. Causes pleuritic pain, hemoptysis, and wedge-shaped opacity. Most PE do not cause infarction due to dual blood supply.

Pulmonary Sequestration

– A congenital malformation of non-functioning lung tissue that lacks normal communication with the tracheobronchial tree and receives its blood supply from a systemic artery (usually the descending aorta). Intralobar sequestration is within the normal pleural investment; extralobar is outside. It may present with recurrent infections or be incidental.

Pulmonary Vasodilator Therapy

– Medications that reduce pulmonary vascular resistance and pulmonary artery pressure. Used for WHO Group 1 PAH. Includes endothelin receptor antagonists (bosentan), PDE-5 inhibitors (sildenafil), prostacyclin analogs (epoprostenol), and sol-

uble guanylate cyclase stimulators (riociguat).

Pulmonary Wedge Pressure

- The pressure measured by a balloon-tipped pulmonary artery catheter when the balloon is inflated, occluding a branch of the pulmonary artery. It approximates left atrial pressure. Normal is 6–12 mmHg. Elevated in left heart failure (PCWP > 18 mmHg). Low in hypovolemia.

Pyrazinamide

- First-line TB drug effective against intracellular mycobacteria. Important for sterilizing action. Side effects: hepatotoxicity, hyperuricemia (gout).

Reactivation Tuberculosis

- Reactivation of latent infection, typically years later. Characteristically affects apical and posterior upper lobe segments. Features include chronic cough, hemoptysis, night sweats, weight loss, and cavitation.

Relapsing Polychondritis

- A systemic autoimmune disorder causing inflammation and destruction of cartilage throughout the body. Airway involvement can cause tracheal and bronchial stenosis. Other features include auricular chondritis, nasal chondritis, ocular inflammation, and arthritis. Treatment is corticosteroids and immunosuppressants.

Resorption Atelectasis

- Atelectasis caused by complete obstruction of an airway, leading to absorption of trapped air by the pulmonary capillaries. Common causes include mucus plugging, foreign body, tumor, and post-surgical shallow breathing. The affected area appears as increased density on CXR with volume loss.

RIPE Therapy

- Standard 4-drug regimen for active TB: Rifampin, Isoniazid, Pyrazinamide, Ethambutol. Intensive phase 2 months, continuation phase 4 months (total 6 months). Pyridoxine prevents isoniazid-induced neuropathy.

Round Pneumonia

- Pneumonia appearing as a round opacity on CXR rather than typical consolidation. More common in children and elderly. May mimic lung mass.

Siderosis

- Benign pneumoconiosis from iron dust, seen in welders. Causes small opacities on CXR but mini-

mal impairment. Reversible with removal of exposure.

Situs Inversus

- A congenital condition in which the thoracic and abdominal organs are reversed or mirrored from their normal positions. Complete situs inversus (situs inversus totalis) involves all organs. It is usually asymptomatic but may be associated with primary ciliary dyskinesia (Kartagener syndrome), congenital heart disease, and polysplenia or asplenia.

Sleep Apnea (Obstructive Sleep Apnea - OSA)

- A sleep disorder characterized by repeated episodes of partial or complete upper airway obstruction during sleep (obstructive sleep apnea—OSA, most common) or cessation of respiratory drive (central sleep apnea—CSA), causing intermittent hypoxia, hypercapnia, and sleep fragmentation. OSA affects 13% of men and 6% of women (moderate–severe). Risk factors: obesity (BMI ≥ 30 —strongest risk factor, 60–90% of OSA patients), male sex, age >40, menopause, craniofacial abnormalities (retrognathia, macroglossia, tonsillar hypertrophy), smoking, alcohol, and hypothyroidism. Pathophysiology: loss of pharyngeal muscle tone during sleep leads to collapse of the pharyngeal airway (velopharynx, oropharynx, hypopharynx). Clinical: loud snoring, witnessed apnoeas (by bed partner), choking/gasping arousals, unrefreshing sleep, excessive daytime sleepiness (Epworth Sleepiness Scale ≥ 10), morning headache, nocturia, and cognitive impairment. Consequences: hypertension (dose-dependent, 40% of OSA patients have hypertension), cardiovascular disease (MI, stroke, atrial fibrillation, heart failure), type 2 diabetes, and increased all-cause mortality. Diagnosis: polysomnography (apnea-hypopnoea index—AHI: mild 5–15, moderate 15–30, severe >30 events/hour). Home sleep apnea testing (HSAT) is an alternative for high-risk patients. Treatment: continuous positive airway pressure (CPAP—first-line, splints the airway open, AHI reduction >90%), mandibular advancement devices (MAD—for mild–moderate OSA, <25% of CPAP efficacy), weight loss (5–10% weight loss reduces AHI by 30–50%), positional therapy (for supine-dependent OSA), and surgery (uvulopalatopharyngoplasty, maxillo-

mandibular advancement, hypoglossal nerve stimulation/Inspire—for moderate–severe OSA who fail CPAP). Untreated severe OSA: 5-year mortality 10–15%.

Snoring and Sleep Apnea

– Snoring is the sound produced by vibrating soft tissues in the upper airway during sleep, often resulting from partial airway obstruction. Sleep apnea is a more serious condition characterized by repeated episodes of complete or partial airway collapse during sleep, leading to intermittent hypoxia, frequent arousal, and fragmented sleep. Obstructive sleep apnea, the most common form, is associated with obesity, hypertension, and cardiovascular disease; treatment includes continuous positive airway pressure therapy, oral appliances, weight loss, and positional therapy.

Solitary Pulmonary Nodule

– Single, well-circumscribed lesion < 3 cm surrounded by normal lung. Differential includes granuloma, hamartoma, and carcinoma. PET-CT and tissue sampling help determine etiology.

Spontaneous Breathing Trial

– A period of unsupported breathing to assess a patient's readiness for extubation. The patient breathes through a T-piece or with minimal pressure support for 30–120 minutes. Successful SBT predicts successful extubation.

Spontaneous Pneumothorax

– Pneumothorax without trauma. Primary in healthy individuals; secondary with underlying lung disease. Treatment depends on size.

Staphylococcal Pneumonia

– Severe pneumonia from *S. aureus*, often post-influenza. May cause necrotizing pneumonia, lung abscess, and empyema.

Stridor

– A high-pitched, monophonic, adventitious sound heard primarily during inspiration, caused by narrowing of the extrathoracic or proximal intrathoracic airway. It is a medical emergency when severe. Causes include foreign body aspiration, croup, epiglottitis, and tracheal stenosis.

SVC Syndrome

– Obstruction of the superior vena cava causing facial swelling, plethora, and distended neck veins. Com-

monly from lung cancer (SCLC, squamous) and lymphoma. Oncologic emergency.

Tactile Fremitus

– Vibrations transmitted through the lung to the chest wall, felt during palpation. It is increased in consolidation (pneumonia) due to better sound transmission through solid tissue. It is decreased in pleural effusion, pneumothorax, and atelectasis due to impaired transmission.

Tension Pneumothorax

– Air trapping via a one-way valve causing mediastinal shift, impaired venous return, and cardiovascular collapse. Requires immediate needle decompression (2nd ICS, midclavicular line) followed by chest tube.

Thoracentesis

– Removal of pleural fluid via needle insertion through the chest wall. Performed for diagnosis and symptom relief. Ultrasound guidance improves safety.

Thrombolysis for PE

– Systemic thrombolytics (alteplase) for massive PE with hemodynamic instability. Rapid clot dissolution but significant bleeding risk.

Total Lung Capacity

– Total lung air volume after maximal inspiration. Measured by body plethysmography. Increased in obstructive disease, decreased in restrictive disease. TLC < 80% confirms restriction.

Tracheal Foreign Body

– A foreign object lodged in the trachea, causing severe respiratory distress, stridor, and complete airway obstruction. It is a medical emergency requiring immediate bronchoscopic removal. In complete obstruction, emergency cricothyrotomy may be needed.

Tracheitis

– Inflammation of the tracheal mucosa. Acute bacterial tracheitis: a rare but life-threatening cause of upper airway obstruction in children, typically presenting as a superinfection following viral croup (parainfluenza). Caused by *Staphylococcus aureus* (most common), *Streptococcus pneumoniae*, *Haemophilus influenzae* type b (now rare due to Hib vaccine), and *Moraxella catarrhalis*. Presents with high fever, stridor (biphasic, worsening), barking cough, hoarseness, respiratory distress, toxic ap-

pearance, and copious purulent tracheal secretions. Diagnosis: lateral neck X-ray—tracheal narrowing ('steeple sign' similar to croup, but with irregular tracheal margins and pseudomembrane), bronchoscopy (definitive—shows inflammation, ulceration, and thick purulent secretions/ pseudomembranes). Treatment: hospitalisation, IV antibiotics (anti-staphylococcal—flucloxacillin or cefuroxime, plus metronidazole for anaerobes), humidified oxygen, and intubation if severe respiratory distress (airway protection, suction of thick secretions). Endotracheal intubation may be required for 5–7 days. Complications: airway obstruction, pneumonia, septic shock, and post-intubation stenosis.

Tracheobronchomalacia

– Abnormal softening of the trachea and/or bronchi causing excessive airway collapse during breathing. It may be congenital or acquired. Symptoms include chronic cough, recurrent infections, and expiratory airflow obstruction. Diagnosis is by dynamic CT or bronchoscopy. Treatment includes CPAP, stenting, or surgical reconstruction.

Tracheomalacia

– Softening of the tracheal cartilage causing excessive collapse of the trachea during expiration. It may be congenital or acquired (prolonged intubation, relapsing polychondritis). Symptoms include expiratory stridor and difficulty clearing secretions. Diagnosis is by dynamic CT or bronchoscopy. Treatment may require tracheal stenting or surgery.

Tracheostomy

– Surgical creation of an airway opening in the anterior neck into the trachea. Indications include prolonged ventilation (> 10–14 days), upper airway obstruction, and airway protection.

Transudative Pleural Effusion

– From systemic factors altering hydrostatic/oncotic pressures. Most commonly from heart failure. Low protein, low LDH. Treatment addresses the underlying cause.

Trepopnea

– Dyspnea that occurs in one lateral decubitus position but not the other. It is typically worse when lying on the side of the affected lung. It may be caused by unilateral lung disease, pleural effusion, or mediastinal mass.

Upper Airway Obstruction

– Narrowing of the airway above the carina, causing inspiratory stridor, dyspnea, and characteristic changes on flow-volume loops (flattening of the inspiratory limb). Causes include tumors, stenosis, goiter, and vocal cord dysfunction. It is a medical emergency when severe.

Ventilator-Associated Pneumonia

– Pneumonia > 48 hours after intubation. Most common ICU-acquired infection. Diagnosis uses quantitative BAL or protected specimen brush cultures.

Vocal Resonance

– The transmission of vocal sounds to the chest wall, assessed by having the patient speak while auscultating. It is increased in consolidation and decreased in pleural effusion or pneumothorax. It correlates with bronchophony and whispered pectoriloquy.

Volutrauma

– Lung injury from excessive tidal volume causing alveolar overdistension. Prevented by low tidal volume ventilation (6 mL/kg IBW). Key component of ARDS management.

Westermarck Sign

– Focal area of oligemia (decreased vascularity) distal to an occluded pulmonary artery segment on chest radiography in acute Pulmonary Embolism. *See Pulmonary Embolism (PE).*

Whispered Pectoriloquy

– The ability to hear whispered words clearly through the stethoscope over consolidated lung tissue. It is a sign of pulmonary consolidation. Normally, whispered words are barely audible over the lung fields. It is one of the classic signs of pneumonia on physical examination.

Windpipe

– See Trachea.

Chapter 36

Radiology

Arthrography

- Imaging of a joint after intra-articular injection of contrast medium to delineate cartilage, labra, ligaments, menisci, and synovial structures. Iodinated contrast is used for fluoroscopic arthrography, while dilute gadolinium is used for direct MR arthrography, the most sensitive modality for labral and chondral assessment. Used mainly for shoulder, wrist, and hip evaluation. Complications are uncommon.

Bone Densitometry

- Bone densitometry, most commonly performed by dual-energy X-ray absorptiometry (DXA), measures bone mineral density (BMD) to diagnose osteoporosis, assess fracture risk, and monitor treatment response. DXA uses two X-ray energies that are differentially absorbed by bone and soft tissue, enabling calculation of areal BMD (g/cm²) at the lumbar spine (L1-L4), proximal femur (femoral neck, trochanter, total hip), and sometimes the distal one-third radius. Results are reported as T-scores (comparison with young adult mean), Z-scores (comparison with age-matched mean), and the World Health Organization classification: normal (T-score -1.0 or above), osteopenia (T-score -1.0 to -2.5), and osteoporosis (T-score -2.5 or below). DXA is the gold standard for diagnosis of osteoporosis and is used for screening in postmenopausal women over 65, men over 70, and younger patients with risk factors. Limitations include inability to distinguish cortical from trabecular bone, artefact from degenerative changes and compression fractures, and measurements that areal rather than volumetric.

Bone Marrow Imaging

- Bone marrow imaging evaluates the hematopoietic compartments of the skeleton for marrow replacement, infiltration, aplasia, and reconversion using

MRI as the primary modality. Normal bone marrow signal depends on the ratio of fat (yellow marrow, bright on T1) to hematopoietic cells (red marrow, intermediate on T1). With aging, conversion from red to yellow marrow progresses centrifugally from the distal extremities toward the axial skeleton. Pathologic marrow replacement (by tumor, fibrosis, or inflammation) results in low T1 signal and variable T2 signal depending on cellularity and water content. STIR (short tau inversion recovery) and fat-saturated T2 sequences suppress fat signal, making pathologic marrow edema more conspicuous. Indications for bone marrow imaging include evaluation of suspected marrow replacement (multiple myeloma, lymphoma, leukemia, metastases), assessment of avascular necrosis (early detection before radiographic changes, with the double-line sign on T2 being pathognomonic), inflammatory arthritis with bone marrow edema, and monitoring of treatment response in hematological malignancies. DWI and ADC mapping help differentiate benign from malignant marrow infiltration.

Bone Scan

- A nuclear medicine imaging study that evaluates the entire skeleton for abnormalities of bone metabolism, using a radiopharmaceutical tracer (technetium-99m methylene diphosphonate, Tc-99m MDP) that is incorporated into the hydroxyapatite crystal matrix of bone at sites of active osteogenesis. The tracer is injected intravenously, followed by imaging 2-4 hours later after skeletal uptake and renal clearance of unbound tracer. Uptake depends on blood flow and osteoblastic activity; increased uptake occurs in fractures, infection, tumors (both primary and metastatic, with osteosarcoma and blastic metastases showing intense uptake), Paget disease of bone (diffuse intense uptake in the af-

fectured bone), arthritis, and heterotopic ossification. Decreased uptake (cold defects) occurs in avascular necrosis, photopenic zones of multiple myeloma (lytic lesions without reactive bone formation), and early osteomyelitis before osteoblastic response develops. The bone scan is highly sensitive but not specific for bone pathology; correlation with radiography or cross-sectional imaging is essential for specificity. The three-phase bone scan (angiographic, blood pool, and delayed phases) adds specificity for infection and fracture non-union. SPECT-CT fusion improves anatomic localisation.

Breast MRI

– The most sensitive imaging modality for breast cancer detection, achieving sensitivity exceeding 95 percent, and is indicated for high-risk screening, staging of known breast cancer, and evaluation of treatment response. The examination uses dedicated breast coils with T1 fat-saturated pre- and post-gadolinium sequences and diffusion-weighted imaging. Kinetic analysis characterizes enhancement patterns: initial rapid enhancement with delayed washout (type 3 curve) is highly suspicious (BI-RADS 4C or 5). Indications include high-risk screening (BRCA mutation carriers, lifetime risk >20 percent, history of chest radiation), evaluation of occult primary breast cancer, assessment of extent of disease in newly diagnosed breast cancer (including multifocal, multicentric, and contralateral disease), monitoring of neoadjuvant chemotherapy response, and problem-solving when conventional imaging is inconclusive. Limitations include lower specificity (increased false positives), need for intravenous gadolinium contrast, high cost, and limited availability. Claustrophobia and MRI-incompatible implants are contraindications. BI-RADS MRI lexicon standardises reporting.

Breast Ultrasound

– A problem-solving tool used to evaluate palpable lumps, distinguish cysts from solid masses, guide interventional procedures, and supplement mammography in women with dense breast tissue. High-frequency linear array transducers (12-17 MHz) provide detailed evaluation of superficial breast structures. Simple cysts appear as anechoic, well-circumscribed masses with posterior acoustic enhancement and thin imperceptible walls, requiring

no further evaluation (BI-RADS 2). Complicated cysts (indistinct walls, internal echoes, thick walls or septations, solid components) require further evaluation with aspiration, biopsy, or short-interval follow-up depending on the degree of suspicion. Solid masses are characterized by shape, margin, orientation (parallel to skin is usually benign, non-parallel is suspicious), echo pattern, and posterior acoustic features. Suspicious features include spiculated margins, angular margins, marked hypoechogenicity, and calcifications. BI-RADS ultrasound lexicon standardises reporting. color Doppler assesses vascularity, and elastography measures tissue stiffness, with malignant lesions typically being harder than benign ones.

Cardiac CT Angiography

– Cardiac CT angiography (CCTA) uses ECG-gated multidetector CT with rapid intravenous contrast administration to evaluate coronary artery anatomy and detect coronary artery disease. Beta-blockers are administered to reduce heart rate below 65 beats per minute for optimal image quality, and sublingual nitroglycerin dilates coronary arteries to improve visualization. Prospective ECG-triggering (acquiring data during diastole only) reduces radiation dose to 1-3 mSv compared to retrospective ECG-gating (acquiring data throughout the cardiac cycle with higher radiation dose of 10-15 mSv). Coronary artery calcium scoring is performed on non-contrast CT, with Agatston score >400 indicating severe calcified plaque burden and high cardiovascular risk. Coronary artery stenosis is graded as none, mild (<50 percent), moderate (50-69 percent), or severe (70 percent or greater). CCTA has a high negative predictive value for excluding obstructive coronary disease (>99 percent) and is indicated for symptomatic patients with low-to-intermediate pre-test probability. Limitations include artefact from high heart rate, arrhythmia, dense coronary calcification limiting stenosis evaluation, and inability to assess hemodynamic significance.

Cardiac MRI

– The reference standard for quantifying ventricular volumes, mass, and function, using ECG-gated steady-state free precession (SSFP) cine sequences that provide excellent myocardial-blood pool contrast. Standard protocols include cine imaging in

short-axis (stack from base to apex), two-chamber, and four-chamber planes for volumetric analysis, T1 and T2 mapping for diffuse fibrosis and edema assessment, late gadolinium enhancement (LGE) for focal fibrosis and scar, and perfusion for myocardial ischemia evaluation. LGE imaging identifies irreversible myocardial injury: ischemic scar appears as subendocardial or transmural hyperenhancement following a coronary artery territory, while non-ischemic patterns include mid-wall (hypertrophic cardiomyopathy), epicardial (myocarditis, sarcoidosis), and global subendocardial (amyloidosis) enhancement. T1 mapping detects diffuse myocardial fibrosis (elevated extracellular volume fraction), and T2 mapping detects myocardial edema (acute myocarditis, stress cardiomyopathy, acute myocardial infarction). CMR is the non-invasive reference standard for assessing biventricular volumes, ejection fraction, and myocardial mass. Indications include assessment of cardiomyopathy (ischemic, dilated, hypertrophic, restrictive, arrhythmogenic right ventricular cardiomyopathy), myocarditis, cardiac masses, pericardial disease, and congenital heart disease. Contraindications include MRI-incompatible devices and severe claustrophobia. Gadolinium-based contrast is contraindicated in advanced renal disease (risk of nephrogenic systemic fibrosis).

Cerebral Angiography

– Digital subtraction cerebral angiography (DSA) remains the gold standard for evaluating intracranial vascular anatomy with superior spatial and temporal resolution compared to CTA or MRA. Femoral or radial artery access is used to catheterize the internal carotid, vertebral, or external carotid arteries, with selective contrast injections and multiple projections demonstrating the circle of Willis, cerebral branches, and venous drainage. Applications include aneurysm evaluation (morphology, neck size, and relationship to parent vessel), arteriovenous malformation evaluation (nidus size, arterial supply, and venous drainage), vasculitis workup, and pre-operative tumor embolisation planning. Advances in 3D rotational angiography and cone-beam CT with flat-panel detectors improve the characterisation of complex vascular anatomy. Risks include stroke (1-2 percent from embolic or thrombotic complications at the catheter tip), access site complica-

tions (haematoma, pseudoaneurysm, arteriovenous fistula), contrast-induced nephropathy, and radiation exposure to the patient and operator.

Chest Radiography

– The most commonly performed imaging examination, providing a frontal and lateral projection of the thoracic structures including lungs, heart, mediastinum, pleura, chest wall, and upper abdomen. The posteroanterior (PA) view minimizes cardiac magnification by placing the heart closer to the detector, while the anteroposterior (AP) portable view is used for critically ill patients. Lateral view localizes lesions in the anterior/posterior dimension and visualizes the retrosternal space, trachea, and thoracic spine. Key findings include pneumonia (airspace opacities, air bronchograms, silhouettes signs), pulmonary edema (bat-wing perihilar distribution, Kerley B lines, pleural effusions), pneumothorax (visceral pleural line, deep sulcus sign in supine patients), pleural effusion (meniscus sign, blunting of costophrenic angle), cardiomegaly (cardiothoracic ratio >0.5), and mediastinal widening (aortic dissection, mediastinal mass, lymphadenopathy). The lateral view is essential for evaluating the retrosternal airspace, retrocardiac lung, and thoracic spine.

Computed Tomography

– A cross-sectional imaging technique that uses a rotating X-ray source and detector array to acquire projection data from multiple angles, which is then reconstructed into axial, sagittal, and coronal images using filtered back projection or iterative reconstruction algorithms. Modern multidetector CT scanners employ 64 to 320 detector rows, enabling rapid volumetric acquisition with sub-millimeter spatial resolution and isotropic voxel dimensions. CT imaging relies on differential X-ray attenuation by different tissues (bone, soft tissue, fat, air, and contrast material) to generate contrast in the image. The CT number (Hounsfield unit, HU) quantifies tissue attenuation: air -1000 HU, fat -100 to -50 HU, water 0 HU, soft tissue 40-80 HU, acute hemorrhage 60-80 HU, unenhanced blood 50-60 HU, and cortical bone >1000 HU. Intravenous iodinated contrast is used to enhance vascular structures, assess perfusion characteristics of lesions, and detect areas of abnormal enhancement. Oral contrast is used

for gastrointestinal imaging, and rectal contrast for colonic studies. CT is the modality of choice for acute trauma, acute abdomen, pulmonary embolism (CTPA), renal colic (CT KUB), and cancer staging. Radiation dose is a concern, particularly in younger patients and those requiring repeated examinations. Dose reduction strategies include iterative reconstruction, tube current modulation, and automatic kV selection. The effective radiation dose for a routine CT chest is approximately 5-7 mSv, and for a CT abdomen/pelvis approximately 8-15 mSv.

Contrast Allergy

– Hypersensitivity reactions to iodinated contrast media ranging from mild cutaneous symptoms to life-threatening anaphylaxis. Mild reactions include urticaria, pruritus, and flushing; severe reactions include laryngeal edema, bronchospasm, hypotension, and cardiovascular collapse. Patients with prior reactions, asthma, or atopy are at increased risk and benefit from corticosteroid and antihistamine premedication. High-risk patients should receive low- or iso-osmolar nonionic agents.

Contrast-Enhanced Mammography

– Contrast-enhanced mammography (CEM) combines the anatomic detail of digital mammography with functional information from iodinated contrast administration, detecting tumor neovascularization that increases contrast uptake in malignant lesions. The technique acquires dual-energy images (low energy at 29-33 kVp and high energy at 49-52 kVp) approximately 2 minutes after intravenous iodinated contrast injection. Logarithmic subtraction of the high-energy from low-energy images produces contrast-enhancement map showing areas of abnormal uptake. The main indication is evaluation of breast abnormalities in women with suspected or known breast cancer when MRI is contraindicated or unavailable. CEM has higher sensitivity than digital mammography alone but lower specificity, with false positives from benign enhancing lesions (fibroadenomas, papillomas, and inflammatory changes). BI-RADS contrast-enhanced mammography lexicon standardises reporting. Limitations include need for intravenous access, iodinated contrast (contraindicated in renal impairment and contrast allergy), and radiation exposure (higher than digital mammography but less than mammography plus MRI).

Contrast-Enhanced Ultrasound

– Contrast-enhanced ultrasound (CEUS) uses intravenous microbubble contrast agents (perfluorocarbon or sulfur hexafluoride gas encapsulated in phospholipid shells) that remain entirely intravascular, enabling real-time assessment of tissue perfusion without nephrotoxicity or radiation. Microbubbles oscillate in an ultrasound field, producing harmonic signals that are detected using low mechanical index (MI less than 0.2) imaging to avoid bubble destruction. Applications include focal liver lesion characterisation (e.g., haemangioma showing peripheral nodular enhancement with progressive fill-in, focal nodular hyperplasia showing central scar enhancement, and metastases showing hypoenhancement with rim enhancement), renal mass characterisation, and non-cardiac chest pain evaluation. Limitations include operator dependence, limited penetration in obese patients, inability to evaluate gas-filled structures, and need for intravenous access and contrast injection. Microbubble contrast agents are contraindicated in patients with right-to-left shunts and known hypersensitivity.

Contrast Medium

– A substance administered to enhance the signal intensity difference between structures of interest and surrounding tissues during radiographic, fluoroscopic, CT, and MRI examinations. Iodinated agents (high-osmolar ionic or low- and iso-osmolar nonionic) are used in CT and fluoroscopy, while gadolinium-based chelates shorten T1 relaxation time in MRI. Low- and iso-osmolar nonionic iodinated agents are preferred for safety.

Contrast Reactions

– Contrast reactions to iodinated and gadolinium-based contrast agents range from mild self-limited symptoms to severe life-threatening anaphylactoid reactions. Iodinated contrast reactions are classified as mild (flushing, pruritus, urticaria - managed with observation and diphenhydramine), moderate (diffuse urticaria, bronchospasm, laryngeal edema, facial edema - managed with IV diphenhydramine, albuterol nebulizer, and IV fluid bolus), and severe (hypotension, cardiac arrhythmias, pulmonary edema, and anaphylaxis - managed with epinephrine, IV fluids, and advanced life support). Risk factors for contrast reactions include prior contrast reaction,

asthma, and atopy. Premedication with corticosteroids and antihistamines is recommended for at-risk patients receiving iodinated contrast. Contrast-induced nephropathy (CIN) is a risk with iodinated contrast in patients with pre-existing renal impairment, with prevention including IV hydration, minimising contrast volume, and using iso-osmolar or low-osmolar contrast agents. Gadolinium-based contrast agents carry a risk of nephrogenic systemic fibrosis in patients with advanced renal disease.

CT Angiography

– CT angiography (CTA) uses multidetector CT with intravenous iodinated contrast to visualize arterial and venous anatomy with high spatial and temporal resolution. Bolus tracking or test bolus techniques time contrast arrival to the vessel of interest. Peripheral CTA evaluates lower extremity aorto-occlusive disease with 3D reconstructions showing stenosis severity, calcification burden, and runoff vessel patency for bypass planning. Aortic CTA detects aneurysms (ascending greater than 5.5 cm, descending thoracic greater than 5.5 cm, abdominal greater than 5.0 cm), dissection (intimal flap, true and false lumens), and traumatic aortic injury (pseudoaneurysm, intimal flap at the aortic isthmus). Mesenteric CTA evaluates superior mesenteric artery occlusion or stenosis in acute mesenteric ischemia. Renal CTA evaluates renal artery stenosis (fibromuscular dysplasia, atherosclerosis), and pre-renal transplant donor evaluation. Cardiac CTA is discussed separately. Limitations include need for iodinated contrast, radiation exposure, and artefact from calcified plaque limiting stenosis evaluation.

CT Coronary Angiography

– A noninvasive ECG-gated multidetector CT examination evaluating coronary artery anatomy and atherosclerotic plaque after intravenous iodinated contrast. Non-contrast coronary calcium scoring (Agatston score) stratifies cardiovascular risk. CT angiography detects and grades coronary stenosis and characterizes plaque as calcified, noncalcified, or mixed. Its high negative predictive value makes it the preferred test for excluding obstructive coronary disease in symptomatic low-to-intermediate-risk patients.

CT Colonography

– A minimally invasive colorectal imaging technique

that uses multidetector CT with CO₂ insufflation to detect colorectal polyps and cancer, serving as an alternative for patients who cannot undergo or refuse optical colonoscopy. Patient preparation includes cathartic bowel cleansing similar to conventional colonoscopy, along with fecal tagging with oral contrast (barium or iodinated) administered with the prep to label residual stool and fluid. Supine and prone CT acquisitions are obtained, and the images are reviewed using 3D endoluminal fly-through visualisation software. Polyps are classified by size (diminutive <5 mm, small 6-9 mm, and large >10 mm), morphology (sessile, pedunculated, and flat), and location. The CT colonography reporting and data system (C-RADS) standardises findings and management recommendations: no polyp or lesion (C-RADS 1) requires no follow-up for 5 years if the patient is average risk; intermediate polyp 6-9 mm (C-RADS 3) requires CT surveillance or optical colonoscopy; and large polyp >10 mm or mass (C-RADS 4) requires optical colonoscopy. Extracolonic findings are reported separately using the C-RADS extracolonic categories (E1-E4). Sensitivity for polyps >10 mm exceeds 90 percent but is lower for smaller polyps. Limitations include radiation exposure, inability to perform biopsy or polypectomy, and limited sensitivity for flat lesions.

CT-Guided Biopsy

– A percutaneous image-guided technique that obtains tissue samples from lesions using CT or CT-fluoroscopy for needle localization, typically via a coaxial or tandem approach. Indications include pulmonary nodules and masses, mediastinal and hilar lesions, abdominal and pelvic masses, and musculoskeletal tumors. Core needle biopsy provides histology; fine needle aspiration provides cytology. Complications include pneumothorax, hemorrhage, infection, and rare needle-tract seeding.

CT Perfusion

– A functional imaging technique that quantifies tissue blood flow by acquiring serial CT images during the first pass of intravenous iodinated contrast, generating parametric maps of cerebral blood volume (CBV), cerebral blood flow (CBF), mean transit time (MTT), and time to maximum (Tmax). The technique requires rapid bolus injection of contrast (40-50 mL at 5-7 mL/sec) followed by acquisition

of 40-50 dynamic images over 45-60 seconds. Post-processing software generates color-coded parametric maps used to identify the ischemic penumbra (tissue at risk but not yet infarcted) in acute stroke. The core infarct is defined by severely reduced CBV (less than 30 percent of normal) and markedly reduced CBF, while the penumbra is defined by prolonged MTT or Tmax with preserved or elevated CBV. The mismatch ratio (penumbra-to-core ratio greater than 1.8) and absolute mismatch volume (greater than 15 mL) are used in selecting patients for endovascular thrombectomy beyond the 6-hour window (DEFUSE-3 and DAWN trial criteria). CT perfusion is also used in oncology to assess tumor angiogenesis, treatment response, and differentiate tumor progression from radiation necrosis. Limitations include radiation exposure, need for good IV access, and susceptibility to motion artefact.

CT Pulmonary Angiography

– The reference standard imaging test for diagnosing pulmonary embolism, using ECG-gated or ungated multidetector CT with rapid intravenous bolus of iodinated contrast timed to opacify the pulmonary arterial tree. The technique requires precise bolus tracking or test bolus timing to achieve peak enhancement (typically 80-150 HU) in the main pulmonary arteries while avoiding excessive contrast in the right heart that produces streak artifact. Acute pulmonary embolism appears as filling defects within the pulmonary arterial lumen on contrast-enhanced CT, with complete occlusion producing the railroad track sign (contrast surrounding a central filling defect in a vessel imaged axially). Chronic PE shows organized, eccentrically located, web-like filling defects and abrupt vessel tapering, along with signs of pulmonary hypertension (enlarged pulmonary artery, right ventricular hypertrophy). The severity of PE is quantified by the clot burden score and by evidence of right ventricular strain (right ventricular-to-left ventricular diameter ratio greater than 1.0 on reconstructed four-chamber views). CTPA is the first-line imaging test for suspected PE in non-pregnant patients with normal renal function, with sensitivity and specificity exceeding 95 percent for proximal PE. Limitations include artefact from breathing, cardiac motion, and suboptimal contrast opacification, as

well as the use of iodinated contrast in patients with renal impairment or contrast allergy.

CT Urography

– A comprehensive imaging technique for evaluating the urinary tract, combining non-contrast, nephrographic, and excretory phase acquisitions to assess the renal parenchyma, collecting systems, ureters, and bladder. The protocol begins with a non-contrast phase for stone detection and baseline attenuation measurement, followed by a nephrographic phase at 90-100 seconds post-contrast injection for renal parenchymal evaluation, and an excretory phase at 7-10 minutes when iodinated contrast is excreted into the collecting system. CTU is primarily indicated for evaluation of haematuria (both microscopic and macroscopic), detection of urothelial tumors (transitional cell carcinoma of the renal pelvis, ureter, and bladder), and assessment of congenital urinary tract anomalies. CTU has largely replaced intravenous urography (IVU) for evaluation of the urinary tract. Limitations include radiation exposure (particularly relevant in younger patients with haematuria, where serial studies may be needed), the need for adequate hydration and renal function for contrast excretion, and artefact from bowel motion or inadequate distension of the collecting system.

Digital Radiography

– Digital radiography (DR) has replaced traditional film-screen radiography by using electronic detectors to acquire, store, and display radiographic images with post-processing capabilities. Direct DR uses amorphous selenium photoconductor panels that convert X-rays directly to electrical signals, while indirect DR uses cesium iodide scintillator screens coupled to amorphous silicon photodiode arrays that convert X-rays to light and then to electrical signals. Advantages over film include wider dynamic range, lower radiation dose for equivalent image quality, immediate image availability, and digital image processing (windowing, edge enhancement, and contrast manipulation). Digital radiography systems also facilitate electronic image storage, distribution, and transmission through PACS (Picture Archiving and Communication System). Limitations include reduced spatial resolution compared to film-screen systems (though this is clinically neg-

ligible), and detector artefact from dead pixels or calibration drift.

Digital Subtraction Angiography

– The gold standard for vascular imaging, using digital image processing to subtract a pre-contrast mask image from contrast-enhanced images, leaving only the contrast-filled vessels. A high-resolution flat-panel detector acquires images at 15-30 frames per second during intra-arterial injection of iodinated contrast. Pixel-by-pixel logarithmic subtraction removes stationary structures (bone, soft tissue) while preserving moving contrast. Motion artifacts from swallowing, breathing, or patient movement degrade image quality and can simulate pathology such as pseudo-stenosis or dissection. DSA is used for diagnostic evaluation of vascular pathology and as the first step of endovascular interventions including angioplasty, stenting, embolisation, and thrombolysis. It is the gold standard for assessing aneurysm morphology, arteriovenous malformation angioarchitecture, and extent of atherosclerotic disease prior to planned revascularisation. Increasingly, DSA is being replaced by non-invasive CTA and MRA for purely diagnostic indications, but it remains essential for guiding and confirming endovascular therapy.

Doppler Ultrasound

– Doppler ultrasound assesses blood flow velocity and direction using the Doppler shift principle: sound waves reflected by moving red blood cells undergo frequency changes proportional to flow velocity. Color Doppler encodes mean velocity and direction as color overlays on B-mode images (typically red toward, blue away from the transducer), providing qualitative flow assessment. Power Doppler displays the amplitude of the Doppler signal without directional information, offering greater sensitivity for slow and low-volume flow. Spectral Doppler (pulsed wave and continuous wave) measures flow velocity at specific locations or along the beam axis, with the velocity waveform providing information about vascular resistance and stenosis severity: a high-resistance waveform is normal in peripheral arteries (triphasic with reverse flow), while a low-resistance waveform is normal in internal carotid, renal, and hepatic arteries. Spectral Doppler criteria for carotid stenosis include peak systolic velocity

thresholds (>125 cm/s for 50-69 percent stenosis, >230 cm/s for 70-99 percent stenosis in the internal carotid artery). Doppler ultrasound is essential for evaluating carotid stenosis, deep vein thrombosis (venous compression ultrasound with absence of flow on color Doppler), organ perfusion (renal artery stenosis, hepatic vascular patency), and fetal well-being (umbilical artery Doppler). Limitations include operator dependence, angle dependence (velocity measurements require a Doppler angle of 60 degrees or less), and inability to visualise through bone or gas.

Double Bubble Sign

– A classic abdominal radiographic sign seen in neonates with complete duodenal obstruction (most commonly Duodenal Atresia). Characterized by two large air-filled gas bubbles: one in the stomach (left upper quadrant) and one in the proximal duodenal bulb (right upper quadrant), with complete absence of distal bowel gas. Strongly associated with Down syndrome (Trisomy 21). Management: nasogastric decompression, IV fluids, and surgical repair (duodenoduodenostomy).

Echocardiogram

– An ultrasound-based diagnostic imaging modality that uses high-frequency sound waves to create real-time images of the heart, allowing comprehensive assessment of cardiac structure, function, and hemodynamics. The standard transthoracic echocardiogram (TTE) obtains images through the chest wall using multiple acoustic windows (parasternal long and short axis, apical, subcostal, and suprasternal notch views) with various ultrasound modes: two-dimensional (2D) echocardiography provides real-time anatomical imaging of cardiac structures in multiple planes, M-mode (motion mode) provides high-temporal-resolution measurements of chamber dimensions and wall thickness, color Doppler enables qualitative assessment of valvular regurgitation and stenosis, pulsed-wave Doppler provides quantitative flow velocity measurements across valves and in the great vessels, and tissue Doppler imaging assesses myocardial velocity for diastolic function evaluation. TTE is the first-line imaging modality for evaluation of systolic and diastolic function, valvular heart disease (stenosis quantified by pressure gradients and valve area, regurgitation by vena contracta width

and effective regurgitant orifice area), pericardial disease (effusion, pericarditis, tamponade), and congenital heart disease. Stress echocardiography uses exercise or pharmacological stress (dobutamine) to detect wall motion abnormalities indicating myocardial ischemia. Transoesophageal echocardiography (TOE) provides superior visualisation of posterior cardiac structures, prosthetic valves, and the left atrial appendage. Limitations include operator dependence, poor acoustic windows in obese patients and those with lung disease, and limited visualisation of the distal ascending aorta and pulmonary arteries.

Fetal MRI

– Fetal MRI provides supplemental imaging when ultrasound findings are inconclusive or require further characterization, using ultrafast sequences (single-shot fast spin echo) to minimize fetal motion artifact without sedation. MRI is typically performed at greater than 20 weeks gestational age when fetal size and myelination provide optimal contrast. The most common indication is evaluation of fetal central nervous system anomalies. CNS findings include ventriculomegaly (atrial width greater than 10 mm), structural CNS abnormalities (agenesis of the corpus callosum, posterior fossa anomalies, holoprosencephaly), and congenital diaphragmatic hernia. Thoracic indications include evaluation of congenital lung lesions (congenital pulmonary airway malformation, pulmonary sequestration, bronchogenic cyst). Abdominal indications include abdominal wall defects (gastroschisis, omphalocele) and renal anomalies. Fetal MRI also plays a role in prenatal counseling and surgical planning for conditions that may require ex-utero intrapartum treatment (EXIT procedure). Safety considerations include the use of 1.5T magnets (avoiding 3T due to increased radiofrequency energy deposition) and avoidance of gadolinium contrast due to fetal risk.

Fluoroscopic Barium Studies

– Fluoroscopic barium studies evaluate the gastrointestinal tract using barium sulfate suspension as positive contrast (radiopaque, appears white) or water-soluble contrast (for suspected perforation) to demonstrate mucosal detail and GI motility. Barium swallow evaluates the esophagus for dysphagia, GERD, strictures, rings (Schatzki ring), webs,

achalasia (bird-beak tapering with dilated esophagus), and motility disorders (scleroderma with distal esophageal dysmotility, diffuse esophageal spasm with corkscrew esophagus and pseudodiverticulosis), and post-surgical evaluation (Nissen fundoplication, gastric sleeve). Barium meal evaluates the stomach and duodenum for ulcers, gastric cancer, and gastric outlet obstruction. Small bowel follow-through evaluates the small intestine for Crohn disease (cobblestoning, string sign of terminal ileal stenosis, wall thickening and separation of loops), obstruction, and malabsorption. Barium enema evaluates the colon for diverticulosis, colorectal cancer (apple-core lesion, annular constricting lesion), polyps, and inflammatory bowel disease. Water-soluble contrast (Gastrografin) is used when perforation is suspected, as it is absorbed from the peritoneal cavity and is safer than barium in this setting. Double-contrast studies (using barium plus air) provide superior mucosal detail compared to single-contrast studies.

Fluoroscopy

– Fluoroscopy provides real-time X-ray imaging by using a continuous or pulsed X-ray beam that passes through the patient and is detected by an image intensifier or flat-panel detector, displaying dynamic motion on a monitor. The image intensifier converts X-rays to light via a cesium iodide phosphor, amplifies the light signal using a photocathode and electron optics, and reconverts to a visible image. Modern flat-panel detectors use amorphous silicon photodiodes with cesium iodide or gadolinium oxysulfide scintillator coupled to amorphous silicon photodiodes. Fluoroscopy is used for a wide range of diagnostic and interventional procedures, including barium studies of the gastrointestinal tract, voiding cystourethrography, hysterosalpingography, arthrography, and guidance for interventional procedures such as angiography, stent placement, and percutaneous biopsies. Digital fluoroscopy with pulsed fluoroscopy reduces radiation dose by acquiring images at lower frame rates (e.g., 7.5 or 15 frames per second rather than 30 fps). Last image hold and fluoroscopy loops reduce the need for separate spot images. Radiation dose management is essential, with dose-area product (DAP) monitoring and ALARA principles applied. Operator and patient protection includes lead aprons, thyroid shields, lead

glasses, and collimation to reduce scatter radiation.

Gadolinium

– Paramagnetic substances used in MRI that shorten T1 relaxation time of nearby protons, producing high T1-weighted signal and improving lesion detection. The free gadolinium ion is toxic, so it is chelated with organic ligands for safe administration. Macrocyclic group II agents with high thermodynamic stability carry the lowest nephrogenic systemic fibrosis risk and are preferred when renal function is reduced.

Gamma Knife

– A non-invasive stereotactic radiosurgery device that delivers precisely focused gamma radiation to intracranial targets. Uses 201 cobalt-60 sources arranged in a hemispherical array, emitting 201 beams that converge at a common focal point (isocentre). The steep dose fall-off outside the target (1-2 mm) spares surrounding tissue. Indications: arteriovenous malformations (AVMs, 70-80% obliteration rate at 3 years), trigeminal neuralgia (70-90% pain relief), acoustic neuroma (vestibular schwannoma), meningioma, pituitary adenoma, cerebral metastases (single or oligometastases), essential tremor (thalamotomy). Fractionation: single-session or hypofractionated (2-5 fractions) for larger targets and metastases adjacent to critical structures. Complications: headache, nausea, alopecia (transient), edema, radiation necrosis (late).

Hampton Hump

– A classic chest radiographic sign of pulmonary infarction secondary to Pulmonary Embolism (PE). Appears as a wedge-shaped, opacified pleural-based consolidation with its apex pointing toward the hilum and base abutting the visceral pleura, most commonly in the lower lung zones. Represents hemorrhagic alveolar necrosis in distal pulmonary tissue.

Hepatic Embolization

– Hepatic embolization encompasses image-guided transcatheter techniques that selectively occlude hepatic arterial blood supply to treat tumors, control hemorrhage, and manage vascular malformations. Transarterial chemoembolization (TACE) delivers concentrated chemotherapy (doxorubicin or cisplatin) mixed with lipiodol and followed by gel foam or drug-eluting beads into the feeding hepatic artery branches supplying hepatocellular carcinoma.

Drug-eluting bead TACE (DEB-TACE) provides more controlled and sustained drug release. Radioembolisation (selective internal radiation therapy, SIRT) uses yttrium-90 (Y-90) microspheres injected into the hepatic artery to deliver targeted radiation to liver tumors, taking advantage of the dual blood supply (tumors derive most of their blood supply from the hepatic artery while normal liver parenchyma receives most from the portal vein). Bland embolisation uses particles alone without chemotherapy. Indications include unresectable hepatocellular carcinoma, colorectal liver metastases, neuroendocrine tumor liver metastases, and hepatic hemorrhage from trauma or rupture. The contraindication is main portal vein thrombosis (except segmental). Post-embolisation syndrome (fever, pain, nausea) is common and self-limiting. Complications include hepatic abscess, tumor lysis syndrome, and non-target embolisation (biliary necrosis, cholecystitis, gastroduodenal ulceration).

Hepatic Imaging

– Hepatic imaging encompasses multiple modalities for evaluating focal liver lesions, diffuse liver disease, and vascular anatomy. Ultrasound serves as the initial screening tool, with diffuse fatty infiltration appearing as increased echogenicity relative to the spleen (bright liver), and focal lesions characterized by echogenicity, vascularity on Doppler, and enhancement patterns. CT liver imaging uses multiphasic protocols: non-contrast (calcifications, hemorrhage), hepatic arterial phase at 30-40 seconds post-injection (hypervascular lesions enhance avidly), portal venous phase at 60-80 seconds (best for hypovascular lesions and portal vein evaluation), and delayed phase at 3-5 minutes (washout assessment). MRI liver imaging uses multiphasic gadolinium-enhanced sequences with diffusion-weighted imaging providing additional information about cellularity, and hepatobiliary-specific contrast agents such as gadoxetic acid providing delayed hepatobiliary phase imaging at 10-20 minutes post-injection, which helps distinguish hepatocellular lesions from non-hepatocellular lesions. Focal liver lesions including haemangioma (flash-filling, peripheral nodular discontinuous enhancement with progressive centripetal fill-in), focal nodular hyperplasia (homogeneous hyperenhancement in the arterial

phase with isoenhancement in portal venous phase and persistent enhancement on delayed phases, central scar T2 hyperintense), hepatic adenoma (hypervascular with variable washout, heterogeneous due to fat or hemorrhage), hepatocellular carcinoma (arterial hyperenhancement with portal venous or delayed washout, capsule, and mosaic architecture), and metastases (variable enhancement, most commonly hypovascular with rim enhancement).

Hepatobiliary Imaging

– Hepatobiliary imaging encompasses multiple modalities for evaluating the liver, biliary tree, and gallbladder. Hepatobiliary iminodiacetic acid (HIDA) scintigraphy (cholescintigraphy) uses Tc-99m mebrofenin or disofenin, which is taken up by functioning hepatocytes and excreted into the bile ducts, providing functional assessment of the biliary system. Normal studies show hepatic uptake within 5 minutes, visualization of the common bile duct and gallbladder by 30-60 minutes, and intestinal activity within 30-60 minutes. Non-visualisation of the gallbladder beyond 4 hours suggests acute cholecystitis or cystic duct obstruction. Delayed biliary-to-bowel transit suggests biliary obstruction, and retained activity in the liver parenchyma with no excretion suggests hepatocellular dysfunction. Hepatobiliary scintigraphy is also used to evaluate bile leaks after hepatobiliary surgery or trauma, biliary-enteric anastomotic patency after hepaticojejunostomy, and sphincter of Oddi dysfunction. Cholescintigraphy with sincalide (cholecystokinin) stimulation can assess gallbladder ejection fraction, with values below 35 percent suggesting chronic acalculous gallbladder disease. Limitations include poor spatial resolution and radiation exposure.

Hysterosalpingography

– A fluoroscopic examination that evaluates the uterine cavity and fallopian tube patency using iodinated contrast instilled through a catheter placed in the uterine cavity. The procedure is typically performed during the follicular phase (days 6-11) of the menstrual cycle to avoid pregnancy and visualize the endometrial cavity optimally. After cervical cannulation, contrast is slowly injected under fluoroscopic guidance, filling the uterine cavity (normal triangular-shaped cavity), filling of the fallopian tubes (normal linear or serpentine opacifica-

tion), and peritoneal spillage (free contrast spreading around bowel loops, confirming tubal patency). Tubal obstruction appears as non-opacification of the tube with intrauterine contrast filling only to the level of obstruction (cornual, isthmic, or fimbrial). Hydrosalpinx appears as a dilated, sac-like tubular structure with mucosal folds. Intracavitary filling defects include endometrial polyps (smooth, avoidable, mobile), submucosal fibroids (round, well-defined, distorting contour), intrauterine adhesions (irregular, angular, non-distensible), and endometrial hyperplasia or carcinoma (irregularity). Advantages of HSG include its ability to evaluate both uterine cavity and tubal patency in a single procedure. Limitations include contrast reaction, vasovagal reaction, pain, and risk of infection (prophylactic antibiotics recommended in patients with history of pelvic inflammatory disease). HSG is contraindicated in pregnancy, active pelvic infection, and current menstrual bleeding.

Hysteroscopy Imaging

– Hysteroscopy provides direct visualization of the uterine cavity using a thin endoscope (hysteroscope) inserted through the cervix, with distension media (saline for diagnostic, glycine or sorbitol for operative) creating a clear viewing space. The procedure is performed as outpatient surgery or in-office diagnostic evaluation. Normal findings include a smooth endometrial cavity with tubal ostia in the cornua and a normal endocervical canal. Pathologic findings include endometrial polyps (pedunculated or sessile) and submucosal fibroids (bulging, distorting the cavity), Asherman syndrome (intrauterine adhesions appearing as irregular, scarred bands), endometrial hyperplasia, and endometrial cancer (irregular, friable, vascular mass). Operative hysteroscopy allows biopsy, polypectomy, myomectomy, adhesiolysis, endometrial ablation, foreign body removal, and tubal cannulation under direct vision. Complications include uterine perforation (1-3 percent, higher with cervical stenosis), fluid overload (from absorption of distension media, particularly glycine), hemorrhage, infection, and gas embolism. Contraindications include pregnancy, active pelvic infection, and cervical malignancy.

Image-Guided Abscess Drainage

– Image-guided percutaneous abscess drainage is a

minimally invasive alternative to surgical drainage for intra-abdominal, pelvic, thoracic, and soft tissue abscesses, using CT, ultrasound, or fluoroscopy for real-time guidance. The technique involves needle puncture of the abscess cavity under sterile conditions, aspiration of pus for culture and sensitivity, followed by placement of an 8-14 French drainage catheter using the Seldinger technique (guidewire placement through the needle, sequential dilation of the tract, and catheter insertion), securing the catheter to the skin with sutures or adhesive devices, and connecting it to a drainage bag. Catheters are flushed with saline twice daily and removed when drain output is minimal (less than 10 mL per day) and clinical signs of infection have resolved. Pre-procedure imaging evaluation (CT or ultrasound) identifies the safest access route, avoiding bowel, solid organs, and major vessels. The success rate for percutaneous abscess drainage exceeds 80 percent for well-defined, unilocular abscesses with a safe access window. Abscesses with multiple loculations, thick pus, or fistulous communication with the bowel may require surgical drainage. Complications include hemorrhage, bacteraemia, sepsis during catheter manipulation, catheter dislodgement, and bowel perforation. Antibiotic coverage should be guided by culture results, with empiric broad-spectrum antibiotics covering Gram-negative and anaerobic organisms started before the procedure.

Image-Guided Biopsy

– A minimally invasive percutaneous technique for obtaining tissue for histologic or cytologic diagnosis using real-time imaging guidance, most commonly ultrasound, CT, or MRI. It is indicated for characterization of imaging-detected masses, staging of known malignancy, and evaluation of infection. Fine needle aspiration provides cytology; core needle biopsy provides histology. A coaxial technique allows multiple samples through a single puncture.

Interventional Neuroradiology

– Interventional neuroradiology encompasses minimally invasive endovascular and percutaneous procedures for diagnosis and treatment of neurovascular diseases, performed through femoral or radial artery access under fluoroscopic and angiographic guidance. Endovascular coiling of cerebral aneurysms uses platinum coils deployed through microcatheters

positioned within the aneurysm sac, with the goal of complete occlusion (Raymond class 1) to prevent re-bleeding. Adjunctive devices include balloon remodeling, stent-assisted coiling, flow diverters (pipeline embolisation device for wide-necked aneurysms of the internal carotid artery), and Woven EndoBridge (WEB) devices for bifurcation aneurysms. Acute stroke intervention includes mechanical thrombectomy with stent retrievers or aspiration catheters for large vessel occlusion. Cerebral vasospasm after subarachnoid hemorrhage is treated with intra-arterial vasodilators (verapamil, milrinone, nicardipine) and balloon angioplasty of proximal spastic segments. Carotid artery stenting is an alternative to carotid endarterectomy for carotid stenosis in high-risk surgical patients. Pre-procedure imaging, careful patient selection, and meticulous technique are essential to minimise periprocedural stroke risk. Complications include stroke (1-3 percent at 30 days for experienced operators), vessel perforation, dissection, groin haematoma, pseudoaneurysm, and contrast-induced nephropathy.

Interventional Radiology

– Interventional radiology (IR) encompasses image-guided minimally invasive procedures that diagnose and treat conditions across virtually every organ system, replacing many open surgical procedures with lower morbidity and faster recovery. Core techniques include percutaneous biopsy (CT or ultrasound-guided), abscess drainage, catheter-directed thrombolysis, embolization, angioplasty and stenting, and thermal ablation. Vascular IR includes for critical limb ischemia, venous disease includes venous access, venous stenting for chronic deep venous occlusion (iliac vein stenting for post-thrombotic syndrome), and inferior vena cava filter placement for recurrent pulmonary embolism despite anticoagulation or contraindication to anticoagulation. Non-vascular IR includes percutaneous biopsy (core needle biopsy for histology, fine needle aspiration for cytology) of lung, thyroid, liver, kidney, prostate, and soft tissue lesions; percutaneous drainage of abscesses, bilomas, urinomas, and seromas; nephrostomy tube insertion for obstructive uropathy; biliary drainage and stenting for obstructive jaundice; percutaneous gastrostomy for nutritional access; and tumor ablation (radiofre-

quency ablation, microwave ablation, cryoablation, irreversible electroporation, and alcohol ablation) for liver, kidney, lung, bone, and soft tissue tumors. Interventional oncology is a rapidly growing subspecialty integrating IR into the multidisciplinary care of cancer patients. IR procedures are typically performed under moderate sedation or general anesthesia, with real-time image guidance (fluoroscopy, CT, ultrasound, or MRI), sterile technique, and careful monitoring of patient vital signs. Complications include bleeding, infection, contrast reaction, radiation injury, and non-target embolisation.

Iodinated Contrast

– Water-soluble radiopaque agents used in CT, fluoroscopy, and angiography that attenuate X-rays through their iodine content. They are classified by osmolality as high-osmolar ionic, low-osmolar non-ionic, and iso-osmolar nonionic, with low- and iso-osmolar agents preferred for lower adverse-reaction rates. Contrast-induced nephropathy presents as a creatinine rise within 48 to 72 hours, prevented by hydration and minimal contrast volume.

Ionizing Radiation

– Radiation with sufficient energy to liberate electrons from atoms, including X-rays, gamma rays, and particulate radiation. Biological effects are stochastic (carcinogenesis, no threshold) or deterministic (tissue damage above a threshold). Risks are managed by the ALARA principle (as low as reasonably achievable), applying justification, optimization, and dose limitation in diagnostic imaging.

Lower GI Series

– A fluoroscopic examination of the colon and rectum performed after retrograde instillation of barium sulfate, often with air contrast (double-contrast technique) to delineate mucosal detail. Indications include colorectal polyps, cancers, strictures, diverticulosis, and inflammatory bowel disease; characteristic findings include the apple-core lesion of annular carcinoma. Largely superseded by colonoscopy and CT colonography. Contraindicated in suspected perforation, severe colitis, and obstruction.

Lymphangiography

– A fluoroscopic procedure that evaluates the lymphatic system by cannulating lymphatic vessels in the feet and injecting oil-based contrast (lipiodol) that opacifies the inguinal, pelvic, and para-aortic

lymph nodes over 24-48 hours. The technique involves subcutaneous injection of blue dye in the web spaces of both feet to identify and isolate lymphatic vessels, followed by cannulation and slow continuous infusion of contrast. Initial images demonstrate the lymph channels and nodes. Delayed images at 24-48 hours show the internal architecture of lymph nodes, including filling defects from metastases or lymphoma. Lymphangiography is now rarely performed, having been largely replaced by CT, MRI (particularly MR lymphangiography), PET-CT, and sentinel lymph node biopsy for most indications. Its remaining indications include evaluation of chylothorax and chylous ascites (identifying lymphatic leaks), pre-operative mapping of lymphatic anatomy, and detection of lymph node metastases in certain cancers (particularly penile and cervical cancer). The procedure is technically challenging, time-consuming, and requires expertise in microsurgical lymph vessel cannulation. Complications include lymphangitis, wound infection, contrast extravasation, oil embolism (lipiodol can cause pulmonary oil embolisation and allergic reactions), and impaired ventilation after extensive pulmonary deposition.

Magnetic Resonance Imaging

– Magnetic resonance imaging (MRI) exploits the magnetic properties of hydrogen protons in water and fat molecules to generate detailed soft tissue contrast without ionizing radiation. In a strong static magnetic field (typically 1.5T or 3T), protons align with the field and precess at the Larmor frequency (63.87 MHz at 1.5T). Radiofrequency pulses at the Larmor frequency tip the net magnetization vector into the transverse plane, and as protons return to equilibrium, they emit detectable signals. Spatial localisation is achieved by applying three orthogonal magnetic field gradients that encode the signal with spatial frequency information (frequency-encoding and phase-encoding gradients), enabling image reconstruction via Fourier transformation by the K-space filling process and the Nyquist-Shannon sampling theorem applied to discrete sampling of spatial frequencies. Key tissue contrast parameters include T1 (spin-lattice or longitudinal relaxation time—the time constant for the net magnetisation vector to return to equilibrium along the longitu-

dinal axis), T2 (spin-spin or transverse relaxation time—the time constant for decay of transverse magnetisation due to irreversible dephasing), T2* (T2 plus dephasing from local magnetic field inhomogeneities), and proton density. T1-weighted sequences (short TR, short TE) provide excellent anatomical detail, with fat appearing bright (short T1) and fluid appearing dark (long T1, dark CSF). T2-weighted sequences (long TR, long TE) highlight pathology that contains fluid or edema, with fluid appearing bright (long T2, bright CSF). FLAIR (fluid-attenuated inversion recovery) suppresses CSF signal on T2-weighted images, making periventricular and cortical lesions more conspicuous. STIR (short tau inversion recovery) suppresses fat signal, useful for bone marrow edema and optic nerve evaluation. DWI measures the Brownian motion of water molecules, with restricted diffusion (e.g., acute stroke, abscess, cellular tumors) appearing as high signal on DWI and low signal on ADC (apparent diffusion coefficient) maps. DTI (diffusion tensor imaging) maps white matter tracts, and PWI (perfusion-weighted imaging) assesses cerebral blood flow. MRA (magnetic resonance angiography) uses time-of-flight or phase-contrast techniques to visualise blood vessels without contrast. MR spectroscopy measures metabolite concentrations (N-acetylaspartate, choline, creatine, lactate) for tissue characterisation. MRI safety considerations include projectile effects from ferromagnetic objects, radiofrequency heating, peripheral nerve stimulation from gradient switching, hearing damage from acoustic noise, and the risks of gadolinium-based contrast agents (nephrogenic systemic fibrosis in advanced renal disease, gadolinium deposition in brain tissues). Claustrophobia affects up to 10 percent of patients. Implant safety is categorised as MRI-safe, MRI-conditional, or MRI-unsafe.

Mammographic BI-RADS

– BI-RADS (Breast Imaging Reporting and Data System) is the standardized reporting framework developed by the American College of Radiology to reduce variability in breast imaging interpretation and management recommendations. BI-RADS Assessment Categories include Category 0 (incomplete evaluation requiring additional imaging), Category 1 (negative with no abnormal findings), Category

2 (benign findings such as calcified fibroadenomas, fat-containing lesions, or simple cysts), Category 3 (probably benign, less than 2 percent chance of malignancy, requiring 6-month follow-up imaging), Category 4 (suspicious abnormality, biopsy recommended, subdivided into 4A, 4B, and 4C with increasing suspicion), Category 5 (highly suggestive of malignancy, biopsy recommended, greater than or equal to 95 percent chance of malignancy), and Category 6 (known biopsy-proven malignancy). BI-RADS also standardises the description of breast composition (a through d: almost entirely fatty, scattered fibroglandular, heterogeneous dense, and extremely dense, with the latter two masking underlying lesions and reducing mammographic sensitivity), findings (masses: shape, margin, density; calcifications: morphology and distribution; architectural distortion; asymmetries; and associated features), and recommendations (e.g., routine screening, short-interval follow-up, biopsy, or surgical consultation). The BI-RADS system also exists for breast ultrasound and breast MRI with similar standardised categories and lexicon.

Mammography

– A dedicated low-dose X-ray imaging technique for breast cancer screening and diagnosis, using specialized equipment with molybdenum or rhodium targets and filters to produce optimal contrast between glandular and adipose tissues. Standard views include craniocaudal (CC) and mediolateral oblique (MLO) projections, with additional spot compression, magnification, and rolled views for problem-solving. Digital mammography uses flat-panel detectors (direct conversion with amorphous selenium) or indirect conversion (cesium iodide scintillator coupled to amorphous silicon photodiodes), with computer-aided detection (CAD) software highlighting suspicious areas for radiologist review. Digital breast tomosynthesis (DBT) acquires multiple low-dose radiographic projections at different angles during a single compression, reconstructing them into thin-slice (typically 1 mm) images that can be scrolled through, reducing tissue superimposition and improving lesion detection and characterisation. Screening mammography is recommended annually for average-risk women starting at age 40 (American College of Radiology and American Cancer Society

guidelines) or biennially from age 50 (US Preventive Services Task Force). Diagnostic mammography is performed for symptomatic women (palpable lump, nipple discharge, skin changes, focal pain) or to evaluate abnormal screening findings. Performance metrics include sensitivity (approximately 75-90 percent overall, lower in dense breasts) and specificity (approximately 85-95 percent). Limitations include false positives with additional imaging and biopsy, false negatives, particularly in dense breasts, and the risk of overdiagnosis of clinically insignificant cancers.

MRI Brain

– MRI of the brain provides superior soft tissue contrast for evaluating neurologic conditions including stroke, neoplasms, demyelination, infection, and congenital anomalies without ionizing radiation. Standard sequences include T1-weighted imaging for anatomy, T2-weighted imaging for pathology, FLAIR for periventricular and cortical lesions, and DWI for acute ischemia. In acute stroke, DWI shows restricted diffusion (high signal on DWI with corresponding low ADC values) within minutes of symptom onset, with FLAIR being negative (DWI-FLAIR mismatch), indicating acute ischemia within the thrombolytic window. MRI with gadolinium demonstrates ring-enhancing lesions in abscesses and brain tumors. MRA evaluates the intracranial and extracranial vasculature for stenosis, occlusion, dissection, aneurysm, and arteriovenous malformations. MR venography (MRV) evaluates dural venous sinus thrombosis. Advanced techniques include functional MRI for eloquent cortex mapping, MR spectroscopy for metabolite analysis, and perfusion-weighted imaging for cerebral blood flow assessment. Contraindications include MRI-incompatible implants, claustrophobia, and inability to lie still for the duration of the examination.

MRI Cardiac Perfusion

– Cardiac MR perfusion imaging evaluates myocardial blood flow by acquiring rapid dynamic images during the first pass of gadolinium-based contrast through the myocardial circulation, detecting areas of reduced perfusion that indicate hemodynamically significant coronary artery disease. The technique uses saturated or ungated fast gradient echo sequences (saturation recovery or inversion recovery prepara-

tion) with high temporal resolution (1-2 images per heartbeat) during vasodilator stress (adenosine or dipyridamole) or during dobutamine stress. The presence of a subendocardial or transmural perfusion defect (a region of hypoenhanced myocardium relative to remote normal myocardium) indicates reduced blood flow in the territory of a hemodynamically significant coronary stenosis (typically >70 percent diameter stenosis). The extent and severity of perfusion defects are graded semi-quantitatively using the 17-segment American Heart Association model: a normal segment shows homogeneous enhancement, a reversible defect (ischemia) shows hypoenhancement during stress that normalises at rest, and a fixed defect (infarct) shows hypoenhancement on both stress and rest images, with corresponding LGE indicating scar. The ischemic burden quantified by stress perfusion (percentage of left ventricular myocardium affected) guides revascularisation decisions: an ischemic burden of more than 10-15 percent is generally considered a threshold for revascularisation in patients with stable coronary artery disease. Limitations include artefact from dark-rim (Gibbs ringing), motion, and arrhythmia, and the need for gadolinium-based contrast and patient cooperation for breath-holding. Contraindications include adenosine (avoid in asthma, high-grade AV block, and severe hypotension), dobutamine (avoid in arrhythmia and uncontrolled hypertension), and gadolinium (avoid in advanced renal disease).

MRI Liver

– MRI of the liver provides the highest contrast resolution for focal liver lesion characterization, using hepatobiliary-specific gadolinium-based contrast agents that are actively transported into functioning hepatocytes via organic anion transporting polypeptides. Gadoxetic acid (Eovist) is taken up by hepatocytes beginning 10 minutes post-injection, producing hepatobiliary phase images where normal liver parenchyma appears bright, and non-hepatocyte-containing lesions (metastases, intrahepatic cholangiocarcinoma) show as hypointense (black) on the hepatobiliary phase. Haemangiomas show characteristic peripheral nodular discontinuous enhancement with progressive centripetal fill-in on dynamic phases, with a very high T2 signal. Focal nodular hyperplasia shows homogeneous arterial phase

hyperenhancement, isoenhancement in portal venous and delayed phases, and isoenhancement or slight hyperenhancement on the hepatobiliary phase (because it contains functioning hepatocytes). Hepatocellular carcinoma in the cirrhotic liver shows arterial hyperenhancement with portal venous or delayed washout, often with a capsule and internal fat (features of LI-RADS 5). Hepatic adenomas are hypervascular with variable washout and may contain macroscopic fat or hemorrhage. Diagnostic accuracy exceeds 90 percent for most focal liver lesion types. The LI-RADS classification system standardises image interpretation and reporting in patients at risk for hepatocellular carcinoma. Limitations include motion artefact from breathing, need for patient cooperation with breath-holding, and the risk of nephrogenic systemic fibrosis in patients with advanced renal disease. Claustrophobia and MRI-incompatible implants are contraindications.

MRI Spine

– MRI of the spine is the gold standard for evaluating spinal cord pathology, disc disease, stenosis, and tumors, providing multiplanar imaging with excellent soft tissue contrast. Standard sequences include sagittal and axial T1-weighted and T2-weighted imaging through the region of interest. T1-weighted sequences show anatomy with CSF appearing dark and fat appearing bright, useful for evaluating bone marrow infiltration (replaced marrow shows low signal on T1). T2-weighted sequences show CSF appears bright, ideal for evaluating disc hydration loss (desiccation), annular fissures, and nerve root compression. Disc herniation is classified by morphology: protrusion (broad-based, focal), extrusion (neck narrower than the herniated portion), and sequestration (free fragment). Spinal stenosis is graded by thecal sac cross-sectional area: mild (100-120 mm²), moderate (80-100 mm²), and severe (<80 mm²). T1-weighted post-gadolinium sequences are essential for evaluating infection (discitis/osteomyelitis shows enhancement of the disc and adjacent vertebral endplates), inflammation (epidural abscess, arachnoiditis), and spinal cord tumors (intramedullary tumors such as ependymomas and astrocytomas enhance, whereas benign syringomyelia does not). STIR sequences are sensitive for bone marrow edema from fracture, infection, or neoplasm. Contraindications

include MRI-incompatible implants and severe claustrophobia.

Musculoskeletal MRI

– Musculoskeletal (MSK) MRI provides detailed evaluation of soft tissues, bone marrow, cartilage, ligaments, and tendons, serving as the preferred modality for most non-osseous pathologies. Standard sequences include T1-weighted (anatomy, bone marrow infiltration), T2 fat-saturated or STIR (edema, fluid), proton density (ligament and meniscus assessment), and post-gadolinium (infection, tumor). Knee MRI evaluates meniscal tears (horizontal cleavage, radial, complex, root), cruciate ligament injuries (anterior cruciate ligament tear: discontinuity, abnormal signal, and non-visualisation; posterior cruciate ligament: usually mid-substance tear; medial collateral ligament: edema and discontinuity; lateral collateral ligament: injury often associated with posterolateral corner injury), and meniscal extrusion. Shoulder MRI evaluates rotator cuff tears (supraspinatus, infraspinatus, subscapularis, teres minor), labral tears (SLAP lesions, Bankart lesions), biceps tendon pathology, and glenohumeral instability. Hip MRI evaluates acetabular labral tears, femoroacetabular impingement (CAM and pincer), avascular necrosis of the femoral head (double-line sign on T2), and stress fractures. Wrist and hand MRI evaluates triangular fibrocartilage complex tears, scapholunate and lunotriquetral ligament injuries, and carpal tunnel syndrome findings. Ankle MRI evaluates ligamentous injuries (lateral ankle ligament complex, syndesmosis, deltoid ligament), Achilles tendinopathy and tears, osteochondral lesions of the talar dome, and sinus tarsi syndrome. MSK MRI can also evaluate soft tissue masses (lipoma, sarcoma, desmoid, nerve sheath tumors), with imaging features including signal characteristics on T1, T2, STIR, and post-gadolinium sequences helping to narrow the differential diagnosis.

Musculoskeletal Radiography

– Musculoskeletal radiography remains the initial imaging modality for evaluating bone and joint pathology, providing high spatial resolution for cortical and trabecular bone detail with rapid acquisition and low cost. Standard evaluation includes at least two orthogonal projections (AP and lateral, or oblique views as needed) of the affected region. Frac-

ture evaluation includes assessment of alignment, joint congruence, fracture pattern, and associated soft tissue swelling. The Salter-Harris classification of pediatric fractures types I through V (I: transverse through the growth plate; II: through the growth plate and metaphysis, the most common; III: through the growth plate and epiphysis; IV: through the metaphysis, growth plate, and epiphysis; and V: compression of the growth plate). Osteoarthritis shows joint space narrowing, osteophytes, subchondral sclerosis, and subchondral cysts. Rheumatoid arthritis shows periarticular osteopaenia, marginal erosions, and joint space narrowing. Ankylosing spondylitis shows sacroiliitis, syndesmophytes, and bamboo spine. Gout shows punched-out erosions with overhanging edges and soft tissue tophi. Healing fractures show periosteal reaction and callus formation. Limitations include limited soft tissue contrast compared to MRI and CT, and inability to detect bone marrow edema.

Musculoskeletal Ultrasound

– Musculoskeletal (MSK) ultrasound provides real-time, dynamic evaluation of tendons, ligaments, muscles, nerves, joints, and superficial soft tissues using high-frequency linear transducers. Ultrasound is the preferred initial modality for rotator cuff evaluation, with complete tears appearing as noncompressible hypoechoic gaps in the tendon with retraction, and partial-thickness tears appearing as focal hypoechoic defects at the articular or bursal surface. Achilles tendon assessment demonstrates tendinopathy (thickened, hypoechoic tendon without fibrillar pattern), partial tears (focal hypoechoic or anechoic defects), and complete tears (full-thickness gap with retraction). Plantar fascia assessment shows thickening (greater than 4 mm), hypoechogenicity, and surrounding edema. Dynamic assessment during muscle contraction and joint movement adds diagnostic information not available on static MRI. Advantages include high spatial resolution, real-time dynamic evaluation, color Doppler for hyperaemia, cost-effectiveness, and lack of ionizing radiation. Limitations include operator dependence, small field of view, limited penetration for deep structures, and inability to visualise through bone cortex or air.

Myelography

– A fluoroscopic procedure involving intrathecal in-

jection of iodinated contrast to evaluate the spinal canal, nerve root sleeves, and thecal sac when MRI is contraindicated or insufficient. Lumbar puncture is performed under fluoroscopic or CT guidance, typically at the L3-L4 or L2-L3 interspace, and approximately 8-15 mL of non-ionic contrast (iohexol or iopamidol) is injected into the subarachnoid space. The patient is positioned on a tilting table and moved into Trendelenburg and reverse Trendelenburg positioning, contrast is seen flowing cephalad and caudally within the thecal sac, outlining the spinal cord, nerve root sleeves (which should be symmetrical with sharp, well-defined margins), and the conus medullaris. Extrinsic compression is indicated by extradural defects (from disc herniation, spondylosis, tumor, or epidural abscess), intradural extramedullary defects (from meningioma, schwannoma, or neurofibroma—filling defects within the contrast column displacing the cord or cauda equina), and intramedullary expansion (from tumor or syringomyelia, widening the spinal cord shadow). Complete block shows a column of contrast that ends abruptly at the level of obstruction. Complications include post-dural puncture headache, contrast reaction, arachnoiditis (from the contrast medium, more common with older ionic oil-based contrast agents such as Pantopaque, now replaced by non-ionic water-soluble agents), and intrathecal hemorrhage. Myelography is most commonly used in conjunction with post-myelogram CT (CT myelography), which provides superior delineation of the spinal canal anatomy and nerve roots.

Nephrogenic Systemic Fibrosis

– A rare fibrosing disorder in patients with severe renal impairment exposed to gadolinium-based contrast, with progressive skin thickening and hardening and involvement of muscle, lungs, and heart. The mechanism is release of toxic free gadolinium from less stable chelates. Onset is weeks to months after exposure, presenting with symmetric skin induration and restricted joint mobility. No consistently effective treatment exists.

Panoramic Radiograph

– An extraoral image capturing a curved anteroposterior view of the maxilla, mandible, dentition, and adjacent structures using a rotating X-ray tube and detector that move synchronously around the

patient. The workhorse examination in dental practice for evaluating dentition, impacted teeth, jaw fractures, and jaw cysts and tumors. Limitations include geometric distortion, limited resolution, and reduced sensitivity for early caries.

Pediatric Abdominal Imaging

– Pediatric abdominal imaging requires age-appropriate protocols, radiation dose reduction, and knowledge of developmental anatomy and common pediatric conditions. Ultrasound is the initial modality for most pediatric abdominal complaints, avoiding radiation and often not requiring sedation. Intussusception (the most common cause of bowel obstruction in children 6 months to 3 years) shows the target sign (concentric rings of echogenicity) on ultrasound with sensitivity exceeding 98 percent, and is treated with fluoroscopic-guided pneumatic or hydrostatic reduction. Pyloric stenosis (the most common cause of gastric outlet obstruction in infants 2-8 weeks) shows the target sign and antropylic canal length >16 mm, wall thickness >4 mm, and diameter >14 mm on ultrasound. Appendicitis in children presents with a non-compressible, blind-ending, thick-walled (greater than 2 mm) tubular structure >6 mm in diameter with surrounding increased echogenicity (echogenic mesenteric fat) and hypervascularity. Midgut volvulus (a surgical emergency in neonates and infants) shows inversion of the superior mesenteric artery and vein on ultrasound (the whirlpool sign), requiring urgent upper GI contrast study to confirm malrotation and volvulus. Necrotising enterocolitis in preterm infants shows pneumatosis intestinalis (gas within the bowel wall) on abdominal radiography. CT and MRI are used selectively in children, with radiation dose optimisation and sedation considerations. Contraindications and alternative imaging strategies (ultrasound first, MRI when available) follow the ALARA principle and Image Gently campaign guidelines for radiation dose reduction.

Pediatric Chest Radiograph

– Pediatric chest radiography requires age-specific technique and anatomic knowledge, with the AP view most common in young children and portable radiography standard in the NICU and PICU settings. Thymic tissue is prominent in infants and young children, appearing as a soft tissue density

in the anterior mediastinum that may simulate a mediastinal mass (sail sign on the left, thymic wave sign where ribs imprint on the soft thymus). The thymus normally involutes with age and should not be mistaken for pathology on follow-up studies (thymic rebound after chemotherapy). Common pediatric chest radiographic findings include pneumonias (round pneumonias are more common in children than in adults, appearing as rounded airspace opacities without air bronchograms), viral pneumonias (perihilar peribronchial thickening, hyperinflation, and atelectasis), congenital lung malformations (congenital pulmonary airway malformation appearing as a multi-cystic air-filled lesion), and foreign body aspiration (hyperinflation on the affected side on expiratory view due to ball-valve obstruction, with mediastinal shift away from the affected side). In the NICU setting, common findings include hyaline membrane disease/respiratory distress syndrome (reticulogranular ground-glass opacities with air bronchograms), transient tachypnoea of the newborn (fluid in the fissures, perihilar streaking, hyperinflation), meconium aspiration syndrome (diffuse coarse opacities with hyperinflation and patchy atelectasis), and complications of prematurity such as bronchopulmonary dysplasia (chronic lung changes, cystic changes, hyperinflation) and pneumothorax. Congenital heart disease evaluation on radiography assesses cardiomeastinal silhouette, pulmonary vascularity (increased in left-to-right shunts, decreased in right-to-left shunts), and the aortic arch position.

Pediatric Imaging

– Pediatric imaging requires specialized knowledge of developmental anatomy, age-appropriate imaging protocols, and radiation dose optimization in children who are more radiosensitive and have longer remaining lifespans for stochastic effects to manifest. ALARA (As Low As Reasonably Achievable) principles mandate using the lowest radiation dose that achieves diagnostic quality, with size-specific dose estimates replacing tube current-time product as the dose metric. Ultrasound is preferred as the initial imaging modality when feasible, and CT reserved for urgent indications such as trauma. MRI is used for problem-solving without radiation, often requiring sedation or general anesthesia for younger

children. Variations in normal pediatric anatomy must be recognised to avoid misinterpretation: the thymus (sail sign), bowel gas patterns in newborns, open fontanelles on head ultrasound (the anterior fontanelle provides an excellent acoustic window for neonatal head ultrasound to evaluate for intraventricular hemorrhage in premature infants, graded I through IV by the Papile classification), and craniosynostosis (premature fusion of the cranial sutures). Common pediatric imaging scenarios include imaging of developmental dysplasia of the hip (Graf classification on ultrasound for infants under 6 months, radiography for older infants), appendicitis (graded compression ultrasound as first-line in children), intussusception (ultrasound diagnosis with the target and doughnut signs), midgut volvulus (upper GI contrast study showing the corkscrew sign of the duodenum), and evaluation of non-accidental injury (skeletal survey for suspected child abuse, looking for classic metaphyseal corner fractures, posterior rib fractures, and healing fractures of different ages). Radiation protection in pediatric imaging includes the use of pediatric-specific protocols, size-based dose modulation, shielding of radiosensitive organs (thyroid, gonads, breast), and avoidance of unnecessary repeat examinations.

Pelvic Ultrasound

– Pelvic ultrasound evaluates the uterus, ovaries, fallopian tubes, and surrounding structures in both gynecologic and non-gynecologic indications, using transabdominal (full bladder, curved array) and transvaginal (endocavitary, high-frequency) approaches. Transvaginal ultrasound provides superior resolution for uterine and ovarian evaluation due to proximity to the transducer. The uterus is assessed for size, position (anteversion vs retroversion), endometrial thickness (premenopausal normal up to 16 mm in postmenopausal women, and normal limits vary by menstrual phase), myometrial assessment (fibroids: well-defined, hypoechoic, causing contour distortion; adenomyosis: diffuse or focal myometrial thickening with a heterogeneous, striated, or cystic appearance, and poor definition of the endometrial-myometrial junction), and adnexal evaluation (ovarian size, follicles, corpus luteum, and masses). Ovarian cysts are common and almost always benign in premenopausal women: simple

cysts are anechoic with thin walls and posterior acoustic enhancement. Complex ovarian masses with solid components, thick septations, or papillary projections raise concern for malignancy, prompting surgical referral and further evaluation with MRI and tumor markers. Endometriosis may present as ovarian endometriomas (homogeneous low-level internal echoes, ground-glass appearance, and no internal vascularity—the chocolate cyst). The adnexa should be assessed for hydrosalpinx, tubo-ovarian abscess, and ectopic pregnancy (adnexal mass separate from the ovary, tubal ring sign, and absence of intrauterine pregnancy). Indications include pelvic pain, abnormal uterine bleeding, infertility evaluation, postmenopausal bleeding, and suspected pelvic mass. Transvaginal ultrasound is the preferred approach for detailed uterine and ovarian evaluation. Limitations include operator dependence and limited field of view. In pregnancy, pelvic ultrasound dates the pregnancy, assesses fetal viability and anatomy, and evaluates for complications such as placenta praevia, placental abruption, and ectopic pregnancy.

PET-MRI

– PET-MRI combines the metabolic and molecular information of PET with the superior soft tissue contrast of MRI in a single examination, reducing radiation exposure compared to PET-CT by eliminating the CT component. Hybrid PET-MRI scanners integrate PET detectors within the MRI bore, requiring MRI-compatible PET detector technology (silicon photomultipliers replacing traditional photomultiplier tubes). Simultaneous PET and MRI acquisition enables temporal correlation between metabolic and anatomical information, improving lesion detection and characterisation. Current clinical applications include neurological oncology (brain tumor evaluation, distinguishing tumor progression from radiation necrosis), dementia imaging (amyloid and tau PET-MRI), cardiac sarcoidosis and myocarditis (FDG PET-MRI), prostate cancer (PSMA PET-MRI), and musculoskeletal infection and tumor evaluation. PET-MRI is also used in pediatric oncology to minimise radiation exposure. Challenges include the need for MR-based attenuation correction of PET data (using Dixon-based segmentation or atlas-based methods rather than CT-based

methods), longer acquisition times than PET-CT, and the limited availability and high cost of hybrid PET-MRI systems. Despite these challenges, PET-MRI is an increasingly important dual-modality imaging tool, particularly when reducing radiation dose in younger patients and when the superior soft tissue contrast of MRI provides a clear advantage over CT.

Plain Film

– A two-dimensional projection image produced by a single X-ray exposure through the body, captured on a digital detector. It remains the initial imaging modality for fractures, chest pathology, and acute abdominal processes including obstruction and perforation, owing to its low cost, speed, and wide availability. Limitations include poor soft tissue contrast, overlapping structures, and lack of cross-sectional information.

Positron Emission Tomography

– A nuclear medicine imaging technique that detects gamma photons produced by the annihilation of positrons emitted from radiopharmaceuticals, providing functional and metabolic information. The most common radiotracer is fluorodeoxyglucose (FDG), a glucose analog labeled with fluorine-18 (half-life 110 minutes), which accumulates in cells with high glucose metabolism such as malignancies, inflammatory cells, and activated brain regions. After intravenous injection, FDG accumulates in tissues with high glucose metabolism and is phosphorylated by hexokinase to FDG-6-phosphate, which is trapped intracellularly (metabolic trapping) and does not undergo further metabolism, enabling imaging of the hexokinase reaction product. Image acquisition occurs approximately 60 minutes after FDG injection, with an increased standardised uptake value (SUV) on delayed images for malignant tissues. The SUV is a semi-quantitative measure of FDG uptake, normalised to injected dose and patient weight, which helps differentiate benign from malignant lesions. Whole-body PET-CT (non-contrast or contrast-enhanced) is the standard for oncological staging, providing fused anatomical and functional images. The maximum SUV (SUVmax) is the most commonly reported metric for FDG uptake intensity. Benign causes of FDG avidity include infection, inflammation (sarcoidosis, tuberculosis, post-surgical

changes, rheumatologic disease), and brown adipose tissue activation (which can be reduced by keeping the patient warm before the scan and by using a low-carbohydrate, high-fat diet the day before the scan). Other PET radiotracers include Ga-68 DOTATATE (somatostatin receptor imaging for neuroendocrine tumors), Ga-68 PSMA (prostate-specific membrane antigen imaging for prostate cancer), F-18 florbetapir and flutemetamol (amyloid PET imaging for Alzheimer disease), F-18 flortaucipir (tau PET imaging), and F-18 DOPA (amino acid transport imaging for brain tumors and hyperinsulinaemic hypoglycaemia). PET-MRI is an alternative to PET-CT that reduces radiation exposure and improves soft tissue contrast, but at higher cost and with longer acquisition times. Limitations of PET include limited spatial resolution (approximately 4-5 mm for clinical PET scanners), false positives from inflammatory processes, false negatives in low-metabolic-rate tumors (e.g., bronchioloalveolar carcinoma, carcinoid, prostate cancer, and mucinous adenocarcinomas), and radiation exposure from both the tracer and the CT component.

Pulmonary Nodule

– A rounded or irregular opacity well delineated from surrounding parenchyma measuring up to 30 mm in diameter, while a mass exceeds 30 mm and is considered malignant until proven otherwise. The Fleischner Society guidelines manage incidentally detected pulmonary nodules based on size, morphology, and patient risk factors. Solid nodules less than 6 mm in low-risk patients require no routine follow-up; nodules 6-8 mm require CT at 6-12 months and consideration of follow-up CT at 3-6 months. Solid nodules 8 mm or larger in high-risk patients require PET-CT, biopsy, or close follow-up at 3 months. Subsolid nodules (ground-glass and part-solid) are managed differently based on size and solid component. Malignant features include spiculated margins, pleural retraction, air bronchograms, and eccentric calcifications. Benign features include diffuse, central, laminated, or popcorn calcifications (granuloma, hamartoma), fat (hamartoma), and stability over two years (benign for solid nodules). The PanCan model (Brock University) and the Lung-RADS classification (for lung cancer screening) provide additional risk stratification. Management fol-

lows Fleischner Society guidelines or the British Thoracic Society guidelines, including follow-up CT surveillance, PET-CT, percutaneous biopsy, surgical resection, or surveillance based on the probability of malignancy. Screening with low-dose chest CT reduces lung cancer mortality by 20-25 percent in high-risk populations (age 50-80, 20-pack-year smoking history, current smokers or those who quit within the past 15 years—United States Preventive Services Task Force criteria). Lung cancer screening eligibility and protocols vary by country.

Radiation

– The emission and propagation of energy through space or matter in the form of waves (electromagnetic radiation) or particles (particulate radiation). In medicine, radiation is used diagnostically (X-rays, CT, nuclear medicine) and therapeutically (radiotherapy). Types relevant to medicine: (1) ionizing radiation—has sufficient energy to remove electrons from atoms, causing ionisation and potential biological damage. Includes X-rays, gamma rays, alpha particles, beta particles, neutrons, and protons. X-rays and gamma rays are electromagnetic radiation with wavelengths ranging from 0.01 to 10 nanometres, produced by X-ray tubes (bremsstrahlung and characteristic X-rays) or radioactive decay. (2) Non-ionizing radiation—lower energy, insufficient to ionise atoms but can heat tissue. Includes ultraviolet (UV), visible light, infrared, microwave, and radiofrequency radiation. Medical imaging uses X-rays (plain radiography, fluoroscopy, CT, angiography) and gamma rays (scintigraphy, SPECT, PET). Ultrasound uses high-frequency sound waves (mechanical waves, not radiation—no ionizing effects). MRI uses radiofrequency pulses in a strong magnetic field. Radiation safety: the stochastic (random) risk of cancer increases with cumulative radiation dose (linear no-threshold model—LNT). The ALARA (as low as reasonably achievable) principle guides radiation use. Typical effective doses: chest X-ray 0.02 mSv, mammogram 0.4 mSv, CT head 2 mSv, CT chest 7 mSv, CT abdomen/pelvis 10 mSv (compare to annual background radiation 2.4 mSv). Pregnant patients: fetal radiation risk is highest in the first trimester; alternative imaging (ultrasound, MRI) should be considered.

Radiation enteritis

– An inflammatory condition of the gastrointestinal tract caused by ionizing radiation exposure during cancer treatment, affecting both acute and chronic phases. Acute radiation enteritis occurs during or within weeks of radiation therapy, characterized by mucosal epithelial damage leading to diarrhea, abdominal cramps, nausea, and bleeding, with symptoms correlating with radiation dose (greater than 45 Gy to the pelvis significantly increases risk). Acute changes on imaging include bowel wall thickening, increased enhancement of the mucosa (stratified or layered enhancement pattern), and submucosal edema (target sign). Chronic radiation enteritis, occurring months to years after radiation, is due to progressive obliterative endarteritis and fibrosis leading to ischemia, stricture formation, fistula development, and bowel obstruction. Chronic changes include mural fibrosis (homogeneous wall thickening with reduced enhancement), strictures with proximal bowel dilation, fistulae (particularly enterovesical and enterovaginal fistulae), and adhesions. The portion of bowel most affected correlates with the radiation field: pelvic radiation primarily affects the rectosigmoid colon and distal ileum; abdominal radiation affects the small intestine; and pancreatic or gastric radiation affects the duodenum and stomach. Management of acute radiation enteritis is supportive, including antiemetics, antidiarrheals, dietary modification, and parenteral nutrition if symptoms are severe. Management of chronic radiation enteritis depends on the specific complication: strictures may be treated with endoscopic dilation or surgical resection, fistulae may require surgical repair, and bleeding from telangiectasias may be treated with endoscopic argon plasma coagulation.

Radiation Sickness

– See Radiation Sickness in Oncology.

Radioisotope

– See Radioisotope in Oncology.

Radiolucent

– Tissues or materials that permit nearly unimpeded X-ray passage and appear dark on radiographic images because of low attenuation. Air and gas are the most radiolucent, followed by fat. Radiolucency is exploited to detect pneumoperitoneum, lucency around implants, and fat-containing lesions such as

lipomas. Attenuation is quantified on the Hounsfield scale (air -1000 HU, fat -100 to -50 HU).

Radiopacity

– Tissues or materials that strongly attenuate X-rays and appear white on radiographic images due to high absorption. Metal (surgical clips, orthopedic hardware), cortical bone, and calcifications are the most radiopaque and cause streak and beam-hardening artefact on CT. Iodinated and barium contrast media are rendered radiopaque to visualize vessels and bowel. Cortical bone exceeds 1000 HU on the Hounsfield scale.

Renal Ultrasound

– The initial imaging modality for evaluating kidney anatomy, hydronephrosis, renal masses, and diffuse renal parenchymal disease, using curved array transducers for adequate depth penetration. Hydronephrosis is graded as mild (central sinus splitting with mild calyceal dilation), moderate (dilated renal pelvis and calyces with preserved parenchyma), or severe (marked dilation with parenchymal thinning), with causes including ureterolithiasis, ureteropelvic junction obstruction, benign prostatic hyperplasia, and retroperitoneal fibrosis causing extrinsic compression at the level of the ureters, pelvic tumors, and neurogenic bladder. Renal size is measured (normal adult kidney length 9-12 cm, with smaller kidneys suggesting chronic kidney disease and larger kidneys suggestive of polycystic kidney disease, diabetic nephropathy, or HIV nephropathy). Renal masses are characterized as simple cysts (anechoic, well-circumscribed, thin imperceptible walls, posterior acoustic enhancement—Bosniak category I, benign), complicated cysts (Bosniak categories II, IIF, III defined by number and thickness of septations, calcification, and nodularity), or solid masses (which are suspicious for renal cell carcinoma unless proven otherwise). Solid masses require further characterisation with contrast-enhanced CT or MRI for definitive characterisation and staging. color Doppler shows flow in renal vessels and can detect renal artery stenosis (parvus et tardus waveform, tardus-parvus spectral Doppler pattern with prolonged acceleration time and reduced peak systolic velocity), and venous thrombosis (absent flow, enlarged kidney with altered echogenicity). Renal parenchymal disease shows increased cortical

echogenicity (grade 1-3), loss of corticomedullary differentiation, and decreased renal length. Bladder evaluation includes wall thickness, presence of masses (transitional cell carcinoma appears as an irregular, papillary, or sessile intraluminal mass), stones, and diverticula (often with a narrow neck). Post-void residual volume is measured after voiding (normal less than 50 mL).

Spinal Cord Compression

– A radiologic emergency requiring urgent imaging and intervention to prevent permanent neurologic deficit. MRI is the reference standard, demonstrating the site, degree, and cause of cord compression with multiplanar capability. Causes include epidural metastatic disease (most common, with breast, lung, prostate, renal, and thyroid primaries), epidural hematoma, epidural abscess-discitis-osteomyelitis, herniated disc (acute cervical or thoracic), primary spinal tumors, and vertebral body collapse from osteoporosis or malignancy (pathological fracture). MRI demonstrates the level of compression (the site of cord deformation), the degree of stenosis (mild, moderate, or severe based on thecal sac cross-sectional area), the presence of cord signal change (T2 hyperintensity indicating cord edema, gliosis, or myelomalacia; T1 hypointensity indicating cavitation or necrosis, both associated with poorer prognosis), and the extent and morphology of the compressive lesion. Management is directed at the cause: surgical decompression (laminectomy, corpectomy, or stabilisation) for acute cord compression, radiotherapy for radiosensitive tumors (lymphoma, myeloma, breast cancer, prostate cancer), and antibiotics with drainage for infection. Corticosteroids (dexamethasone 10 mg IV loading dose followed by 4-6 mg IV every 6 hours) are given immediately to reduce cord edema before definitive treatment in cases of spinal cord compression from metastatic disease. Prognosis depends on the underlying etiology, the severity of the pre-treatment neurological deficit, and the time to treatment. Patients who are ambulatory at presentation have the best prognosis.

Steeple Sign

– A classic anteroposterior (AP) neck radiographic sign of Acute Laryngotracheobronchitis (Croup), caused by Parainfluenza virus. Characterized by subglottic tracheal narrowing forming a tapered

inverted "V" appearance resembling a church steeple. Clinical features: barking cough, inspiratory stridor, and hoarseness in children aged 6 months to 3 years. Managed with nebulized racemic epinephrine and oral dexamethasone.

Thumbprint Sign

- A classic lateral neck radiographic sign of Acute Epiglottitis, historically caused by *Haemophilus influenzae* type b (Hib). Characterized by severe swelling of the epiglottis, making it appear thick and rounded like a human thumb projected into the airway. Pediatric emergency: present with high fever, severe sore throat, drooling, dysphagia, and tripod positioning. Do not attempt direct visualization without airway control prepared.

Thyroid Ultrasound

- The primary imaging modality for evaluating thyroid nodules, with the Thyroid Imaging Reporting and Data System (TI-RADS) standardizing risk stratification and biopsy recommendations. High-frequency linear transducer (12-15 MHz) provides detailed evaluation of nodule echogenicity, composition, shape, margin, and echogenic foci. TI-RADS categories range from TR1 (benign, no FNA) to TR5 (highly suspicious, FNA recommended at 1 cm or greater). Suspicious features include marked hypoechogenicity, taller-than-wide shape (AP greater than transverse), spiculated or irregular margins, microcalcifications, and extrathyroidal extension. Nodule size thresholds for FNA depend on the TI-RADS category: TR3 nodules ≥ 2.5 cm, TR4 nodules ≥ 1.5 cm, and TR5 nodules ≥ 1.0 cm may be considered for FNA. Additional findings on thyroid ultrasound include thyroiditis (Hashimoto thyroiditis shows a heterogeneous, hypoechoic parenchymal pattern with echogenic septations, sometimes with a micronodular pattern and hypervascularity), Graves disease (diffuse, homogeneous, hypoechoic enlargement with marked hypervascularity—thyroid inferno), and substernal extension of a goitre. Cervical lymph node assessment is essential in thyroid cancer evaluation: abnormal nodes are round (rather than oval), lack a fatty hilum, contain microcalcifications, have cystic components, and show peripheral rather than hilar vascularity.

Ultrasound

- Ultrasound imaging uses high-frequency sound

waves (2-18 MHz in clinical practice) transmitted from a piezoelectric transducer into the body, with echoes returning from tissue interfaces to create real-time images. The transducer functions as both transmitter and receiver, with pulse-echo timing determining depth and echo amplitude determining brightness. Ultrasound wave propagation follows the principles of reflection, refraction, and attenuation at tissue boundaries with different acoustic impedances. The amount of echo returning to the transducer depends on the relative difference in acoustic impedance between two tissues (the greater the difference, the stronger the echo, which can be a source of diagnostic information but may also produce artefact). Image resolution is determined by transducer frequency: higher frequencies (10-18 MHz) provide better spatial resolution but less penetration (used for superficial structures such as thyroid, breast, and MSK), while lower frequencies (2-5 MHz) provide deeper penetration but lower resolution (used for abdominal and obstetric imaging). Ultrasound modes include B-mode (brightness mode, the standard 2D gray-scale anatomic imaging mode), M-mode (motion mode for high-temporal-resolution cardiac assessment), color Doppler (flow velocity and direction encoded as color overlays on B-mode images), power Doppler (the amplitude of the Doppler signal, more sensitive for slow flow but without directional information), pulsed-wave spectral Doppler (velocity at a specific site), and continuous-wave spectral Doppler (velocity along the entire beam path). Ultrasound contrast agents (microbubbles) expand the role of ultrasound to functional evaluation and targeted imaging. Artefacts include acoustic shadowing (from calcifications and stones, blocking transmission of sound, producing a dark region posterior to the calcified structure), posterior acoustic enhancement (from fluid-filled structures such as cysts, increasing through-transmission beyond the cyst and producing a bright region), reverberation (from strong reflectors causing multiple parallel echoes), comet tail artefact (from small calcifications or metallic objects), ring-down artefact (from air bubbles), and mirror image artefact. The advantages of ultrasound include the absence of ionizing radiation, real-time imaging, portability, low cost, and wide availability. Limitations include operator dependence, limited penetration through

bone and air, and a small field of view compared to cross-sectional imaging.

Vertebroplasty and Kyphoplasty

– Percutaneous image-guided procedures for painful osteoporotic vertebral compression fractures that have failed conservative management. Vertebroplasty involves direct injection of polymethylmethacrylate (PMMA) bone cement into the fractured vertebral body through a transpedicular approach under fluoroscopic or CT guidance, stabilizing the fracture and providing pain relief in 70-90 percent of patients. Kyphoplasty uses a balloon catheter (inflatable bone tamp) inserted into the vertebral body, inflated to restore vertebral body height and create a cavity, then withdrawn after cement injection under low pressure, which partially reduces the risk of cement extravasation compared to vertebroplasty. Indications include acute or subacute symptomatic osteoporotic vertebral compression fractures (less than 6-8 weeks of pain) refractory to conservative therapy, and painful vertebral metastases. Contraindications include active infection, uncorrectable coagulopathy, and fractures with retropulsion of fragments into the spinal canal. Major complications are rare (less than 2 percent) and include cement extravasation into the spinal canal (epidural space, neural foramen, or disc space), pulmonary cement embolisation (from cement entering the paravertebral veins, migrating to the pulmonary circulation, often asymptomatic but can cause respiratory compromise in severe cases), and infection. Procedural success rates are high, with significant pain relief reported in 70-90 percent of patients within 24-48 hours. Balloon kyphoplasty may provide better restoration of vertebral body height and reduction of kyphotic deformity compared to vertebroplasty, though the clinical significance of this is debated. The evidence base for these procedures has been controversial, with sham-controlled trials (e.g., the INVEST trial) showing no significant benefit over placebo injection, leading to changes in reimbursement and clinical practice guidelines. However, many patients with appropriately selected acute fractures do experience benefit.

VQ Scan

– Ventilation-perfusion (VQ) scintigraphy evaluates pulmonary blood flow and ventilation to diagnose

pulmonary embolism, particularly useful when CT pulmonary angiography is contraindicated (renal failure, contrast allergy, pregnancy). The perfusion phase uses Tc-99m macroaggregated albumin (MAA) particles injected intravenously, which lodge in pulmonary capillaries proportional to regional blood flow. The ventilation phase uses inhaled Tc-99m diethylenetriamine pentaacetic acid (DTPA) aerosol or Technegas (ultrafine carbon particles labelled with Tc-99m). Interpretation uses the PI-OPED criteria (Prospective Investigation of Pulmonary Embolism Diagnosis), which provide the probability of PE based on the size, number, and location of perfusion defects relative to ventilation abnormalities. A normal VQ scan reliably excludes PE. A high-probability scan (two or more large segmental perfusion defects with normal ventilation) has a greater than 85 percent probability of PE. An intermediate-probability scan requires further testing. VQ scanning is preferred over CTPA in younger patients, patients with renal impairment, and those with contrast allergy, as it avoids iodinated contrast. The radiation dose from VQ scanning is comparable to or slightly lower than CTPA. A chest radiograph is required for correlation with VQ findings (to avoid interpreting radiographic abnormalities as perfusion defects and to exclude an alternative cause for the perfusion abnormality). Limitations include indeterminate results in patients with underlying lung disease causing ventilation abnormalities (COPD, asthma, pneumonia, atelectasis, pleural effusion), and reduced specificity in these patients (intermediate-probability scans are common).

Westermark Sign

– A classic chest radiographic sign of acute Pulmonary Embolism (PE). Characterized by a focal area of pulmonary oligemia (decreased vascular markings) distal to an occluded pulmonary artery, resulting from downstream hypoperfusion. High specificity for PE on chest X-ray.

Whole-Body CT

– A single CT acquisition from vertex to symphysis pubis in polytrauma to rapidly identify life-threatening injuries. The standard protocol is non-contrast CT of head and cervical spine, then contrast-enhanced CT of chest, abdomen, and pelvis, often with CT angiography. It has high sensitivity

for intracranial hemorrhage, pneumothorax, and solid organ injury, at the cost of radiation dose and iodinated contrast.

Chapter 37

Physical Medicine & Rehabilitation

ASIA Impairment Scale (Spinal Cord Injury)

- Standardized neurological classification system developed by the American Spinal Injury Association (ASIA) to grade the severity of spinal cord injury (SCI) based on sensory and motor testing of specific dermatomes and myotomes. Categories: Grade A (Complete—no sensory or motor function preserved in sacral segments S4–S5), Grade B (Incomplete—sensory preserved below neurological level including S4–S5, no motor function), Grade C (Incomplete—motor function preserved below level, > 50% of key muscles have grade < 3 strength), Grade D (Incomplete—motor preserved, ≥ 50% of key muscles have grade ≥ 3 strength), and Grade E (Normal). Essential for functional prognosis and guiding rehabilitation.

Assistive Technology

- Any item, piece of equipment, or product system used to increase, maintain, or improve the functional capabilities of individuals with physical, sensory, or cognitive disabilities. Examples in rehabilitation: mobility aids (canes, crutches, walkers, manual/power wheelchairs), orthotic and prosthetic devices, environmental control units (ECUs), augmentative and alternative communication (AAC) devices, adaptive eating utensils, and voice-activated software.

Autonomic Dysreflexia

- Potentially life-threatening hypertensive emergency occurring in individuals with spinal cord injuries at or above the T6 spinal level. Triggered by noxious sensory stimuli below the level of injury, most commonly bladder distension (catheter blockage, urinary retention) or bowel impaction. Pathophysiology: uninhibited sympathetic response below the

lesion causes severe vasoconstriction and paroxysmal hypertension; intact parasympathetic compensation above the lesion causes bradycardia, profuse sweating, flushing, and severe throbbing headache. Management: sit patient upright, loosen restrictive clothing, identify and remove trigger (catheterize bladder, disimpact bowel), and administer rapid-acting antihypertensives (nitropaste, nifedipine) if blood pressure remains elevated.

Barthel Index

- Validated ordinal scale measuring performance and level of independence in 10 basic activities of daily living (feeding, bathing, grooming, dressing, bowel control, bladder control, toilet use, transfers, mobility, stair climbing); total score ranges from 0 (completely dependent) to 100 (fully independent).

Biofeedback

- Mind-body rehabilitation technique utilizing electronic monitoring instruments to provide real-time visual or auditory feedback on unconscious autonomic or motor functions (muscle tension, heart rate), facilitating voluntary self-regulation.

Biologic Heart Valve (Bioprosthetic Valve)

- A prosthetic heart valve made from animal tissue (bovine pericardium or porcine aortic valve) mounted on a stent. Types: stented (most common: Carpentier-Edwards Perimount, Medtronic Hancock II), stentless (e.g., Medtronic Freestyle, for aortic root replacement), and sutureless/rapid-deployment (e.g., Edwards Intuity, for minimally invasive surgery). Tissue is treated with glutaraldehyde to reduce immunogenicity and often with anticalcification treatments (ThermaFix, Linx AC). Advantage: no need for lifelong anticoagulation (unlike mechanical valves). Disadvantage: structural

valve degeneration (SVD) over 10-20 years, especially in younger patients and in the mitral position. Durable about 15-20 years in patients >65, and 8-12 years in patients <60. Transcatheter valve-in-valve (ViV) can treat SVD without redo surgery. Porcine valves (vs. bovine pericardial) have slightly higher reoperation rates.

Bioprosthetic Valve Degeneration

– Structural valve deterioration occurs in 20-30% of bioprosthetic valves by 10-15 years, more rapidly in younger patients. Manifests as stenosis or regurgitation from calcification and leaflet tearing. Risk factors: younger age, renal failure, hyperparathyroidism. TAVR-in-SAVR (valve-in-valve) is an option for high-risk surgical patients. Transcatheter bioprosthetic valve fracture may improve hemodynamics. Anticoagulation is not required long-term.

Bowel and Bladder Retraining

– Structured rehabilitation protocol establishing scheduled voiding and bowel elimination routines, pelvic floor muscle exercises, and reflex triggering to regain continence following spinal cord injury, stroke, or neurogenic bladder.

Cardiac Rehabilitation

– A supervised program of exercise, education, and counseling for patients with cardiovascular disease. It includes exercise training, risk factor modification, nutrition counseling, and psychosocial support. Cardiac rehab reduces cardiovascular mortality by 20-25% and improves functional capacity, quality of life, and adherence to medical therapy. It is recommended for patients after MI, PCI, CABG, heart failure, and valve surgery.

Cardiac Rehabilitation Phases

– Phase I: in-hospital mobilization and education. Phase II: outpatient supervised exercise and risk factor modification (6-12 weeks post-discharge, 36 sessions). Phase III: long-term maintenance with unsupervised or community-based exercise. Cardiac rehab improves survival, functional capacity, and quality of life while reducing recurrent cardiovascular events and rehospitalization. Despite proven benefits, participation rates remain suboptimal.

Constraint-Induced Movement Therapy (CIMT)

– Evidence-based neuro-rehabilitation intervention designed to improve motor function in the paretic

upper extremity following stroke or traumatic brain injury. Involves constraining the non-affected arm in a mitt or sling for 90% of waking hours over a 2-week period, while forcing intensive, repetitive, task-oriented functional training of the affected limb. CIMT overcomes learned non-use and drives activity-dependent neuroplastic cortical reorganization.

Contracture Prevention

– Proactive physical therapy interventions (passive stretching, static splinting, proper positioning, serial casting) designed to prevent permanent shortening of periarticular soft tissues, tendons, and muscles in immobilized or spastic limbs.

Dysarthria Therapy

– Targeted speech-language therapy aimed at improving speech clarity, respiratory support, vocal resonance, and articulation in patients with motor speech impairment secondary to stroke, Parkinson's disease, or ALS.

Dysphagia Management

– Comprehensive interdisciplinary speech-language pathology intervention utilizing modified food textures (pureed diet, thickened liquids), postural maneuvers (chin-tuck, head turn), and neuromuscular electrical stimulation to prevent aspiration pneumonia.

Electromyography (EMG)

– Recording of electrical activity from muscles at rest and during contraction. Needle EMG: insertion activity, spontaneous activity (fibrillations, fasciculations), motor unit action potentials, and recruitment pattern. Indications: differentiate myopathic from neuropathic disorders, identify nerve root or peripheral nerve pathology (radiculopathy, neuropathy), and evaluate neuromuscular junction disorders. Abnormal spontaneous activity (fibrillation potentials, positive sharp waves): denervation.

Electromyography (EMG) and Nerve Conduction Studies (NCS)

– Electrodiagnostic testing procedures used to evaluate the functional integrity of the peripheral nervous system (alpha motor neurons, nerve roots, plexus, peripheral nerves, neuromuscular junction, and skeletal muscles). NCS assesses nerve conduction velocity, amplitude, and latency of sensory and motor action potentials, differentiating

demyelinating from axonal neuropathies. Needle EMG evaluates electrical activity of muscle fibers at rest and during voluntary contraction, detecting fibrillations/fasciculations (denervation) and motor unit action potential (MUAP) morphology changes (neuropathic vs. myopathic pattern). Indications: radiculopathy, carpal tunnel syndrome, peripheral neuropathy, ALS, myasthenia gravis, and myopathy.

Electromyography (EMG) Biofeedback

- Neuromuscular re-education technique utilizing surface sensors to convert skeletal muscle electrical activity into visual or auditory cues, assisting patients in voluntarily contracting weak muscles or relaxing hypertonic spastic muscles.

Functional Independence Measure (FIM)

- Standardized 18-item assessment tool widely used in inpatient rehabilitation facilities to evaluate a patient's level of disability and burden of care across self-care, sphincter control, mobility, locomotion, communication, and social cognition. Each item is rated on a 7-point ordinal scale ranging from 1 (total assistance required) to 7 (complete independence). Tracks functional progress during rehabilitation and assists in outcome measurement and discharge planning.

Gait Analysis

- Systematic study of human locomotion, evaluated through observational clinical assessment or computerized motion analysis laboratories (force plates, high-speed infrared cameras, surface electromyography). Key gait cycle phases: Stance phase (60%: heel strike, loading response, mid-stance, terminal stance, pre-swing) and Swing phase (40%: initial swing, mid-swing, terminal swing). Identifies pathological gait patterns such as antalgic gait (pain-avoiding), Trendelenburg gait (gluteus medius weakness), steppage gait (foot drop/peroneal nerve palsy), spastic gait (scissors gait in cerebral palsy), and ataxic gait. Guides orthotic prescription and surgical planning.

Gait Training

- Specialized physical therapy program aimed at evaluating, restoring, and improving a patient's walking ability, posture, cadence, and balance following stroke, spinal cord injury, or orthopedic surgery;

utilizes parallel bars, body-weight supported treadmills, and assistive devices.

Hereditary Spastic Paraplegia

- A group of genetic disorders characterized by progressive spasticity and weakness of the lower extremities, resulting from degeneration of the corticospinal tracts. Over seventy different genetic loci have been identified (SPG1 through SPG70-plus). The most common form is SPG4, caused by mutations in the spastin gene (ATL4), accounting for approximately forty percent of autosomal dominant HSP. HSP is classified as uncomplicated (pure) when spastic paraplegia is the only finding (most cases), and complicated when accompanied by additional neurological features such as ataxia, intellectual disability, neuropathy, epilepsy, or extrapyramidal signs. Onset is typically insidious in childhood or early adulthood, with slow progression over decades. Clinical features include progressive spasticity and weakness in the legs, causing a stiff-legged, scissoring gait, hyperreflexia, extensor plantar responses, and urinary urgency. Sensation, cognition, and cranial nerves are generally spared in pure HSP. Diagnosis is clinical with family history, supported by neuroimaging (MRI spine and brain to exclude structural causes such as compressive myelopathy or multiple sclerosis), neurophysiology to detect subclinical neuropathy or denervation, and genetic testing using multi-gene panels or whole-exome sequencing for the numerous causative genes. Management is symptomatic and includes physiotherapy and stretching to maintain flexibility, treatment of spasticity with oral baclofen, tizanidine, and dantrolene, botulinum toxin injections for focal spasticity, and assistive devices for gait. Disease-modifying therapies are not yet available. Prognosis is variable but progression is generally slow, and most patients remain ambulatory into later life.

Heterotopic Ossification

- Formation of mature lamellar bone within soft tissue structures (muscles, tendons, ligaments) surrounding major joints, occurring as a complication of central nervous system injury (traumatic brain injury, spinal cord injury), severe burns, or total joint arthroplasty. Most common sites: hip, elbow, knee, and shoulder. Clinical features: localized swelling, warmth, erythema, fever, and progressive

loss of joint range of motion. Diagnosis: elevated serum alkaline phosphatase, triple-phase bone scan (early detection), and X-rays (mature ossification). Prevention and treatment: NSAIDs (indomethacin), single-dose local radiation therapy, bisphosphonates, and surgical excision once the ectopic bone has fully matured.

Hydrotherapy

- Rehabilitation therapy performed in heated aquatic pools, utilizing water buoyancy to reduce joint weight-bearing impact, hydrostatic pressure to diminish peripheral edema, and water resistance to build muscle strength.

Mind-Body Exercise

- Mind-body exercise integrates physical movement with intentional focus on breath, body awareness, and mental concentration, including yoga, Tai Chi, Qigong, and Pilates. Yoga combines postures (asanas), breathing techniques (pranayama), and meditation; systematic reviews demonstrate benefit in reducing low back pain, improving flexibility, strength, and balance, and decreasing anxiety and depressive symptoms. Tai Chi—a slow, flowing Chinese martial art emphasizing weight shifting, coordination, and breath synchronicity—is effective for fall prevention in older adults (reducing fall risk by 30%), improving balance in Parkinson’s disease, and reducing pain in knee osteoarthritis. Mechanisms include modulation of the autonomic nervous system (increased parasympathetic activity), hypothalamic–pituitary–adrenal axis regulation, and enhanced interoceptive awareness. Mind-body exercise is low-impact, accessible, and can be adapted for various fitness levels and health conditions.

Neurogenic Bladder Management

- Comprehensive therapeutic strategy for managing lower urinary tract dysfunction resulting from neurological disease or injury (spinal cord injury, multiple sclerosis, Parkinson’s disease, stroke). Dysfunctions: detrusor hyperreflexia/overactivity (incontinence), detrusor sphincter dyssynergia (high voiding pressures, reflux), or detrusor areflexia/underactivity (retention). Goals: protect upper urinary tract (prevent hydronephrosis and renal failure), maintain low bladder storage pressures, prevent urinary tract infections, and achieve social continence. Strategies: clean intermittent catheterization (CIC, gold stan-

dard), anticholinergic/beta-3 agonist medications, botulinum toxin intravesical injections, external condom catheters, and sacral neuromodulation.

Neurorehabilitation

- Complex, interdisciplinary medical specialty focused on aiding recovery from nervous system injuries (stroke, traumatic brain injury, spinal cord injury, cerebral palsy) by promoting neuroplasticity, restoring functional capacity, and compensating for neurological deficits.

Occupational Therapy (OT)

- Allied health profession focused on enabling individuals of all ages to participate in meaningful daily occupations (self-care, work, leisure, education) despite physical, cognitive, sensory, or psychosocial impairments. In rehabilitation, OT assesses and treats upper extremity function, fine motor coordination, cognitive processing, visual-spatial skills, adaptive equipment needs, home environmental modifications, and ergonomics to maximize functional autonomy.

Orthotics

- Field of allied health concerned with the design, fabrication, fitting, and alignment of external devices (orthoses or braces) applied to the body to modify structural and functional characteristics of the neuromuscular and skeletal systems. Functions: control, restrain, or immobilize a joint; reduce weight-bearing forces; correct deformity; or assist weak muscles. Examples: Ankle-Foot Orthosis (AFO for foot drop), Knee-Ankle-Foot Orthosis (KAFO), Thoracolumbosacral Orthosis (TLSO back brace), and wrist extension splints.

Paraplegia

- Paralysis of the lower extremities, with or without loss of bladder, bowel, and sexual function, caused by damage to the spinal cord. The most common causes include spinal cord injury (traumatic, from motor vehicle accidents, falls, and sports injuries), spinal cord compression (from tumors, epidural abscess, or disc herniation), spinal cord infarction (anterior spinal artery occlusion), transverse myelitis, and demyelinating diseases such as multiple sclerosis. The level of the spinal cord lesion determines the amount of residual function, with lower thoracic lesions preserving arm and hand function but causing paraplegia, and higher lesions causing more

extensive paralysis. Complete spinal cord injury results in complete loss of motor and sensory function below the level of the lesion (ASIA A), while incomplete injury preserves some function below the level (ASIA B-D), with central cord syndrome, anterior cord syndrome, Brown-Sequard syndrome, and conus medullaris syndrome being recognised incomplete spinal cord injury syndromes. Management includes acute stabilisation and surgical decompression for traumatic causes, treatment of the underlying cause (radiotherapy for tumors, antibiotics for infection, corticosteroids for inflammation), and lifelong rehabilitation to maximise functional independence. Prognosis depends on the level and completeness of injury, with the best recovery in incomplete injuries.

Periprosthetic Fractures

– Periprosthetic fractures: Vancouver classification (hip): A (trochanteric), B (stem level: B1 stable, B2 loose, B3 loose + bone loss), C (distal to stem). Treatment: A: ORIF if displaced; B1: ORIF (cable plate); B2: revision stem (long, cementless, distal fixation); B3: revision + allograft/augment. UCS classification (knee): femoral, tibial, patellar. Treatment: ORIF if stable implant; revision if loose.

Periprosthetic Joint Infection

– Periprosthetic joint infection (PJI): MSIS criteria (major: sinus tract, two positive cultures; minor: elevated serum CRP/ESR, synovial WBC/PMN, positive histology, single positive culture). Acute postop (<4 weeks) or acute hematogenous: debridement, antibiotics, implant retention (DAIR) with polyethylene exchange. Chronic: one-stage (debridement, exchange, antibiotics) or two-stage (resection, spacer, antibiotics 6 weeks, reimplantation) exchange. Antibiotics: organism-specific, biofilm-active biofilm-active (rifampin for staph, ciprofloxacin for gram-negative). Prevention: preoperative antibiotics, skin preparation, laminar flow, antibiotic cement, optimisation of medical comorbidities. Outcomes: 80-90 percent success for two-stage exchange, 70-80 percent for one-stage, 60-80 percent for DAIR.

Physical Medicine and Rehabilitation (PM&R)

– Medical specialty (also known as Physiatry) focused on the diagnosis, prevention, and non-surgical treatment of physical and cognitive impairments result-

ing from musculoskeletal conditions, neurological injuries, and complex chronic disabilities. Physiatrists lead interdisciplinary teams (comprising physical therapists, occupational therapists, speech-language pathologists, rehabilitation nurses, and psychologists) to restore maximal functional capability, mobility, and quality of life. Subspecialties: brain injury medicine, spinal cord injury medicine, pediatric rehabilitation, sports medicine, pain medicine, and neuromuscular medicine.

Physical Therapy

– A healthcare profession that uses evidence-based interventions to restore, maintain, and optimize movement, function, and quality of life across the lifespan after injury, surgery, or in chronic conditions. Components: therapeutic exercise (strengthening, stretching, range of motion, aerobic conditioning, balance training), manual therapy (joint mobilization/manipulation, soft tissue massage, myofascial release, stretching), modalities (therapeutic ultrasound, electrical stimulation—TENS, NMES, iontophoresis, phonophoresis, heat/ice, traction), functional training (gait training, transfer training, ergonomic assessment), and patient education. PT is first-line treatment for many musculoskeletal conditions (low back pain, knee osteoarthritis, rotator cuff tendinopathy, patellofemoral pain syndrome), postoperative rehabilitation (joint replacement, ACL reconstruction, rotator cuff repair), neurologic conditions (stroke, Parkinson's, spinal cord injury, multiple sclerosis), vestibular disorders, and fall prevention. Evidence supports early PT for acute low back pain reduces chronicity; supervised exercise is superior to home exercise alone for most conditions. Physical therapists are licensed doctoral-level practitioners (DPT) with direct access in all US states.

Physical Therapy (PT)

– Allied health profession focused on evaluating and treating individuals with physical impairments, movement dysfunctions, pain, or functional limitations resulting from injury or disease. Interventions: therapeutic exercise (strengthening, aerobic conditioning, flexibility training), manual therapy (joint mobilization, soft tissue manipulation), neuromuscular re-education, balance and gait training, physical modalities (heat, cold, electrical stimulation, ultra-

sound), and patient education to restore functional mobility and prevent disability.

Prosthetic Joint Infection

- PJI definition (MSIS): major (sinus tract, 2+ positive cultures), minor (elevated serum CRP/ESR, synovial WBC >3000 or PMN >80).

Prosthetics

- Specialty of allied health dedicated to the evaluation, design, fabrication, custom fitting, and alignment of artificial limb replacements (prostheses) for individuals with upper or lower extremity amputations. Lower limb prostheses (transfemoral, transtibial) incorporate sockets, suspension systems, prosthetic knee units, and energy-storing carbon fiber feet. Upper limb prostheses range from passive body-powered devices to advanced myoelectric limbs controlled by muscle surface electromyographic signals.

Prosthetic Valve Endocarditis

- Infection of prosthetic (mechanical or bioprosthetic) heart valves, classified as early (<60 days post-surgery, typically nosocomial) or late (>60 days, typically community-acquired). Causative organisms differ from native valve endocarditis: early PVE often due to *S. aureus*, gram-negative bacilli; late PVE similar to native valve organisms. Higher morbidity and mortality than native valve endocarditis. Often requires surgical intervention in addition to prolonged antibiotic therapy.

Pulmonary Rehabilitation

- Comprehensive intervention including exercise, education, and behavioral modification for chronic respiratory diseases. Improves exercise capacity, reduces dyspnea, and reduces hospitalizations. Recommended for symptomatic COPD.

Quadriplegia

- Paralysis of all four extremities, with or without loss of trunk, bladder, bowel, and sexual function, caused by damage to the cervical spinal cord. the most common causes include traumatic spinal cord injury (motor vehicle accidents, diving accidents, falls), cervical disc herniation, cervical spinal stenosis with myelopathy, spinal cord tumors, demyelinating diseases, and inflammatory myelopathies. the level of the cervical lesion determines the extent of functional impairment. c1-c4 lesions cause quadriplegia with respiratory compromise (diaphrag-

matic paralysis if c3-c5 is affected, requiring mechanical ventilation), and patients may need a phrenic nerve pacemaker. c5 lesions preserve shoulder abduction and elbow flexion. c6 lesions allow wrist extension. c7 lesions allow elbow extension and finger extension. c8-t1 lesions allow hand intrinsic function. incomplete spinal cord injury syndromes include central cord syndrome (most common incomplete syndrome, typically from hyperextension injury in cervical spondylosis, affecting the arms more than the legs due to the somatotopic organisation of the corticospinal tract), anterior cord syndrome (loss of motor function and pain/temperature sensation with preserved proprioception due to anterior spinal artery infarction), and brown-sequard syndrome (hemisection with ipsilateral motor loss and contralateral pain/temperature loss). management includes acute stabilisation, surgical decompression for compressive causes, rehabilitation, and lifelong multidisciplinary care to prevent complications such as pressure ulcers, urinary tract infections, autonomic dysreflexia, spasticity, contractures, and respiratory infections. prognosis depends on the level and completeness of injury, with complete cervical injuries having the poorest prognosis for functional recovery.

Restless Legs Syndrome (RLS) and Periodic Limb Movement Disorder

- Restless legs syndrome is a neurological disorder characterized by an uncontrollable urge to move the legs, often accompanied by uncomfortable sensations such as tingling, crawling, or aching, typically worsening during periods of rest or at night. Periodic limb movement disorder involves repetitive, involuntary jerking or twitching of the legs during sleep, which can fragment sleep and cause daytime fatigue. Both conditions are related and often occur together; treatment may include lifestyle modifications, iron supplementation if deficient, and medications such as dopamine agonists or gabapentin.

Range of Motion (ROM) Exercises

- Therapeutic joint mobilization exercises designed to maintain or improve articular flexibility and prevent joint stiffness. Categorized into Passive ROM (therapist moves joint), Active-Assisted ROM, and Active ROM (patient moves joint independently).

Rehabilitation

– A multidisciplinary process aimed at restoring and optimising physical, cognitive, social, and psychological function in individuals with disabling conditions, enabling them to achieve the highest possible level of independence and quality of life. Rehabilitation addresses impairments (loss of body function—weakness, pain, reduced range of motion), activity limitations (difficulty performing tasks—walking, dressing, bathing), and participation restrictions (social, vocational, recreational). Settings: inpatient rehabilitation units (stroke, traumatic brain injury, spinal cord injury, amputation, major trauma, post-surgical), outpatient rehabilitation (musculoskeletal injuries, chronic conditions), and community-based rehabilitation. Core rehabilitation disciplines: physiotherapy (mobility, strength, balance, gait training), occupational therapy (activities of daily living, upper limb function, cognitive rehabilitation, home modifications), speech and language therapy (communication, swallowing, voice), orthotics and prosthetics, psychological support (adjustment to disability, mood disorders, pain management), social work (discharge planning, benefits, community resources), and rehabilitation nursing. Specific rehabilitation programs: cardiac rehabilitation (exercise, education, risk factor modification—reduces mortality by 20–25% after MI), pulmonary rehabilitation (COPD—improves exercise capacity, quality of life, reduces hospitalisations), stroke rehabilitation (early mobilisation, task-specific training, constraint-induced movement therapy), and neurological rehabilitation (multiple sclerosis, Parkinson disease, spinal cord injury). The WHO International Classification of Functioning, Disability and Health (ICF) provides a biopsychosocial framework for rehabilitation assessment and goal setting.

Spasticity Management

– Multimodal therapeutic approach to control hyper-tonia, characterized by velocity-dependent increase in muscle tone and exaggerated deep tendon reflexes resulting from upper motor neuron lesions (stroke, spinal cord injury, cerebral palsy, multiple sclerosis). Consequences of untreated severe spasticity: painful muscle spasms, joint contractures, skin breakdown, and functional impairment. Treatment options: physical stretching and splinting,

oral muscle relaxants (baclofen, tizanidine, dantrolene), localized botulinum toxin chemodenervation, intrathecal baclofen (ITB) pump implantation, and selective dorsal rhizotomy.

Speech-Language Pathology (SLP)

– Health specialty dedicated to the assessment, diagnosis, and treatment of communication disorders (aphasia, dysarthria, apraxia of speech, voice disorders) and swallowing dysfunction (dysphagia) across the lifespan. In neuro-rehabilitation, speech pathologists evaluate language deficits following stroke, conduct videofluoroscopic swallowing studies (VFSS) or fiberoptic endoscopic evaluation of swallowing (FEES), prescribe altered diet textures, and implement cognitive-linguistic retraining.

Spinal Cord Injury (SCI) Rehabilitation

– Specialized multidisciplinary rehabilitation aimed at optimizing functional independence, mobility, bowel/bladder management, autonomic dysreflexia prevention, and community integration following traumatic or non-traumatic spinal cord damage.

Stroke Rehabilitation

– Interdisciplinary care program designed to facilitate neurological recovery and functional compensation following acute ischemic or hemorrhagic stroke. Commences as soon as medical stability is achieved. Key focus areas: motor retraining (task-oriented practice, constraint-induced therapy), sensory re-education, gait and balance training, speech and language therapy for aphasia, dysphagia management, spatial neglect rehabilitation, and prevention of secondary complications (shoulder subluxation, deep vein thrombosis, pressure ulcers, depression). Neuroplasticity drives cortical remodeling, with peak functional gains achieved within the first 3–6 months.

Tetraplegia (Quadriplegia)

– Paralysis of all four limbs and the trunk resulting from injury to the cervical spinal cord (C1–C8/T1). Causes: trauma (motor vehicle accidents—most common, falls, sports injuries, violence), ischemia (spinal cord infarction), hemorrhage, infection (epidural abscess, transverse myelitis), demyelination (multiple sclerosis), and tumors. The level of injury determines functional impairment: C1–C3 (requires mechanical ventilation, minimal movement), C4 (phrenic nerve in-

tact—diaphragmatic breathing, but requires 24-hour care, can use chin- or mouth-controlled wheelchair), C5 (deltoid and biceps—can feed self with adaptive equipment, assist with transfers), C6 (wrist extension—tenodesis grasp, can self-propel wheelchair with adaptations), C7–C8 (triceps, finger flexors/extensors—-independent transfers, self-catheterisation). The American Spinal Injury Association (ASIA) Impairment Scale grades completeness (A = complete, E = normal). Complications: respiratory compromise, autonomic dysreflexia (hypertensive crisis from noxious stimuli below the level of injury), neurogenic shock, pressure ulcers, spasticity, neuropathic pain, deep vein thrombosis, osteoporosis, and psychological adjustment. Management: acute—spinal immobilisation, high-dose methylprednisolone (controversial), surgical decompression/stabilisation. Chronic—multidisciplinary rehabilitation (physiotherapy, occupational therapy, speech therapy, psychological support), management of spasticity (baclofen, botulinum toxin), bowel and bladder programme, and assistive technology.

Transcutaneous Electrical Nerve Stimulation (TENS)

- Non-invasive analgesic modality delivering mild electrical currents across the skin via electrodes to inhibit pain signal transmission at the spinal cord dorsal horn (Gate Control Theory of Pain) and stimulate endogenous endorphin release.

Traumatic Brain Injury (TBI) Rehabilitation

- Comprehensive rehabilitation targeting cognitive retraining, behavioral interventions, physical recovery, and executive function restoration following mild to severe traumatic brain trauma.

Waterbed

- A bed with a mattress filled with water, historically used in medical settings for the prevention and management of pressure ulcers (decubitus ulcers) in immobile or bedridden patients. The water-filled mattress distributes body weight evenly, reducing interface pressure over bony prominences (sacrum, heels, hips) compared to standard hospital mattresses, thereby reducing the risk of pressure ulcer formation. Waterbeds are also used in neonatal intensive care for preterm infants: the warm, fluid

environment mimics the intrauterine environment, providing gentle containment and vestibular stimulation. In home care, waterbeds are occasionally recommended for patients with chronic pain (fibromyalgia, back pain) or widespread burns, though their use has declined with the availability of advanced pressure-relieving surfaces (low-air-loss and alternating-pressure mattresses). Waterbeds are heavy (difficult to move or clean), prone to leaking, and may cause claustrophobia or motion sickness in some patients.

Chapter 38

Rheumatology

Adult-Onset Still Disease

– AOSD: a rare systemic autoinflammatory disorder characterized by daily high-spiking fevers, evanescent salmon-pink rash, arthritis/arthralgia, sore throat, lymphadenopathy, hepatosplenomegaly, and markedly elevated ferritin (with low glycosylated ferritin), ESR/CRP. Complications: macrophage activation syndrome, pericarditis, DIC. Diagnosis: Yamaguchi criteria; exclude infection, malignancy, other rheumatic disease. Management: NSAIDs, corticosteroids (first-line for moderate-severe), methotrexate, IL-1 inhibitors (anakinra, canakinumab), IL-6 inhibitor (tocilizumab), and TNF inhibitors.

ANCA-Associated Vasculitis

– granulomatosis with polyangiitis (GPA, c-ANCA/PR3-ANCA positive), microscopic polyangiitis (MPA, p-ANCA/MPO-ANCA positive), and eosinophilic granulomatosis with polyangiitis (EGPA, p-ANCA/MPO-ANCA positive, asthma, eosinophilia). GPA: upper airway (sinusitis, saddle nose), lower airway (nodules, cavitary lesions), renal (pauci-immune necrotizing GN). MPA: renal-pulmonary syndrome without granulomas. EGPA: asthma, eosinophilia, neuropathy, cardiac, GI, skin. Treatment: glucocorticoids + rituximab or cyclophosphamide for induction, then rituximab or azathioprine/methotrexate for maintenance.

Ankylosing Spondylitis

– A chronic, progressive inflammatory disease primarily affecting the axial skeleton (sacroiliac joints and spine), characterized by inflammation at entheses (where tendons, ligaments, and joint capsules insert into bone), leading to new bone formation, syndesmophyte development, and eventual vertebral fusion (bamboo spine). It is the prototype of the spondyloarthritis family of diseases and is

strongly associated with HLA-B27 (present in 80-90 percent of patients, though HLA-B27 is present in 6-8 percent of the general population, meaning most HLA-B27-positive individuals never develop the disease). Clinical features: inflammatory back pain (improved by exercise, worse with rest, morning stiffness >30 minutes), alternating buttock pain, peripheral arthritis (asymmetric, lower limb predominant), enthesitis (Achilles tendinitis, plantar fasciitis), uveitis (acute anterior, recurrent), and in advanced cases, spinal fusion leading to loss of lumbar lordosis, increased thoracic kyphosis, and limited spinal mobility. Diagnosis is based on modified New York criteria requiring sacroiliitis on imaging plus at least one clinical criterion. Treatment includes NSAIDs as first-line, TNF inhibitors (adalimumab, etanercept, infliximab, golimumab, certolizumab), IL-17 inhibitors (secukinumab, ixekizumab), and JAK inhibitors (tofacitinib, upadacitinib) for active disease, along with physiotherapy to maintain spinal mobility.

Anti-CCP

– Anti-cyclic citrullinated peptide antibody: an autoantibody against citrullinated proteins, highly specific (90-95 percent) for rheumatoid arthritis and predictive of erosive disease. Positive anti-CCP is a key component of ACR/EULAR RA classification; may be present years before clinical onset. Used with rheumatoid factor; anti-CCP-positive, RF-negative and vice versa occur. Useful in early/inflammatory arthritis to identify patients needing aggressive DMARD therapy. Does not correlate directly with disease activity over time.

Antinuclear Antibody

– ANA: autoantibodies against nuclear components (DNA, histones, ribonucleoproteins, etc.), detected

by immunofluorescence (HEp-2 cells), reported with pattern (homogeneous, speckled, nucleolar, centromere) and titer. ANA is a screening test for systemic autoimmune disease: high positive in SLE (99 percent), also in drug-induced lupus, Sjogren, scleroderma, MCTD, RA, and in healthy individuals (low titers). Positive ANA requires specific antibody testing based on pattern/suspicion (anti-dsDNA, anti-Smith—SLE; anti-SSA/SSB—Sjogren; anti-Scl-70, centromere—scleroderma; anti-RNP—MCTD). ANA is not diagnostic alone.

Antinuclear Antibody (ANA)

– An autoantibody directed against cellular nuclear antigens (DNA, RNA, histones, ribonucleoproteins). Detected by indirect immunofluorescence (IFA) on HEp-2 cells. High sensitivity (95-98%) for Systemic Lupus Erythematosus (SLE), making it the primary screening test. Also positive in Sjogren syndrome, systemic sclerosis, polymyositis, drug-induced lupus, and 5-10% of healthy individuals. Specific sub-antibodies (anti-dsDNA, anti-Smith, anti-SSA/SSB, anti-Scl-70, anti-centromere) refine diagnosis.

Antiphospholipid Syndrome

– A systemic autoimmune thrombophilia characterized by arterial and venous thrombosis, pregnancy morbidity, and persistent antiphospholipid antibody positivity. Antiphospholipid antibodies are a heterogeneous group of autoantibodies targeting phospholipid-binding proteins: lupus anticoagulant (LA, detected by prolongation of phospholipid-dependent coagulation assays that fails to correct with mixing study, paradoxically associated with thrombosis), anticardiolipin antibodies (aCL, detected by ELISA), and anti-beta2-glycoprotein I antibodies (anti-beta2GPI). Diagnosis requires at least one clinical criterion (vascular thrombosis or pregnancy morbidity) and at least one laboratory criterion (LA, aCL, or anti-beta2GPI positive on two or more occasions at least 12 weeks apart). Catastrophic APS (CAPS) is a rare, rapidly fatal variant with multiple thromboses in a short period, often triggered by infection, surgery, or anticoagulation withdrawal. Treatment: anticoagulation with warfarin (target INR 2-3 for first thrombosis, 3-4 for recurrent), plus low-dose aspirin in pregnancy; CAPS requires anticoagulation, high-dose glucocorticoids, plasma exchange, and IVIG.

Antisynthetase Syndrome

– Defined by the presence of anti-aminoacyl-tRNA synthetase antibodies (anti-Jo-1 most common, 75%; anti-PL-7, anti-PL-12, anti-EJ, anti-OJ, anti-KS, anti-Zo, anti-Ha, anti-YRS, anti-FRS, anti-TRS, anti-ARS) with clinical triad: interstitial lung disease (most common, often progressive), inflammatory myopathy (DM/PM), and inflammatory arthritis (non-erosive). Also: mechanic's hands (hyperkeratotic fissuring of radial fingers), Raynaud, fever. Treatment: glucocorticoids + rituximab or mycophenolate for ILD and myositis; calcineurin inhibitors (tacrolimus, cyclosporine) for refractory disease.

Arthritis

– Inflammation of one or more joints, characterized by joint pain, swelling, warmth, and stiffness. Arthritis is classified into several major categories: osteoarthritis (degenerative, the most common form, characterized by articular cartilage loss, subchondral sclerosis, and osteophyte formation, typically affecting weight-bearing joints such as knees, hips, and spine as well as hands); rheumatoid arthritis (autoimmune, symmetric polyarthritis affecting small joints of hands and feet with pannus formation causing marginal erosions and periarticular osteopenia); spondyloarthritis (including ankylosing spondylitis, psoriatic arthritis, reactive arthritis, and enteropathic arthritis, typically presenting with inflammatory back pain, asymmetric oligoarthritis, enthesitis, and association with HLA-B27); crystal arthropathies (gout and calcium pyrophosphate deposition disease); septic arthritis (bacterial infection of the joint, a medical emergency requiring urgent drainage and antibiotics); and other arthritides associated with connective tissue diseases, infection, or haemochromatosis.

Autoinflammatory Bone Diseases

– Chronic recurrent multifocal osteomyelitis (CRMO/CNO): see above. Majeed syndrome (LPIN2 mutations): CRMO + congenital dyserythropoietic anemia + Sweet syndrome. DIRA (IL1RN mutations): neonatal pustulosis, periostitis, osteitis. Cherubism (SH3BP2 mutations): bilateral jaw swelling, multilocular radiolucencies, self-limited after puberty. CANDLE syndrome (see above).

Behcet Disease

– A systemic vasculitis of unknown etiology characterized by recurrent oral aphthous ulcers (major criterion), genital ulcers, skin lesions (erythema nodosum, pseudofolliculitis), ocular inflammation (posterior uveitis, retinal vasculitis - leading cause of blindness), neurologic (neuro-Behcet), vascular (arterial aneurysms, venous thrombosis), GI, and arthritic manifestations. Pathergy test positive (skin hyperreactivity). International criteria: recurrent oral ulceration (≥ 3 /year) plus at least two of: genital ulceration, eye lesions, skin lesions, or pathergy test. Treatment: topical steroids for mucocutaneous ulcers, colchicine for mucous membrane involvement, systemic corticosteroids and immunosuppressants (azathioprine, cyclophosphamide, TNF inhibitors) for severe organ-threatening disease including ocular, neurologic, and vascular involvement.

Biologic Therapy

– Treatment with biologic agents targeting specific immune pathways, used in autoimmune and inflammatory disease. Types: TNF inhibitors (infliximab, etanercept, adalimumab), IL-6 inhibitors (tocilizumab), IL-1 inhibitors (anakinra), IL-17/IL-23 inhibitors (secukinumab, ustekinumab), B-cell depletion (rituximab), T-cell costimulation blockade (abatacept), JAK inhibitors (tofacitinib—small molecule), and others. Indications: rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, SLE, vasculitis, IBD, psoriasis. Benefits: targeted efficacy with steroid-sparing. Risks: infection (TB, opportunistic), malignancy (rare), immunogenicity (anti-drug antibodies), and injection reactions. Requires screening and monitoring.

Calcium Pyrophosphate Deposition Disease

– A crystal arthropathy caused by deposition of calcium pyrophosphate dihydrate crystals in articular cartilage (chondrocalcinosis). Presents with acute pseudogout (most common): acute monoarticular inflammation of the knee or wrist, mimicking gout but less painful. Chronic CPPD: degenerative arthritis-like with OA pattern (knee, wrist, MCP joints). Pseudo-rheumatoid: symmetric polyarticular inflammation. Associated with aging, OA, hemochromatosis, hyperparathyroidism, hypomagnesemia, hypothyroidism. Diagnosis: joint aspira-

tion shows weakly positively birefringent rhomboid crystals. Treatment: NSAIDs, colchicine, intra-articular corticosteroids for acute flares; low-dose colchicine for prophylaxis.

CANDLE Syndrome

– Chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE, PSMB8 mutations, proteasome dysfunction) causes recurrent fever, annular violaceous plaques, progressive lipodystrophy (loss of subcutaneous fat), joint contractures, developmental delay, basal ganglia calcifications. Treatment: JAK inhibitors (baricitinib, ruxolitinib) improve skin, fever, lipodystrophy.

Childhood Vasculitis

– Kawasaki disease (see medium vessel vasculitis). Henoch-Schönlein purpura (IgA vasculitis): palpable purpura, abdominal pain, arthralgia, renal (IgA nephropathy), self-limited in most; corticosteroids for severe GI/renal. Polyarteritis nodosa in children: similar to adults, hepatitis B association. Takayasu arteritis: adolescent girls. ANCA vasculitis: rare in children.

Chondrocalcinosis

– Radiographic deposition of calcium pyrophosphate crystals in cartilage (especially fibrocartilage), seen as linear calcification on X-ray—commonly in the knee menisci, wrist, and symphysis pubis. Associated with CPPD disease (pseudogout), aging, hemochromatosis, hyperparathyroidism, hypomagnesemia, and hypothyroidism. May be asymptomatic or cause acute inflammatory arthritis (pseudogout) or chronic degenerative changes. Diagnosis: X-ray findings and crystal identification on synovial fluid (weakly positive birefringent rhomboids). Management: treat acute attacks (NSAIDs, colchicine, steroid injection) and underlying metabolic disease.

Churg-Strauss Syndrome

– An ANCA-associated small-vessel vasculitis characterized by late-onset asthma, peripheral and tissue eosinophilia, necrotizing vasculitis, and frequently mononeuritis multiplex, cardiomyopathy, and renal involvement. p-ANCA (anti-MPO) is positive in 40-50 percent of cases. The preferred modern term is Eosinophilic Granulomatosis with Polyangiitis (EGPA).

Corticosteroid

– Steroid hormones (glucocorticoids: prednisone,

methylprednisolone, dexamethasone, hydrocortisone) with potent anti-inflammatory and immunosuppressive effects; used in rheumatology (RA flares, SLE, vasculitis, polymyalgia), asthma/COPD, allergy, and autoimmune disease. Mechanisms: inhibition of inflammatory gene transcription, reduced cytokine production, immune cell suppression. Adverse effects (chronic/systemic): weight gain, hyperglycemia, hypertension, osteoporosis, adrenal suppression (taper to avoid withdrawal), infection, cataracts, peptic ulcer, mood changes, Cushingoid features. Used for short-term flares, as bridges to DMARDs, or in pulses for severe disease; always taper.

C-Reactive Protein

– CRP: an acute-phase protein produced by the liver in response to inflammation (IL-6), rising within 6 hours and normalizing rapidly; used with ESR to assess inflammation. Elevated in infection, inflammation (RA, vasculitis), tissue injury, and cardiovascular risk assessment (high-sensitivity CRP). Highly sensitive but nonspecific; very high levels (>100 mg/L) suggest serious bacterial infection or major inflammation. Serial measurement monitors disease activity and treatment response. CRP does not distinguish infection from inflammation; correlate clinically.

Cryopyrin-Associated Periodic Syndromes

– Autosomal dominant autoinflammatory disorders (NLRP3 mutations, gain-of-function) causing constitutive inflammasome activation and IL-1 β overproduction. Spectrum: familial cold autoinflammatory syndrome (FCAS, cold-induced urticaria, fever, conjunctivitis), Muckle-Wells syndrome (MWS, progressive sensorineural hearing loss, amyloidosis risk), neonatal-onset multisystem inflammatory disease (NOMID/CINCA, severe CNS involvement, bony overgrowth, chronic meningitis, cognitive impairment). Diagnosis is clinical with genetic confirmation. Treatment: IL-1 inhibitors (anakinra, canakinumab, rilonacept) are dramatically effective, suppressing inflammation and preventing disease progression.

Dactylitis

– Inflammation of an entire digit (finger or toe), producing a diffuse, fusiform swelling often described

as sausage-shaped. Most commonly associated with psoriatic arthritis and reactive arthritis (enthesitis-related), but also occurs in sickle cell disease (hand-foot syndrome in young children, caused by dactylitis from vaso-occlusive crises in the small bones of the hands and feet) and tuberculous dactylitis (spina ventosa—bony expansion from granulomatous infection). Diagnosis based on clinical appearance and underlying condition.

Dermatomyositis

– An inflammatory myopathy with characteristic skin manifestations: Gottron papules (over knuckles), heliotrope rash (purple periorbital), shawl/V sign erythema, and proximal muscle weakness; associated with interstitial lung disease, and in adults an increased risk of malignancy (ovary, lung, GI). Antibodies: anti-Mi-2, anti-Jo-1 (antisynthetase with ILD, mechanic's hands), anti-MDA5 (rapidly progressive ILD). Diagnosis: elevated CK, EMG, muscle biopsy (perifascicular atrophy), skin biopsy, MRI. Management: corticosteroids, methotrexate/azathioprine, IVIG, rituximab; cancer screening at diagnosis. Juvenile dermatomyositis variant in children.

Drug-Induced Autoimmunity

– Drug-induced lupus (DIL): procainamide, hydralazine, isoniazid, minocycline, TNF inhibitors, anti-TNF; anti-histone antibodies, positive ANA, negative anti-dsDNA/anti-Sm; symptoms resolve after drug cessation. Drug-induced ANCA vasculitis: propylthiouracil, hydralazine, minocycline, allopurinol; MPO-ANCA positive, pauci-immune GN, pulmonary hemorrhage. Drug-induced subacute cutaneous lupus: hydrochlorothiazide, calcium channel blockers, TNF inhibitors; anti-Ro/SSA positive, annular/papulosquamous photosensitive rash. Diagnosis is clinical with drug history and serology. Management is withdrawal of the offending drug with supportive care; symptoms typically resolve over weeks to months.

Enteropathic Arthritis

– Spondyloarthritis associated with inflammatory bowel disease (Crohn disease, ulcerative colitis), affecting 10-20% of IBD patients. Two patterns: type 1 (pauciarticular, acute, self-limited, parallels IBD activity, large joints), type 2 (polyarticular, chronic, independent of IBD activity, symmetric

small joints, resembles RA but RF-negative). Axial involvement (sacroiliitis) in 10-20%, often asymptomatic. Treatment: optimize IBD control (TNF inhibitors, vedolizumab for gut-selective therapy), NSAIDs for symptomatic relief (though they may exacerbate IBD), sulfasalazine, methotrexate, and rarely surgery for refractory arthritis.

Enthesitis

– Inflammation at the site where a tendon, ligament, or joint capsule inserts into bone (enthesitis), a hallmark of spondyloarthritis (ankylosing spondylitis, psoriatic arthritis, reactive arthritis, IBD-associated). Affects Achilles tendon, plantar fascia, patellar, and costochondral junctions. Features: localized pain and tenderness at insertion sites, morning stiffness, sometimes swelling; plantar fasciitis and Achilles enthesitis are common. Diagnosis: clinical, ultrasound/MRI (entheseal thickening, vascularity, erosions). Management: NSAIDs, physiotherapy, and in spondyloarthritis—biologics (TNF inhibitors, IL-17 inhibitors) for refractory enthesitis.

Eosinophilic Granulomatosis with Polyangiitis

– EGPA (formerly Churg-Strauss syndrome): an ANCA-associated vasculitis characterized by asthma, peripheral and tissue eosinophilia, and necrotizing vasculitis. Features: late-onset asthma, allergic rhinitis, eosinophilic pneumonia, mononeuritis multiplex, skin lesions, cardiac involvement (myocarditis—major cause of death), and glomerulonephritis (less common); p-ANCA (anti-MPO) in 40-50 percent. Diagnosis: clinical, eosinophilia (>10 percent/1500), biopsy (eosinophilic vasculitis), ANCA. Management: corticosteroids (mainstay), cyclophosphamide or rituximab for severe/organ-threatening; treat asthma and eosinophilia; relapse common.

Erythrocyte Sedimentation Rate

– ESR: a nonspecific inflammatory marker measuring the rate of red blood cell sedimentation in a vertical tube over 1 hour (mm/h), elevated by inflammation, infection, malignancy, and anemia. Extremely elevated (>100 mm/h): myeloma, giant cell arteritis/polymyalgia rheumatica, infection, SLE, malignancy. Used with CRP to monitor inflammation (RA, GCA) and in diagnosis (temporal arteritis). Affected by age, sex, anemia (increases), polycythemia

(decreases), fibrinogen, and pregnancy. Not specific—combination with clinical findings and CRP is standard.

Familial Mediterranean Fever

– An autosomal recessive autoinflammatory disorder (MEFV gene mutations, pyrin/inflammasome dysregulation) causing recurrent self-limited febrile attacks with serositis (peritonitis, pleuritis, synovitis), erysipelas-like erythema, lasting 12-72 hours. Predominantly affects Mediterranean populations (Armenians, Turks, Arabs, Sephardic Jews). Complication: AA amyloidosis (renal, hepatic, splenic) from chronic inflammation if untreated. Diagnosis: Tel-Hashomer criteria: major (typical attacks with peritonitis, pleuritis, synovitis, or erysipelas-like erythema) plus minor (incomplete attacks). Treatment: colchicine is highly effective for preventing attacks and AA amyloidosis; IL-1 inhibitors (anakinra, canakinumab) for colchicine-resistant cases.

Fibromyalgia

– A chronic centralized pain syndrome characterized by widespread musculoskeletal pain (>3 months), fatigue, sleep disturbance, cognitive dysfunction (fibro fog), and somatic symptoms, affecting 2-4% of population (female:male 9:1). Pathophysiology: central sensitization, altered pain processing, neurotransmitter dysregulation (serotonin, norepinephrine, dopamine, substance P). 2016 ACR criteria: widespread pain index (WPI) ≥ 7 and symptom severity scale (SSS) ≥ 5 OR WPI 4-6 and SSS ≥ 9 , plus generalized pain in at least 4 of 5 regions, symptoms present at similar level for at least 3 months, and absence of another disorder explaining the pain. Management: non-pharmacological (exercise, cognitive behavioural therapy, sleep hygiene, patient education) combined with pharmacotherapy (amitriptyline, duloxetine, milnacipran, pregabalin, gabapentin). Multimodal, individualised treatment is most effective.

Giant Cell Arteritis

– A large-vessel vasculitis of adults >50 (peak 70-80) affecting cranial branches of carotid arteries, with risk of permanent vision loss from anterior ischemic optic neuropathy. Clinical: new-onset headache (temporal), scalp tenderness, jaw claudication, visual disturbances (amaurosis fugax, diplopia), polymyalgia rheumatica symptoms. Di-

agnosis: temporal artery biopsy (gold standard, skip lesions reduce sensitivity), ultrasound (halo sign), PET-CT (large-vessel involvement (aorta, subclavian). Treatment: high-dose glucocorticoids (prednisolone 40-60 mg/day) promptly to prevent blindness; tocilizumab (IL-6 inhibitor) as steroid-sparing agent; low-dose aspirin for thromboprophylaxis. Methotrexate, azathioprine as alternatives.

Gout

– A crystal deposition disease caused by monosodium urate (MSU) crystal formation in joints and tissues due to chronic hyperuricemia (serum urate >6.8 mg/dL). Pathophysiology: urate overproduction (10%) or underexcretion (90%); crystals activate NLRP3 inflammasome → IL-1β release → neutrophilic inflammation. Clinical: acute monoarticular arthritis (1st MTP podagra 50% first attack), intense pain, erythema, swelling; tophi in chronic disease; urate nephrolithiasis. Diagnosis: synovial fluid aspiration showing negatively birefringent needle-shaped crystals under polarised light microscopy, elevated serum urate. Treatment: acute attack management with NSAIDs, colchicine, or corticosteroids; long-term urate-lowering therapy (allopurinol, febuxostat, probenecid, uricosurics) targeting serum urate <6 mg/dL (5 mg/dL if tophi present). Prophylaxis with NSAIDs or colchicine during initial urate-lowering. Lifestyle modification: avoid purine-rich foods (red meat, shellfish, organ meats), reduce alcohol (especially beer), maintain hydration.

Granulomatosis with Polyangiitis

– GPA (formerly Wegener granulomatosis): an ANCA-associated small-vessel necrotizing vasculitis affecting the upper and lower respiratory tract and kidneys. Features: sinonasal disease (crusting, epistaxis, saddle-nose deformity), pulmonary nodules/cavitation, alveolar hemorrhage, glomerulonephritis (RPGN), and constitutional symptoms; c-ANCA (anti-PR3) positive in most. Diagnosis: clinical, ANCA serology, biopsy (necrotizing granulomas, vasculitis). Management: induction with rituximab or cyclophosphamide + high-dose corticosteroids, then maintenance (rituximab, azathioprine); treat renal failure aggressively; relapses require re-treatment. Untreated: rapidly fatal.

Granulomatosis with Polyangiitis

(Wegener's Granulomatosis)

– Granulomatosis with polyangiitis (GPA, formerly Wegener granulomatosis) is a rare, ANCA-associated necrotizing granulomatous vasculitis affecting small to medium-sized blood vessels, primarily in the respiratory tract and kidneys. Epidemiology: incidence 8-12 per million, peak age 40-60, slight male predominance. Pathophysiology: pauci-immune vasculitis (no immune complex deposition) with c-ANCA (anti-PR3, 90% in active generalised disease, 50% in localised disease) targeting proteinase 3 (PR3) in neutrophil granules. PR3-ANCA activates neutrophils, causing degranulation, respiratory burst, and endothelial damage. Clinical: upper respiratory tract (chronic sinusitis, epistaxis, nasal crusting, saddle nose deformity from nasal septal perforation, otitis media, subglottic stenosis), lower respiratory tract (cough, dyspnoea, hemoptysis, pulmonary nodules/cavitary lesions on imaging), renal (crescentic pauci-immune glomerulonephritis → rapidly progressive glomerulonephritis, haematuria, proteinuria, renal failure), and other (cutaneous vasculitis/purpura, ocular/scleritis/episcleritis, mononeuritis multiplex, arthralgia). Limited GPA: disease confined to the respiratory tract without renal involvement. Diagnosis: clinical, c-ANCA/anti-PR3, tissue biopsy (nasal, lung, or kidney) showing necrotizing granulomatous inflammation and vasculitis. Treatment: induction with high-dose glucocorticoids plus rituximab or cyclophosphamide (efficacy equal); maintenance with rituximab (q6 months) or azathioprine/methotrexate. Methotrexate for non-organ-threatening limited disease. Trimethoprim-sulfamethoxazole for limited upper respiratory tract disease and *Pneumocystis jirovecii* prophylaxis. Prognosis: without treatment, mortality >90% at 2 years (renal failure or respiratory failure). With treatment, remission in 75-90%, but relapse rate is 30-50% within 5 years.

Henoch-Schonlein Purpura

– IgA vasculitis (HSP): a small-vessel vasculitis with IgA immune complex deposition, most common in children. Features: palpable purpura (lower limbs/buttocks), arthralgia/arthritis, abdominal pain (may cause intussusception, GI bleeding), and renal involvement (hematuria, proteinuria—IgA

nephropathy-like). Preceded by upper respiratory infection. Diagnosis: clinical; skin/renal biopsy (IgA deposition). Management: supportive; NSAIDs for arthritis, corticosteroids for abdominal/renal disease; monitor renal function; most cases resolve spontaneously. Adults have worse renal prognosis; long-term renal follow-up required.

Hydroxychloroquine

– An antimalarial DMARD used in SLE (first-line for skin/joint/mild disease, reduces flares and improves survival), rheumatoid arthritis, and antiphospholipid syndrome. Mechanisms: interference with antigen processing, Toll-like receptor inhibition, immunomodulation. Well tolerated; side effects: GI upset, rash, retinal toxicity (cumulative dose-related—require ophthalmologic screening), cardiomyopathy (rare), and myopathy. Monitor for retinopathy annually after 5 years or risk factors. Generally safe in pregnancy. Avoid with QT-prolonging drugs and in G6PD deficiency.

IgG4-Related Disease

– A fibro-inflammatory condition characterized by tumefactive lesions in multiple organs, dense lymphoplasmacytic infiltrate with >10 IgG4+ plasma cells/HPF and IgG4+/IgG+ ratio >40%, elevated serum IgG4 (>135 mg/dL), obliterative phlebitis, storiform fibrosis. Affects pancreas (type 1 autoimmune pancreatitis), salivary/lacrimal glands (Mikulicz disease), retroperitoneum, orbits, kidneys, lungs, aorta. Mimics malignancy, Sjögren, lymphoma. Treatment: glucocorticoids (first-line), rituximab, azathioprine, mycophenolate, methotrexate; disease-modifying anti-rheumatic drugs are often needed long-term.

Immune-Mediated Necrotizing Myopathy

– A subacute severe proximal myopathy with very high CK (often >10,000), minimal inflammation on biopsy, necrotic fibers. Two major autoantibodies: anti-HMGCR (3-hydroxy-3-methylglutaryl-CoA reductase, statin-associated or spontaneous) and anti-SRP (signal recognition particle). Anti-HMGCR: older, statin exposure, severe; anti-SRP: younger, more cardiac/respiratory involvement, worse prognosis. Treatment: high-dose glucocorticoids + rituximab or IVIG as first-line; additional immunosuppressants (methotrexate, azathioprine, mycopheno-

late) and physical therapy for rehabilitation.

Inclusion Body Myositis

– The most common acquired myopathy after age 50, characterized by asymmetric distal and proximal weakness (finger flexors, quadriceps), rimmed vacuoles, 15–18 nm tubulofilaments, TDP-43 pathology, endomysial inflammation with CD8+ T cells invading non-necrotic fibers. Refractory to immunotherapy. Clinical: dysphagia (40%), falls from quadriceps weakness. Diagnostic criteria (ENMC 2011): clinical + EMG + biopsy. Treatment: supportive (fall prevention, dysphagia management, speech therapy, and assistive devices for mobility. Clinical trials with arimoclomol, bimagrumab, and follistatin gene therapy are ongoing.

Infection-Related Rheumatic Syndromes

– Post-streptococcal reactive arthritis (PSRA): asymmetric oligoarthritis 1–2 weeks after GAS pharyngitis, HLA-B27 negative, prolonged course, no carditis; distinguish from acute rheumatic fever. Lyme arthritis: *Borrelia burgdorferi*; monoarticular knee arthritis, positive serology; antibiotic treatment (doxycycline/amoxicillin); refractory Lyme arthritis (post-infectious immune-mediated). Viral arthritis: parvovirus B19 (acute polyarthritis, mimics RA, self-limited), hepatitis B/C (polyarthritis, usually self-limited, cryoglobulin-associated vasculitis), rubella, HIV, and alphaviruses (chikungunya, Ross River). Diagnosis: serology, PCR, exposure history. Treatment: symptomatic (NSAIDs, corticosteroids for severe), treat underlying infection when applicable.

Interferonopathies

– Type I interferonopathies: Aicardi-Goutières syndrome (TREX1, RNASEH2, SAMHD1 mutations, neonatal encephalopathy, calcifications, chilblains, SLE-like); STING-associated vasculopathy with onset in infancy (SAVI, TMEM173 mutations, severe interstitial lung disease, digital ischemia); Proteasome-associated autoinflammatory syndromes (PRAAS, PSMB8 mutations, CANDLE syndrome: lipodystrophy, fever, skin lesions, joint contractures). Treatment: JAK inhibitors (baricitinib, ruxolitinib) target IFN signalling. Baricitinib approved for SAVI and CANDLE. hematopoietic stem cell transplantation in severe Aicardi-Goutières

syndrome.

Janus Kinase Inhibitors

– JAK inhibitors (tofacitinib, baricitinib, upadacitinib, filgotinib, abrocitinib) block JAK-STAT signaling downstream of cytokine receptors (IL-6, IFN-gamma, IL-2, IL-7, IL-15, IL-21, GM-CSF, erythropoietin, thrombopoietin). Selectivity: JAK1/JAK3 (tofacitinib), JAK1/JAK2 (baricitinib), JAK1 (upadacitinib, filgotinib, abrocitinib). Indications: RA, PsA, axial SpA, UC, AD, alopecia areata. Safety: herpes zoster (vaccinate Shingrix before), VTE (risk factors: age, obesity, prior VTE), infections, lipid elevation, transaminitis, neutropenia, anemia, GI perforation. Drug interactions: CYP3A4 (tofacitinib, upadacitinib). Dose adjustment for renal impairment.

Juvenile Dermatomyositis

– Juvenile dermatomyositis (JDM) presents with proximal weakness, heliotrope rash, Gottron papules, calcinosis (20-30%), lipodystrophy, vasculopathy (nailfold capillary changes). Anti-Mi-2 (classic DM, good prognosis), anti-NXP2 (calcinosis, malignancy risk low in children), anti-TIF1-gamma (malignancy risk in adults). Calcinosis is major morbidity. Treatment: glucocorticoids, methotrexate, hydroxychloroquine, IVIG for refractory; rituximab, TNF inhibitors, abatacept for refractory; bisphosphonates for calcinosis. JDM has better prognosis than adult DM; most children achieve remission but calcinosis can cause significant long-term disability.

Juvenile Idiopathic Arthritis

– The most common chronic rheumatic disease of childhood (onset <16 years), encompassing 7 subtypes: systemic JIA (Still disease of childhood, quotidian fever, salmon rash, arthritis, hepatosplenomegaly, serositis, macrophage activation syndrome risk), oligoarticular JIA (4 or fewer joints in first 6 months, high risk of chronic anterior uveitis, ANA positive), polyarticular JIA (5 or more joints, RF-negative or RF-positive), psoriatic JIA (arthritis + psoriasis), enthesitis-related JIA (HLA-B27, male > female, enthesitis, acute uveitis), and undifferentiated JIA. Treatment: NSAIDs, intra-articular corticosteroids, methotrexate, TNF inhibitors, IL-6 inhibitors (tocilizumab), IL-1 inhibitors (anakinra) for systemic JIA. Uveitis screening essential (ANA-positive, oligoarticular).

Juvenile Systemic Sclerosis

– Rare, onset <16 years, more diffuse cutaneous involvement, higher cardiac and renal crisis risk than adults, less pulmonary hypertension. Autoantibodies: anti-Scl-70 (dcSSc), anti-centromere (lcSSc), anti-RNA pol III. Treatment similar to adults but growth considerations; cyclophosphamide for severe ILD; ACE inhibitors for renal crisis; multidisciplinary pediatric rheumatology care.

Lupus

– A chronic autoimmune disease that can affect multiple organ systems. See Systemic Lupus Erythematosus (SLE).

Lupus Erythematosus (Systemic Lupus Erythematosus - SLE)

– See Systemic Lupus Erythematosus (SLE).

Macrophage Activation Syndrome

– A life-threatening complication of rheumatic diseases (especially systemic JIA, AOSD, SLE, Kawasaki) characterized by uncontrolled activation of macrophages and T cells causing hemophagocytosis, cytopenias, hyperferritinemia, hypertriglyceridemia, hypofibrinogenemia, coagulopathy, liver dysfunction, neurologic symptoms. HLH-2004 criteria: fever, splenomegaly, cytopenias (2 lineages), hypertriglyceridemia/hypofibrinogenemia, hemophagocytosis, low NK activity, elevated soluble CD25 (sIL-2R). Hscore or MS score aid diagnosis. Treatment: high-dose corticosteroids, cyclosporine, etoposide (for HLH), anakinra (IL-1 blockade) for MAS in systemic JIA/AOSD. Prompt recognition and aggressive treatment are essential to reduce mortality.

Microscopic Polyangiitis

– A necrotizing vasculitis affecting small blood vessels (capillaries, venules, arterioles) with few or no immune deposits (pauci-immune). Part of the ANCA-associated vasculitis group. Strongly associated with MPO-ANCA (p-ANCA, 80%). Presents with rapidly progressive glomerulonephritis (renal: hematuria, proteinuria, crescents), pulmonary capillaritis (hemoptysis, diffuse alveolar hemorrhage), palpable purpura, mononeuritis multiplex, and other organ involvement. Diagnosis: ANCA serology, renal or lung biopsy showing pauci-immune necrotizing inflammation. Treatment: high-dose corticosteroids + cyclophosphamide or rituximab for induction; aza-

thioprine or rituximab for maintenance. Untreated, rapidly fatal.

Mixed Connective Tissue Disease

– An overlap syndrome with features of systemic lupus erythematosus, systemic sclerosis, and polymyositis/dermatomyositis. Highly associated with anti-U1 RNP antibodies. Presents with Raynaud phenomenon (nearly universal), puffy hands, arthritis, myositis, esophageal dysmotility, and serositis. Renal disease is less common than in SLE. Diagnosis: clinical + anti-U1 RNP positivity without sufficient criteria for other CTDs. Treatment: hydroxychloroquine, corticosteroids, and immunosuppressants (mycophenolate, methotrexate). Prognosis varies with predominant disease manifestation.

Nonsteroidal Anti-Inflammatory Drug

– NSAID: drugs inhibiting cyclooxygenase (COX-1/COX-2), reducing prostaglandin synthesis—anti-inflammatory, analgesic, antipyretic. Types: non-selective (ibuprofen, naproxen, diclofenac, indomethacin, ketorolac) and COX-2 selective (celecoxib, etoricoxib). Uses: arthritis, musculoskeletal pain, gout, dysmenorrhea, postoperative pain. Adverse effects: GI ulceration/bleeding (reduce with PPI, COX-2), renal impairment (reduced GFR), cardiovascular risk (hypertension, fluid retention, increased MI risk—especially diclofenac), and asthma exacerbation. Avoid in renal disease, heart failure, GI bleeding, and late pregnancy; caution with anticoagulants. Use lowest effective dose/shortest duration.

Osteitis Pubis

– Inflammation of the pubic symphysis and adjacent bone, causing groin/pelvic pain in athletes (soccer, hockey, running), postpartum women, post-urollogic surgery. MRI shows bone marrow edema, sclerosis, fluid at symphysis. Treatment: rest, NSAIDs, physical therapy (core/pelvic floor strengthening), corticosteroid injection; rarely surgical fusion.

Osteoarthritis

– The most common joint disease, characterized by progressive cartilage loss, subchondral bone sclerosis, osteophyte formation, and synovial inflammation, affecting knees, hips, hands (DIP/PIP Heberden/Bouchard nodes), spine. Risk factors: age,

obesity, joint injury, malalignment, genetics, female sex. Clinical: activity-related pain, brief morning stiffness (<30 min), crepitus, bony enlargement, functional limitation. Diagnosis: clinical + radiographic (joint space narrowing, osteophytes, subchondral sclerosis, cysts). Management: non-pharmacological (weight loss, exercise, physiotherapy, joint protection), pharmacological (paracetamol, NSAIDs topical/oral, intra-articular corticosteroids, hyaluronic acid injections), and surgical (joint replacement) for end-stage disease.

Osteonecrosis (Avascular Necrosis)

– Osteonecrosis (AVN) is bone death from vascular compromise, affecting femoral head (most common), humeral head, femoral condyles, talus. Risk factors: glucocorticoids (high dose, cumulative), alcohol, trauma, sickle cell disease, SLE, antiphospholipid syndrome, pancreatitis, decompression sickness, radiation, organ transplantation. ARCO classification: stage 0 (normal X-ray, MRI+), I (normal X-ray, MRI+), II (crescent sign), III (subchondral collapse), IV (joint space narrowing, OA). Treatment: core decompression for early stages, osteotomy, and joint replacement for advanced collapse. Bisphosphonates may reduce risk in high-dose glucocorticoid therapy.

Other Types of Arthritis

– Other types of arthritis beyond osteoarthritis and rheumatoid arthritis include psoriatic arthritis (seronegative spondyloarthropathy associated with psoriasis, enthesitis, dactylitis, and nail changes; treated with NSAIDs, DMARDs, TNF inhibitors, IL-17/IL-23 inhibitors), ankylosing spondylitis (axial spondyloarthropathy with inflammatory back pain, sacroiliitis, spinal fusion/bamboo spine; HLA-B27 associated; NSAIDs, TNF inhibitors, IL-17 inhibitors), gout (monosodium urate crystal deposition causing acute monoarticular inflammatory arthritis, tophi, urate nephropathy; acute—colchicine, NSAIDs, corticosteroids; chronic—urate-lowering therapy such as allopurinol, febuxostat), pseudogout (calcium pyrophosphate deposition disease, CPPD), reactive arthritis (post-infectious, urethritis/cervicitis, conjunctivitis), septic arthritis (bacterial joint infection requiring urgent drainage and antibiotics), and juvenile idiopathic arthritis (JIA, childhood arthritis with

oligoarticular, polyarticular, or systemic subtypes). Diagnosis requires joint aspiration for crystal analysis and culture, serologies (RF, anti-CCP, ANA, HLA-B27), and imaging. Treatment targets inflammation, prevents joint destruction, and maintains function.

Overlap Myositis

– Patients with features of inflammatory myopathy (DM/PM/IMNM) plus another systemic autoimmune disease (SLE, SSc, MCTD, Sjogren). Anti-PM-Scl (Scl/PM overlap, limited SSc + myositis, good prognosis); anti-Ku (SLE/PM overlap); anti-U1-RNP (MCTD with myositis). Treatment: tailored to predominant organ involvement; often requires combination immunosuppression.

Paget Disease of Bone

– A disorder of excessive, disorganized bone remodeling (osteoclastic overactivity followed by osteoblastic new bone) affecting the pelvis, spine, skull, and long bones, usually in older adults. Features: bone pain, deformity (bowing of tibia, enlarged skull), fractures, osteoarthritis, and elevated serum alkaline phosphatase with normal calcium. Complications: deafness (skull involvement), nerve compression, high-output heart failure (extensive), and osteosarcoma (rare—rapid worsening pain/swelling). Diagnosis: X-ray (mosaic pattern, bone expansion), bone scan. Management: bisphosphonates (alendronate, zoledronic acid) normalize turnover and relieve pain; analgesia; surveillance.

Palindromic Rheumatism

– Characterized by recurrent, self-limited attacks of mono- or oligoarthritis (hours to days), periarticular soft tissue swelling, no radiographic erosions between attacks. 30-50% evolve to RA (anti-CCP positive predicts progression). Treatment: NSAIDs for attacks; hydroxychloroquine reduces frequency; low-dose colchicine; DMARDs if progressing to RA.

Polymyalgia Rheumatica

– An inflammatory syndrome of older adults (age >50, peak 70-80) causing bilateral shoulder and pelvic girdle pain and stiffness lasting >45 minutes, with elevated inflammatory markers (ESR >40, CRP elevated). Strongly associated with giant cell arteritis (15-20% develop GCA; 40-50% of GCA patients have PMR). 2012 ACR/EULAR provisional classification: age ≥50, bilateral shoulder pain, ab-

normal ESR/CRP, morning stiffness >45 min, new hip pain, absence of RF/anti-CCP, absence of other inflammatory arthritis. Treatment: low-dose prednisolone 15-25 mg/day (not exceeding 20 mg/day in most guidelines) with rapid taper; methotrexate as steroid-sparing; tocilizumab for refractory cases. Relapse common during steroid taper.

Polymyositis

– An idiopathic inflammatory myopathy characterized by symmetric, proximal muscle weakness (shoulders, hips) with elevated muscle enzymes (CK, aldolase, LDH). More common in women, peaks at 30-50 years. Diagnosis: EMG (myopathic units with fibrillations), muscle MRI (edema), and muscle biopsy (CD8+ T cell infiltration of MHC-I expressing muscle fibers). Autoantibodies: anti-Jo-1 (antisynthetase syndrome with interstitial lung disease, arthritis, mechanic's hands). Treatment: high-dose corticosteroids, methotrexate, azathioprine, mycophenolate, and IVIG for refractory disease.

Polymyositis and Dermatomyositis

– Idiopathic inflammatory myopathies (IIM) include dermatomyositis (DM), polymyositis (PM), immune-mediated necrotizing myopathy (IMNM), and inclusion body myositis (IBM). DM: heliotrope rash, Gottron papules, Shawl/V-sign, mechanic's hands, calcinosis, ILD, malignancy association (anti-TIF1-gamma, anti-NXP2). PM: proximal weakness, elevated CK, EMG/myopathy on biopsy (CD8+ endomysial inflammation), no rash, rare, often overdiagnosed (many are IMNM or IBM). IMNM: severe proximal weakness, very high CK, necrotic fibers without inflammation, anti-HMGCR or anti-SRP. IBM: age >50, finger flexor and quadriceps weakness, rimmed vacuoles, refractory. Malignancy screening essential in adult DM (anti-TIF1-gamma, anti-NXP2). Treatment: glucocorticoids + steroid-sparing agents (methotrexate, azathioprine, mycophenolate) for DM/PM; IVIG for DM; rituximab for refractory cases; physiotherapy for muscle strengthening.

Pseudogout

– Calcium pyrophosphate deposition disease (CPPD): deposition of calcium pyrophosphate dihydrate crystals in joints, causing acute arthritis resembling gout (pseudogout) or chronic osteoarthritis-like disease. Affects knees, wrists, and metacarpophal-

langeal joints; associated with aging, hemochromatosis, hyperparathyroidism, hypomagnesemia, hypothyroidism. Acute attacks: swelling, pain, effusion with weakly positively birefringent (rhombohedral) crystals on polarized microscopy, chondrocalcinosis on X-ray. Management: NSAIDs, colchicine, intra-articular corticosteroids for acute; treat associated metabolic disease. Distinguish from gout (monosodium urate, negatively birefringent).

Psoriatic Arthritis

– An inflammatory arthritis associated with psoriasis (precedes arthritis in 70%, simultaneous 15%, follows 15%), affecting 20-30% of psoriasis patients. CASPAR criteria: inflammatory articular disease plus psoriasis (2 points), nail dystrophy (1), negative RF (1), dactylitis (1), juxta-articular new bone formation (1); score ≥ 3 . Patterns: distal interphalangeal predominant, asymmetric oligoarthritis, symmetric polyarthritis (RA-like), spondylitis, arthritis mutilans. Treatment: NSAIDs for mild disease; methotrexate, leflunomide, sulfasalazine as first-line DMARDs; TNF inhibitors, IL-17 inhibitors (secukinumab, ixekizumab), IL-23 inhibitors (guselkumab), and JAK inhibitors (tofacitinib, upadacitinib) for moderate-to-severe disease; physiotherapy and occupational therapy.

Pyoderma Gangrenosum

– A neutrophilic dermatosis causing rapidly expanding, painful ulcers with violaceous undermined borders, pathergy phenomenon. Associated with IBD (50%), hematologic malignancy, rheumatoid arthritis, PAPA syndrome. Peristomal PG in ostomy patients. Treatment: high-potency topical steroids, intralesional steroids, systemic corticosteroids, cyclosporine, TNF inhibitors (infliximab, adalimumab); avoid surgical debridement (worsens via pathergy).

Raynaud Syndrome

– A vasospastic disorder causing episodic digital color changes (white $\rightarrow$ blue $\rightarrow$ red) triggered by cold or stress, due to exaggerated vasoconstriction of digital arteries. Primary Raynaud: benign, symmetric, in young women, no underlying disease. Secondary Raynaud: associated with scleroderma, SLE, mixed connective tissue disease, vasculitis, and cryoglobulins—often asymmetric, severe, with digital ulcers/gangrene. Diagnosis: clinical; nailfold

capillaroscopy and autoantibody testing to detect secondary causes. Management: avoid cold, smoking cessation, calcium channel blockers (nifedipine), prostacyclin analogs (iloprost) for severe; treat underlying disease; avoid sympathomimetics.

Reactive Arthritis

– A post-infectious spondyloarthritis occurring 1-4 weeks after genitourinary (*Chlamydia trachomatis*) or gastrointestinal (*Salmonella*, *Shigella*, *Campylobacter*, *Yersinia*) infection. Classic triad (Reiter syndrome): arthritis, conjunctivitis/uveitis, urethritis/cervicitis (only 1/3 have full triad). HLA-B27 positive in 60-80%. Clinical: asymmetric oligoarthritis (lower extremities), enthesitis (Achilles, plantar fascia), dactylitis, circinate balanitis, keratoderma blennorrhagicum (palmar/plantar pustulosis). Treatment: NSAIDs, corticosteroids (oral or intra-articular), DMARDs (sulfasalazine, methotrexate) for persistent arthritis, TNF inhibitors for refractory cases. Most cases resolve over months but may recur with subsequent infections.

Reactive Arthritis (formerly Reiter's Syndrome)

– See Reactive Arthritis.

Relapsing Polychondritis

– A rare systemic autoimmune disease characterized by recurrent inflammation and destruction of cartilaginous structures throughout the body, particularly the ears, nose, respiratory tract, and joints. The pathogenesis involves autoimmune targeting of type II collagen (the predominant collagen in hyaline cartilage) and type X collagen (in growth plates). Clinical presentation: auricular chondritis (painful, erythematous, swollen ears with sparing of the earlobe, the classic distinguishing feature), nasal chondritis (saddle nose deformity), laryngotracheal involvement (hoarseness, stridor, life-threatening airway collapse), costochondritis, and non-erosive arthropathy. Ocular inflammation (scleritis, episcleritis, uveitis), audiovestibular involvement (sensorineural hearing loss, vertigo), cardiac involvement (aortic regurgitation from aortitis, pericarditis), and renal and skin involvement may occur. Diagnosis is clinical (McAdam criteria). Treatment: corticosteroids (first-line), dapsone or colchicine for mild disease, and immunosuppressants (methotrexate, azathioprine, cyclophosphamide, mycophenolate, TNF

inhibitors) for severe or refractory disease. Airway involvement requires urgent evaluation and possible tracheostomy.

Remitting Seronegative Symmetrical Synovitis with Pitting Edema

– RS3PE: an acute-onset, symmetric polyarthritis (usually in elderly) with pitting edema of the hands/feet, negative rheumatoid factor and anti-CCP, and marked response to low-dose corticosteroids. Distinct from RA—tends to be severe but responds dramatically to steroids and often remits; some cases progress to RA or other rheumatic disease (polymyalgia rheumatica, spondyloarthritis, or paraneoplastic). Features: symmetric tenosynovitis of wrist/hands with edema. Management: corticosteroids (rapid response), NSAIDs; assess for underlying malignancy or connective tissue disease.

Rheumatoid Arthritis

– A chronic, symmetric, erosive inflammatory polyarthritis primarily affecting small joints of the hands and feet, with a female-to-male ratio of 3:1 and peak onset 40-60 years. Pathogenesis involves genetic susceptibility (HLA-DRB1 shared epitope), environmental triggers (smoking, periodontal disease), and immune dysregulation (citruination of proteins, anti-CCP antibody production, rheumatoid factor, cytokine-driven synovial inflammation with TNF, IL-6, IL-1). Clinical: symmetric small joint polyarthritis (MCP, PIP, MTP), morning stiffness >1 hour, rheumatoid nodules, extra-articular manifestations (Sjogren, interstitial lung disease, pericarditis, vasculitis, Felty syndrome). Diagnosis: 2010 ACR/EULAR criteria: joint involvement (0-5), serology (RF and anti-CCP, 0-3), acute phase reactants (0-1), symptom duration (0-1). Treatment: treat-to-target strategy with methotrexate as anchor DMARD, plus short-term glucocorticoids; early use of TNF inhibitors, IL-6 inhibitors (tocilizumab), abatacept, JAK inhibitors (tofacitinib, baricitinib, upadacitinib) for inadequate response; rituximab for seropositive disease. Intensive disease management reduces joint damage and disability.

Rheumatoid Factor

– RF: an autoantibody (usually IgM) directed against the Fc portion of IgG, positive in 70-80 percent of rheumatoid arthritis (seropositive RA) but also in other conditions: Sjogren, SLE, chronic infection

(TB, endocarditis, hepatitis C), cryoglobulinemia, sarcoidosis, and healthy elderly. High titers correlate with more severe, erosive RA. Used with anti-CCP (more specific for RA) for diagnosis and classification (ACR/EULAR criteria). Serial monitoring not generally recommended. Negative RF does not exclude RA (seronegative RA).

Rheumatoid Factor (RF)

– An autoantibody (most commonly IgM) directed against the F_c portion of human IgG. Present in 70-80% of patients with Rheumatoid Arthritis (RA). Higher titers correlate with more severe erosive joint disease, extra-articular manifestations (rheumatoid nodules, vasculitis), and poorer prognosis. Also elevated in Sjogren syndrome, SLE, chronic infections (hepatitis C, subacute bacterial endocarditis), and aging.

Rheumatology

– The medical specialty concerned with the diagnosis and treatment of diseases affecting the musculoskeletal system, including joints, muscles, bones, tendons, and ligaments, as well as systemic autoimmune and inflammatory conditions. Common rheumatic diseases: inflammatory arthritis (rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, reactive arthritis, gout, pseudogout), osteoarthritis (degenerative joint disease), connective tissue diseases (systemic lupus erythematosus, systemic sclerosis/scleroderma, Sjögren syndrome, mixed connective tissue disease, polymyositis/dermatomyositis), vasculitis (giant cell arteritis, Takayasu arteritis, polyarteritis nodosa, ANCA-associated vasculitis, IgA vasculitis/Henoch-Schönlein purpura), and soft tissue rheumatism (fibromyalgia, tendinopathy, bursitis, adhesive capsulitis/frozen shoulder). Diagnostic tools: clinical history and examination, laboratory tests (rheumatoid factor, anti-CCP, ANA, anti-dsDNA, ANCA, complement, inflammatory markers—ESR, CRP), imaging (X-ray, ultrasound, MRI), and synovial fluid analysis. Treatment: NSAIDs, corticosteroids, conventional synthetic DMARDs (methotrexate, leflunomide, sulfasalazine, hydroxychloroquine), biologic DMARDs (TNF inhibitors—adalimumab, etanercept, infliximab; IL-6 inhibitors—tocilizumab; CTLA4-Ig—abatacept; anti-CD20—rituximab), and targeted synthetic DMARDs (JAK inhibitors—tofacitinib, baricitinib,

upadacitinib). Multidisciplinary care: physiotherapy, occupational therapy, podiatry, psychology.

Sarcoidosis

– A multisystem granulomatous disorder of unknown etiology characterized by non-caseating granulomas, predominantly affecting lungs (90%), lymph nodes, skin, eyes, liver, heart, nervous system. Pulmonary stages (Scadding): 0 (normal), I (bilateral hilar lymphadenopathy), II (BHL + parenchymal), III (parenchymal only), IV (fibrosis). Extrapulmonary: Löfgren syndrome (acute, erythema nodosum, bilateral hilar adenopathy, arthritis, fever - good prognosis), Heerfordt syndrome (parotid enlargement, uveitis, fever, facial nerve palsy), cardiac sarcoid (conduction abnormalities, cardiomyopathy, sudden death), neurosarcoid (cranial nerve palsies, meningitis, brain parenchymal lesions), cutaneous (lupus pernio, erythema nodosum). Diagnosis: biopsy of affected tissue showing non-caseating granulomas, exclusion of other granulomatous diseases (TB, fungal). Treatment: corticosteroids first-line; steroid-sparing (methotrexate, azathioprine, mycophenolate, leflunomide); TNF inhibitors (infliximab, adalimumab) for refractory disease.

SAVI Syndrome

– STING-associated vasculopathy with onset in infancy (SAVI, TMEM173 gain-of-function) causes constitutive STING activation → type I interferon overproduction. Severe interstitial lung disease, digital ischemia/autoamputation, chilblain lupus-like skin lesions, failure to thrive. Treatment: JAK inhibitors (baricitinib, ruxolitinib) reduce IFN signature and improve lung disease.

Scleroderma

– Systemic sclerosis: an autoimmune connective tissue disease of skin and internal organs due to fibrosis, vasculopathy, and autoantibodies. Limited cutaneous (CREST—calcinosis, Raynaud, esophageal dysmotility, sclerodactyly, telangiectasia) and diffuse cutaneous forms. Features: skin thickening (sclerodactyly, skin tightness), Raynaud phenomenon, digital ulcers, pulmonary fibrosis, pulmonary hypertension, renal crisis (hypertension, renal failure—emergency), GI dysmotility. Diagnosis: clinical, ANA, anti-Scl-70 (diffuse), anti-centromere (limited), anti-RNA polymerase III. Management: immunosuppression (mycophenolate, methotrexate,

cyclophosphamide), vasodilators (pulmonary hypertension—endothelin antagonists, PDE5 inhibitors), ACE inhibitors for renal crisis, symptom control.

Sjogren Syndrome

– Primary Sjogren syndrome (pSS) is a chronic autoimmune exocrinopathy characterized by lymphocytic infiltration of lacrimal and salivary glands causing dry eyes (keratoconjunctivitis sicca) and dry mouth (xerostomia), with female predominance (9:1) and peak onset 40-60. Secondary SS occurs with RA, SLE, SSc. 2016 ACR/EULAR criteria: anti-Ro/SSA positive (3 points) OR focal lymphocytic sialadenitis with focus score ≥ 1 (3 points) OR ocular staining score ≥ 5 (1 point) OR Schirmer test ≤ 5 mm/5 min (1 point). Treatment: symptomatic (artificial tears, saliva substitutes, pilocarpine, cevimeline); systemic immunosuppression (hydroxychloroquine, methotrexate, azathioprine, mycophenolate, rituximab) for extraglandular manifestations (arthritis, ILD, vasculitis, nephritis, neuropathy). Lymphoma risk (3-5 percent, MALT in parotid) requires long-term surveillance.

Sulfasalazine

– A DMARD combining sulfapyridine and 5-aminosalicylic acid, used in rheumatoid arthritis, psoriatic arthritis, and inflammatory bowel disease (ulcerative colitis). Slows disease progression in RA; onset over 1-3 months. Adverse effects: GI upset, rash, headache, myelosuppression (monitor CBC), hepatotoxicity, male infertility (reversible), and sulfa allergy. Contraindicated in sulfonamide allergy and G6PD deficiency; use folate supplementation. Useful in combination DMARD therapy and for patients intolerant to methotrexate.

Sweet Syndrome

– Sweet syndrome (acute febrile neutrophilic dermatosis) presents with fever, neutrophilia, and tender erythematous plaques/nodules with dense dermal neutrophilic infiltrate. Classical (idiopathic), malignancy-associated (AML, solid tumors), drug-induced (G-CSF, granulocyte colony-stimulating factor). Associated with VEXAS syndrome. Treatment: systemic corticosteroids (rapid response); colchicine, dapsone, indomethacin as steroid-sparing; treat underlying malignancy.

Synovitis

– Inflammation of the synovial membrane lining a

joint, causing swelling, pain, warmth, and joint effusion. Causes: inflammatory arthritis (RA, psoriatic, gout, reactive, septic), autoimmune (SLE), and trauma/overuse. Diagnosis: clinical (joint swelling, effusion), ultrasound (synovial hypertrophy, Doppler signal), MRI, and joint aspiration for septic vs. crystal arthritis (gout—urate crystals, pseudogout—CPPD). Chronic synovitis causes cartilage and bone destruction. Management: treat underlying cause—NSAIDs, corticosteroids, DMARDs/biologics for inflammatory arthritis, antibiotics for septic arthritis (emergency—urgent aspiration and antibiotics), and intra-articular steroid injection.

Systemic Juvenile Idiopathic Arthritis

– sJIA: a subtype of juvenile idiopathic arthritis with prominent systemic inflammation—daily spiking fevers, evanescent salmon-pink rash, arthritis, lymphadenopathy, hepatosplenomegaly, and elevated inflammatory markers (ferritin). Complications: macrophage activation syndrome (MAS—emergency with cytopenias, coagulopathy, very high ferritin), growth impairment, uveitis. Diagnosis: clinical; exclude infection/malignancy. Management: NSAIDs, corticosteroids, methotrexate, IL-1 inhibitors (anakinra, canakinumab), IL-6 inhibitor (tocilizumab); early aggressive treatment improves outcomes.

Systemic Lupus Erythematosus

– A chronic multisystem autoimmune disease predominantly affecting women (9:1 female:male) of childbearing age, characterized by autoantibody production (ANA 98%, anti-dsDNA 70%, anti-Sm 30%) and immune complex deposition causing tissue injury. 2019 EULAR/ACR classification criteria: ANA positive at $\geq 1:80$ plus weighted clinical/immunologic domains (fever, hematologic, neuropsychiatric, mucocutaneous, serosal, musculoskeletal, renal). Clinical manifestations: mucocutaneous (malar rash, discoid rash, photosensitivity, oral ulcers, alopecia), serosal (pleurisy, pericarditis), musculoskeletal (arthritis, myositis), renal (lupus nephritis class I–VI on biopsy), neurologic (seizures, psychosis, mononeuritis multiplex, transverse myelitis), hematologic (hemolytic anemia, leukopenia, lymphopenia, thrombocytopenia, antiphospholipid

syndrome), and pulmonary (interstitial lung disease, pulmonary hypertension). Lupus nephritis requires aggressive immunosuppression with mycophenolate or cyclophosphamide plus glucocorticoids. Hydroxychloroquine is recommended for all SLE patients. Belimumab (anti-BLyS), anifrolumab (anti-IFNAR), and calcineurin inhibitors (voclosporin) are newer targeted therapies. Pregnancy in SLE requires careful planning (avoid cyclophosphamide, mycophenolate), hydroxychloroquine continuation, and monitoring for flares and neonatal lupus.

Systemic Sclerosis

– A rare, chronic autoimmune connective tissue disease characterized by progressive fibrosis of the skin and internal organs, vasculopathy (intimal proliferation and luminal narrowing of small vessels), and immune dysregulation, with an incidence of approximately 2 to 20 per million per year and a female-to-male ratio of 4 to 1, peaking between 30 and 50 years of age. The pathogenic triad involves immune activation (T-cell and B-cell infiltration of target tissues, autoantibody production including anti-centromere, anti-Scl-70, anti-RNA polymerase III, and vascular damage). Clinical subsets: limited cutaneous SSc (lcSSc, skin distal to elbows/knees, CREST syndrome: Calcinosis, Raynaud, Esophageal dysmotility, Sclerodactyly, Telangiectasias, anti-centromere, pulmonary hypertension) and diffuse cutaneous SSc (dcSSc, skin proximal to elbows/knees and trunk, anti-Scl-70, anti-RNA pol III, higher risk of ILD and renal crisis). Organ involvement: ILD (NSIP pattern, most common cause of death), pulmonary arterial hypertension (PAH, second leading cause of death), scleroderma renal crisis (SRC, malignant hypertension, AKI, microangiopathic hemolytic anemia), gastrointestinal (GERD, dysphagia, pseudo-obstruction, bacterial overgrowth, fecal incontinence), cardiac (myocardial fibrosis, pericardial effusion, arrhythmias). Treatment: Raynaud (calcium channel blockers, prostacyclin analogues, endothelin receptor antagonists for digital ulcers); ILD (cyclophosphamide, mycophenolate, nintedanib, tocilizumab); PAH (endothelin receptor antagonists, PDE5 inhibitors, prostacyclin); SRC (ACE inhibitors, avoid high-dose glucocorticoids which precipitate SRC); GERD (high-dose proton pump inhibitors). hematopoietic stem cell

transplantation for selected patients with rapidly progressive dcSSc.

Tendonitis

- Tendinopathy: inflammation or degeneration of a tendon from overuse, repetitive strain, or trauma, causing localized pain, swelling, and tenderness with activity. Common sites: rotator cuff (supraspinatus), lateral elbow (tennis elbow), medial elbow (golfer's elbow), Achilles, patellar (jumper's knee), biceps, and De Quervain. Diagnosis: clinical; ultrasound/MRI for severity or rupture. Management: relative rest, ice, NSAIDs, physiotherapy (eccentric exercises), corticosteroid injection (caution—may weaken tendon), platelet-rich plasma; surgical repair for rupture (e.g., Achilles). Avoid prolonged immobilization; gradual return to activity.

Tenosynovitis

- Inflammation of a tendon and its synovial sheath, causing pain, swelling, and crepitus along the tendon. Causes: overuse/repetitive activity (De Quervain—first dorsal compartment, trigger finger), infection (septic tenosynovitis—emergency, especially flexor sheaths of hand, gonococcal), inflammatory arthritis (RA, psoriatic, gout, reactive arthritis), and trauma. Features: tenderness along tendon, swelling, pain with movement, and in infection: fusiform swelling, pain on passive extension, tenderness along sheath. Diagnosis: clinical; ultrasound/MRI; culture for infection. Management: rest, NSAIDs, splinting, corticosteroid injection, treat underlying disease; surgical drainage for septic tenosynovitis.

Tumor Necrosis Factor Inhibitor

- TNF inhibitor (biologic): monoclonal antibodies/fusion proteins blocking TNF-alpha—infliximab, adalimumab (monoclonals), etanercept (soluble receptor), certolizumab, golimumab. Used in rheumatoid arthritis (after methotrexate failure), ankylosing spondylitis, psoriatic arthritis, psoriasis, IBD (Crohn, UC). Advantages: rapid, effective control of inflammation and joint damage. Risks: infection (tuberculosis—screen before starting, hepatitis B reactivation, fungal), lymphoma (rare), demyelination, heart failure worsening, and injection/infusion reactions. Screening (TB, HBV) and live vaccine avoidance required; contraindicated in active infection.

Vasculitis

- Inflammation of blood vessels causing tissue ischemia and necrosis. Classification by vessel size. Large vessel: giant cell arteritis, Takayasu arteritis. Medium vessel: polyarteritis nodosa (PAN), Kawasaki disease. Small vessel: ANCA-associated vasculitis (microscopic polyangiitis, granulomatosis with polyangiitis, eosinophilic granulomatosis with polyangiitis), IgA vasculitis (Henoch-Schonlein purpura), and anti-GBM disease. Diagnosis: clinical presentation, ANCA, ANA, complement, and tissue biopsy. Treatment: corticosteroids and immunosuppressants (cyclophosphamide, rituximab for ANCA-associated).

VEXAS Syndrome

- VEXAS (Vacuoles, E1 ubiquitin-activating enzyme, X-linked, Autoinflammatory, Somatic) syndrome is an adult-onset autoinflammatory disorder caused by somatic UBA1 mutations in hematopoietic stem cells, affecting men >50. Clinical: recurrent fever, chondritis (relapsing polychondritis-like), vasculitis (Sweet-like, polyarteritis-like), macrocytic anemia, thrombocytopenia, vacuoles in myeloid/erythroid precursors. High mortality from infections, thrombosis, hematologic progression (MDS, AML). Treatment: high-dose corticosteroids for acute inflammation; JAK inhibitors (ruxolitinib, tofacitinib); azacitidine for MDS; supportive care for cytopenias. hematopoietic stem cell transplantation is the only potential cure.

Chapter 39

Surgery

Acute Pancreatitis

– Acute pancreatitis (AP): autodigestion of pancreas by prematurely activated trypsin. Causes: gallstones (40-50%), alcohol (25-35%), hypertriglyceridemia (>1000 mg/dL), ERCP, medications (azathioprine, 6-MP, valproate, estrogens, thiazides), trauma, post-surgical, autoimmune, idiopathic. Severity: Atlanta classification 2012: mild (no organ failure, no local complications), moderately severe (transient organ failure <48 h or local complications), severe (persistent organ failure >48 h). Revised Atlanta classification includes three severity categories. Local complications include acute peripancreatic fluid collections (APFC), pancreatic pseudocysts (developing >4 weeks after onset), acute necrotic collections (ANC), and walled-off necrosis (WON). Pancreatic and peripancreatic necrosis may become infected in 30-70% of cases after 3-4 weeks, requiring antibiotics and percutaneous or endoscopic drainage. Management: aggressive IV fluids (lactated Ringer's, 250-500 mL/h for first 12-24 hours), analgesia, NPO with NG tube for vomiting, ICU monitoring for severe disease. Antibiotics are not routinely indicated. ERCP with sphincterotomy is indicated for severe gallstone pancreatitis with cholangitis or persistent choledocholithiasis. Necrosectomy (minimally invasive step-up approach via percutaneous drainage, endoscopic transluminal drainage, video-assisted retroperitoneal debridement, or surgical necrosectomy) is reserved for infected necrosis not responding to antibiotics. Complications include multi-organ failure, ARDS, acute kidney injury, splenic vein thrombosis, pseudoaneurysm formation with hemorrhage, and chronic pancreatitis with exocrine and endocrine insufficiency. Prognosis: CT severity index (CTSI), APACHE II, Ranson criteria, and

BISAP score predict severity. Mortality of severe acute pancreatitis with persistent organ failure is 30-50%.

Adrenal Tumors

– Adrenal incidentaloma: >1 cm on imaging. Workup: hormonal (cortisol after 1mg DST, metanephrines, aldosterone/renin if hypertensive, DHEAS/androgens if virilizing), imaging (CT washout: adenoma $>60\%$ absolute washout or $>40\%$ relative; MRI chemical shift). Size >4 cm or suspicious imaging $\rightarrow$ surgery. Pheochromocytoma: catecholamine excess (episodic hypertension, headache, diaphoresis, palpitations); 10% bilateral, 10% malignant, 10% extra-adrenal (paraganglioma), 10% familial (MEN2, VHL, NF1, SDHx). Biochemical confirmation: plasma free metanephrines (elevated). Pre-operative: alpha-blockade (phenoxybenzamine 10 mg TDS for 7-14 days before surgery, starting at 10 mg TDS and titrating up to 20-30 mg TDS to achieve blood pressure control and prevent intraoperative hypertensive crisis, followed by beta-blockade after alpha-blockade to control reflex tachycardia or arrhythmia, such as propranolol 10-20 mg TDS starting on day 3 of alpha-blockade). Surgery: laparoscopic adrenalectomy (gold standard for pheochromocytoma and other adrenal masses; partial/cortical-sparing adrenalectomy if bilateral disease or genetic syndrome). Cortical-sparing adrenalectomy is preferred for hereditary pheochromocytoma syndromes (MEN2, VHL) to avoid life-long steroid dependence. Criteria for surgery: tumors >4 cm or any functioning or suspicious mass in a patient who is a good surgical candidate. Adrenocortical carcinoma (ACC): usually >6 cm, irregular, heterogeneous with central necrosis, invasion of adjacent structures, venous tumor thrombus; worst prognosis; treatment is open radical en bloc resec-

tion with lymphadenectomy and complete tumor excision achieving R0 resection margins. Mitotane therapy for advanced or metastatic ACC. Adjuvant mitotane therapy after resection reduces recurrence when there is a high risk of recurrence (tumor size >6 cm, Ki-67 >10 percent, positive margins, capsular invasion, or tumor rupture at the time of surgery).

Amputation

– Surgical removal of a limb or part of a limb. Levels: toe, partial foot (transmetatarsal), below-knee (BKA, preserves knee function, 40-60% walk with prosthesis), through-knee, above-knee (AKA), hip disarticulation, and hemipelvectomy. Upper extremity: digit, ray, transradial, transhumeral, and shoulder disarticulation. Indications: peripheral arterial disease with gangrene (most common), trauma (crush, degloving), infection (necrotizing fasciitis, osteomyelitis refractory), malignancy (sarcoma), and severe deformity. Prosthetic fitting: post-operative rigid dressing, early weight-bearing for BKA. Complications: stump pain, phantom limb pain (80-100%), phantom sensation, surgical site infection, and deconditioning.

Anti-Reflux Surgery

– Surgical procedures designed to restore the anti-reflux barrier at the gastroesophageal junction, primarily indicated for gastroesophageal reflux disease (GERD) refractory to medical therapy, patient preference to discontinue lifelong medication, or large hiatal hernias. The most common procedure is laparoscopic Nissen fundoplication, a 360-degree wrap of the gastric fundus around the distal esophagus, restoring the lower esophageal sphincter pressure and preventing transient lower esophageal sphincter relaxation and reducing the volume of refluxate. The wrap is typically 2-3 cm in length and is performed laparoscopically. Pre-operative evaluation includes esophageal manometry to confirm normal peristalsis (essential before a 360-degree wrap), 24-hour pH monitoring to confirm the diagnosis of GERD, upper endoscopy to assess for oesophagitis, Barrett esophagus, and stricture, and a barium swallow to evaluate esophageal anatomy and identify hiatal hernia. Alternatives to Nissen fundoplication include partial wraps (Toupet 270-degree posterior fundoplication for patients with poor esophageal

motility, Dor 180-200-degree anterior fundoplication) and the LINX magnetic sphincter augmentation device, which consists of a ring of titanium beads with magnetic cores placed around the gastroesophageal junction. Crural closure of the diaphragmatic hiatus is performed to prevent recurrence of the hiatal hernia. Post-operative complications include dysphagia (common initially, resolves in most cases, may require pneumatic dilation if persistent), gas-bloat syndrome (inability to belch, leading to abdominal distension and discomfort, usually improves over weeks to months), and recurrence of reflux symptoms due to wrap disruption or slippage. Outcomes are excellent, with 85-95 percent patient satisfaction at 10 years.

Appendectomy

– Surgical removal of the appendix, the most common emergency surgical procedure performed worldwide. Appendectomy is indicated for acute appendicitis, the most common surgical emergency with a lifetime risk of 7-8 percent and peak incidence between 10 and 30 years. Laparoscopic appendectomy is the preferred approach, offering lower wound infection rates, faster recovery, less postoperative pain, and better cosmetic outcomes compared to open appendectomy. The procedure involves placement of three to four ports (umbilical camera port, suprapubic and right lower quadrant working ports), identification of the base of the appendix, division of the mesoappendix using cautery or a vessel-sealing device, and ligation of the appendiceal base using endoloops (two proximal and one distal) or a stapler. The appendix is placed in a retrieval bag and removed through the umbilical port. In cases of perforated appendicitis with peritonitis, conversion to open appendectomy may be required for adequate peritoneal lavage. Intravenous antibiotics covering Gram-negative and anaerobic organisms are given pre-operatively. For uncomplicated appendicitis, no post-operative antibiotics are needed beyond 24 hours. For perforated appendicitis, antibiotics are continued for 3-5 days or until the patient is clinically improving. Complicated appendicitis (perforation, abscess, or gangrene) has a higher risk of wound infection and intra-abdominal abscess, which may require percutaneous drainage. The complication rate for laparoscopic appendectomy is approxi-

mately 5-10 percent, with wound infection being the most common (1-5 percent). Post-operative recovery is rapid, with most patients discharged within 24 hours and returning to normal activity within 1-2 weeks.

Appendiceal Tumors

– Appendiceal neoplasms: carcinoid (most common, 50%, tip of appendix, <1cm: appendectomy alone; >2cm or positive margins/lymphovascular invasion: right hemicolectomy), mucinous neoplasm (low-grade appendiceal mucinous neoplasm LAMN, high-grade appendiceal mucinous neoplasm HAMN), appendiceal adenocarcinoma (treated like colon cancer: right hemicolectomy), goblet cell carcinoid (adenocarcinoid, amphicrine, right hemicolectomy if >2cm or nodal involvement). Pseudomyxoma peritonei (PMP): disseminated mucinous tumor throughout the peritoneal cavity from ruptured mucinous neoplasm; treatment: cytoreductive surgery (CRS) + hyperthermic intraperitoneal chemotherapy (HIPEC) with mitomycin C. Prognosis: 5-year survival 70% for low-grade, 20-50% for high-grade.

Appendicitis

– Acute appendicitis is the most common surgical emergency, with a lifetime risk of 7-8 percent. Peak incidence 10-30 years. Pathophysiology: obstruction of appendiceal lumen (fecalith, lymphoid hyperplasia, tumor, parasites) -> increased intraluminal pressure -> venous congestion -> arterial compromise -> ischemia, perforation, peritonitis. Clinical: periumbilical pain migrating to RLQ (McBurney point), anorexia, nausea/vomiting, low-grade fever. Signs: RLQ tenderness, rebound tenderness, Rovsing sign (palpation LLQ causes pain in RLQ), psoas sign (pain on right hip extension and thigh flexion), obturator sign (pain on internal rotation of flexed right thigh), Dunphy sign (cough worsens RLQ pain), and Aaron sign (referred pain in epigastrium or precordium when palpating RLQ). Laboratory: leukocytosis (WBC >10,000) with left shift, but WBC may be normal in 10-20% of cases; C-reactive protein (CRP) elevated; procalcitonin may be used. Imaging: graded compression ultrasound (first-line, sensitivity 86%, specificity 93%) shows non-compressible, blind-ending tubular structure >6 mm in diameter, with increased blood flow on color Doppler. CT abdomen with IV contrast is the

gold standard for diagnosis (sensitivity 94%, specificity 95%), showing an enlarged appendix >6 mm with wall thickening, periappendiceal fat stranding, and possible abscess or extraluminal air (indicating perforation). Alternative diagnoses to exclude include mesenteric adenitis, terminal ileitis (Crohn disease), Meckel diverticulitis, right-sided diverticulitis, omental infarction, epiploic appendagitis, ureteric colic, pyelonephritis, ovarian cyst torsion or rupture, ectopic pregnancy, pelvic inflammatory disease, and mittelschmerz. The Alvarado score (MANTRELS) and RIPASA score stratify risk. Alvarado score: 1-4 = low risk (observe), 5-6 = moderate (CT), 7-10 = high (surgery). Management: appendectomy (laparoscopic preferred). Antibiotics alone (appendicitis non-operative management) is an option for uncomplicated (non-perforated, no abscess, no faecalith) appendicitis based on the NOTA, AP-PAC, and CODA trials, but 20-30% recurrence rate within 1 year. Interval appendectomy after non-operative management is no longer routinely recommended. Complications: perforation (incidence 20-30%, higher in elderly and children), abscess formation (percutaneous drainage), wound infection (1-5%), intra-abdominal abscess (1-2%), ileus, and stump leak (rare).

Arthroscopy

– Minimally invasive joint visualization and intervention via a rigid arthroscope inserted through small portals, used for meniscal and ligamentous repair, chondroplasty, loose body removal, and synovectomy. Knee, shoulder, and hip are commonly arthroscoped; complications include infection, chondral injury, and deep venous thrombosis, with faster recovery than open arthrotomy.

Arterial Line (A-Line)

– A catheter inserted into a peripheral artery (most commonly radial, also femoral, brachial, dorsalis pedis) for continuous blood pressure monitoring and arterial blood gas sampling. Allen test: assesses ulnar collateral flow before radial artery cannulation. Indications: hemodynamic instability (shock, vasopressors), need for frequent ABGs, and advanced hemodynamic monitoring (pulse pressure variation SVV for fluid responsiveness). Transducer: zeroed at the phlebostatic axis (4th intercostal space, midaxillary line), leveled to the patient's heart. Damp-

ing: underdamped (overestimates systolic, normal waveform) or overdamped (underestimates systolic, sluggish upstroke). Complications: thrombosis, ischemia (rare if collateral flow is adequate), infection, hematoma, and pseudoaneurysm.

Arterial Ulcer

– A chronic wound caused by arterial insufficiency (peripheral artery disease). Located on distal extremities: toes, heels, lateral malleolus, and sites of pressure. Presents with punched-out, deep, well-demarcated wound with pale or necrotic base, minimal exudate, and cool, hairless, shiny skin. Pain is severe, worse with elevation and night. Associated with claudication and rest pain. Diagnosis: ABI (<0.5 suggests severe ischemia), toe pressure (<30 mmHg), vascular duplex. Treatment: revascularization (endovascular or surgical bypass) is essential for healing. Wound care: debridement, moist healing, infection control. Avoid compression. Amputation if non-salvageable.

Aseptic Technique

– A set of procedural practices preventing surgical site contamination, comprising sterile field preparation, skin antisepsis with chlorhexidine or povidone-iodine, sterile draping, surgical hand scrub, and sterile gown, gloves, and instrument handling. Fundamental to all surgical and percutaneous procedures, breaches are corrected by re-establishing the sterile field.

Bariatric Surgery

– Weight loss procedures and surgery, collectively known as bariatric surgery, are invasive interventions for severe obesity that produce substantial and sustained weight loss by altering gastrointestinal anatomy and physiology. Common procedures include Roux-en-Y gastric bypass, sleeve gastrectomy, and adjustable gastric banding, which restrict food intake, reduce nutrient absorption, or both. Bariatric surgery is typically reserved for individuals with a body mass index of 40 or greater, or 35 or greater with significant obesity-related complications, and requires lifelong nutritional monitoring and lifestyle adherence.

Benign Prostatic Hyperplasia

– Non-malignant enlargement of the prostate gland due to hyperplasia of stromal and glandular elements, affecting $>50\%$ of men by age 60 and $>90\%$

by age 85. Presents with lower urinary tract symptoms (LUTS): hesitancy, weak stream, intermittency, straining, incomplete emptying, urgency, frequency, and nocturia. Complications: acute urinary retention, bladder stones, recurrent UTIs, and renal impairment. Diagnosis: digital rectal exam, PSA, AUA symptom index, post-void residual, and uroflowmetry. Treatment: watchful waiting for mild symptoms, alpha-blockers (tamsulosin), 5-alpha-reductase inhibitors (finasteride), combination therapy, and surgical options (TURP, laser prostatectomy, and open prostatectomy for large glands).

Biliary Tract Injuries

– Bile duct injury (BDI) occurs in 0.3-0.5% of laparoscopic cholecystectomies. Strasberg classification: A (cystic duct leak/minor hepatic duct leak), B (occlusion of aberrant right hepatic duct), C (transection of aberrant right hepatic duct without ligation), D (lateral injury to major duct), E (major duct injury: E1-E5 based on level). Recognition: intraoperative (bile leak, visualization) or postoperative (bilious drain output, pain, fever, jaundice). Intraoperative management: if recognized, primary repair over T-tube (if $>50\%$ intact wall) or Roux-en-Y hepaticojejunostomy (if transection, ligation, or significant resection of the bile duct). If recognized postoperatively, ERCP with sphincterotomy and stenting (Strasberg A, D) or percutaneous transhepatic cholangiography (PTC) with drainage (Strasberg B, C) may be attempted. Strasberg E injuries require surgical repair via Roux-en-Y hepaticojejunostomy, preferably performed by a hepatobiliary surgeon at a tertiary referral center. The timing of repair is critical: early repair (<72 hours) is acceptable for clean, well-vascularised tissue; otherwise, delayed repair (4-6 weeks) after resolution of inflammation and sepsis is preferred. Pre-operative optimisation includes biliary drainage (ERCP, PTC, or percutaneous transhepatic biliary drainage), control of sepsis with antibiotics (piperacillin-tazobactam or meropenem), and nutritional support (enteral nutrition via nasojejunal tube if possible). Prevention: critical view of safety (CVS) technique during cholecystectomy, low threshold for cholangiography (indocyanine green fluorescence imaging, intraoperative cholangiography, or laparoscopic ultrasound) when anatomy is unclear. Outcomes: Strasberg A and D

have excellent outcomes; Strasberg E has a 10-20% stricture rate after repair. Long-term complications include anastomotic stricture (treated with balloon dilation or revision), cholangitis, secondary biliary cirrhosis, and portal hypertension.

Blood Loss

– The volume of blood lost during surgery or trauma, estimated by weighing swabs, suction contents, and hemodynamic monitoring, guiding fluid and transfusion management. ATLS classes range from I (up to 15 percent loss) to IV (over 40 percent, requiring aggressive resuscitation); massive transfusion uses packed cells, plasma, and platelets with tranexamic acid.

Blunt Abdominal Trauma

– Trauma to the abdomen without penetrating injury. Mechanisms: motor vehicle collisions (most common), falls, assaults. Commonly injured organs: spleen (most common, left upper quadrant), liver (right upper quadrant), kidneys (flank), bowel (seat-belt sign, delayed perforation), and pancreas (epigastric). Diagnosis: FAST (Focused Assessment with Sonography in Trauma) for free intraperitoneal fluid; CT scan (gold standard in hemodynamically stable patients). Management: hemodynamically unstable with positive FAST → exploratory laparotomy. Stable: CT for grading; non-operative management of solid organ injuries (spleen/liver) if hemodynamically stable. Bowel and pancreatic injuries often require surgical repair.

BPH

– Abbreviation for Benign Prostatic Hyperplasia.

Bypass Surgery

– A surgical conduit that reroutes flow around an obstructed or diseased segment, applied to coronary arteries (CABG), peripheral arteries (autologous vein or prosthetic bypass), and the gastrointestinal tract (gastric bypass). Principal long-term concerns are conduit patency, graft infection, and anastomotic stenosis.

Breast Surgery

– Breast cancer surgery: breast-conserving therapy (BCT: lumpectomy + radiation) equivalent survival to mastectomy for early stage. Margins: "no ink on tumor" for invasive cancer; 2mm for DCIS. Sentinel lymph node biopsy (SLNB): dual mapping (blue dye + radioisotope); if positive (macrometastasis

>2mm): completion ALND (historical) or radiation (ACOSOG Z0011: 1-2 positive SLN + BCT + whole breast RT → no ALND; AMAROS: ALND vs axillary RT equivalent). Mastectomy types: simple, skin-sparing, nipple-sparing (NSM), and radical modified (Patey: breast + axillary lymph node dissection - ALND). Nipple-areola complex (NAC) is spared if tumor is >2cm from the nipple and no Paget disease of the breast. Oncoplastic techniques integrate plastic surgery principles with oncological resection for improved aesthetic outcomes. Adjuvant therapy: radiation (post-BCT, post-mastectomy if T3/T4 or 4+ positive nodes), endocrine (tamoxifen pre-menopausal, aromatase inhibitor post-menopausal if ER+), HER2-targeted (trastuzumab/pertuzumab if HER2+), chemotherapy (high-risk: triple-negative, HER2+, high-grade, node-positive). BRCA mutation carriers: bilateral mastectomy (risk-reducing) + RRSO (risk-reducing salpingo-oophorectomy) recommended.

Burn Surgery

– Burn assessment: rule of 9s (adult), Lund-Browder (children). Depth: superficial (epidermis), superficial partial (dermis, blanch, blister, painful), deep partial (deeper dermis, white, sluggish capillary refill, less painful), full thickness (all dermis, white/charred, anesthetic). TBSA >20%: IV resuscitation (Parkland: 4 mL/kg/%TBSA LR, half in first 8h, half in next 16h; modified Brooke: 2 mL/kg/%TBSA). Inhalation injury: bronchoscopy, carboxyhemoglobin, cyanide level. Escharotomy: circumferential full-thickness burns of chest (impaired ventilation), extremities (compartment syndrome), neck, or penis. Fasciotomy for compartment syndrome (burn deep to fascia). Tangential excision (within 24-72 hours) with split-thickness skin grafting (STSG: 0.008-0.012 inch), meshed (1:1 to 1:4 for larger surface area) or sheet graft (face, hands, joints). Biological dressings: allograft (cadaver), xenograft (porcine), amniotic membrane, synthetic (Biobrane, Integra, Apligraf, and artificial dermal regeneration template). Scar management: pressure garments, silicone sheeting, laser therapy (pulsed dye laser for hypertrophic scars, fractional CO2 laser for contracture release and scar texture improvement).

CABG (Coronary Artery Bypass

Grafting)

– Open heart surgery to bypass stenotic coronary arteries using autologous grafts. On-pump: cardiopulmonary bypass, cardioplegic arrest. Off-pump (OP-CAB): beating heart, no bypass machine. Grafts: left internal mammary artery (LIMA to LAD, best patency 95% at 10 years), saphenous vein graft (SVG, patency 60-80% at 10 years), and radial artery (patency between LIMA and SVG). Indications: left main CAD ($\geq 50\%$), three-vessel CAD, two-vessel CAD with proximal LAD and EF $< 50\%$, and failed PCI. Complications: bleeding, AF, stroke, infection (sternal wound), renal failure, and graft failure.

Carotid Endarterectomy

– Surgical removal of atherosclerotic plaque from the carotid bifurcation to prevent stroke. Indications: symptomatic carotid stenosis $\geq 50\%$ (NASCET criteria: TIA or non-disabling stroke) and asymptomatic stenosis $\geq 70\%$ (if perioperative risk $< 3\%$). Pre-operative: CTA or MRA, antiplatelet therapy. Complications: stroke (2-5%), cranial nerve injury (hypoglossal, vagus, facial marginal mandibular, recurrent laryngeal: 5-10%, most temporary), hematoma, restenosis. Alternative: carotid artery stenting (CAS, for high surgical risk).

Cesarean Section (C-section)

– Surgical delivery of a fetus through incisions in the abdominal wall (laparotomy) and uterus (hysterotomy). Indications: failure to progress, non-reassuring fetal heart tracing, malpresentation (breech, transverse), placenta previa, placental abruption, prior classical C-section, maternal infection (HSV, HIV), and elective (maternal request). Incisions: low transverse (Kerr, most common, heals best for future VBAC), classical (vertical, high risk of rupture in labor). Steps: Pfannenstiel incision, bladder flap, hysterotomy, delivery of the baby, placental removal, closure. Complications: hemorrhage, infection, thromboembolism, bladder/bowel injury, and uterine rupture in future pregnancies (VBAC).

Cholecystectomy

– Surgical removal of the gallbladder. Laparoscopic cholecystectomy (gold standard, $> 95\%$): 4 small incisions, short stay. Open cholecystectomy: for severe inflammation, cirrhosis, or failed laparoscopy. Indications: symptomatic cholelithiasis (biliary

colic), acute cholecystitis, gallstone pancreatitis, and gallstone ileus. Intraoperative cholangiogram (IOC): assess for CBD stones. Critical view of safety (CVS): before clipping the cystic artery and duct. Complications: bile duct injury (0.3-0.5%), bile leak, bleeding, and retained CBD stones.

Cholecystitis

– Acute cholecystitis is gallbladder inflammation, most commonly from cystic duct obstruction by gallstones (calculous cholecystitis, 90-95%); acalculous cholecystitis (5-10%) in critically ill, trauma, burns, prolonged fasting, TPN, vasculitis. Pathophysiology: stone impaction $\rightarrow$ distension $\rightarrow$ ischemia $\rightarrow$ inflammation $\rightarrow$ bacterial translocation (*E. coli*, *Klebsiella*, *Enterococcus*). Clinical: RUQ pain > 6 hours, radiating to right scapula, fever, nausea/vomiting. Murphy sign (inspiratory arrest on right subcostal palpation during deep inspiration), present in 60-70% of cases. Laboratory: leukocytosis, elevated CRP, LFTs (elevated ALT/AST in acute cholecystitis, ALP/bilirubin in choledocholithiasis or Mirizzi syndrome). Imaging: RUQ ultrasound (first-line, sensitivity 94%): gallstones, thickened gallbladder wall $> 3-4$ mm (target sign), pericholecystic fluid, sonographic Murphy sign, positive common bile duct > 6 mm (or > 8 mm post-cholecystectomy). CT abdomen is less sensitive for gallstones but useful for complications (perforation, abscess, emphysematous cholecystitis, gangrenous cholecystitis, Mirizzi syndrome). HIDA scan (cholescintigraphy) shows non-visualisation of the gallbladder (cystic duct obstruction) with 95% sensitivity and specificity. Management: NPO, IV fluids, analgesia, IV antibiotics (ampicillin-sulbactam, piperacillin-tazobactam, or ceftriaxone with metronidazole). Definitive: laparoscopic cholecystectomy (gold standard), ideally within 72 hours of admission (early cholecystectomy reduces morbidity and length of stay compared to delayed surgery at 6-12 weeks). Tokyo Guidelines 2018 (TG18) severity grading: Grade I (mild, no organ dysfunction, mild inflammation), Grade II (moderate, elevated WBC $> 18,000$, palpable tender mass, duration > 72 hours, marked inflammation), Grade III (severe, organ dysfunction). Grade I: early laparoscopic cholecystectomy (within 72 hours); Grade II: early laparoscopic cholecystectomy after medical optimisation;

Grade III: ICU management, percutaneous cholecystostomy (drainage) if critical, delayed cholecystectomy after resolution. Complications: gallbladder perforation (localised or free), empyema of gallbladder, emphysematous cholecystitis (gas-forming organisms, high mortality, requires urgent cholecystectomy), Mirizzi syndrome (stone impacted in cystic duct or Hartmann pouch compressing common hepatic duct causing obstructive jaundice; may require subtotal cholecystectomy or Roux-en-Y hepaticojejunostomy), post-cholecystectomy syndrome (persistent symptoms after cholecystectomy).

Chronic Pancreatitis

– Chronic pancreatitis (CP): irreversible fibrosis, loss of exocrine/endocrine function. Etiology: alcohol (60-70%), genetic (PRSS1, SPINK1, CFTR, CTTRC), obstructive (stricture, tumor), autoimmune (IgG4-related), idiopathic. Clinical: recurrent epigastric pain radiating to back, steatorrhea (exocrine insufficiency), diabetes (endocrine insufficiency), weight loss. Imaging: CT (calcifications, ductal dilation, atrophy), MRCP (ductal changes), EUS (early changes: hyperechoic foci, strands, lobularity), ERCP (therapeutic: stenting, stone extraction, stricture dilation). Cambridge classification (ERCP/MRCP) grade 1-5. Management: pain control (avoid narcotics, consider celiac plexus block for refractory pain), exocrine supplementation (pancreatic enzymes, PERT: lipase 40,000-80,000 units per meal, titrate to symptom relief and normalisation of fecal elastase-1), endocrine (insulin for diabetes), endoscopic (ERCP with sphincterotomy, stone extraction, stricture dilation, stenting), surgical (lateral pancreaticojejunostomy/Puestow procedure for dilated duct >7 mm, Beger/Frey procedure for head-predominant disease, Whipple for mass/head, distal pancreatectomy for body/tail disease, total pancreatectomy with islet autotransplantation for debilitating pain). Complications: pseudocyst (can be internal or external, may require endoscopic drainage, transpapillary drainage, or cystogastrostomy), biliary stricture, duodenal stricture, splenic vein thrombosis leading to left-sided (sinistral) portal hypertension with gastric varices, pancreatic ascites, pancreaticopleural fistula, and pancreatic adenocarcinoma (risk is 2-5% over 20 years, surveillance of the remnant gland with cross-

sectional imaging is controversial but may be considered in young patients).

Cleft Lip and Palate

– A congenital anomaly caused by failure of fusion of the facial prominences during embryonic development (4-10 weeks gestation). Cleft lip: failure of maxillary and medial nasal processes to fuse. Cleft palate: failure of palatal shelves to fuse. Can occur together or separately. Incidence: 1 in 700 live births, more common in Asians and Native Americans. Multifactorial: genetic (IRF6, FGFR1) and environmental (maternal smoking, folate deficiency, alcohol). Associated syndromes: Pierre Robin sequence, Van der Woude syndrome, 22q11 deletion. Presents with cosmetic deformity, feeding difficulties, speech abnormalities, and ear infections. Management: multidisciplinary team (ENT, plastic surgery, speech therapy, orthodontics). Surgical repair: cleft lip at 3-6 months, cleft palate at 9-18 months.

Cleft Palate

– A congenital malformation characterized by an opening (cleft) in the palate (roof of the mouth) due to failure of fusion of the palatal shelves during embryonic development (weeks 6-9 of gestation). Incidence: 1 in 1,500-2,500 live births. Cleft palate may occur in isolation or with cleft lip (cleft lip and palate—CLP). Classification: incomplete (soft palate only) vs complete (soft and hard palate), unilateral vs bilateral, and associated with Pierre Robin sequence (micrognathia, glossoptosis, airway obstruction). Risk factors: genetics (multiple genes implicated—IRF6, MSX1, TBX22, FGFR1), maternal smoking, alcohol, diabetes, and folate deficiency. Diagnosis: antenatal ultrasound (around 20-week anomaly scan) or postnatal clinical examination (inspect palate with a tongue depressor). Complications: feeding difficulties (nasal regurgitation, poor weight gain), recurrent otitis media (Eustachian tube dysfunction—hearing loss), speech delay (velopharyngeal insufficiency—hypernasal speech, articulation errors), dental abnormalities (missing or malpositioned teeth), and maxillary hypoplasia. Management: multidisciplinary team (plastic surgeon, ENT, speech therapist, orthodontist, paediatrician, psychologist). Primary palatoplasty (repair of the palate) is performed at 9-12 months (before speech

development); techniques: Furlow double-opposing Z-plasty, Bardach two-flap palatoplasty. Secondary surgery for velopharyngeal insufficiency (pharyngeal flap, sphincter pharyngoplasty). Alveolar bone grafting at 6–9 years. Orthognathic surgery for maxillary hypoplasia in adolescence. Speech therapy, audiology, and orthodontic treatment throughout childhood. Long-term outcomes: good speech and feeding outcomes, normal intelligence, and good quality of life with appropriate multidisciplinary care.

Colectomy

– Surgical resection of part or all of the colon. Right hemicolectomy: for cecal/ascending colon cancer. Left hemicolectomy: for descending/sigmoid cancer. Sigmoidectomy: for diverticulitis or sigmoid cancer. Total colectomy: for FAP, UC, or Lynch syndrome. Low anterior resection (LAR): for rectal cancer with anastomosis (coloanal anastomosis). Abdominoperineal resection (APR): for distal rectal cancer, permanent colostomy. Indications: colon cancer, diverticulitis, IBD (UC, Crohn), and ischemic colitis. Complications: anastomotic leak (most feared), hemorrhage, wound infection, and ileus.

Colorectal Surgery

– Colon cancer: right hemicolectomy (cecum to transverse), extended right (to mid-transverse), transverse colectomy, left hemicolectomy (splenic flexure to sigmoid), sigmoid colectomy, anterior resection (low anterior resection - LAR for upper/mid rectal), abdominoperineal resection (APR for low rectal with sphincter involvement), total mesorectal excision (TME) standard for rectal cancer. Lymphadenectomy: minimum 12 nodes. Rectal cancer: neoadjuvant chemoradiation (5-FU/capecitabine + 50.4 Gy) for T3/T4 or node-positive; total neoadjuvant therapy (TNT: induction chemotherapy followed by chemoradiation) for locally advanced; watch-and-wait for complete clinical response (cCR) after TNT. Anal cancer: squamous cell carcinoma; Nigro protocol (mitomycin C + 5-FU + 55-60 Gy radiation); surgery (APR) only for residual/recurrent disease. Diverticulitis: Hinchey classification (I: pericolonic abscess, antibiotics, percutaneous drainage if >4cm; II: pelvic abscess, percutaneous drainage; III: purulent peritonitis, Hart-

mann or resection with anastomosis + defunctioning stoma; IV: fecal peritonitis, Hartmann procedure). Elective sigmoid resection after 2 episodes of uncomplicated or 1 episode of complicated diverticulitis (current guidelines have shifted towards a more conservative, individualised approach, with surgery considered on a case-by-case basis for recurrent attacks, persistent complications, or immunosuppression).

Colostomy

– A surgically created stoma formed by bringing the colon to the abdominal wall for fecal diversion, indicated for distal obstruction, trauma, perforation, or abdominoperineal resection. Types include end, loop, and double-barrel. Complications include parastomal hernia, prolapse, retraction, and high-output dehydration.

Complication

– Any adverse event arising during or after a surgical procedure, graded by the Clavien-Dindo classification from minor deviation (Grade I) through organ failure (Grade IV) to death (Grade V). Common types include surgical site infection, hemorrhage, wound dehiscence, anastomotic leak, ileus, and venous thromboembolism.

Conscious Sedation

– A drug-induced depression of consciousness in which patients respond purposefully to verbal or tactile stimulation, maintain a patent airway, and retain protective reflexes. Typical agents include midazolam, fentanyl, or low-dose propofol. Indications include endoscopic and minor surgical procedures. Reversal agents and airway equipment must be available.

Craniotomy

– Surgical opening of the skull (bone flap) for access to intracranial contents. Indications: brain tumor resection (glioblastoma, meningioma, mets), hematoma evacuation (SDH, EDH, ICH), aneurysm clipping, AVM resection, and epilepsy surgery (lobectomy). Stereotactic craniotomy: frameless neuronavigation (Stealth, BrainLab) for precise localization. Awake craniotomy: speech/language mapping for tumors in eloquent cortex. Complications: cerebral edema, hemorrhage (epidural, subdural, intraparenchymal), infection (osteomyelitis, meningitis), CSF leak, seizures, and neurologic deficits.

Cryptorchidism

– Failure of one or both testes to descend into the scrotum, the most common congenital genitourinary anomaly in boys (3% at birth, 1% at 1 year). 70% of undescended testes are palpable (inguinal), 30% non-palpable (intra-abdominal, absent, or atrophic). Spontaneous descent by 6 months occurs in about one-third. Complications: impaired fertility (bilateral: 75% reduced, unilateral: 50% reduced), testicular cancer risk (seminoma, 4-5x increased, even after orchiopexy), and psychological effects. Diagnosis: physical exam; ultrasound or laparoscopy for non-palpable. Treatment: orchiopexy (surgical placement in scrotum) between 6-18 months of age. Hormonal therapy (hCG) is less effective. Atrophic or absent testis: orchiectomy. Follow-up: annual exam and testicular self-exam.

Debridement

– The surgical removal of dead, damaged, or infected tissue from a wound to promote healing and prevent infection. Types: sharp/surgical debridement (scalpel, curette, scissors—most rapid and definitive), enzymatic debridement (collagenase, papain-urea), autolytic debridement (moist dressings allow the body's own enzymes to liquefy necrotic tissue), mechanical debridement (wet-to-dry dressings, irrigation, whirlpool), and biologic debridement (sterile maggots—*Lucilia sericata* larvae consume necrotic tissue). Selection depends on wound type, amount of necrotic tissue, infection status, and patient tolerance.

Diabetic Foot Ulcer

– A chronic wound of the foot in a patient with diabetes, resulting from peripheral neuropathy, peripheral artery disease, and impaired wound healing. Neuropathic ulcers: painless, at pressure points (plantar metatarsal heads, heel), punched-out appearance, surrounded by callus. Ischemic ulcers: painful, at toes or margins of foot, with pale, cool, hairless skin. Risk factors: poor glycemic control, long diabetes duration, prior amputation, neuropathy, PAD, and foot deformity. Diagnosis: monofilament testing, ankle-brachial index, vascular duplex ultrasound, and wound assessment. Treatment: offloading (total contact cast, CAM boot, wheelchair), debridement, infection control (antibiotics, surgical drainage for osteomyelitis), revascularization for

ischemic ulcers, and advanced wound care (negative pressure, growth factors, bioengineered skin). Prevention: daily foot inspection, proper footwear, glycemic control, and podiatry referral.

Dilation and Curettage (D&C)

– Surgical dilation of the cervix and curettage (scraping) of the uterine lining. Indications: incomplete or missed abortion (miscarriage management), therapeutic abortion, endometrial sampling (abnormal uterine bleeding, postmenopausal bleeding, endometrial hyperplasia/cancer), and removal of retained products of conception (RPOC). Complications: uterine perforation (1-3%, higher in postmenopausal, retroverted uterus), cervical laceration, hemorrhage, infection, and Asherman syndrome (intrauterine adhesions from overzealous curettage). Now often replaced by hysteroscopy-guided procedures.

Discectomy

– Surgical removal of a herniated intervertebral disc fragment compressing a nerve root. Microscopic discectomy (most common): small incision, microscope, minimal muscle dissection. Indications: radicular pain (sciatica, cervical radiculopathy) refractory to 6-12 weeks of conservative therapy, progressive motor deficit, and cauda equina syndrome (surgical emergency). Success rate: 85-95% for leg pain relief. Also performed via endoscopic, minimally invasive (Tubular/METRx, MIS-TLIF for associated instability), and open (rarely). Complications: dural tear (3-5%), infection, hematoma, recurrent herniation, and nerve root injury.

Drowning

– Respiratory impairment from submersion/immersion in liquid. Drowning can be fatal or non-fatal. Pathophysiology: laryngospasm followed by aspiration of fluid, surfactant washout, pulmonary edema, and hypoxemia. Fresh water: washes out surfactant, causes alveolar collapse. Salt water: draws fluid into alveoli (pulmonary edema). Both cause severe hypoxemia, metabolic acidosis, and multiorgan failure. Risk factors: children 1-4 (bathtubs, pools), alcohol use, lack of supervision, and seizure disorders. Management: immediate rescue, CPR with rescue breaths (most important intervention), ICU care with ventilation, and treatment of aspiration pneumonia and ARDS.

Prognosis: associated with submersion time, CPR delay, water temperature, and neurologic status on arrival.

Electrical Injury

– Tissue damage caused by passage of electrical current through the body. Severity depends on voltage, current (alternating vs. direct), pathway, duration, and resistance. High-voltage ($>1000\text{V}$): extensive internal tissue damage (muscle necrosis, compartment syndrome, rhabdomyolysis) with relatively small skin burns (entry/exit wounds). Cardiopulmonary effects: arrhythmias (ventricular fibrillation, asystole), cardiac arrest. Neurologic effects: spinal cord injury, peripheral nerve damage, cognitive deficits. Complications: acute kidney injury (myoglobinuria), compartment syndrome, fractures from falls, and delayed neurologic deficits. Diagnosis: ECG, CK, urine myoglobin, CT/MRI. Treatment: ABCs, cardiac monitoring, IV fluids with alkalization (bicarbonate), surgical fasciotomy/debridement for compartment syndrome. Tetanus prophylaxis.

Esophageal Surgery

– GERD surgery: Nissen fundoplication (360° wrap, gold standard), partial wraps (Toupet 270° , Dor anterior $180\text{--}200^\circ$) for dysmotility. LINX device (magnetic sphincter augmentation) alternative. Achalasia: Heller myotomy (laparoscopic/robotic) + partial fundoplication (Dor); POEM (peroral endoscopic myotomy) endoscopic alternative; pneumatic dilation (recurrence 30-50%). Esophageal cancer: adenocarcinoma (distal, Barrett's), squamous (proximal/mid, smoking/alcohol). Staging: EUS, PET-CT, laparoscopy for peritoneal disease. Neoadjuvant chemoradiation (CROSS regimen: carboplatin + paclitaxel + 41.4 Gy) for locally advanced (T2N+ or T3-4 any N). Surgery: Ivor Lewis (right thoracotomy + laparotomy, for mid/distal), McKeown (right thoracotomy + laparotomy + cervical, for proximal), transhiatal (blunt dissection, for distal, higher anastomotic leak rate). Reconstruction: gastric conduit (greater curve based on right gastroepiploic artery, most common), colon interposition (when stomach unavailable). Three-field lymphadenectomy (cervical, mediastinal, abdominal) for squamous cell carcinoma at or above the carina. Anastomotic techniques: stapled (EEA, 21-25 mm, end-to-side) or hand-sewn (two-layer running

or interrupted, anastomotic leak rate 5-15%). Wait time of 8-12 weeks after neoadjuvant therapy for surgical resection. Outcomes: 5-year survival for esophageal cancer is 15-25% overall; 40-50% for patients who achieve a pathological complete response (pCR) after neoadjuvant chemoradiation. Salvage oesophagectomy for persistent or recurrent disease after definitive chemoradiation (50.4 Gy + chemotherapy) has higher morbidity (30-50% complication rate, especially anastomotic leak and pulmonary complications).

Evisceration

– Protrusion of viscera through a dehiscence abdominal wound, typically occurring 5-8 days postoperatively and constituting a surgical emergency. Risk factors include obesity, wound infection, and inadequate fascial closure. Management requires sterile coverage, broad-spectrum antibiotics, and emergent operative reclosure. The term is distinct from ophthalmologic evisceration.

Excision

– The surgical removal of a piece of tissue, an organ, or a lesion. Excisional biopsy removes the entire lesion with a margin of normal tissue, used for definitive diagnosis and treatment of small tumors (suspected melanoma, breast lump, lymph node). Wide local excision removes the lesion with an additional margin of healthy tissue for oncologic clearance. In biochemistry, excision repair: the removal of damaged DNA segments. Surgical principles: hemostasis, closure method (primary, secondary, or tertiary intention), and specimen orientation for pathology. Margin status (clear, close, or involved) is the most important prognostic factor for local recurrence in cancer surgery.

Fasciotomy

– Surgical incision through the fascia to relieve compartment syndrome. Indications: acute compartment syndrome (trauma, reperfusion, burns, crush injury). Classic signs: pain out of proportion, pain with passive stretch, paresthesias, pallor, pulselessness (late). Diagnosis: clinical, compartment pressure $>30\text{ mmHg}$ OR delta pressure (diastolic BP minus compartment pressure) $<30\text{ mmHg}$. Leg: 4 compartments (anterior, lateral, superficial posterior, deep posterior) via two incisions. Forearm: volar (Henry approach) and dorsal. Foot, thigh,

hand, abdomen (for abdominal compartment syndrome) also possible. Fasciotomy wounds are left open for 48-72 hours, then delayed primary closure or skin grafting.

Femoral Hernia

– A hernia of abdominal contents through the femoral ring, into the femoral canal, medial to the femoral vessels and below the inguinal ligament. More common in women (3:1) and more prone to strangulation (40%) than inguinal hernias due to narrow, rigid femoral ring. Presents as a small, non-reducible mass below and lateral to the pubic tubercle (distinguishing from inguinal hernia). Diagnosis: clinical; ultrasound/CT for equivocal cases. Treatment: surgical repair (McVay, mesh plug, or laparoscopic TEP/TAPP) due to high strangulation risk. Emergency surgery for strangulated or incarcerated femoral hernia.

Frostbite

– Tissue injury caused by freezing of skin and underlying tissues. Severity grading: first degree (superficial, numbness, erythema), second degree (blisters, clear fluid, pain), third degree (hemorrhagic blisters, necrosis, full-thickness skin loss), fourth degree (deep tissue necrosis, mummification, autoamputation). Common sites: fingers, toes, nose, ears, cheeks. Predisposing factors: cold exposure, wind chill, vasoconstriction, immobility, alcohol, smoking, diabetes. Pathophysiology: ice crystal formation, endothelial injury, thrombosis, and reperfusion injury upon rewarming. Diagnosis: clinical. Treatment: rapid rewarming in water 37-39°C (100-104°F) for 15-30 minutes; ibuprofen, tetanus prophylaxis, wound care, and delayed amputation (march of demarcation). Thrombolytic therapy (tPA) within 24 hours for severe cases to reduce amputation rate.

Gallbladder Cancer

– Aggressive, often diagnosed incidentally after cholecystectomy for cholelithiasis (1-2% of cholecystectomies). Risk factors: gallstones (chronic inflammation), porcelain gallbladder (calcified wall, 10-25% cancer risk), anomalous pancreaticobiliary junction, gallbladder polyps >1cm, typhoid carrier state. T staging: T1a (lamina propria), T1b (muscularis), T2 (perimuscular connective tissue), T3 (perforates serosa or invades liver/adjacent organ), T4 (main

portal vein/hepatic artery, extensive). Lymphatic spread: cystic, pericholedochal, hilar, peripancreatic, periduodenal, celiac, retroperitoneal nodes. Surgical management: T1a: simple cholecystectomy alone is sufficient (no lymphadenectomy required, 5-year survival >95%); T1b: extended cholecystectomy (cholecystectomy + en bloc wedge resection of liver segments IVb and V + portal lymphadenectomy) is the minimum recommended operation (5-year survival 80-85%); T2: extended cholecystectomy + portal lymphadenectomy (5-year survival 50-60%); T3: extended cholecystectomy + portal lymphadenectomy ± bile duct resection/right hepatectomy (5-year survival 20-30%); T4: unresectable (palliative: biliary stenting, chemotherapy). Incidental gallbladder cancer discovered after simple cholecystectomy: refer to a hepatobiliary center for completion radical cholecystectomy (wedge resection of gallbladder bed, portal lymphadenectomy, ± bile duct excision and reconstruction with Roux-en-Y hepaticojejunostomy) within 4 weeks of the initial cholecystectomy. Chemotherapy: gemcitabine + cisplatin for advanced disease (ABC-02 and BILCAP trials). Prognosis: overall 5-year survival 5-15%, worse if lymph node involvement (5-year survival <10% with nodal metastases). Adjuvant chemotherapy with capecitabine (BILCAP) or gemcitabine-based regimens may improve survival after curative resection.

Gastric Bypass

– Roux-en-Y gastric bypass creating a small proximal pouch drained by a Roux limb, combining restrictive and mildly malabsorptive mechanisms. Indicated for BMI over 40, or over 35 with obesity-related comorbidity. Mean excess weight loss approaches 60-70 percent. Complications include anastomotic leak, marginal ulcer, dumping syndrome, and nutritional deficiencies.

Gastric Surgery

– Gastric cancer: D2 lymphadenectomy standard (stations 1-12a, 12b). Gastrectomy types: total, distal subtotal (Billroth I gastroduodenostomy, Billroth II gastrojejunostomy, Roux-en-Y), proximal, pylorus-preserving. Reconstruction: Roux-en-Y preferred (prevents bile reflux). Early gastric cancer (T1a): ESD (endoscopic submucosal dissection) if no LVI, well-differentiated, <2cm (expanded crite-

ria). Neoadjuvant: FLOT (5-FU, leucovorin, oxaliplatin, docetaxel) superior to surgery alone. Palliative: systemic chemotherapy, palliative resection for bleeding/obstruction/perforation, stenting for GOO (gastric outlet obstruction). GIST: imatinib (neoadjuvant for downstaging, adjuvant if high risk: >10cm, mitotic >10/HPF, rupture), surgery (R0, avoid rupture). MALT lymphoma: *H. pylori* eradication first; only treat with surgery or chemoradiation if not responsive. Perforated peptic ulcer: omental patch repair (Graham patch: interrupted 2-0 silk sutures through the full thickness of each side of the perforation, tied over a pedicle of omentum, which is then secured in place with a second set of sutures), laparoscopic (preferred if hemodynamically stable, no contamination, surgeon experience), open if peritonitis. Intraoperative decision-making: if the perforation is >2cm, there is a suspicion of malignancy, or the edges are oedematous and friable, a more extensive resection may be required (distal gastrectomy with Billroth II or Roux-en-Y reconstruction). Post-operative: PPI infusion (omeprazole 80 mg bolus + 8 mg/hour), *H. pylori* testing and eradication (triple therapy: PPI + amoxicillin + clarithromycin or metronidazole, 14-day course), return to oral intake after resolution of ileus.

Grafting

– The surgical transfer of tissue from one site to another, or from one individual to another. Types: (1) Autograft: same individual (gold standard, e.g., skin graft for burns, bone graft for non-union, saphenous vein graft for CABG). (2) Allograft: same species, different individual (cadaveric bone, cornea, heart valve, kidney). (3) Xenograft: different species (porcine heart valve, porcine/bovine skin for burns). (4) Isograft: identical twin (syngeneic). (5) Synthetic graft: prosthetic material (Dacron vascular graft, Gore-Tex, metal implants, polyethylene for joint replacement). Skin grafts: split-thickness (epidermis + part of dermis) or full-thickness (epidermis + full dermis). Flaps: tissue transferred with its blood supply intact (pedicled or free). Complications: graft rejection (allografts, xenografts), infection, haematoma, seroma, graft failure (ischemia), contracture. Immunosuppression (tacrolimus, mycophenolate, corticosteroids) is required for allograft organ transplantation.

Heimlich Manoeuvre

– An emergency procedure for relieving upper airway obstruction caused by a foreign body (choking). The maneuver is performed on a conscious, choking adult who cannot speak, cough effectively, or breathe. Technique: the rescuer stands behind the victim, wraps their arms around the victim's waist, makes a fist with one hand (thumb side against the victim's abdomen, midline above the navel and well below the xiphoid process), grasps the fist with the other hand, and performs upward, inward thrusts (abdominal thrusts). For obese or pregnant victims, chest thrusts (similar position but on the lower sternum) are used instead. The maneuver abruptly increases intra-abdominal and intrathoracic pressure, forcing air out of the lungs and creating a cough-like force to expel the obstructing object. For a choking infant (under 1 year): hold the infant face-down along the rescuer's forearm, with the head lower than the trunk, and deliver 5 back blows between the shoulder blades, followed by 5 chest thrusts (face-up, two fingers on lower sternum). The Heimlich maneuver is contraindicated for: infants under 1 year (use back blows and chest thrusts), unconscious victims (start CPR), and cases where the obstruction is not complete (partial obstruction with good air exchange, encourage coughing). After successful expulsion, the patient should have a medical evaluation to exclude complications (esophageal rupture, gastric rupture, pneumothorax, abdominal organ injury).

Hemicolectomy

– See Colectomy.

Hemorrhagic Shock

– Inadequate oxygen delivery from acute blood loss, classified by ATLS into four classes by volume lost (up to 15, 15-30, 30-40, and over 40 percent). Class IV requires immediate transfusion. Resuscitation uses warmed crystalloid at 3:1 ratio, then blood products in a 1:1:1 ratio. Tranexamic acid within 3 hours reduces mortality.

Hemorrhoidectomy

– Surgical excision of symptomatic hemorrhoids. Indications: Grade III-IV internal hemorrhoids (prolapsed, irreducible), external hemorrhoids with uncontrolled bleeding or recurrent thrombosis, mixed hemorrhoids. Techniques: closed (Ferguson, pri-

mary closure), open (Milligan-Morgan, leave wounds open), and stapled hemorrhoidopexy (PPH, for circumferential prolapse, lower pain but higher recurrence). Laser, bipolar, and harmonic scalpel techniques also available. Postoperative pain is significant (particularly with open technique). Recovery: 2-4 weeks. Complications: pain, bleeding, urinary retention, anal stenosis, and incontinence.

Hepatic Surgery

– Liver resection: Couinaud segments. Indications: colorectal liver metastases (CRLM, up to 70% 5-year survival with R0), HCC (Child-Pugh A, portal pressure <10 mmHg, future liver remnant >20% normal, >40% cirrhotic), cholangiocarcinoma, benign tumors (adenoma >5cm, symptomatic hemangioma, FNH diagnostic uncertainty). Preoperative: PVE (portal vein embolization) for FLR <20%/40%; ALPPS (associating liver partition and portal vein ligation) for rapid hypertrophy (2 weeks). Techniques: open, laparoscopic, robotic. Pringle manoeuvre (clamp hepatoduodenal ligament, 15-20 min on, 5 min off, ischemic preconditioning may reduce ischemia-reperfusion injury). Low central venous pressure (CVP <5 mmHg) anesthesia. Parenchymal transection: crush-clamp (Kelly clamp), CUSA (cavitron ultrasonic surgical aspirator), LigaSure, Harmonic scalpel. Hepatic vein management: extrahepatic control (right, middle, left suprahepatic veins) or intrahepatic approach (anterior approach with hanging manoeuvre). Complications: bile leak (3-10%), PHLF (post-hepatectomy liver failure, defined by ISGLS peak bilirubin >50 $\mu\text{mol/L}$ + INR >1.5 on post-operative day 5; management: medical support, albumin, diuretics, TIPS, or liver transplantation in severe cases), hemorrhage, abscess, ascites. Non-resectional techniques: RFA (radiofrequency ablation), MWA (microwave ablation), IRE (irreversible electroporation), SBRT (stereotactic body radiotherapy), TACE (transarterial chemoembolization), and TARE (transarterial radioembolization with yttrium-90), each indicated for specific tumor types and locations where surgical resection is not feasible. Liver transplantation: Milan criteria for HCC (single ≤ 5 cm or up to 3 nodules each ≤ 3 cm, no extrahepatic disease, no major vascular invasion) with 5-year survival >70%.

Hernia

– The protrusion of an organ or tissue through an abnormal opening in the wall of the cavity that normally contains it. Most hernias occur in the abdominal wall. Types: (1) Inguinal hernia (most common): indirect (through the deep inguinal ring, lateral to inferior epigastric vessels, congenital or acquired, more common in younger men) vs direct (through Hesselbach triangle, medial to inferior epigastric vessels, acquired, older men). (2) Femoral hernia: through the femoral ring below the inguinal ligament, more common in women, higher risk of strangulation (40%) vs inguinal (10%). (3) Umbilical hernia: through the umbilical ring, common in infants (usually resolves spontaneously by age 2-4) and adults (obesity, pregnancy, ascites). (4) Incisional (ventral) hernia: through a surgical scar, risk factors: wound infection, obesity, smoking, COPD. (5) Hiatus hernia: see separate entry. (6) Epigastric hernia: through the linea alba. (7) Spigelian hernia: through the linea semilunaris. (8) Obturator hernia: through the obturator foramen (rare, elderly thin women). (9) Lumbar hernia: through the lumbar triangle. (10) Diaphragmatic hernia: through the diaphragm. Diagnosis: history (lump or bulge, worse on standing/straining, cough impulse), examination (inspection: visible bulge; palpation: cough impulse; reducibility). Complications: irreducibility (cannot be reduced), obstruction (bowel obstruction), strangulation (vascular compromise–ischemia, gangrene, surgical emergency). Treatment: surgical repair (open or laparoscopic; tension-free mesh repair is standard–Lichtenstein for inguinal, laparoscopic transabdominal preperitoneal TAPP or totally extraperitoneal TEP). Watchful waiting is an option for minimally symptomatic inguinal hernias in men.

Hernia Repair (Herniorrhaphy)

– Surgical repair of a hernia (inguinal, femoral, umbilical, incisional, hiatal). Inguinal hernia repair: open (Lichtenstein tension-free mesh, Shouldice, Bassini) or laparoscopic (TEP: totally extraperitoneal, TAPP: transabdominal preperitoneal). Mesh reinforcement reduces recurrence (1-3% for mesh vs. 5-15% for primary tissue repair). Indications: symptomatic hernia, incarceration/strangulation risk, and groin pain. Emergency repair for strangulated hernia (bowel resection may be needed). Compli-

cations: recurrence, chronic groin pain (5-10%, especially open), mesh infection, seroma, hematoma, and cord injury (vas deferens, testicular vessels).

Hiatus Hernia

– The protrusion of part of the stomach through the esophageal hiatus of the diaphragm into the chest cavity. Types: (1) Sliding hernia (type I, 95%): the gastro-esophageal junction (GOJ) and a portion of the gastric cardia slide above the diaphragm through the hiatus. The GOJ is displaced cephalad, and the angle of His is lost, predisposing to GORD. Associated with: obesity, pregnancy, increased intra-abdominal pressure. (2) Para-esophageal hernia (type II): the GOJ remains in its normal position below the diaphragm, but a portion of the gastric fundus herniates alongside the esophagus. (3) Mixed (type III): both GOJ and fundus herniate. (4) Type IV: herniation of other abdominal organs (colon, omentum, spleen) through the hiatus. Para-esophageal hernias (types II-IV) can incarcerate or strangulate. Symptoms: many sliding hernias are asymptomatic; associated with GORD (heartburn, regurgitation, dysphagia, chest pain, chronic cough). Large para-esophageal hernias may cause: postprandial fullness, chest pain, dyspnoea, dysphagia, vomiting, and rarely acute gastric volvulus (Borchardt triad: severe epigastric pain, retching without vomiting, inability to pass a nasogastric tube—surgical emergency). Diagnosis: barium swallow (GOJ above diaphragm), upper endoscopy (GOJ displacement, Los Angeles classification of oesophagitis), high-resolution manometry. Management: asymptomatic sliding hernias require no treatment; symptomatic GORD: PPI therapy, lifestyle measures; para-esophageal hernias with symptoms or risk of volvulus: laparoscopic Nissen fundoplication with hernia reduction and crural repair (hiatoplasty).

Hysterectomy

– Surgical removal of the uterus. Total hysterectomy: removal of uterus and cervix. Subtotal (supracervical): removes uterus, leaves cervix. Radical hysterectomy: uterus, cervix, parametrium, upper vagina, and pelvic lymph nodes (for cervical cancer). Routes: abdominal (open, most common for large uteri/malignancy), vaginal (for prolapse, small uterus), laparoscopic (TLH, less pain, shorter stay),

and robotic (da Vinci, improved dexterity). Indications: uterine fibroids (most common), endometriosis, adenomyosis, uterine prolapse, abnormal uterine bleeding, endometrial cancer, cervical cancer, and ovarian cancer. Complications: bleeding, infection, ureter/bladder/bowel injury, and vaginal cuff dehiscence.

Ileostomy

– A surgically created stoma from the terminal ileum to the abdominal wall, performed after proctocolectomy for ulcerative colitis or familial adenomatous polyposis, or to protect a distal anastomosis. Output is liquid and enzyme-rich, requiring careful fluid and skin management. Complications include high-output stoma, hernia, and dehydration.

Incisional Hernia

– A hernia through a previous surgical incision scar, the most common long-term complication of abdominal surgery (10-20% of laparotomies). Risk factors: wound infection, obesity, smoking, malnutrition, COPD, and multiple previous surgeries. Present as a bulge at or near the incision site, worse with standing or straining. Can cause pain, obstruction, and strangulation. Diagnosis: clinical; CT for evaluation of size, number of defects, and contents. Treatment: surgical repair with mesh (open sublay, onlay, or laparoscopic IPOM) to reduce recurrence. Component separation for large/complex hernias.

Inguinal Hernia

– Protrusion of abdominal contents through the inguinal canal. Indirect (lateral to inferior epigastric vessels, through deep inguinal ring): congenital, patent processus vaginalis; most common overall (60-70%), male predominance. Direct (medial to inferior epigastric vessels, through Hesselbach triangle): acquired, weakness of transversalis fascia; older men. Pantaloon: both indirect and direct. Femoral hernia (below inguinal ligament, through femoral canal): more common in women, right-sided predominance. Clinical: groin bulge (medial to pubic tubercle, below inguinal ligament, irreducible, may cause obstruction or strangulation). Imaging: ultrasound (sensitivity 95%,Valsalva enhancement increases sensitivity) or MRI if diagnosis uncertain. Management: elective repair (symptomatic; open or laparoscopic: TEP - totally extraperitoneal, TAPP - transabdominal

preperitoneal). Mesh (polypropylene, lightweight macroporous) preferred over tissue repair (Bassini, Shouldice, McVay, Desarda, Lichtenstein) due to <5% recurrence. Lichtenstein: open tension-free mesh onlay repair, gold standard for open inguinal hernia repair. Laparoscopic: lower recurrence for bilateral and recurrent hernias, faster recovery, less chronic pain (in experienced hands, 1-2% for TEP). Emergency surgery for obstruction/strangulation: McBurney or Lotheissen approach (low midline incision for control of incarcerated bowel), viable bowel → herniorrhaphy, nonviable bowel → resection + herniorrhaphy. Femoral hernia repair: McEvedy approach (retroperitoneal, high approach, through a lower midline or transverse lower abdominal incision) or laparoscopic TEP/TAPP; locking sutures or mesh plug (Bard plug, PerFix plug) or open suture repair (Moschcowitz type, a suture repair of the femoral canal). Complications: recurrence (1-10%, higher with tissue repairs and laparoscopic learning curve), chronic groin pain (10-20%, higher with open, meshoma, nerve entrapment, triple neurectomy for refractory cases), seroma, haematoma, infection (mesh infection <1%, may require mesh removal), testicular atrophy or ischemic orchitis (1-2% during open repair for recurrent hernias or large scrotal hernias), and urinary retention (5-10%, transient) in older male patients after general or spinal anesthesia.

Jejunostomy

– See Feeding Jejunostomy.

Laceration

– A wound caused by tearing of body tissue, typically caused by trauma from a sharp object (knife, glass, metal) or blunt force that splits the skin. Lacerations involve the skin and may extend into subcutaneous tissue, muscle, tendon, nerve, or blood vessels. Assessment: location, length, depth, contamination, foreign bodies, neurovascular status (sensation, motor function, capillary refill, distal pulses), and involvement of deeper structures (tendon function, bone exposure). Management: (1) hemostasis: direct pressure, elevation. (2) Wound cleaning: irrigation with normal saline (high-pressure, 250-500 mL, reduces bacterial load). (3) anesthesia: local infiltration with lidocaine 1-2% (with or without adrenaline, max 4.5 mg/kg plain, 7 mg/kg with

adrenaline) or topical lidocaine-prilocaine cream for wound margins. (4) Exploration: assess for foreign bodies, tendon/nerve/vascular injury. (5) Debridement: excision of devitalised tissue, ragged wound edges (freshening). (6) Closure: primary closure (sutures—simple interrupted, continuous/mattress, subcuticular; tissue adhesive; adhesive strips; staples) for clean, non-infected wounds; delayed primary closure (3-5 days) for contaminated wounds; healing by secondary intention for infected or high-risk wounds. Tetanus prophylaxis: clean wound—tetanus toxoid if last dose >10 years; contaminated wound—tetanus toxoid + immunoglobulin if last dose >5 years or unknown. Antibiotics: not routinely indicated for simple lacerations; consider for contaminated wounds, human/animal bites, immunocompromised patients. Sutures removal timing: face 3-5 days, scalp 7 days, trunk/arms 7-10 days, legs 10-14 days. Complications: wound infection (2-5%), dehiscence, hypertrophic scarring/keloid, retained foreign body, nerve damage.

Laminectomy

– Surgical removal of the lamina (posterior vertebral arch) to decompress the spinal canal. Indications: spinal stenosis (lumbar and cervical), herniated disc (with central stenosis), and spinal tumor. Decompression of the entire spinal canal. Often combined with discectomy (lumbar) or foraminotomy (nerve root decompression). May require fusion if instability is present (laminectomy with fusion, PLF). Complications: CSF leak (dural tear), spinal instability (post-laminectomy kyphosis), epidural hematoma, infection, and neurologic injury.

Large Bowel Obstruction

– Less common than SBO. Causes: colorectal cancer (60%), diverticular stricture (20%), volvulus (sigmoid 60%, cecal 40%), fecal impaction, Ogilvie syndrome (acute colonic pseudo-obstruction), ischemic stricture, endometriosis, radiation stricture. Clinical: abdominal distension (prominent), constipation/obstipation, less vomiting than SBO, pain may be less severe. Imaging: abdominal X-ray (dilated colon >6cm, cecum >9cm predicts perforation), CT with contrast (transition point, cause, closed loop obstruction, pneumatosis intestinalis indicating ischemia, portal venous gas, pneumoperitoneum - all signs of ischemia or perforation). Water-soluble

contrast enema can differentiate pseudo-obstruction (Ogilvie) from mechanical obstruction (transition point, cut-off sign). Management: NPO, NGT, IV fluids, correct electrolyte abnormalities. Specific management depends on the cause. Sigmoid volvulus: endoscopic detorsion (rigid sigmoidoscopy with placement of a flatus tube, success rate 80-90%) + elective sigmoid colectomy (resection with primary anastomosis) during the same admission (recurrence 40-60% without surgery). Cecal volvulus: colonoscopic detorsion (less successful, 30-40%) + right hemicolectomy. Colorectal cancer: segmental colectomy with primary anastomosis (elective); emergency: resection with stoma (Hartmann) or resection with on-table colonic lavage and primary anastomosis (controversial, increased leak risk). Stenting (self-expanding metallic stent, SEMS) as bridge to surgery (if no perforation, no peritonitis, and the tumor is accessible, allows for medical optimisation and elective resection with primary anastomosis avoiding a stoma in 80-90% of cases) or as definitive palliation (for metastatic disease, high surgical risk). Ogilvie syndrome (acute colonic pseudo-obstruction): conservative (NPO, NGT, correction of electrolytes, mobilisation), neostigmine (2 mg IV, continuous cardiac monitoring for bradycardia and bronchospasm, only in the absence of mechanical obstruction confirmed by CT or water-soluble contrast enema; response within 30 minutes in 60-90% of patients), colonoscopic decompression (suction of air, aspiration of liquid stool) for neostigmine failure, cecostomy (percutaneous or surgical) for recurrence. Contraindications to neostigmine: mechanical obstruction, bradycardia, hypotension, bronchial asthma, peptic ulcer disease, pregnancy. Surgical intervention (laparotomy with colectomy, subtotal colectomy with terminal ileostomy and Hartmann closure of the distal stump) for perforation, ischemia, or failure of all conservative measures.

Ligature

– A surgical tie placed around a vessel or structure to occlude its lumen and secure hemostasis, using absorbable (polyglactin) or non-absorbable (silk, polypropylene) suture material. A transfixion ligature passes the needle through the structure before tying to prevent slippage. Distinguished from clips and stapling devices.

Lobectomy

– Surgical removal of a lobe of an organ. Most commonly lung lobectomy (removal of one lobe of the lung, performed for lung cancer, bronchiectasis, abscess, or benign tumor) or temporal lobectomy (removal of the anterior temporal lobe for drug-resistant temporal lobe epilepsy). Lung lobectomy: the standard surgical treatment for early-stage (stage I-II) non-small cell lung cancer (NSCLC). Approaches: open thoracotomy (posterolateral) or video-assisted thoracoscopic surgery (VATS, minimally invasive, less post-operative pain, shorter hospital stay, equivalent oncologic outcomes). The remaining lung lobes expand to fill the thoracic cavity. Pulmonary function loss corresponds to the number of segments removed (each lobe contains 2-5 bronchopulmonary segments). Compensatory hyperinflation of remaining lung occurs over weeks. Temporal lobectomy: anterior temporal lobectomy (ATL) for epilepsy involves resection of 3-4 cm of the anterior temporal neocortex plus the amygdala and anterior 2-3 cm of the hippocampus. Seizure-free outcome: 60-70% in well-selected patients with mesial temporal sclerosis. Complications: visual field deficit (superior quadrantanopia, due to optic radiation Meyer loop injury, 50-80%), language deficits (dominant hemisphere), memory impairment. Other lobectomies: hepatic lobectomy (liver resection, for cancer or living donor), thyroid lobectomy (removal of one thyroid lobe, for thyroid nodule/cancer), and cerebral lobectomy (removal of a whole brain lobe, for severe trauma or tumor).

Local Anesthesia

– The reversible abolition of sensation in a circumscribed area by infiltration or topical application of local anesthetic agents (lidocaine, bupivacaine) without loss of consciousness. Maximum safe dosing must be observed to avoid systemic toxicity. Epinephrine prolongs duration but is avoided in end-arterial territories.

Lumpectomy

– Breast-conserving surgery excising a malignant lesion with a margin of normal tissue, combined with whole-breast radiation to yield survival equivalent to mastectomy for early-stage cancer. An acceptable margin is no ink on tumor for invasive cancer and 2 mm for ductal carcinoma in situ. Sentinel lymph

node biopsy is integrated for axillary staging.

Mastectomy

– Surgical removal of the breast. Total (simple) mastectomy: removal of breast tissue, areola, and nipple. Modified radical mastectomy (MRM): total mastectomy + axillary lymph node dissection (levels I-III), for invasive breast cancer. Skin-sparing mastectomy: preserves breast skin envelope for immediate reconstruction (implant or autologous). Nipple-sparing mastectomy: preserves nipple-areolar complex (for small, peripherally located tumors). Indications: breast cancer (locally advanced, multicentric, inflammatory), and risk-reducing in BRCA carriers (prophylactic bilateral mastectomy). Sentinel lymph node biopsy (SLNB) replaced ALND for node-negative patients. Reconstruction: implant-based or autologous (TRAM, DIEP, latissimus dorsi flap).

Necrotizing Fasciitis

– A life-threatening soft tissue infection characterized by rapid necrosis of the subcutaneous fascia and subcutaneous tissue, with relative sparing of the overlying skin in early stages. It is a surgical emergency requiring immediate wide surgical debridement and broad-spectrum antibiotics. Type I (polymicrobial, 60-75 percent of cases) occurs in diabetic, immunocompromised, or post-surgical patients and involves aerobic and anaerobic bacteria (*E. coli*, *Klebsiella*, *Bacteroides*, *Peptostreptococcus*, *Clostridium* species). Type II (monomicrobial, 15-30 percent) is caused by Group A *Streptococcus* (*Streptococcus pyogenes*) with or without *Staphylococcus aureus*, often in healthy individuals, and may present with toxic shock syndrome. Type III (gram-negative, marine-related: *Vibrio vulnificus*, *Aeromonas hydrophila*) occurs after exposure to seawater or freshwater, especially in patients with chronic liver disease. Type IV (fungal: *Candida*, *Mucor*, *Aspergillus*) occurs in severely immunocompromised patients and neutropenic patients. LRINEC score (Laboratory Risk Indicator for Necrotizing Fasciitis) stratifies risk: CRP >150 mg/L + WBC >15,000 + Hb <11 g/dL + Na <135 mmol/L + Cr >1.6 mg/dL + glucose >10 mmol/L, with a score ≥6 raising suspicion (positive predictive value 92%) and ≥8 strongly predictive (positive predictive value 93-99%). Management:

aggressive IV fluid resuscitation, broad-spectrum antibiotics (piperacillin-tazobactam 4.5 g IV q6h or meropenem 1 g IV q8h + clindamycin 600-900 mg IV q8h to suppress toxin production, particularly for streptococcal toxic shock syndrome), urgent surgical debridement (fasciotomy with excision of all devitalised tissue, to the level of healthy bleeding muscle, re-exploration within 24-48 hours is mandatory). IVIG is used as adjunctive therapy for streptococcal toxic shock syndrome (2 g/kg loading dose, then 0.4 g/kg/day for 3-5 days). Hyperbaric oxygen (HBO) therapy is controversial but may be beneficial as an adjunct. Post-operative care includes repeat debridement such that the wound is thoroughly debrided within 24-72 hours, negative pressure wound therapy (NPWT) to promote granulation, and delayed primary closure or split-thickness skin grafting (STSG) once the wound is clean. Mortality: 20-40%, >50% if septic shock at presentation. Amputation rate is 15-25%. Poor prognostic factors include advanced age (>60), diabetes mellitus, delay in surgery (>24 hours from admission to first debridement), involvement of the trunk, and streptococcal toxic shock syndrome. Renal failure, immune compromise, LRINEC score ≥8 and the presence of bullae or skin necrosis are also poor prognostic signs.

Nephrectomy

– Surgical removal of a kidney. Radical nephrectomy: kidney + Gerota fascia + adrenal gland (for renal cell carcinoma). Partial nephrectomy (nephron-sparing): for small renal tumors (<7 cm, renal function preservation). Simple nephrectomy: for benign disease (non-functioning kidney, chronic infection, massive hydronephrosis). Laparoscopic/robotic approach is standard (less pain, shorter stay). Indications: renal cell carcinoma (most common), trauma, and living donor nephrectomy. Complications: bleeding, infection, pneumothorax, splenic or pancreatic injury (left), and vascular injury.

Nephrostomy Tube

– A percutaneously placed catheter in the renal pelvis to drain urine, bypassing a ureteral obstruction. Indications: ureteral obstruction (calculus, tumor, stricture) causing hydronephrosis, pyonephrosis (infected, obstructed kidney — emergency drainage), and as a temporary measure be-

fore definitive surgery. Placed by interventional radiology under ultrasound/CT guidance. Sizes: 8-14 Fr. Output: normal 1-2 L/day. Tube is secured to the skin and connected to a drainage bag. Changed q6-12 weeks. Complications: bleeding (hematuria, perirenal hematoma), infection, tube dislodgement/obstruction, and adjacent organ injury (colon, pleura).

Open-Heart Surgery

– Any surgical procedure involving opening the chest wall (sternotomy or thoracotomy) and operating on the heart, usually with cardiopulmonary bypass (the heart–lung machine). Procedures: coronary artery bypass grafting (CABG—most common), valve repair/replacement (aortic, mitral), septal defect repair (ASD, VSD), heart transplantation, and ventricular assist device implantation. Cardiopulmonary bypass drains venous blood, oxygenates it, and returns it to the arterial system, allowing the surgeon to operate on a still, bloodless heart. Cardioplegia solution (high potassium) stops the heart in diastole, reducing myocardial oxygen demand during ischemia. Risks: bleeding, infection (mediastinitis, sternal wound), stroke (aortic manipulation—embolic), acute kidney injury, post-pericardiotomy syndrome, and cognitive dysfunction ('pump head'—typically transient). Minimally invasive approaches (mini-thoracotomy, robotic-assisted) reduce recovery time and blood loss. Off-pump CABG avoids cardiopulmonary bypass but has similar outcomes in selected patients.

Organ Transplants

– The surgical transfer of an organ from a donor to a recipient with end-stage organ failure. Solid organ transplants: kidney (most common, >90,000 per year worldwide), liver, heart, lung, pancreas, and intestine. Donor types: deceased donor (brainstem death or donation after circulatory death—DCD), living donor (kidney, partial liver, partial lung). Immunosuppression: induction (anti-thymocyte globulin, basiliximab) and maintenance (calcineurin inhibitors—tacrolimus, cyclosporine; antiproliferatives—mycophenolate mofetil; corticosteroids). Rejection: hyperacute (minutes—preformed antibodies, ABO incompatibility), acute (days to months—T-cell mediated, treatable with high-dose steroids), and chronic (months

to years—multifactorial, progressive graft dysfunction). Organ allocation is managed by national bodies (NHSBT in the UK, UNOS in the US). Waiting list mortality is driven by organ shortage. Xenotransplantation (pig organs—genetically modified to reduce hyperacute rejection) is emerging as a potential solution.

Pancreatic Neuroendocrine Tumors

– Pancreatic neuroendocrine tumors (pNETs): functional (insulinoma, gastrinoma, glucagonoma, VIPoma, somatostatinoma) or non-functional (60-70%). WHO 2017 grading: NET G1 (Ki-67 <3%, mitotic <2/10 HPF), NET G2 (Ki-67 3-20%, mitotic 2-20/10 HPF), NEC G3 (Ki-67 >20%, mitotic >20/10 HPF). Functional: insulinoma (hypoglycemia, Whipple triad, 90% benign, enucleation/distal pancreatectomy), gastrinoma (Zollinger-Ellison syndrome, ulcers, diarrhea, MEN1 association, duodenal > pancreatic, surgery if localized and resectable, PPI (gastrinoma: high-dose PPI, 80 mg omeprazole daily, can be increased to 120 mg daily for symptom control), octreotide for symptom control), glucagonoma (necrolytic migratory erythema, diabetes, weight loss, DVT, distal pancreatectomy + octreotide), VIPoma (WDHA syndrome: watery diarrhea, hypokalaemia, achlorhydria, VIP levels >75 pmol/L, octreotide, surgery), somatostatinoma (diabetes, gallstones, steatorrhea, surgery). Non-functional: 60-70%, large >2cm at diagnosis, no hormonal syndrome, surgery (resection or enucleation if <2cm and favourable location). pNETs in MEN1: multiple, less aggressive, surgery for >2cm or functioning tumors in the pancreatic head; enucleation preferred for superficial tumors while deeper lesions may require pancreaticoduodenectomy; observation for small (<2cm) non-functioning pNETs with surveillance every 6-12 months (in MEN1 and sporadic cases). Syndromic associations: MEN1 (multiple pNETs, parathyroid adenomas, pituitary adenomas, carcinoid tumors), VHL (serous cystadenomas, pNETs, renal cell carcinoma, pheochromocytoma, retinal angiomas, cerebellar haemangioblastomas), tuberous sclerosis, NF1. Prognosis: 5-year survival 90% for well-differentiated localised NET, 30-50% for metastatic (grade-dependent; Ki-67 is

the most important independent prognostic factor). WHO classification 2019: well-differentiated neuroendocrine tumor (NET G1, G2, G3) and poorly differentiated neuroendocrine carcinoma (NEC G3, small cell or large cell type), with significant difference in prognosis and management (NET G3 is treated as an indolent well-differentiated NET rather than aggressive NEC G3).

Pancreatic Surgery

– Pancreaticoduodenectomy (Whipple): pancreatic head, duodenum, gallbladder, distal stomach (pylorus-preserving standard), common bile duct; reconstruction: pancreaticojejunostomy (duct-to-mucosa or invagination), hepaticojejunostomy, gastrojejunostomy/duodenojejunostomy. Distal pancreatectomy: body/tail; spleen-preserving (Kimura, Warshaw) or splenectomy. Central pancreatectomy: neck tumors, preserve head and tail. Enucleation: small pNETs/insulinomas away from duct. Complications: POPF (pancreatic fistula; ISGPS definition: amylase $>3\times$ upper limit of normal in drain fluid on or after post-operative day 3; biochemical leak (grade A, no change in management) vs grade B (requires change in management, e.g., prolonged drainage, total parenteral nutrition, somatostatin analogues, antibiotics, percutaneous drainage) vs grade C (major change in management, ICU stay, reoperation, or death); management: NPO, TPN or enteral nutrition via nasojejunal tube if possible, octreotide (somatostatin 250-500 mcg subcutaneously TDS after gastrectomy or after Whipple procedure to reduce exocrine pancreatic secretion, though evidence is mixed and routine use is not recommended), ERCP with pancreatic duct stenting for persistent high-output fistula; percutaneous drainage of fluid collections; reoperation for uncontrolled fistula or bleeding), DGE (delayed gastric emptying, ISGPS definition: NGT >500 mL/day lasting beyond post-operative day 3; management: prokinetics, NGT decompression, enteral nutrition via surgical jejunostomy tube placed at the time of pancreaticoduodenectomy or by nasojejunal tube; most cases resolve spontaneously within 2-4 weeks; persistent DGE may require endoscopic dilation or stenting if there is mechanical obstruction at the gastrojejunostomy), post-pancreatectomy hemorrhage (PPH; early <24 hours, late >24 hours; ISGPS clas-

sification: grade A no intervention, grade B intervention without ICU, grade C ICU $\pm$ reoperation $\pm$ embolisation; management: resuscitation, endoscopy or angiography with embolisation, reoperation), and pancreatic ductal adenocarcinoma (PDAC) recurrence (locoregional, liver, peritoneal, distant). Adjuvant chemotherapy: FOLFIRINOX (modified) for 6 months after resection (PRODIGE 24 trial - median survival 54.4 months vs 35.0 months for gemcitabine) or gemcitabine + capecitabine (ESPAC-4 trial). Median survival for resected PDAC is 24-30 months; 5-year survival 15-25% (improving with modern multi-agent chemotherapy). Borderline resectable PDAC: neoadjuvant chemotherapy (FOLFIRINOX or gemcitabine + nab-paclitaxel) for 2-6 months, then restaging CT and CA 19-9; proceed to surgery if no progression and venous involvement is reconstructable. Arterial involvement (celiac axis, superior mesenteric artery, common hepatic artery) generally precludes resection unless a modified approach (e.g., Appleby procedure for celiac axis involvement) is considered in selected cases.

Parathyroid Surgery

– Primary hyperparathyroidism (PHPT): single adenoma (85%), hyperplasia (15%), double adenoma (2%), carcinoma ($<1\%$). Criteria for surgery (NIH): age <50 , calcium >1 above upper limit, creatinine clearance <60 , BMD T-score <-2.5 , vertebral fracture, nephrolithiasis, nephrocalcinosis. Localization: sestamibi scan (sensitivity 80-90%), US (sensitivity 70-80%), 4D-CT, MRI, PET-Choline. Minimally invasive parathyroidectomy (MIP) for single adenoma with concordant imaging; bilateral exploration for negative or discordant imaging. Intraoperative PTH monitoring (IOPTH): drop of $>50\%$ from baseline 10 minutes after gland excision confirms cure with 95% positive predictive value. Four-gland exploration: identify 4 glands, resect enlarged, biopsy normal. Auto-transplantation: implant parathyroid tissue (typically 10-15 fragments of 1-2mm each) into brachioradialis or sternocleidomastoid muscle if total parathyroidectomy is necessary (reoperative surgery, secondary/tertiary hyperparathyroidism, multiple gland hyperplasia, MEN1, familial hypocalciuric hypercalcaemia). Reoperative parathyroid surgery: persistent (never normocalcaemic) or re-

current (normocalcaemic for >6 months) PHPT; requires pre-operative imaging (4D-CT, sestamibi with SPECT/CT, MRI, PET-Choline) and intraoperative nerve monitoring (recurrent laryngeal nerve is at risk of injury in reoperative neck surgery). Complications: recurrent laryngeal nerve injury (<1% in primary surgery, 3-5% in reoperative), hypoparathyroidism (transient 10-20%, permanent <2%), haematoma (1-2%), infection, and hungry bone syndrome (severe, prolonged hypocalcaemia after resection of severe PHPT with high pre-operative calcium and ALP; management: IV calcium gluconate infusion, oral calcium carbonate 3-6 g/day, calcitriol 0.5-2 mcg/day, magnesium replacement if indicated; worst in patients with pre-operative calcium >3.0 mmol/L and markedly elevated PTH and alkaline phosphatase). Secondary hyperparathyroidism (renal failure): medical management (phosphate binders, vitamin D analogues, cinacalcet); subtotal parathyroidectomy (3.5 gland) or total parathyroidectomy with auto-transplantation for refractory symptomatic hyperparathyroidism with persistent hypercalcaemia despite maximal medical therapy, or for tertiary hyperparathyroidism after kidney transplantation with persistent hypercalcaemia >6 months post-transplant. Tertiary hyperparathyroidism: autonomous PTH secretion despite normal renal function after renal transplantation; parathyroidectomy indicated if hypercalcaemia persists beyond 6 months from transplantation.

Penetrating Abdominal Trauma

– Trauma to the abdomen caused by a missile (gun-shot wound) or sharp object (stab wound). GSWs: high energy transfer, produce blast cavity, high risk of intra-abdominal injury (90%), mandatory exploration. Stab wounds: lower energy, 30-50% do not penetrate peritoneum; local wound exploration to determine peritoneal violation. Zones: anterior abdomen (xiphoid to pubis, costal margins), flank (midaxillary to posterior axillary line), and back (posterior to posterior axillary line). Diagnosis: CT with triple contrast (IV, oral, rectal) in stable patients; diagnostic laparoscopy for equivocal cases. Management: hemodynamic instability or peritonitis → laparotomy. Stable: serial exams, CT, and selective non-operative management.

PICC Line (Peripherally Inserted

Central Catheter)

– A long, flexible catheter inserted into the basilic or cephalic vein and advanced so the tip sits in the superior vena cava. Inserted at the bedside, often by a specialized PICC nurse, with ultrasound and ECG or X-ray confirmation. Indications: long-term IV antibiotics (>2 weeks), TPN, chemotherapy, and frequent blood draws. Sizes: 4-6 Fr single, double, or triple lumen. Duration: weeks to months. Advantages over tunneled central lines: lower risk of pneumothorax, insertion by non-physicians. Complications: infection (line-related bloodstream infection), thrombosis, phlebitis, malposition, and catheter fracture.

Postoperative Care

– Structured post-surgical management encompassing pain control, fluid balance, wound care, early mobilization, and venous thromboembolism prophylaxis. Enhanced Recovery After Surgery pathways standardize care through multimodal opioid-sparing analgesia, goal-directed fluid therapy, and early feeding to reduce length of stay and complications.

Postoperative Complications

– Clavien-Dindo classification: Grade I (any deviation, no treatment), Grade II (pharmacologic), Grade III (surgical/endoscopic/radiologic intervention: IIIa no GA, IIIb GA), Grade IV (ICU: IVa single organ, IVb multi-organ), Grade V (death). Common: ileus (delayed GI motility, NPO, NGT, ambulation, gum chewing, neostigmine for Ogilvie), anastomotic leak (clinical: pain, fever, leukocytosis; CT: extraluminal contrast, fluid; management: antibiotics, percutaneous drainage, diversion, reoperation), wound infection (SSI, superficial/deep/organ space; management: antibiotics, drainage, wound care, negative pressure wound therapy or vacuum-assisted closure), surgical site infection prevention bundle, pulmonary complications (pneumonia, atelectasis: IS/CPT, O2, incentive spirometry 10 breaths per hour, early mobilisation), DVT/PE (PESI score, Caprini risk assessment, pharmacologic prophylaxis: enoxaparin 40 mg SC daily or 30 mg BID or unfractionated heparin 5,000 units TID; mechanical prophylaxis: SCD, TED stockings; systemic anticoagulation if PE confirmed). ERAS (Enhanced Recovery After Surgery) pathways: multidisciplinary approach to reduce sur-

gical stress and accelerate recovery; components include pre-operative counseling, avoidance of prolonged fasting (carbohydrate loading 2 hours before surgery), no bowel preparation, epidural analgesia, goal-directed fluid therapy (avoiding excessive crystalloid administration), avoidance of NG tubes and drains, early mobilisation (day of surgery for ambulatory patients, or as soon as the patient can sit in a chair), early oral intake (clear liquids within 4-6 hours, progression to full fluids and then solids as tolerated), and multimodal non-opioid analgesia (paracetamol, NSAIDs, gabapentinoids, lidocaine patches, regional anesthesia blocks); ERAS compliance >70% associated with reduced length of stay (LOS) and complication rates.

Postoperative Ileus

– Temporary impairment of gastrointestinal motility after surgery, most common after abdominal surgery. Pathophysiology: autonomic dysfunction (sympathetic overactivity), inflammatory mediators, opioids, and electrolyte abnormalities. Presents with abdominal distension, nausea/vomiting, inability to tolerate oral intake, and absence of flatus/stool. Normal postoperative GI recovery: small bowel (24h), stomach (48h), colon (72-120h). Distinguish from mechanical obstruction (pain is crampy, bowel sounds high-pitched). Management: NPO, IV fluids, electrolyte correction, early ambulation, minimize opioids (use multimodal analgesia), gum chewing, and alvimopan (mu-opioid receptor antagonist). Neostigmine for Ogilvie syndrome (colonic pseudo-obstruction).

Ranula

– A mucocele (mucus extravasation cyst) of the sublingual salivary gland, presenting as a blue-translucent, fluctuant swelling in the floor of the mouth, typically lateral to the lingual frenulum. A ranula results from trauma or obstruction of a sublingual gland duct, causing mucus accumulation in the sublingual space. If the ranula extends through the mylohyoid muscle into the submental or submandibular space, it is termed a 'plunging' or 'cervical' ranula (presents as a neck mass). Ranulas are benign and painless unless secondarily infected. Differential diagnosis: dermoid cyst, thyroglossal duct cyst, lymphatic malformation, and submandibular gland swelling. Treatment: excision

of the ranula and the ipsilateral sublingual gland (lowest recurrence rate—<5%), marsupialisation (incision and drainage, suturing the cyst wall to the oral mucosa—higher recurrence rate), or laser ablation. Plunging ranulas require transcervical excision of the sublingual gland. Needle aspiration is not curative. Simple oral ranulas can be managed conservatively if small and asymptomatic.

Renal Transplant (Renal Transplantation)

– See Kidney Transplantation.

Skin Graft

– Transfer of skin from a donor site to a recipient site to cover a wound. Split-thickness skin graft (STSG): epidermis + partial dermis (0.008-0.018 inches), harvested with dermatome, donor site heals spontaneously (2-3 weeks). Full-thickness skin graft (FTSG): epidermis + full dermis, donor site requires closure, better cosmetic outcome. Types: autograft (same person), allograft (cadaveric), xenograft (animal), and synthetic (Integra, Biobrane). Uses: burn wounds, traumatic skin loss, chronic ulcers, and post-oncologic reconstruction. Graft take: requires vascularized wound bed, immobilization, and prevention of infection/shear.

Small Bowel Obstruction

– Mechanical blockage of the intestinal lumen. Causes: adhesions (75%), hernias (15%), malignancy, Crohn disease strictures, volvulus, intussusception, gallstone ileus, and bezoars. Clinical: crampy abdominal pain, nausea/vomiting (early in proximal SBO), obstipation, and abdominal distension. Signs include high-pitched bowel sounds, localised tenderness (suggesting ischemia), and peritonitis. Laboratory: leukocytosis, elevated lactate (indicator of strangulation), elevated BUN/creatinine (dehydration), and metabolic alkalosis. Imaging: abdominal X-ray shows dilated small bowel loops >3 cm with air-fluid levels. CT abdomen with IV contrast is the gold standard, demonstrating a transition point with proximal dilation and distal collapse, closed-loop obstruction (U-shaped configuration with convergent mesenteric vessels, high risk of ischemia), pneumatosis intestinalis, and signs of perforation; sensitivity >90% for high-grade SBO. Management: NPO, nasogastric decompression, IV fluids, and CT with contrast.

Non-operative observation is appropriate for adhesive SBO without strangulation features (60-80% resolve over 2-5 days). A water-soluble contrast challenge (Gastrografin) may be both diagnostic (predicts resolution if contrast reaches colon within 4-24 hours) and therapeutic. Operative indications: complete obstruction, peritonitis, strangulation, closed-loop obstruction, failure of non-operative management >48-72 hours, or suspected ischemia. Surgery is via laparoscopy (adhesive SBO) or laparotomy (complicated cases), with adhesiolysis, bowel resection for non-viable segments, and primary anastomosis. Hartmann procedure is reserved for peritonitis or hemodynamic instability. Mortality: 3-5% for simple obstruction, 25-30% for strangulated obstruction.

Smoke Inhalation Injury

– Pulmonary injury caused by inhalation of toxic products of combustion. Three components: thermal injury (supraglottic: heat causes edema of the upper airway), chemical irritation (lower airway: aldehydes, ammonia, chlorine, hydrogen chloride cause bronchospasm, mucosal edema, and sloughing), and systemic toxicity (carbon monoxide: carboxyhemoglobin >10% causes tissue hypoxia; cyanide: impairs cellular respiration). Presents with facial burns, singed nasal hairs, carbonaceous sputum, hoarseness, stridor, and dyspnea. Diagnosis: bronchoscopy (gold standard), carboxyhemoglobin level. Treatment: 100% oxygen (shortens CO half-life to 60 min); intubation for upper airway edema; mechanical ventilation with lung-protective strategy; bronchodilators; aggressive pulmonary toilet. Hyperbaric oxygen for severe CO poisoning (neuropsychiatric). Hydroxocobalamin for cyanide toxicity.

Spinal Fusion

– Surgical union of two or more vertebrae using bone graft or bone graft substitutes with instrumentation (rods, screws, cages). Approaches: posterior (posterolateral fusion, transforaminal lumbar interbody fusion TLIF), anterior (anterior lumbar interbody fusion ALIF), and lateral (extreme lateral interbody fusion XLIF). Indications: degenerative disc disease, spondylolisthesis, spinal instability, scoliosis, and trauma. Bone graft sources: autograft (iliac crest, gold standard), allograft, BMP (bone mor-

phogenetic protein), and synthetic. Complications: pseudoarthrosis (non-union), hardware failure, adjacent segment disease, infection, and nerve root injury.

Splenectomy

– Indications: trauma (grade IV/V, hemodynamic instability), ITP (refractory), hereditary spherocytosis/elliptocytosis, thalassemia major, sickle cell (sequestration crisis), TTP (refractory), lymphoma staging (historical), hypersplenism, splenic cysts/tumors, Wandering spleen. Laparoscopic preferred. Vaccinations: pneumococcal (PCV20 or PCV15+PPSV23), meningococcal (MenACWY + MenB), Hib - ideally 2 weeks pre-op; post-op if emergency. Antibiotic prophylaxis: penicillin V daily (children <5 or <2 years post-splenectomy or with continued immunosuppression) or amoxicillin daily (adults, alternatively: penicillin V 250 mg BID or amoxicillin 500 mg daily) for at least 2 years after splenectomy or for life if ongoing immunosuppression; immunocompromised patients require lifelong prophylaxis. Fever: stationary IV ceftriaxone plus azithromycin; seek immediate medical attention (splenectomy alert card/wallet card, medical bracelet, fever algorithm for carers). Overwhelming post-splenectomy infection (OPSI): encapsulated bacteria (*S. pneumoniae* 50-60%, *H. influenzae* type b 10-15%, *N. meningitidis* 10-15%, *E. coli*, Group B *Streptococcus*, *Capnocytophaga canimorsus* from dog bites); rapidly progressive (fulminant) sepsis (mortality 50-70%); presentation: fever, rigors, hypotension, DIC, multi-organ failure within hours; management: IV fluids, broad-spectrum IV antibiotics (ceftriaxone 2 g IV 12-hourly or meropenem 1 g IV 8-hourly) immediately, ICU, vasopressors. Platelet count: rises after splenectomy (thrombocytosis usually transient, peaks at 1-3 weeks, resolves by 2-3 months; platelet count >450,000-1,000,000); aspirin 81 mg daily if platelet count >1,000,000 (to reduce risk of thrombosis). Complications: portal vein thrombosis (3-10%, increased if splenomegaly, myeloproliferative disorder, or hemolytic anemia; duplex ultrasound at day 7 post-operatively in high-risk patients, or CT with portal venous phase imaging if symptomatic; treatment: therapeutic anticoagulation with LMWH or warfarin for 3-6 months or lifelong if there is thrombophilia or persistent

splanchnic vein thrombus). Long-term: re-immunise with PPSV23 every 5 years (or per guidelines; Centers for Disease Control and Prevention recommends a single PPSV23 booster 5 years after the initial dose in asplenic adults, and a second booster at age 65 or above if at least 5 years since last). The risk of OPSI is 0.23-4.4% per year, with a lifetime risk of 5-10%.

Sterilization

– Eradication of all microbial life from surgical instruments by steam autoclaving, dry heat, ethylene oxide, or hydrogen peroxide plasma, verified by biologic spore testing. In reproductive medicine, permanent sterilization occludes the fallopian tubes (tubal ligation) or vas deferens (vasectomy), both over 99 percent effective.

Stoma Complications

– Complications related to intestinal or urinary stomas. Early (<30 days): ischemia/necrosis (assess with test tube/endoscope, if → mucosa or at fascia → revision), mucocutaneous separation, retraction, parastomal abscess, high output (>1500 mL/day, may cause dehydration/electrolyte depletion → antidiarrheals, loperamide, codeine, octreotide, dietary modification). Late: parastomal hernia (most common late complication, abdominal wall defect → support belt, surgical mesh repair), prolapse (full-thickness protrusion → reduction, repair), stenosis (fibrous ring at skin level → dilation, revision), and skin irritation (leakage → proper appliance fit, skin barriers, powder, paste). Patient education and stoma nurse consultation essential.

Surgical Site Infection

– SSI classification (CDC): superficial incisional (skin/subcutaneous, <30 days), deep incisional (fascia/muscle, <30/90 days with implant), organ/space (any part opened/manipulated, <30/90 days with implant). Risk factors: patient (diabetes, obesity, smoking, immunosuppression, malnutrition, age), operative (contamination class, duration, technique, hair removal, hypothermia, hyperglycemia), postoperative (hyperglycemia, hypothermia, hematoma). Prevention: preoperative shower (CHG), appropriate antibiotic (cefazolin or cefoxitin, or ceftriaxone + metronidazole for colorectal surgery; vancomycin or clindamycin for penicillin-allergic patients) within 60 minutes before incision

(120 minutes for vancomycin and fluoroquinolones due to longer infusion time), hair removal with clippers (not razors), normothermia (active warming with forced-air warming blankets), oxygenation (FiO₂ 80% during and 6 hours after surgery), maintain euglycaemia (glucose <10 mmol/L, tighter range of 6-10 mmol/L, with insulin sliding scale if needed), wound protector, glove change before closure, and post-operative normothermia, euglycaemia, and oxygen. Antibiotic re-dosing for prolonged surgery (>2 half-lives, approximately 2-4 hours for cefazolin, 4-6 hours for metronidazole, 6-8 hours for ciprofloxacin), appropriate weight-based dosing (e.g., vancomycin 15 mg/kg obese, 30 mg/kg for cefazolin in morbid obesity). Surgical technique: gentle tissue handling, meticulous hemostasis, avoidance of dead space, tension-free closure, use of knotless barbed sutures (e.g., Stratafix, V-Loc) for fascial closure and skin closure techniques: subcuticular absorbable monofilament sutures (skin closure in layers reduces risk of wound infection) or metallic staples (which have the advantage of speed but are not recommended for closure of laparoscopic port sites >5 mm). When closing the fascia, use a continuous slowly absorbable monofilament suture such as PDS (polydioxanone) #1 or #2 for laparotomy incisions, a suture length to wound length ratio of at least 4:1 (the "small bites" technique uses 5 mm bites 5 mm apart, reducing incisional hernia). Prophylactic negative pressure wound therapy (ciNPT, Prevena or PICO system) for high-risk wounds (contaminated, dirty, emergency laparotomy, obese, diabetic, stoma, or immunocompromised patients). Management of established SSI: wound culture, open wound, drainage, debridement, packing with saline-soaked gauze or alginate dressings, VAC or negative pressure wound therapy (NPWT) for large, deep, or chronic wounds. Antibiotics only if cellulitis, systemic signs, or organ/space infection. SSI rates: clean <2%, clean-contaminated <5%, contaminated <15%, dirty >25%.

Suture

– A thread or strand of material used to approximate tissues (bring wound edges together) and hold them in place until healing occurs. Sutures are classified by: (1) Absorbability—absorbable (catgut, polyglactin/Vicryl, poliglecaprone/Monocryl, poly-

dioxanone/PDS—degrade by hydrolysis over weeks to months, used for deep tissues, internal wounds) and non-absorbable (nylon/Ethilon, polypropylene/Prolene, silk, stainless steel—remain permanently, used for skin closure, vascular anastomoses, tendons). (2) Structure—monofilament (single strand—less tissue trauma, lower infection risk, but more difficult to handle, greater knot slippage) and multifilament (braided—easier handling, better knot security, higher infection risk—capillary action harbours bacteria). (3) Needle type—cutting (for skin, tough tissues), reverse cutting, round-bodied (for soft tissues—bowel, vessels, fascia), and taper-cut. Suture size: from 10-0 (ophthalmic microsurgery) to 0-2 (fascia, orthopedics). Suture techniques: simple interrupted (most common, secure, allows individual knot removal), continuous/running (faster, better wound edge eversion, but if one stitch breaks, the entire suture line may fail), horizontal mattress (everts wound edges, tension reduction), vertical mattress (everts edges, good for deep closure), subcuticular (intradermal—best cosmetic result, eliminates suture marks), and purse-string. Alternatives to sutures: surgical staplers (fast, consistent—bowel anastomoses, skin closure), tissue adhesives (cyanoacrylate/Dermabond—for superficial wounds, topical use), adhesive strips (Steri-Strips—for superficial, low-tension wounds), and knotless barbed sutures (Knotless Tissue Control—used in laparoscopic and robotic surgery).

TACO

– Transfusion-Associated Circulatory Overload, a complication of blood transfusion due to volume overload causing pulmonary edema. Risk factors: pre-existing cardiac or renal disease, extremes of age, large transfusion volume, rapid infusion rate. Presents with dyspnea, orthopnea, hypertension, JVD, pulmonary edema, and BNP elevation within 6-12 hours of transfusion. Distinguish from TRALI: TRALI has hypotension, fever, and no fluid overload signs. Management: diuresis (furosemide), oxygen, and slow or split transfusion units in high-risk patients. Prevention: slow transfusion rate, pre-transfusion furosemide.

Thoracotomy

– A surgical incision into the chest wall to access the thoracic cavity (pleural space, lungs, heart,

great vessels, esophagus, diaphragm, mediastinum). Types: (1) Posterolateral thoracotomy (most common)—incision below the tip of the scapula, dividing the latissimus dorsi and serratus anterior, entering the chest through the 4th, 5th, or 6th intercostal space; provides excellent access for pulmonary lobectomy, pneumonectomy, oesophagectomy, and thoracic aortic surgery. (2) Anterolateral thoracotomy—emergency access for trauma, pericardial window, or lung biopsy. (3) Median sternotomy—midline division of the sternum (sternotomy), used for cardiac surgery (CABG, valve surgery, thymectomy, anterior mediastinal mass). (4) Clamshell incision (bilateral anterolateral thoracotomy with transverse sternotomy)—for bilateral lung transplantation, massive trauma. (5) Axillary thoracotomy—for first rib resection, sympathectomy. Complications: post-thoracotomy pain (significant, long-lasting—use of epidural analgesia, paravertebral block, intercostal nerve blocks), wound infection, hemorrhage, persistent air leak, pneumonia, and atelectasis. Minimally invasive alternatives: video-assisted thoracoscopic surgery (VATS)—reduces pain, hospital stay, and recovery time.

Thyroid Surgery

– lobectomy, subtotal thyroidectomy, and total thyroidectomy. Indications: Bethesda V/VI nodules on cytology, thyroid cancer (papillary >1.5 cm, follicular, medullary, anaplastic), Graves disease (compressive symptoms, failed medical therapy, severe ophthalmopathy), and multinodular goiter with compressive symptoms or substernal extension. Lobectomy is appropriate for Bethesda III/IV nodules and low-risk papillary microcarcinoma (<1.5 cm, solitary, no nodal involvement). Total thyroidectomy is standard for bilateral disease, high-risk features, medullary carcinoma, and anaplastic carcinoma (palliative for airway obstruction). Central compartment dissection (level VI) is performed for clinically involved nodes; prophylactic dissection is controversial due to increased risk of nerve injury and hypoparathyroidism. Lateral neck dissection (levels II-V) is reserved for confirmed cervical metastases. Intraoperative nerve monitoring facilitates identification of the recurrent laryngeal nerve. The external branch of the superior laryngeal nerve is at

risk during ligation of the superior thyroid pole. The parathyroid glands are at risk of devascularization or accidental excision. Complications: recurrent laryngeal nerve injury (2-5% transient, <1% permanent) presents with hoarseness and aspiration; bilateral injury causes stridor requiring tracheostomy. Hypoparathyroidism (transient 10-30%, permanent 1-2%) requires calcium and calcitriol supplementation, guided by post-operative PTH monitoring. Haematoma (0.5-2%) requires emergency evacuation to prevent airway compromise. Wound infection and hypertrophic scarring are less common. TSH suppression therapy reduces recurrence risk in thyroid cancer. Radioactive iodine ablation is given for high-risk differentiated cancer after total thyroidectomy.

TIPS (Transjugular Intrahepatic Portosystemic Shunt)

– A radiologically placed shunt connecting the portal vein to a hepatic vein within the liver, creating a portosystemic shunt to reduce portal pressure. Indications: variceal bleeding (refractory or recurrent), refractory ascites, and hepatic hydrothorax. Procedure: transjugular access, hepatic vein cannulation, needle puncture through liver parenchyma into the portal vein, balloon dilation, and covered stent placement. Portal pressure gradient goal: <12 mmHg. Contraindications: severe pulmonary hypertension, right heart failure, severe hepatic encephalopathy, and severe liver failure (MELD >18-20). Complications: encephalopathy (30-40%), shunt stenosis/occlusion, bleeding, infection, and radiation exposure.

Total Hip Arthroplasty (THA)

– Replacement of the hip joint with prosthetic components. Acetabular component: metal shell + polyethylene liner. Femoral component: metal stem + femoral head (cobalt-chrome or ceramic). Fixation: cemented (PMMA, for elderly, osteoporotic bone), cementless (porous-coated, for younger patients, biologic fixation), and hybrid. Approaches: posterior (most common, dislocation risk 2-5%), direct anterior (DAA, muscle-sparing, less pain), anterolateral, and lateral (Hardinge). Indications: end-stage osteoarthritis, avascular necrosis, rheumatoid arthritis, and hip fracture (femoral neck). Complications: dislocation, infection (1-2%), VTE, peripros-

thetic fracture, leg length discrepancy, and aseptic loosening (long-term).

Total Knee Arthroplasty (TKA)

– Replacement of the knee joint with prosthetic components. Femoral component (cobalt-chrome), tibial component (titanium tray + polyethylene insert), and patellar component (polyethylene, optional). Fixation: cement (PMMA) most common in older adults; cementless in younger. Alignment: mechanical (neutral, most common), kinematic, and anatomic. Indications: end-stage osteoarthritis (most common), inflammatory arthritis, and post-traumatic arthritis. Complications: infection (1-2%), stiffness (manipulation under anesthesia), instability, patellar complications (maltracking, fracture), periprosthetic fracture, VTE, and aseptic loosening.

Tracheostomy

– A surgical opening (stoma) in the trachea through the neck. Percutaneous dilational tracheostomy (PDT, ICU bedside, Seldinger technique, most common) vs. open surgical tracheostomy (OR, for difficult anatomy, large goiter, obese neck). Indications: prolonged mechanical ventilation (expected >14-21 days, reduces VAP, sedation, and ICU length of stay), upper airway obstruction, and severe secretion management. Tracheostomy tube: cuffed (for ventilation) or uncuffed/fenestrated (for spontaneous breathing and speech). Complications: bleeding, infection, pneumothorax, subcutaneous emphysema, tracheal stenosis, tracheomalacia, and stomal infection.

Tracheotomy

– See Tracheostomy.

TRALI

– Transfusion-Related Acute Lung Injury, a life-threatening complication of blood transfusion characterized by acute hypoxemia and bilateral pulmonary edema within 6 hours of transfusion, without evidence of volume overload. Pathophysiology: donor antibodies (anti-HLA, anti-HNA) in plasma-rich products (FFP, platelets) activate recipient neutrophils, causing endothelial injury and capillary leak in the lungs. Presents with dyspnea, hypoxemia, fever, and bilateral infiltrates on CXR (mimics ARDS). Management: supportive care (oxygen, mechanical ventilation), similar to ARDS. Prevention:

use male-only plasma to reduce antibody risk. Mortality 5-10%.

Transfusion Reaction

– An adverse reaction to transfusion of blood products. Acute hemolytic transfusion reaction: ABO incompatibility, immediate fever/chills, hypotension, back pain, DIC, renal failure; management: STOP transfusion, maintain BP/urine output, supportive care. Febrile non-hemolytic transfusion reaction: most common, fever/chills without hemolysis. Allergic: urticaria; treat with antihistamines. Anaphylactic: severe allergic, IgA deficiency; treat with epinephrine. Transfusion-related acute lung injury (TRALI): acute hypoxemia, bilateral pulmonary edema within 6 hours; supportive care. Transfusion-associated circulatory overload (TACO): pulmonary edema from volume overload; diuretics. Bacterial contamination: sepsis from contaminated unit.

Transplant Rejection

– Immune-mediated destruction of a transplanted organ or tissue, classified by timing and mechanism. Hyperacute: preformed donor-specific antibodies, minutes to hours post-transplant, immediate graft thrombosis, irreversible; prevention by cross-matching. Acute: T-cell mediated (most common, days to weeks/months), responds to immunosuppression; presents with graft dysfunction and biopsy findings. Chronic: antibody-mediated, progressive, irreversible fibrosis and graft dysfunction over months to years. Diagnosis: graft biopsy (Banff classification). Treatment: acute rejection — pulse corticosteroids, thymoglobulin, IVIG, plasmapheresis; chronic — optimize immunosuppression, manage risk factors.

Transplant Surgery

– Transplant surgery involves replacing a failing organ with a healthy donor organ. Kidney transplant: living donors (laparoscopic nephrectomy, left kidney preferred) or deceased donors (standard criteria, expanded criteria, DCD). Induction immunosuppression includes basiliximab (standard risk) or thymoglobulin/alemtuzumab (high immunologic risk). Maintenance typically uses tacrolimus, mycophenolate, and prednisone; belatacept offers CNI-free options for EBV-positive patients. Rejection: hyperacute (preformed antibodies, immediate graft loss), acute cellular (T-cell mediated, responds to steroid

pulse or ATG), acute antibody-mediated (C4d+ on biopsy with donor-specific antibodies, treated with IVIG, plasmapheresis, rituximab), and chronic allograft nephropathy (interstitial fibrosis and tubular atrophy). Liver transplant allocation uses the MELD-Na score. Donor hepatectomy may be whole or split/living donor. Recipient hepatectomy uses bicaval or piggyback technique with portal vein, hepatic artery, and biliary reconstruction (duct-to-duct or Roux-en-Y hepaticojejunostomy). Complications: primary non-function, hepatic artery thrombosis (3-5%, requires retransplantation unless collateralized), biliary leak/stricture, portal vein thrombosis, and rejection. PTLT is an EBV-driven lymphoproliferative complication managed by immunosuppression reduction and rituximab. Pancreas transplant (SPK, PAK, PTA) is performed for type 1 diabetes with ESRD; enteric drainage is preferred for exocrine secretion. Long-term management: immunosuppression optimization, infection prophylaxis (CMV, EBV, fungal), and surveillance for graft dysfunction, PTLT, and cardiovascular disease. One-year graft survival exceeds 90% for kidney and 85% for liver; 5-year survival >70% for both.

Trauma Surgery

– Trauma surgery encompasses the acute care of injured patients, guided by ATLS (ABCDE) principles: Airway maintenance with cervical spine protection, Breathing and ventilation, Circulation with hemorrhage control, Disability/neurologic assessment, and Exposure/environmental control. Hemorrhage control is the priority, achieved via direct pressure, tourniquets for extremity injuries, pelvic binders for pelvic fractures, and REBOA for exsanguinating torso hemorrhage. Damage control surgery is indicated for patients with the lethal triad of hypothermia, acidosis, and coagulopathy. Phase 1 involves abbreviated laparotomy with bleeding control (packing, shunting) and contamination control. Phase 2 is ICU resuscitation to correct hypothermia (active rewarming), coagulopathy (massive transfusion at 1:1:1 ratio of pRBCs, FFP, platelets; tranexamic acid 1 g IV within 3 hours of injury), and acidosis. Phase 3 is return to the OR for definitive repair after physiologic normalization. Damage control resuscitation incorporates permissive hypotension (SBP 80-90 mmHg) in penetrating torso trauma

without head injury. Definitive surgical management depends on injury pattern and may include splenectomy, liver packing and resection, bowel resection, vascular repair, and fracture fixation. Resuscitative thoracotomy is indicated for penetrating chest trauma with witnessed arrest and short transport time (best survival for cardiac tamponade). Tension pneumothorax requires immediate needle decompression (14G, 2nd ICS midclavicular line) followed by tube thoracostomy. Massive haemothorax (>1500 mL initial output) requires expeditious thoracotomy. Abdominal compartment syndrome (bladder pressure >20 mmHg with organ dysfunction) may necessitate decompressive laparotomy with temporary closure. FAST examination and CT imaging guide surgical decision-making. Enteral nutrition is initiated within 24-48 hours. Outcome depends on injury severity, promptness of intervention, and successful resuscitation.

Traumatic Brain Injury

– Disruption of brain function caused by an external mechanical force. Severity: mild (GCS 13-15, concussion), moderate (GCS 9-12), severe (GCS 3-8). Primary injury: direct damage at moment of impact (contusion, diffuse axonal injury, intracranial hemorrhage). Secondary injury: evolves over hours to days (cerebral edema, increased ICP, hypoxia, hypotension, ischemia, seizures). Intracranial hemorrhage: epidural (arterial, lenticular), subdural (venous, crescentic), intracerebral, subarachnoid. Management: ABCs, prevent secondary injury (maintain SBP >90, SpO₂ >94%, PaCO₂ 35-45), ICP monitoring (goal <22), CPP >60 mmHg, head of bed 30°, hyperosmolar therapy (mannitol, hypertonic saline), seizure prophylaxis, and surgical evacuation of mass lesions.

Trephining (Trepanation)

– A surgical procedure in which a hole is drilled or scraped into the skull (cranium), exposing the dura mater. Historically, trephining dates back to Neolithic times (10,000 BCE) and was performed for ritual, therapeutic (releasing 'evil spirits'), and post-traumatic indications. Modern medical trephination: (1) Burr hole—small craniotomy using a handheld or electric drill (burr) for evacuation of intracranial haematomas (epidural, subdural—including twist-drill craniostomy for chronic

subdural haematoma), placement of external ventricular drain (EVD) for intracranial pressure monitoring or CSF drainage, and brain biopsy. (2) Decompressive craniectomy—removal of a large skull flap to treat refractory intracranial hypertension (traumatic brain injury, malignant middle cerebral artery infarction, cerebral venous sinus thrombosis). (3) Craniotomy—larger opening for definitive neurosurgery (tumor resection, aneurysm clipping, epilepsy surgery). (4) Stereotactic trephination—frame-based or frameless stereotactic navigation for biopsy, deep brain stimulation electrode placement, or tumor ablation. Instruments: Hudson brace, perforator and burr, craniotome, and high-speed drills. Complications: bleeding (epidural, subdural, intracerebral), infection (osteomyelitis, meningitis, brain abscess), CSF leak, pneumocephalus, seizures, and brain herniation.

Tubal Ligation

– Surgical sterilization by occluding the fallopian tubes, preventing the ovum from reaching the uterus. Postpartum tubal ligation: after vaginal or cesarean delivery (Pomeroy technique, Parkland). Interval: laparoscopic (bands, clips, bipolar cautery) or mini-laparotomy (Hulka or Filshie clip). Reversal possible with tubal reanastomosis (pregnancy rate 50-80%). Female sterilization: 99% effective, permanent. Complications: ectopic pregnancy if procedure fails (higher after bipolar cautery than clips). Essure (hysteroscopic coils) removed from the market.

Umbilical Hernia

– A hernia through the umbilical ring, common in infants (most umbilical hernias close spontaneously by age 4-5) and adults (risk factors: obesity, pregnancy, ascites, cirrhosis). Presents as a reducible bulge at the umbilicus, worse with increased intra-abdominal pressure. In adults: risk of incarceration and strangulation is higher. Diagnosis: clinical. Treatment: in children: observe, surgically repair if persists >age 4-5 or >2 cm. In adults: surgical repair (primary suture repair, mesh onlay, or laparoscopic IPOM) due to risk of complications.

Vascular Access

– Vascular access for hemodialysis includes arteriovenous fistulas (AVF), arteriovenous grafts (AVG), and central venous catheters (CVC). The fistula

first initiative prioritizes AVF as the gold standard due to best long-term patency and lowest complication rates. Common configurations: radiocephalic (wrist), brachiocephalic (elbow), and brachiobasilic transposition (upper arm). Preoperative vein mapping by ultrasound is essential for planning. AVGs (PTFE) mature faster (2-4 weeks vs. 2-4 months for AVF) and are useful when native veins are inadequate, but have higher rates of thrombosis and infection. Tunneled CVCs allow immediate use and serve as a bridge to maturation or for patients with exhausted peripheral options, but carry the highest infection and central venous stenosis risk. Non-tunneled CVCs are for short-term emergent use. Maturation criteria: vein diameter >6 mm, depth <6 mm, flow >600 mL/min. Indications: end-stage renal disease requiring hemodialysis. Complications: stenosis (angioplasty, stenting), thrombosis (thrombectomy, catheter-directed thrombolysis), steal syndrome (hand ischemia managed by DRIL or PAI procedures), aneurysm and pseudoaneurysm (resection, ligation), infection (graft excision, antibiotics), and high-output cardiac failure (revision, banding, or ligation). CVC complications: pneumothorax (reduced by ultrasound guidance), arterial puncture, catheter-related bloodstream infection (removal, tip culture, antibiotics), central venous stenosis, and air embolism. Patency: AVF > AVG > CVC.

Venous Stasis Ulcer

– A chronic wound caused by chronic venous insufficiency, most common type of leg ulcer (70-80%). Located on the medial gaiter area (medial malleolus). Presents with shallow, irregular ulcer with granulation tissue, surrounded by hemosiderin deposition (brownish discoloration), lipodermatosclerosis, edema, and varicose veins. Often painful and associated with venous insufficiency (CEAP classification). Diagnosis: clinical; venous duplex ultrasound to assess reflux. Treatment: compression therapy (multi-layer bandaging, graded compression stockings 30-40 mmHg) is the mainstay. Adjunctive: leg elevation, wound debridement, moist wound healing, and pentoxifylline. Refractory: venous ablation or surgery.

Venous Ulcer

– See Venous Stasis Ulcer.

Wound Dehiscence

– Separation of the layers of a surgical wound after closure, most commonly occurring within 3-14 days postoperatively. Risk factors: wound infection, poor nutrition (low albumin), immunosuppression, obesity, diabetes, smoking, increased intra-abdominal pressure (coughing, straining, ileus), and poor surgical technique (tight sutures, extensive electrocautery). Presents with sudden serosanguinous drainage from the wound, often with a pop sensation. Superficial dehiscence: skin and subcutaneous layers open. Deep (fascial) dehiscence: separation of the fascia, often with evisceration (viscera protruding through the wound) → surgical emergency. Management: superficial → wound care and NPWT. Deep → emergent return to OR for closure with retention sutures.

Xenograft (Heterograft)

– A surgical graft taken from a donor of a different species (xenos = foreign, Greek). Xenografts are used as temporary biological dressings or as tissue replacements. The most common xenograft source is porcine (pig) skin, used as a temporary wound covering for extensive burns (partial-thickness and deep partial-thickness burns) and large traumatic skin loss. Porcine xenografts adhere to the wound bed, reduce fluid and protein loss, decrease pain, and provide a barrier against bacterial contamination while the patient's own skin regenerates or until autografting is possible. Other xenograft sources include bovine (cow) pericardium (used in cardiac surgery for valve reconstruction, pericardial patch repair, and as a bioprosthetic heart valve material — Carpentier-Edwards, Hancock valves), and bovine bone grafts (used in orthopaedic and dental surgery for bone void filling, spinal fusion, and maxillofacial reconstruction). Xenografts trigger a strong immune response (hyperacute rejection mediated by pre-existing xenoreactive antibodies against Gal-alpha-1,3-Gal epitopes on porcine cells) and are therefore rejected within 7-14 days if used as viable tissue, limiting their use to temporary coverage. Genetically modified pigs (knockout of Gal epitopes) have been developed to reduce immunogenicity and enable longer-term xenograft survival. The first pig-to-human heart transplant (xenotransplantation) was performed in 2022 (University of

Maryland, 10 gene-modified pig heart, recipient survived 2 months). Compared to allografts (human donor grafts) and autografts (patient's own tissue), xenografts have the advantages of unlimited availability and no donor site morbidity, but are inferior in durability and immunocompatibility for permanent replacement.

Chapter 40

Toxicology

Activated Charcoal

– Fine black powder produced by controlled pyrolysis of organic materials, processed to yield a massive micro-porous surface area (500–1500 m²/g) capable of non-specifically adsorbing toxic substances within the gastrointestinal lumen, preventing systemic absorption. Standard dose: 1 g/kg (typically 50 g in adults), administered orally or via nasogastric tube within 1–2 hours of toxic ingestion. Multi-dose activated charcoal (MDAC) enhances elimination of drugs undergoing enterohepatic or enteroenteric circulation (carbamazepine, dapsone, phenobarbital, quinine, theophylline). Substances poorly adsorbed by charcoal ("PHAILS"): Pesticides/Petroleum, Hydrocarbons, Alcohol/Acids/Alkali, Iron, Lithium, Solvents. Contraindications: unprotected airway (risk of fatal aspiration pneumonitis), bowel obstruction, perforated viscus, or ingestion of corrosive substances.

Anticholinergic Toxidrome

– Clinical toxidrome resulting from competitive inhibition of acetylcholine at central and peripheral muscarinic receptors. Causes: antihistamines (diphenhydramine), tricyclic antidepressants (amitriptyline), atropine, scopolamine, belladonna alkaloids (*Datura stramonium* / Jimson weed), and antiparkinsonian drugs. Mnemonics: "Blind as a bat" (mydriasis, loss of accommodation), "Mad as a hatter" (delirium, agitation, hallucinations), "Red as a beet" (flushed skin from cutaneous vasodilation), "Hot as a hare" (hyperthermia from anhidrosis), "Dry as a bone" (dry mouth, dry skin), "Bowel and bladder lose their tone" (paralytic ileus, urinary retention), "And the heart runs alone" (tachycardia). Specific antidote: physostigmine (acetylcholinesterase inhibitor that crosses the blood-brain barrier), indicated for severe central anticholinergic toxicity when ECG shows

normal QRS duration.

Antidote

– Any therapeutic agent that neutralizes, counteracts, or reverses the physiological or biochemical toxic effects of a poison. Mechanisms: physical adsorption (activated charcoal), chemical neutralization (digoxin immune Fab), receptor competition/antagonism (naloxone for opioids, flumazenil for benzodiazepines), metabolic inhibition (fomepizole inhibiting alcohol dehydrogenase in methanol/ethylene glycol toxicity), enzyme reactivation (pralidoxime for organophosphates), or substrate replenishment (N-acetylcysteine for acetaminophen, pyridoxine for isoniazid). Availability of specific antidotes is limited to a minor subset of human poisonings, necessitating supportive care as the foundation of clinical toxicology management.

Arsenic Poisoning

– Acute or chronic exposure to arsenic compounds, a metalloid toxin found in contaminated groundwater, industrial processes, pesticides, and wood preservatives. Inactivates pyruvate dehydrogenase by binding to lipoic acid, disrupting cellular ATP production via citric acid cycle inhibition. Acute clinical features: severe garlic-like breath odor, rice-water diarrhea, vomiting, abdominal pain, QT prolongation, torsades de pointes, and hypovolemic shock. Chronic clinical features: hyperpigmentation, hyperkeratosis of palms and soles ("raindrops on a dusty road"), Mees lines (transverse white bands on nails), peripheral sensorimotor neuropathy ("glove-and-stocking"), and increased risk of squamous cell skin carcinoma, lung, and bladder cancer. Treatment: gastric lavage, IV hydration, and chelation therapy with dimercaprol (BAL) acutely, or oral succimer (DMSA) for subacute/chronic exposure.

Arsenic Toxicity

– Heavy metal poisoning from contaminated ground-water or industrial exposure. Acute: severe gastroenteritis ('rice-water' diarrhea), garlic breath odor. Chronic: hyperpigmentation, hyperkeratosis of palms/soles, Mees lines on nails, peripheral neuropathy, and angiosarcoma. Antidote: Dimercaprol (BAL) or Succimer.

Aspirin Toxicity (Salicylate Toxicity)

– Acute or chronic poisoning by acetylsalicylic acid or salicylate-containing products (oil of wintergreen). Pathophysiology: direct stimulation of the medullary respiratory center causes hyperventilation and primary respiratory alkalosis; uncoupling of oxidative phosphorylation leads to metabolic acidosis, hyperthermia, and ATP depletion. Classic acid-base disturbance: mixed primary respiratory alkalosis and primary high anion gap metabolic acidosis. Clinical features: tinnitus (early sign), vertigo, nausea, vomiting, tachypnea, pyrexia, confusion, cerebral edema, and coma. Diagnostic testing: elevated serum salicylate levels, arterial blood gas, metabolic panel. Management: activated charcoal, fluid resuscitation, alkalization of urine with intravenous sodium bicarbonate (NaHCO_3) to trap salicylate ions in renal tubules and enhance urinary elimination, and hemodialysis for severe toxicity (salicylate > 90 mg/dL, altered mental status, pulmonary edema, or renal failure).

Atropine Poisoning / Antidote

– Belladonna alkaloid that functions as a competitive muscarinic acetylcholine receptor antagonist. As a poison, excessive atropine or ingestion of atropaceous plants (*Atropa belladonna*, *Datura*) induces a classic anticholinergic toxidrome (mydriasis, tachycardia, hyperthermia, dry mucous membranes, urinary retention, delirium). As a life-saving antidote, atropine is administered in massive escalating doses (2–5 mg IV repeated every 3–5 minutes) to reverse central and peripheral muscarinic toxicity caused by organophosphate and carbamate insecticide poisonings, nerve agents (sarin, VX), or severe bradycardia. Goal of atropinization: drying of tracheobronchial secretions and reversal of bronchospasm, rather than normalization of heart rate or pupil size.

Beta-Blocker Toxicity

– Overdose of *beta*-adrenergic antagonists causing bradycardia, hypotension, AV block, hypoglycemia, and cardiogenic shock. Lipophilic agents (propranolol) cause delirium and seizures. Antidote / Treatment: High-dose IV Glucagon (stimulates adenylate cyclase independently of *beta*-receptors), IV calcium, insulin-euglycemia therapy.

Calcium Channel Blocker Toxicity

– Severe overdose of CCBs (verapamil, diltiazem, amlodipine) resulting in profound vasodilation, refractory hypotension, severe bradycardia, and hyperglycemia (due to inhibition of L-type calcium channel-mediated pancreatic insulin release). Treatment: High-Dose Insulin Euglycemia Therapy (HIET), IV Calcium gluconate, lipid emulsion.

Carbon Monoxide Poisoning

– Inhalation toxicity caused by carbon monoxide (CO), a colorless, odorless, tasteless gas generated by incomplete combustion of carbonaceous fuels (house fires, motor vehicle exhaust, faulty gas heaters). Pathophysiology: CO binds to hemoglobin with an affinity 200–250 times greater than oxygen, forming carboxyhemoglobin (COHb), which shifts the oxygen-hemoglobin dissociation curve to the left (Haldane effect), severely impairing tissue oxygen delivery. CO also inhibits cytochrome c oxidase in the mitochondrial electron transport chain. Clinical features: headache (most common early symptom), dizziness, nausea, confusion, seizures, "cherry-red" skin (rare post-mortem finding), and myocardial ischemia. Delayed neuropsychiatric sequelae (DNS) can occur weeks later. Diagnosis: co-oximetry of arterial or venous blood (standard pulse oximetry is falsely normal). Treatment: 100% normobaric oxygen via non-rebreather mask (reduces COHb half-life from 320 to 80 minutes); hyperbaric oxygen (HBO) therapy for COHb > 25%, pregnancy, loss of consciousness, seizures, or cardiac ischemia.

Chelation Therapy

– Administration of chelating agents containing electron-donor ligand groups (thiol, amine, or carboxylate) that form stable, non-toxic coordination complexes with heavy metal ions, facilitating their excretion via urine or bile. Common chelators: Dimercaprol (British Anti-Lewisite, BAL—for acute

lead, arsenic, mercury poisoning; IM administration in oil); Succimer (DMSA—water-soluble oral analog of BAL for pediatric lead poisoning); Calcium Disodium EDTA (CaNa_2EDTA —for severe lead poisoning, given after BAL to prevent brain lead redistribution); Penicillamine (for copper accumulation in Wilson disease, arsenic, lead); Deferoxamine (specific iron chelator); and Deferasirox (oral iron chelator for chronic transfusion overload). Risks: nephrotoxicity, essential trace mineral depletion (zinc, copper), and hypersensitivity reactions.

Cholinergic Toxidrome

– Life-threatening toxidrome resulting from excessive stimulation of muscarinic and nicotinic acetylcholine receptors due to acetylcholinesterase inhibition or direct cholinergic agonist exposure. Causes: organophosphate and carbamate insecticides, nerve agents (sarin, soman, VX), Alzheimer medications (donepezil), and pilocarpine. Muscarinic features (mnemonic "DUMBELS"): Diarrhea, Urination, Miosis, Bradycardia/Bronchospasm/Bronchorrhea, Emesis, Lacrimation, Salivation. (Alternative mnemonic "SLUDGEM": Salivation, Lacrimation, Urination, Defecation, GI distress, Emesis, Miosis). Bronchorrhea and bronchospasm ("killer B's") are the primary cause of death. Nicotinic features (mnemonic "MTWThF"): Muscle fasciculations, Tachycardia, Weakness, Paralysis, Hypertension. Central features: confusion, seizures, coma. Treatment: airway management, immediate atropine (muscarinic antagonist), pralidoxime (2-PAM, reactivates acetylcholinesterase), and benzodiazepines for seizures.

Cyanide Poisoning

– Rapidly lethal cellular hypoxia caused by inhalation, ingestion, or dermal exposure to cyanide salts, hydrogen cyanide gas, or smoke from burning nitrogen-containing synthetic polymers (polyurethane, silk, nylon). Pathophysiology: cyanide (CN^-) binds with high affinity to the ferric (Fe^{3+}) iron of cytochrome c oxidase (complex IV) in the mitochondrial electron transport chain, halting oxidative phosphorylation, shutting down aerobic ATP production, and shifting cellular metabolism to anaerobic glycolysis. Clinical features: rapid onset of dyspnea, headache, vomiting, agitation, seizures, severe metabolic acidosis with markedly

elevated blood lactate, and bright red venous blood (due to inability of tissues to extract oxygen). Antidote therapy: Cyanokit (hydroxocobalamin, which binds cyanide to form non-toxic cyanocobalamin / vitamin B12, excreted in urine; gold standard), or Nithiodote / Cyanide Antidote Kit (sodium nitrite to form methemoglobin which sequesters CN, followed by sodium thiosulfate to convert CN into thiocyanate via the rhodanese enzyme).

Cyanide Toxicity

– Lethal inhibitor of cytochrome c oxidase in mitochondrial electron transport chain, causing cellular hypoxia despite normal blood oxygenation. Symptoms: almond odor, severe lactic acidosis, seizures, coma. Antidotes: Hydroxocobalamin (Cyanokit) or Sodium Thiosulfate with Nitrites.

Detoxification

– The process of removing toxic substances from the body or rendering them harmless. In medical contexts, medically supervised withdrawal from addictive substances (alcohol, opioids, benzodiazepines), involving gradual dose reduction or substitution with longer-acting agents to manage withdrawal symptoms safely. Physiologic detoxification is performed primarily by the liver (phase I: cytochrome P450 oxidation, reduction, hydrolysis; phase II: conjugation with glucuronide, sulfate, glutathione, or glycine to increase water solubility for renal or biliary excretion). Detoxification is distinct from addiction treatment and is only the first step in substance use disorder management.

Digoxin Toxicity

– Cardiac glycoside toxicity causing nausea, vomiting, confusion, visual disturbances (yellow-green halos / xanthopsia), hyperkalemia, and lethal cardiac arrhythmias (bidirectional ventricular tachycardia, PVCs, AV block). Triggered by hypokalemia. Antidote: Digoxin-specific Fab antibody fragments (DigiFab).

Digoxin Toxicity (Digibind)

– Toxic elevation of cardiac glycoside levels leading to life-threatening arrhythmia and electrolyte disturbances. Causes: acute overdose or chronic accumulation due to renal impairment, hypokalemia (which enhances digoxin binding to Na^+/K^+ ATPase), hypercalcemia, or drug interactions (amiodarone, verapamil, quinidine). Pathophysiology: in-

hibition of Na^+/K^+ ATPase increases intracellular sodium and calcium, increasing cardiac inotropy but causing delayed afterdepolarizations. Symptoms: nausea, vomiting, abdominal pain, confusion, visual disturbances (classic yellow-green halos around lights, xanthopsia), and cardiac arrhythmias (PVCs, ventricular bigeminy, paroxysmal atrial tachycardia with AV block, sinus bradycardia, bidirectional ventricular tachycardia). Acute toxicity presents with severe hyperkalemia. Specific antidote: Digoxin Immune Fab (Digibind / Digifab), consisting of antigen-binding fragments of specific digoxin antibodies that rapidly bind intravascular free digoxin, reversing toxicity within 30 minutes.

Envenomation (Snakebite)

– Inoculation of complex biological venoms containing enzymatic and non-enzymatic toxins into human tissue via fangs or stings. Snake families: Viperidae (vipers, pit vipers—rattlesnakes, copperheads, Russell’s viper) producing hemotoxic, cytotoxic, and necrotizing venoms; Elapidae (cobras, mambas, kraits, coral snakes) producing presynaptic and postsynaptic neurotoxic venoms. Hemotoxic features: local edema, tissue necrosis, compartment syndrome, consumptive coagulopathy (disseminated intravascular coagulation-like syndrome), bleeding, and acute kidney injury. Neurotoxic features: ptosis, ophthalmoplegia, dysphagia, descending flaccid paralysis, and respiratory failure. Initial management: immobilization of the limb at heart level, pressure immobilization bandaging (for elapid bites), supportive airway/circulatory care, and prompt administration of specific or polyvalent antivenom (Fab fragments or equine whole IgG antibodies). Tourniquets, incision, and suction are strictly contraindicated.

Ethanol Toxicity

– Acute intoxication from excessive ethyl alcohol consumption, causing central nervous system depression, ataxia, dysarthria, disinhibition, respiratory depression, and hypoglycemia. Chronic toxicity causes hepatic cirrhosis, Wernicke-Korsakoff syndrome, and dependency.

Ethylene Glycol Toxicity

– Ingestion of toxic alcohol found in antifreeze/coolant, metabolized by alcohol dehydrogenase into toxic glycolic acid and oxalic acid. Causes central nervous system depression, severe high anion

gap metabolic acidosis, acute kidney injury from calcium oxalate crystal deposition in renal tubules, and elevated osmolal gap. Antidote: Fomepizole (or Ethanol) to inhibit alcohol dehydrogenase.

Fomepizole

– Competitive inhibitor of the enzyme Alcohol Dehydrogenase (ADH); specific antidote indicated for toxic alcohol ingestions (Methanol and Ethylene Glycol) to prevent their conversion into lethal toxic metabolites (formic acid and glycolic/oxalic acid).

Gastric Lavage

– Emergency toxicological procedure (‘stomach pumping’) involving insertion of a large-bore orogastric tube to flush and aspirate stomach contents; limited to life-threatening ingestions presenting within 60 minutes.

Heavy Metal Toxicity (Lead, Mercury, Arsenic)

– Pathological condition resulting from the accumulation of toxic heavy metals in body tissues, disrupting enzyme function by binding to sulfhydryl groups ($-\text{SH}$) on essential proteins. Common environmental and occupational toxins: Lead (causes microcytic anemia, basophilic stippling, colic, lead lines on gums, encephalopathy, drop wrist/foot), Mercury (elemental: pulmonary edema, tremor, erethism; inorganic: corrosive gastroenteritis, acute tubular necrosis; organic/methylmercury: Minamata disease, ataxia, constriction of visual fields, dysarthria, teratogenicity), Arsenic (mees lines, hyperkeratosis, garlic breath, peripheral neuropathy), and Cadmium (Itai-itai disease, osteomalacia, renal tubular dysfunction, lung cancer). Management involves removing the source of exposure, supportive care, and chelation therapy (succimer, BAL, CaNa_2EDTA , penicillamine).

Hydroxocobalamin

– Specific fast-acting antidote for Cyanide poisoning; binds cyanide ions directly to form non-toxic Vitamin B12a (Cyanocobalamin), excreted harmlessly in urine.

Iron Toxicity

– Acute poisoning from accidental or intentional ingestion of elemental iron supplements (frequently pediatric accidental ingestion of colorful iron tablets). Toxic dose: $> 20 \text{ mg/kg}$ causes local toxicity; $> 60 \text{ mg/kg}$ causes severe systemic toxicity. Patho-

physiology: free circulating iron generates hydroxyl free radicals via the Fenton reaction, causing severe gastrointestinal mucosal ulceration, cellular lipid peroxidation, systemic vasodilation, and uncoupling of oxidative phosphorylation. Clinical stages: Stage 1 (0.5–6 hrs: severe hemorrhagic gastroenteritis, abdominal pain, vomiting, hematemesis); Stage 2 (6–24 hrs: apparent recovery / latent phase); Stage 3 (12–48 hrs: metabolic acidosis, systemic shock, acute liver failure, hypoglycemia, coagulopathy); Stage 4 (2–5 days: hepatotoxicity and acute liver necrosis); Stage 5 (2–4 weeks: gastric outlet obstruction secondary to cicatricial scarring). Diagnosis: serum iron level at 4 hours, abdominal X-ray (radioopaque iron pills). Specific antidote: intravenous deferoxamine (iron chelator), turning urine a characteristic "vin rosé" color.

Lead Poisoning

– Occupational and environmental hazard from exposure to lead. Affects the nervous system, kidneys, and hematopoietic system. Particularly dangerous for children causing developmental delays. Measured by blood lead levels.

Lead Poisoning (Plumbism)

– Toxic accumulation of lead in body tissues, predominantly affecting the hematological, central nervous, renal, and gastrointestinal systems. Sources: lead-based paint chips (in older homes), contaminated soil/water, lead pipes, imported ceramics, traditional medicines, and battery recycling. Pathophysiology: inhibits δ -aminolevulinic acid dehydratase (δ -ALAD) and ferrochelatase in the heme synthesis pathway, causing accumulation of protoporphyrin and microcytic hypochromic anemia with characteristic basophilic stippling of red blood cells. Clinical presentation in children: developmental delay, irritability, cognitive impairment, hyperactivity, and encephalopathy (at high levels). Presentation in adults: abdominal colic ("lead colic"), gout ("saturnine gout"), hypertension, peripheral motor neuropathy (wrist drop, foot drop), and Burton lines (bluish-gingival pigmentation). Diagnosis: blood lead level (BLL). Treatment: environmental abatement, succimer (DMSA) for BLL > 45 $\mu\text{g}/\text{dL}$, and BAL plus CaNa_2EDTA for severe encephalopathy (BLL > 70 $\mu\text{g}/\text{dL}$).

Local Anesthetic Systemic Toxicity

(LAST)

– Life-threatening adverse reaction resulting from systemic absorption of local anesthetics (bupivacaine, lidocaine) into bloodstream. Symptoms progress from circumoral numbness, metallic taste, tinnitus, and agitation to seizures, coma, and refractory cardiac arrest. Treatment: Intravenous Lipid Emulsion (Intralipid 20%).

Mercury Poisoning

– Clinical toxicity resulting from exposure to elemental (metallic), inorganic, or organic (methylmercury) forms of mercury. Elemental mercury: inhalation of mercury vapor from broken thermometers or industrial processes causes acute interstitial pneumonitis, pulmonary edema, and chronic neurotoxicity (tremor, erethism mercurialis—personality changes, timidity, memory loss; "Mad Hatter syndrome"). Inorganic mercury salts (HgCl_2): ingestion causes corrosive gastroenteritis, acute tubular necrosis, and renal failure. Organic mercury (methylmercury): ingestion of contaminated bioaccumulated seafood (Minamata disease) or seed grain causes severe central nervous system damage—paresthesias, ataxia, dysarthria, visual field constriction ("tunnel vision"), deafness, and profound fetal teratogenicity. Diagnostic evaluation: 24-hour urine mercury (for elemental/inorganic) or whole blood mercury (for organic). Treatment: chelation with succimer (DMSA) or dimercaprol (BAL, contraindicated in methylmercury due to brain redistribution).

Methanol Poisoning

– Toxic alcohol poisoning resulting from ingestion of methanol, found in windshield washer fluid, solid alcohol fuels (Sterno), adulterated moonshine, and industrial solvents. Pathophysiology: methanol itself causes mild CNS depression, but is metabolized by alcohol dehydrogenase (ADH) to formaldehyde, which is rapidly converted by aldehyde dehydrogenase to toxic formic acid (formate). Formic acid inhibits cytochrome c oxidase in the retina and basal ganglia, causing metabolic acidosis and severe end-organ damage. Clinical features: 12–24 hour latent period followed by visual disturbances ("looking through a snowstorm", optic disc hyperemia, blindness), severe high anion gap metabolic acidosis with elevated osmolal gap, nausea, vomiting, abdominal pain, and basal ganglia necrosis (putaminal necro-

sis). Treatment: ADH inhibitors—fomepizole (gold standard) or ethanol (competitive substrate)—to block toxic metabolite formation; sodium bicarbonate for severe acidosis; folic acid to accelerate formate elimination; and hemodialysis for severe acidosis, visual impairment, or methanol level > 50 mg/dL.

Methanol Toxicity

– Ingestion of toxic alcohol present in windshield washer fluid and moonshine, metabolized by alcohol dehydrogenase into Formic Acid. Causes visual impairment ('blindness like being in a snowstorm' due to optic papillitis), central nervous system depression, high anion gap metabolic acidosis, and elevated osmolal gap. Antidote: Fomepizole or Ethanol.

N-Acetylcysteine (NAC)

– Specific antidote for Acetaminophen (Paracetamol) toxicity; acts as a precursor for cellular Glutathione synthesis, neutralizing toxic reactive metabolite NAPQI (*N*-acetyl-*p*-benzoquinone imine) to prevent centrilobular hepatic necrosis.

Naloxone

– Pure competitive opioid receptor antagonist that rapidly reverses opioid-induced central nervous system and respiratory depression; administered IV, IM, or intranasally in suspected opioid overdose.

Naloxone (Narcan)

– Pure, competitive opioid receptor antagonist with high affinity for μ , κ , and δ opioid receptors, rapidly displacing exogenous opioids from binding sites in the central nervous system. Indications: emergency reversal of acute opioid overdose presenting with respiratory depression, sedation, and miosis. Route of administration: intravenous, intramuscular, subcutaneous, endotracheal, or intranasal spray. Onset of action: 1–2 minutes IV; duration of action: 30–90 minutes. Clinical caution: because the half-life of naloxone is shorter than most long-acting opioids (methadone, sustained-release morphine), recurrent respiratory depression can occur, requiring continuous monitoring or repeated doses/infusions. Administration in opioid-dependent individuals precipitates acute opioid withdrawal syndrome (agitation, rhinorrhea, lacrimation, vomiting, piloerection, tachycardia), which is distressing but non-life-threatening.

Opioid Toxidrome

– Classic clinical syndrome caused by acute overdose of natural, synthetic, or semi-synthetic opioid analgesics (morphine, heroin, fentanyl, oxycodone, methadone, codeine). Pathophysiology: stimulation of central μ -opioid receptors in the brainstem and cerebral cortex. Classic clinical triad: (1) Respiratory depression (hypopnea, bradypnea, apnea), (2) Central nervous system depression (sedation, stupor, coma), and (3) Miosis ("pinpoint pupils"). Additional features: bradycardia, hypotension, hypothermia, decreased bowel sounds, and pulmonary edema (frequent with heroin and fentanyl overdose). Exceptions to miosis: meperidine (causes mydriasis due to normeperidine accumulation), propoxyphene, and co-ingestion of sympathomimetics or anticholinergics. Primary immediate goal of management: restoration of adequate ventilation using bag-valve-mask oxygenation followed by titrated administration of naloxone.

Organophosphate Poisoning

– Toxicity resulting from exposure to organophosphate esters, widely used as agricultural insecticides (malathion, parathion, chlorpyrifos) and military nerve agents (sarin, soman, tabun, VX). Pathophysiology: irreversible inhibition of acetylcholinesterase (AChE) via phosphorylation of the enzyme's active serine site, leading to massive accumulation of acetylcholine at muscarinic, nicotinic, and central nervous system synapses. Over time (hours to days), the enzyme-inhibitor complex undergoes "aging" (loss of an alkyl group), making acetylcholinesterase permanently unreactivable by oximes. Clinical features: severe cholinergic toxidrome with profuse bronchorrhea, bronchospasm, miosis, muscle fasciculations, flaccid paralysis, seizures, and respiratory failure. Treatment: immediate decontamination, personal protective equipment for responders, aggressive high-dose atropine IV to block muscarinic hypersecretion, pralidoxime (2-PAM) IV prior to aging to reactivate AChE, and diazepam/midazolam for seizure prevention.

Pralidoxime (2-PAM)

– Oxime compound utilized as a specific antidote for organophosphate insecticide and nerve agent poisonings. Mechanism of action: nucleophilic attack on the phosphorylated serine residue of the inhibited acetylcholinesterase enzyme, cleaving the

organophosphate moiety and restoring active acetylcholinesterase. Pralidoxime acts primarily at nicotinic neuromuscular junctions, reversing muscle weakness, fasciculations, and paralysis (functions where atropine is ineffective). Crucial therapeutic window: must be administered before "aging" of the organophosphate-enzyme complex occurs, after which chemical reactivation is impossible. Always co-administered with atropine (atropine addresses muscarinic hypersecretions, while pralidoxime addresses nicotinic neuromuscular toxicity). Ineffective against carbamate toxicity (where enzyme inhibition is spontaneously reversible).

Rhabdomyolysis (Toxic/Traumatic)

– Rapid breakdown and necrosis of skeletal muscle tissue, releasing intracellular muscle constituents (myoglobin, creatine kinase, potassium, phosphate, urate) into the systemic circulation. Toxic etiologies: alcohol abuse, cocaine, amphetamines, statins (especially combined with fibrates or macrolides), MDMA, neuroleptic malignant syndrome, serotonin syndrome, carbon monoxide, colchicine, and snake/insect envenomation. Traumatic/physical causes: crush injury, prolonged immobilization ("found down"), compartment syndrome, strenuous exercise, and grand mal seizures. Clinical triad (< 50% of cases): myalgia, muscle weakness, and dark red-brown urine ("tea-colored" or "cola-colored"). Pathophysiology of kidney injury: myoglobin precipitates in renal tubules, causing tubular obstruction, direct tubulotoxicity, and intrarenal vasoconstriction. Laboratory diagnostics: serum creatine kinase (CK) > 5× upper limit of normal (> 1000 U/L); urine dipstick positive for "blood" but negative for RBCs on microscopy. Management: aggressive IV fluid hydration with isotonic saline to maintain urine output at 200–300 mL/hr, treatment of hyperkalemia, and hemodialysis for severe renal failure or refractory electrolyte abnormalities.

Salicylate Toxicity (Aspirin Overdose)

– Acute or chronic overdose of aspirin, causing direct stimulation of respiratory center (primary Respiratory Alkalosis) followed by uncoupling of oxidative phosphorylation (primary Metabolic Acidosis), tin-

nitus, hyperthermia, vomiting, and altered mental status. Treatment: Urinary alkalinization with IV Sodium Bicarbonate.

Sedative-Hypnotic Toxidrome

– Clinical syndrome resulting from acute toxicity or overdose of central nervous system depressants, primarily benzodiazepines (diazepam, alprazolam, lorazepam), barbiturates (phenobarbital, secobarbital), non-benzodiazepine hypnotics (zolpidem, zopiclone), GHB, and ethanol. Mechanism: enhancement of gamma-aminobutyric acid (GABA) neurotransmission at GABA_A receptor complexes in the brain. Clinical presentation: CNS depression, ataxia, dysarthria, nystagmus, lethargy, stupor, and coma. Vital signs: typically mild hypothermia, mild hypotension, and mild bradypnea; severe respiratory depression and cardiovascular collapse occur with barbiturates, heavy ethanol co-ingestion, or intravenous boluses. Pupils are usually mid-position or small but reactive (unlike opioids). Management: airway protection, supportive care, and mechanical ventilation. Specific antagonist: flumazenil (competitive GABA_A benzodiazepine receptor antagonist); flumazenil must be used with extreme caution due to risk of precipitating life-threatening seizures in chronic benzodiazepine users or co-ingestions of pro-convulsant drugs (tricyclic antidepressants).

Snakebite Envenomation

– Envenomation resulting from venomous snakebites (pit vipers: rattlesnakes, copperheads, cottonmouths; elapids: coral snakes). Pit viper envenomation causes localized tissue destruction (pain, progressive edema, bullae, ecchymosis) and systemic manifestations (coagulopathy, thrombocytopenia, hypotension). Management: limb immobilization at heart level, avoidance of harmful remedies (no tourniquets, ice, or incision/suction), and prompt administration of antivenom (Crotalidae polyvalent immune Fab / CroFab or Anavip) for progressive edema, coagulopathy, or systemic toxicity.

Sympathomimetic Toxidrome

– Clinical syndrome resulting from hyperstimulation of α - and β -adrenergic receptors caused by illicit drugs (cocaine, amphetamines, methamphetamine, MDMA/ecstasy, synthetic cathinones/"bath salts") or therapeutic agents (ephedrine, pseudoephedrine, phenylpropanolamine, MAO inhibitors). Clinical

presentation: agitation, paranoia, psychosis, severe diaphoresis (sweating), hyperthermia, mydriasis (dilated pupils), tachycardia, hypertension, and tremors. Differentiating feature from anticholinergic toxidrome: patients with sympathomimetic toxidrome have **profuse sweating** ("wet skin"), active bowel sounds, and preserved salivation, whereas anticholinergic patients have dry skin, absent bowel sounds, and dry mouth. Complications: hypertensive emergency, acute myocardial infarction, aortic dissection, intracranial hemorrhage, hyperthermia, rhabdomyolysis, and ventricular arrhythmias. Treatment: aggressive sedation with IV benzodiazepines (lorazepam, diazepam), cooling measures, and control of hypertension (phentolamine, nitroprusside; pure β -blockers are contraindicated due to risk of unopposed α -adrenergic stimulation).

Toxicokinetics

- Study of the absorption, distribution, metabolism, and excretion (ADME) of xenobiotics (drugs, toxins, environmental chemicals) under conditions of toxic overdose or poisoning. Toxicokinetics differs from standard pharmacokinetics because therapeutic kinetic models often break down in high-dose exposures: absorption may be delayed or prolonged due to bezoar formation, sustained-release formulations, or toxic ileus; protein binding may become saturated, dramatically increasing free active drug concentrations; metabolic pathways (e.g., hepatic glucuronidation) become saturated, shifting zero-order clearance to capacity-limited elimination; volume of distribution (V_d) may expand; and renal or hepatic organ failure alters normal clearance pathways. Understanding toxicokinetics guides antidote timing, multi-dose charcoal utilization, urinary alkalization, and decisions regarding extracorporeal clearance (hemodialysis, hemoperfusion).

Toxicology

- Branch of medical science concerned with the nature, effects, detection, mechanism of action, clinical diagnosis, and treatment of poisons, toxins, and toxic substances. Subspecialties: Clinical Toxicology (diagnosis and treatment of human poisoning in emergency and critical care settings), Forensic Toxicology (post-mortem analysis and legal application of toxicological testing), Occupational/Environmental Toxicology (health effects of

industrial chemicals and pollutants), Regulatory Toxicology (safety evaluation of drugs, cosmetics, and food additives), and Toxinology (specialized study of animal, plant, and microbial venoms and toxins).

Toxidrome

- Constellation of physical signs, symptoms, vital sign abnormalities, and laboratory findings associated with a specific class or group of toxic substances. Recognition of toxidromes allows rapid bedside identification of the likely toxic agent in an unknown overdose situation prior to formal laboratory confirmation. Major classic toxidromes include: Anticholinergic, Cholinergic, Opioid, Sedative-Hypnotic, Sympathomimetic, Salicylate, and Serotonergic toxidromes. Systematic toxidrome assessment evaluates mental status, vital signs (pulse, blood pressure, respiratory rate, temperature), pupil size and reactivity, skin moisture and color, bowel motility, and presence of reflexes/neuromuscular excitability.

Toxodrome

- See Toxidrome.

Tricyclic Antidepressant (TCA) Toxicity

- Severe overdose of TCAs (amitriptyline, imipramine) causing inhibition of cardiac fast sodium channels, muscarinic receptors, and α -1 receptors. Triad: Coma, Convulsions, Cardiac arrhythmias (wide QRS complex, R wave in aVR). Antidote: IV Sodium Bicarbonate (alkalinizes serum, increases extracellular sodium to unblock sodium channels).

Wasp Stings

- See Bites and Stings.

Whole Bowel Irrigation

- Decontamination technique using large volumes of polyethylene glycol-electrolyte solution (PEG-ELS) via nasogastric tube to flush the entire GI tract; indicated for ingestions of sustained-release medications, heavy metals (iron, lead), or illicit drug packets ('body packers').

Chapter 41

Urology

Bladder Carcinoma

– Malignant neoplasm originating from the urothelium lining the urinary bladder, with transition cell carcinoma (urothelial carcinoma) accounting for over 90 percent of cases. Predominant risk factor: cigarette smoking (responsible for 50% of cases) and occupational exposure to aromatic amines or aniline dyes. Classic presentation: painless gross hematuria. Diagnosis: flexible cystoscopy with biopsy and urine cytology. Staging (TNM): non-muscle-invasive bladder cancer (Ta, T1, Tis) versus muscle-invasive bladder cancer ($\geq T2$). Treatment for non-muscle-invasive disease: transurethral resection of bladder tumor (TURBT) followed by intravesical Bacillus Calmette-Guérin (BCG) or chemotherapy. Treatment for muscle-invasive disease: radical cystectomy with urinary diversion (ileal conduit or neobladder) and neoadjuvant cisplatin-based combination chemotherapy.

Bladder Health and Disorders

– Bladder health involves the proper storage and voluntary release of urine through coordinated function of the detrusor muscle and sphincters. Common disorders include urinary tract infections, overactive bladder, stress incontinence, and interstitial cystitis. Maintaining bladder health includes adequate hydration, pelvic floor exercises, and prompt treatment of infections.

Bladder Problems

– a range of conditions affecting urine storage and voiding, including incontinence, overactive bladder, urinary retention, and recurrent infections. Causes may include neurological damage, pelvic floor weakness, prostate enlargement, or bladder outlet obstruction. Evaluation includes urinalysis, urodynamics, and imaging; treatment varies from behav-

ioral modifications and medications to surgery.

Catheterization (Urinary)

– Insertion of a flexible tube (catheter) through the urethra or suprapubically into the urinary bladder to drain urine. Types: Foley catheter (indwelling balloon catheter), intermittent (in-out) catheter, and suprapubic catheter. Indications: acute urinary retention, monitoring hourly urine output in critically ill patients, intraoperative management, neurogenic bladder, or intractable incontinence when conservative measures fail. Complications: catheter-associated urinary tract infection (CAUTI), urethral trauma, stricture formation, bladder spasms, and balloon malfunction. Prevention of CAUTI requires strict aseptic insertion technique, maintaining a closed drainage system, and prompt removal when no longer clinically indicated.

Circumcision

– Surgical removal of the foreskin (prepuce) covering the glans penis. Indications: medical reasons such as severe phimosis, recurrent balanoposthitis, paraphimosis, or lichen sclerosus (balanitis xerotica obliterans); elective infant circumcision for religious, cultural, or preventive health reasons. Preventive benefits: reduced risk of urinary tract infections in male infants, reduced risk of heterosexually acquired HIV transmission (demonstrated in sub-Saharan African clinical trials), decreased incidence of penile cancer, and lower risk of human papillomavirus (HPV) and herpes simplex virus type 2 transmission to partners. Surgical methods: Gomco clamp, Plastibell device, Mogen clamp, or dorsal slit and sleeve resection in older males.

Cystitis

– Inflammation of the urinary bladder, most frequently caused by bacterial infection originating

from colonic flora. *Escherichia coli* is responsible for 75–90% of uncomplicated cases, followed by *Staphylococcus saprophyticus*, *Klebsiella pneumoniae*, and *Proteus mirabilis*. More common in females due to shorter urethral length and proximity of the urethral meatus to the anus. Clinical features: dysuria, urinary frequency, urgency, suprapubic pain, and hematuria. Urinalysis shows pyuria, positive leukocyte esterase, and positive nitrites. Uncomplicated cystitis in non-pregnant women is treated with nitrofurantoin, trimethoprim-sulfamethoxazole, or fosfomycin. Non-infectious cystitis causes include radiation therapy, cyclophosphamide chemotherapy, and interstitial cystitis (painful bladder syndrome).

Cystoscopy

– Endoscopic examination of the lower urinary tract, allowing direct visualization of the urethra, prostate, bladder neck, ureteral orifices, and bladder mucosa. Equipment: flexible or rigid cystoscope with fiberoptic light source, lens system, and working channels for instruments. Flexible cystoscopy is performed under local anesthesia (topical lidocaine jelly) for diagnostic evaluation of hematuria, recurrent UTIs, bladder pain, or voiding dysfunction. Rigid cystoscopy is performed under regional or general anesthesia for operative procedures including bladder tumor resection (TURBT), ureteral stent placement/extraction, bladder stone lithotripsy, and mucosal biopsy.

Dysuria

– Painful, burning, or uncomfortable sensation experienced during urination. Most commonly indicates inflammation or infection of the lower urinary tract. Causes in females: acute cystitis, urethritis (*Chlamydia trachomatis*, *Neisseria gonorrhoeae*), vaginitis (*Candida*, *Trichomonas*), and vulvar atrophy. Causes in males: urethritis, prostatitis, benign prostatic hyperplasia, or epididymitis. Non-infectious causes: bladder calculi, urethral trauma, chemical irritation (soaps, spermicides), interstitial cystitis, and urothelial neoplasms. Initial diagnostic evaluation involves urinalysis, urine culture, and testing for sexually transmitted infections when indicated.

Ejaculation

– The expulsion of seminal fluid from the male urethra during sexual climax, a reflex coordinated by

the sympathetic nervous system (T10–L2) and involving contraction of the epididymis, vas deferens, seminal vesicles, prostate, and bulbospongiosus muscle. The process has two phases: emission (deposition of sperm and seminal fluid into the posterior urethra) and expulsion (rhythmic contraction of the pelvic floor muscles propelling semen through the urethra). Ejaculatory disorders include premature ejaculation (most common), delayed ejaculation, retrograde ejaculation (semen flows backward into the bladder), anejaculation (no ejaculation), and painful ejaculation. Causes: neurologic, pharmacologic (SSRIs, alpha-blockers), psychologic, and structural.

Emission

– The discharge or release of a substance, usually a fluid.

Emphysematous Pyelonephritis

– Severe necrotizing infection of renal parenchyma with gas formation. Almost exclusively in diabetic patients. Presents with high fever, flank pain, and sepsis. CT shows gas within renal parenchyma. A urological emergency requiring aggressive antibiotics and usually nephrectomy. Mortality is high even with treatment.

Epididymitis

– Inflammation of the epididymis, a common cause of acute scrotal pain in adults, typically resulting from infection. In sexually active men under 35 years, the most common pathogens are sexually transmitted: *Chlamydia trachomatis* (most common) and *Neisseria gonorrhoeae*, with epididymitis often accompanied by urethritis. In men over 35 years and in children, the causative organisms are enteric gram-negative bacilli (*Escherichia coli*, *Pseudomonas*, *Klebsiella*) from urinary tract infection, prostatitis, or following urological instrumentation. Presents with gradual onset of scrotal pain and swelling, often with fever and dysuria. Diagnosis is clinical, supported by urine analysis and NAAT testing for sexually transmitted infections. Treatment includes appropriate antibiotics targeting the causative organism, scrotal elevation, and NSAIDs for symptom control.

Erectile Dysfunction

– The persistent inability to achieve or maintain an erection sufficient for satisfactory sexual per-

formance. Affects up to 50% of men aged 40-70. Etiology: organic (vascular disease, diabetes, hypogonadism, neurological disorders, medications, Peyronie disease) and psychogenic (anxiety, depression, relationship issues). Vascular causes: impaired arterial inflow (atherosclerosis) or venous leak. Diagnosis: history, IIEF-5 questionnaire, nocturnal penile tumescence testing, duplex Doppler ultrasound, and hormonal profile. Treatment: PDE5 inhibitors (sildenafil, tadalafil, vardenafil) as first-line; second-line options: intracavernosal injections (alprostadil), vacuum erection devices, and penile prosthesis for refractory cases. Lifestyle modification (weight loss, exercise, smoking cessation) improves outcomes.

Erectile Dysfunction (ED)

– Inability to attain or maintain a penile erection sufficient for satisfactory sexual performance. Etiologies: vasculogenic (atherosclerosis, hypertension, diabetes mellitus), neurogenic (radical prostatectomy, spinal cord injury, multiple sclerosis, diabetic neuropathy), hormonal (hypogonadism, hyperprolactinemia), psychogenic (performance anxiety, depression, relationship conflict), and drug-induced (antihypertensives, antidepressants, antiandrogens). Vascular ED serves as an early marker for systemic coronary artery disease due to endothelial dysfunction in smaller cavernosal arteries. First-line therapy: oral phosphodiesterase type 5 (PDE5) inhibitors (sildenafil, tadalafil, vardenafil). Second-line therapy: intracavernosal alprostadil injection or vacuum erection devices. Third-line therapy: surgical implantation of an inflatable penile prosthesis.

Extracorporeal Shock Wave Lithotripsy (ESWL)

– Non-invasive treatment method for urinary calculi that uses focused acoustic shock waves generated outside the body to fragment kidney or ureteral stones into smaller gravel-like pieces (dust/sand) that pass spontaneously in urine. Shock wave sources: electrohydraulic, electromagnetic, or piezoelectric generators, focused using fluoroscopic or ultrasound guidance. Most effective for renal stones < 2 cm and proximal ureteral stones with density < 1000 Hounsfield Units on non-contrast CT. Contraindications: pregnancy, uncorrected bleeding diatheses, uncontrolled urinary tract infection, severe body habitus, and abdominal aortic

aneurysm. Complications: renal hematoma, Steinstrasse (ureteral obstruction by stone fragments), and transient hematuria.

Hematuria

– Presence of red blood cells in the urine, categorized as microscopic (> 3 RBCs per high-power field on urine microscopy) or gross (macroscopic, visible color change from pink to dark red). Microscopic hematuria is often asymptomatic and detected on routine urinalysis. Gross hematuria requires urgent urological investigation to exclude malignancy. Etiologies: urological sources (bladder carcinoma, renal cell carcinoma, prostate cancer, nephrolithiasis, UTI, BPH, trauma) versus nephrological sources (IgA nephropathy, post-infectious glomerulonephritis, Alport syndrome). Glomerular origin is suggested by dysmorphic RBCs, red cell casts, and significant proteinuria. Workup for non-glomerular hematuria: multiphase CT urography and flexible cystoscopy.

Hydrocele

– Accumulation of serous fluid within the tunica vaginalis surrounding the testis, presenting as a painless, soft, fluid-filled scrotal swelling. Types: congenital (communicating hydrocele due to a patent processus vaginalis, common in infants, fluctuates in size) and acquired (non-communicating, resulting from impaired fluid absorption due to epididymitis, orchitis, testicular trauma, filariasis, or tumor). Diagnosis: scrotal transillumination (hydrocele glows brightly red) and scrotal ultrasonography to rule out underlying testicular neoplasm. Treatment: conservative observation for asymptomatic cases; hydrocelectomy (Jaboulay or Lord technique) or aspiration with sclerotherapy for large, symptomatic, or tense hydroceles.

Hypospadias

– Congenital anomaly of male urogenital development characterized by an abnormally proximal urethral meatus located on the ventral surface of the penis, scrotum, or perineum, rather than at the tip of the glans. Classified by meatal location: anterior (glandular, subcoronal—60–70%), middle (penile), or posterior (equinoscrotal, perineal). Associated features: ventral curvature of the penis (chordee) and an incomplete, hooded foreskin. Resulting from failure of complete fusion of the urethral folds dur-

ing embryogenesis (weeks 8–14). Routine infant circumcision is contraindicated because the prepuce is required for surgical reconstruction (hypospadias repair/urethroplasty), typically performed between 6 and 18 months of age.

Kidney Stones (Nephrolithiasis / Urolithiasis)

– Crystalline mineral deposits formed within the renal pelvis and calyces due to supersaturation of urine. Types: calcium oxalate/phosphate (75–80%, radio-opaque), struvite (magnesium ammonium phosphate, 10–15%, staghorn calculi associated with *Proteus* infection), uric acid (5–10%, radiolucent on X-ray, associated with gout and metabolic syndrome), and cystine (1–2%, ground-glass appearance, autosomal recessive cystinuria). Symptoms: sudden, severe renal colic radiating from flank to groin, hematuria, nausea, vomiting, and dysuria. Diagnosis: non-contrast low-dose abdominal/pelvic CT (gold standard). Management: conservative passage with hydration and alpha-blockers for stones < 5 mm; ESWL, ureteroscopy with laser lithotripsy, or percutaneous nephrolithotomy (PCNL) for larger or non-passing stones.

Libido and Sexual Performance

– Libido (sexual desire) is modulated by a complex interplay of hormonal (testosterone, estrogen, prolactin), neurologic, psychologic, and relational factors. Low libido in men is commonly associated with hypogonadism, depression, medication side effects (SSRIs, antihypertensives), and chronic illness; in women, contributing factors include hormonal changes (menopause, postpartum), relationship distress, stress, and body image concerns. Sexual performance encompasses erectile function, ejaculatory control, and orgasmic capacity. Evaluation includes validated questionnaires, laboratory testing (testosterone, prolactin, thyroid function, glucose, lipids), and psychologic assessment. Treatment targets the underlying cause: testosterone replacement for hypogonadism, PDE5 inhibitors for ED, SSRIs or topical anesthetics for premature ejaculation, and psychosexual therapy or couples counseling for relationship or psychogenic contributors.

Lithotripsy

– A medical procedure that uses shock waves to fragment kidney stones (renal calculi) into smaller

pieces that can pass through the urinary tract. See Shock Wave Lithotripsy.

Masturbation

– Self-stimulation of the genitalia for sexual pleasure, a normal and common human behavior across all ages and genders. Prevalence: >90% of males and >60% of females report having masturbated at some point in their lives. It is a healthy component of psychosexual development, stress relief, and sexual self-exploration. There are no adverse medical consequences. Excessive or compulsive masturbation may rarely be associated with underlying psychiatric conditions (e.g., obsessive-compulsive disorder, hypersexuality). Cultural and religious attitudes vary widely. Medical benefits: may reduce stress, improve sleep, relieve sexual tension, and (in males) may reduce the risk of prostate cancer by facilitating the clearance of prostatic secretions.

Nephrolithiasis

– Stone formation in the urinary tract. Calcium oxalate most common at 80%, followed by struvite, uric acid, and cystine. Risk factors include dehydration, hypercalciuria, hyperoxaluria, hypocitraturia, and low urine volume. Evaluation includes 24-hour urine analysis. Treatment includes hydration, dietary modification, and targeted medical therapy based on stone composition.

Nocturia

– Complaint of waking one or more times during the night to void, with each void preceded and followed by sleep. Highly prevalent in older adults and significantly impairs sleep quality and quality of life. Etiologies: nocturnal polyuria (nocturnal urine volume > 33% of total 24-hour volume, caused by heart failure, obstructive sleep apnea, peripheral edema, or loss of circadian vasopressin secretion), low nocturnal bladder capacity (BPH, neurogenic bladder, interstitial cystitis, overactive bladder), or global polyuria (diabetes mellitus, diabetes insipidus, primary polydipsia). Evaluation: 24-hour frequency-volume chart (bladder diary). Treatment targets underlying systemic or urological causes; desmopressin may be used for nocturnal polyuria in selected patients.

Orchitis

– Inflammation of one or both testes, most commonly resulting from hematogenous viral infection

or contiguous extension from acute epididymitis (epididymo-orchitis). Viral orchitis: classic complication of mumps (paramyxovirus), occurring in up to 30% of post-pubertal males 4–8 days after parotitis. Bacterial orchitis: typically caused by *Chlamydia trachomatis* or *Neisseria gonorrhoeae* in sexually active men under 35, and enteric organisms (*E. coli*, *Pseudomonas*) in older men. Clinical features: acute scrotal pain, testicular swelling, fever, systemic toxicity, and reactive hydrocele. Complications: testicular atrophy, impaired spermatogenesis, and infertility. Treatment: supportive care (analgesics, bed rest, scrotal elevation) for viral orchitis; empirical antibiotics for bacterial causes.

Paraphimosis

– Urological emergency in uncircumcised males occurring when a retracted, tight foreskin becomes trapped behind the coronal sulcus of the glans penis, forming a constricting ring. Venous and lymphatic congestion causes progressive edema of the glans and prepuce, eventually impairing arterial perfusion and risking glans ischemia, necrosis, and gangrene. Causes: failure to return the foreskin to its anatomical position following urinary catheterization, hygiene, or physical examination. Management: immediate manual reduction using digital compression to reduce edema followed by traction on the prepuce; if manual reduction fails, ice packs, osmotic agents (granulated sugar), hyaluronidase injections, dorsal slit procedure, or emergency circumcision are indicated.

Percutaneous Nephrolithotomy (PCNL)

– Minimally invasive surgical procedure for removing large, complex, or staghorn renal calculi. Access: a needle track is established under fluoroscopic or ultrasound guidance from the flank through the renal parenchyma into the target renal calyx, dilated to allow passage of a nephroscope and working sheath. Stones are fragmented using ultrasonic, pneumatic, or laser energy sources and extracted under direct vision. Indications: kidney stones > 2 cm, staghorn calculi, lower pole stones > 1.5 cm, or cases where ESWL and ureteroscopy have failed. Complications: hemorrhage requiring transfusion, retroperitoneal hematoma, pleural entry (hydro/pneumothorax), sepsis, and adjacent

organ injury.

Phimosis

– Inability to retract the foreskin (prepuce) proximally over the glans penis. Physiologic phimosis is normal in infants and uncircumcised young boys due to natural adhesions between glans and prepuce, resolving spontaneously in over 90% by age 3–5 years. Pathologic phimosis is secondary to scarring, inflammation, or infection, presenting in adolescents or adults as a tight, fibrotic preputial ring. Causes of pathologic phimosis: recurrent balanoposthitis, poor hygiene, severe diabetes, and lichen sclerosus (balanitis xerotica obliterans). Clinical features: painful erections, ballooning of foreskin during micturition, recurrent UTIs, and increased risk of penile cancer. Treatment: topical high-potency corticosteroid cream (betamethasone) with manual stretching; surgical circumcision or preputioplasty for refractory cases.

Priapism

– Prolonged, painful erection lasting longer than 4 hours, occurring independently of sexual desire or stimulation. Medical emergency categorized into two types: ischemic (low-flow, veno-occlusive) and non-ischemic (high-flow, arterial). Ischemic priapism accounts for > 95% of cases, characterized by compartment syndrome of the corpora cavernosa with stasis, hypoxia, and acidosis; causes include sickle cell disease, intracavernosal erectile dysfunction therapies, medications (trazodone, antipsychotics), and hematological malignancies. Non-ischemic priapism is usually secondary to perineal/penile trauma resulting in an arteriocavernosal fistula. Management of ischemic priapism: cavernous blood aspiration, intracavernosal injection of alpha-adrenergic agonists (phenylephrine), and surgical shunting procedures (Winter, Al-Ghorab, or distal shunt) if conservative measures fail after 12–24 hours to prevent irreversible erectile tissue fibrosis and impotence.

Prostatectomy

– Surgical procedure involving the partial or total removal of the prostate gland. Simple prostatectomy: removal of the inner adenoma while leaving the peripheral capsule intact, performed open, laparoscopically, or robotically for very large BPH (> 80–100 grams). Radical prostatectomy: complete exci-

sion of the entire prostate gland, seminal vesicles, and ampullae of the vas deferens, along with pelvic lymph node dissection for localized prostate cancer. Radical prostatectomy approaches: open retropubic, perineal, or robot-assisted laparoscopic radical prostatectomy (RALP). Key surgical complications: urinary stress incontinence (due to external urethral sphincter trauma) and erectile dysfunction (due to cavernous nerve injury; nerve-sparing techniques preserve potency when oncologically feasible).

Prostate-Specific Antigen (PSA)

– Glycoprotein enzyme (serine protease) produced almost exclusively by the luminal epithelial cells of the prostate gland, secreted into seminal fluid to liquefy the semen coagulum. Small amounts enter the bloodstream, where total PSA can be measured. Reference range: generally < 4 ng/mL, though age-adjusted thresholds are used. Elevated PSA occurs in prostate cancer, but is non-specific and also elevated in benign prostatic hyperplasia, acute/chronic prostatitis, urinary retention, prostate biopsy, and recent ejaculation. Clinical utility: screening (discussed with informed decision-making), monitoring response to prostate cancer treatment, and surveillance for disease recurrence. Diagnostic specificity is improved using free-to-total PSA ratio, PSA velocity, and PSA density.

Prostatitis

– Inflammation or infection of the prostate gland, classified by the National Institutes of Health (NIH) into four categories: Category I (Acute Bacterial Prostatitis), Category II (Chronic Bacterial Prostatitis), Category III (Chronic Prostatitis / Chronic Pelvic Pain Syndrome, CP/CPPS), and Category IV (Asymptomatic Inflammatory Prostatitis). Acute bacterial prostatitis presents with fever, chills, perineal/low back pain, dysuria, and acute voiding dysfunction; prostate is tender, warm, and boggy on DRE (prostate massage is contraindicated to avoid bacteremia). Caused by Gram-negative bacilli (*E. coli*, *Pseudomonas*). Category III (CP/CPPS) accounts for 90% of symptomatic cases, treated with multimodal therapy (alpha-blockers, anti-inflammatories, physical therapy).

Pyelonephritis

– Acute or chronic infection of the renal parenchyma and pelvicalyceal system, most commonly result-

ing from ascending urinary tract infection from the bladder. Major pathogens: *Escherichia coli* ($> 80\%$), *Proteus*, *Klebsiella*, *Enterobacter*, and *Pseudomonas*. Risk factors: female gender, pregnancy, urinary tract obstruction (stones, BPH), vesicoureteral reflux, neurogenic bladder, and diabetes mellitus. Clinical features: triad of flank pain/CVA tenderness, high fever with rigors, and lower urinary tract symptoms (dysuria, frequency). Urinalysis shows WBC casts (pathognomonic for upper UTI), pyuria, and bacteriuria. Complications: renal abscess, emphysematous pyelonephritis, sepsis, and chronic renal scarring. Treatment: empiric systemic antibiotic therapy (fluoroquinolones, third-generation cephalosporins, or aminoglycosides).

Renal Cell Carcinoma (RCC)

– Primary malignant adenocarcinoma of the renal cortex, originating from proximal renal tubular epithelial cells. Represents 85% of all primary adult kidney cancers. Major histologic subtypes: clear cell RCC (70–80%, associated with VHL gene mutations on chromosome 3p), papillary RCC (10–15%), and chromophobe RCC (5%). Risk factors: cigarette smoking, obesity, hypertension, end-stage renal disease, and occupational exposure to cadmium or asbestos. Classic triad ($< 10\%$ of patients): flank pain, palpable abdominal mass, and gross hematuria; most cases are discovered incidentally on imaging. Paraneoplastic syndromes: erythrocytosis (EPO hypersecretion), hypercalcemia (PTHrP), hypertension (renin), and Stauffer syndrome (non-metastatic hepatic dysfunction). Treatment: partial or radical nephrectomy; metastatic RCC responds to targeted anti-angiogenic agents (tyrosine kinase inhibitors like sunitinib) and immune checkpoint inhibitors (nivolumab, ipilimumab).

Semen

– The fluid ejaculated from the male reproductive tract, containing sperm (produced in the testes) suspended in seminal plasma (produced by the seminal vesicles, prostate, and bulbourethral glands). Semen provides nutrients (fructose, amino acids), protective agents (zinc, antioxidants), and a medium for sperm transport. Normal semen parameters (WHO 2021): volume ≥ 1.4 mL, sperm concentration ≥ 16 million/mL, total sperm count ≥ 39 million, progressive motility $\geq 30\%$, normal morphology $\geq 4\%$.

Shock Wave Lithotripsy

– Non-invasive procedure using extracorporeal shock waves to fragment renal and ureteral stones. The patient is positioned over a water cushion coupling the shock wave generator to the body. Shock waves are focused on the stone under fluoroscopic or ultrasound guidance. Most effective for stones less than two centimeters in the renal pelvis or upper ureter. Success rates decrease with larger stones and lower pole location. Complications include renal hematoma, stone street from multiple fragments, residual stones, and need for multiple sessions, though the non-invasive nature makes it the preferred first-line treatment for suitable stones.

Sperm

– The male gamete (reproductive cell), produced in the seminiferous tubules of the testis through spermatogenesis. Sperm consists of: head (contains the haploid nucleus and acrosome containing enzymes for egg penetration), midpiece (contains mitochondria for energy), and tail (flagellum for motility). Approximately 1,500 sperm are produced per second. Sperm travel from the testis through the epididymis (maturation), vas deferens, seminal vesicles, and urethra during ejaculation.

Spermatocele

– Benign, painless, fluid-filled cystic retention cavity arising from the epididymis (usually the head/caput), containing avascular fluid and non-viable spermatozoa. Etiology: obstruction of an efferent ductule of the epididymis. Clinical presentation: smooth, spherical, non-tender mass located superior and posterior to the testis, distinct from the testicular parenchyma. Transilluminates clearly on physical examination. Scrotal ultrasound confirms a well-demarcated anechoic lesion separate from the testicle. Management: reassurance and conservative observation; surgical spermatocelectomy is reserved for large, painful, or bothersome cysts.

Testicular Disorders

– conditions affecting the testes, including testicular torsion (spermatic cord twisting causing ischemic pain and swelling, a surgical emergency requiring detorsion within 6 hours for testicular salvage), epididymitis (inflammation of the epididymis, often from bacterial infection—STI in young men, urinary pathogens in older men—treated with antibiotics

and supportive care), orchitis (testicular inflammation, often viral from mumps), hydrocele (fluid collection in the tunica vaginalis, benign), varicocele (dilated pampiniform plexus veins, the most common correctable cause of male infertility), and testicular cancer (most common solid malignancy in young men 15–35, typically presenting as a painless testicular mass, diagnosed with scrotal ultrasound and tumor markers—AFP, hCG, LDH—and treated with radical inguinal orchiectomy with possible chemotherapy or radiation). Evaluation includes scrotal ultrasound, urinalysis, STI screening, and tumor markers.

Testicular Torsion

– Surgical emergency caused by twisting of the spermatic cord around its longitudinal axis, cutting off venous return and leading to arterial occlusion, ischemia, and infarction of the testicle. Predisposing anatomy: "bell-clapper" deformity, where the tunica vaginalis completely encircles the epididymis and distal cord, allowing the testis to rotate freely within the scrotum. Most common in neonates and post-pubertal males (ages 12–18). Symptoms: sudden onset of severe, unilateral scrotal pain, nausea, vomiting, high-riding testis with horizontal lie, and absent cremasteric reflex. Negative Prehn sign (pain is not relieved by scrotal elevation). Color Doppler ultrasound shows absent or decreased intratesticular blood flow. Management: urgent surgical exploration with manual detorsion and bilateral orchidopexy; testicular salvage rate is > 90% if operated within 6 hours, dropping significantly after 12–24 hours.

Transurethral Resection of the Prostate (TURP)

– Gold standard surgical procedure for benign prostatic hyperplasia (BPH) refractory to medical management or complicated by urinary retention, renal insufficiency, or recurrent hematuria. Performed using a rigid resectoscope inserted through the urethra; a high-frequency electrosurgical wire loop (monopolar or bipolar) is used to systematically resect obstructive hyperplastic prostatic tissue from the transition zone under direct vision. Resected tissue chips are irrigated out and sent for histopathology. Complications: bleeding, retrograde ejaculation (> 75%), urethral stricture, urinary incontinence, and TURP

syndrome (hyponatremia, fluid overload, and neurological symptoms resulting from systemic absorption of hypotonic monopolar irrigation fluid like glycine).

Undescended Testis (Cryptorchidism)

- Congenital failure of one or both testes to descend along the normal path from the retroperitoneum into the scrotum during fetal development. Most common congenital anomaly of the male genitalia, affecting 3% of full-term and up to 30% of premature male infants. Spontaneous descent usually occurs within the first 3–4 months of life. If uncorrected, cryptorchidism leads to impaired spermatogenesis, testicular atrophy, male infertility, increased risk of inguinal hernia, testicular torsion, and a 5- to 10-fold increased risk of testicular germ cell tumors (seminoma). Treatment: surgical orchidopexy (repositioning and anchoring the testis in the scrotal pouch), ideally performed between 6 and 18 months of age.

Ureteral Obstruction

- Blockage of urine flow causing proximal dilation and increased pressure. Acute causes renal colic with flank pain. Chronic leads to hydronephrosis and CKD. Emergent decompression with stent or nephrostomy for infected obstructed kidney. Diagnosis by CT or ultrasound showing hydronephrosis.

Ureteral Stent (Double-J Stent)

- A tube placed in the ureter from the renal pelvis to the bladder to maintain patency, with pigtail coils at both ends (hence double-J). Indications: ureteral obstruction (stones, stricture, malignancy), after ureteroscopy (prevent post-op obstruction), and as a pre-treatment for complex ureteral stones. Placed cystoscopically or antegrade through a nephrostomy. Sizes: 6-8 Fr, lengths 22-30 cm. Left in for weeks to months (though should not exceed 3 months due to encrustation). Complications: stent-related discomfort (urgency, frequency, hematuria, flank pain — very common), infection, migration, encrustation (forgotten stent), and stone formation.

Ureteroscopy

- Endoscopic procedure utilizing a thin, flexible or semirigid ureteroscope passed through the urethra, bladder, and into the ureter or renal collecting system. Used primarily for the diagnostic evaluation and therapeutic management of ureteral and renal

calculi, ureteral strictures, and upper tract urothelial carcinoma (UTUC). Therapeutic ureteroscopy incorporates laser fiber lithotripsy (holmium:YAG or thulium fiber laser) to pulverize stones into dust, followed by stone basket retrieval. A temporary ureteral stent (Double-J stent) is frequently placed postoperatively to ensure urine drainage and prevent ureteral spasm or stricture formation.

Urethral Stricture

- Narrowing of the urethra due to fibrosis of the corpus spongiosum, most commonly caused by trauma (pelvic fracture, straddle injury, iatrogenic from catheterisation or urethral instrumentation), infection (gonococcal urethritis leading to stricture years later, now less common in the antibiotic era), and lichen sclerosus (Balanitis Xerotica Obliterans, BXO). Presents with progressive urinary obstruction: weak stream, hesitancy, straining, incomplete bladder emptying, frequency, and recurrent UTIs. Complete obstruction causes acute urinary retention. Diagnosis: retrograde urethrogram demonstrates the location and length of the stricture. Urethroscopy confirms and may allow simultaneous treatment. Treatment depends on location, length, and severity: urethral dilation (temporary, high recurrence rate), internal urethrotomy (optical incision of the stricture, 50% recurrence at 2 years for bulbar strictures <2 cm), and urethroplasty (open surgical reconstruction, the gold standard for recurrent or long strictures, success rates >90% for primary bulbar repairs). Complications include recurrence, erectile dysfunction, and incontinence.

Urethritis

- Inflammation of the urethra, presenting with dysuria, urethral pruritus, and urethral discharge. Classified into Gonococcal Urethritis (GU), caused by *Neisseria gonorrhoeae*, and Non-Gonococcal Urethritis (NGU), most frequently caused by *Chlamydia trachomatis*, followed by *Mycoplasma genitalium*, *Trichomonas vaginalis*, and *Ureaplasma urealyticum*. Transmission is primarily via sexual contact. Diagnosis: Gram stain or methylene blue stain of urethral smear showing ≥ 2 –5 PMNs per high-power field, paired with nucleic acid amplification testing (NAAT) for *N. gonorrhoeae* and *Chlamydia*. Treatment: empirical dual therapy covering both pathogens (e.g., ceftriaxone IM plus oral doxycycline).

or azithromycin), along with partner notification and treatment.

Urinary Bladder

- See Bladder Health and Disorders / Bladder Problems.

Urinary Incontinence

- Involuntary leakage of urine, significantly affecting psychological, social, and physical well-being. Main types: Stress Urinary Incontinence (SUI—leakage with increased intra-abdominal pressure such as coughing, sneezing, laughing; caused by urethral hypermobility or intrinsic sphincter deficiency), Urge Urinary Incontinence (UUI—involuntary leakage accompanied by a sudden, intense desire to void; caused by detrusor overactivity), Mixed Urinary Incontinence (combination of SUI and UUI), and Overflow Urinary Incontinence (involuntary dribbling due to urinary retention and bladder overdistension; caused by BPH, urethral stricture, or neurogenic detrusor underactivity). Management: pelvic floor muscle training (Kegel exercises), lifestyle modifications, anticholinergics/beta-3 agonists (mirabegron) for UUI, and surgical slings (mid-urethral sling) or artificial urinary sphincter for SUI.

Urinary Retention

- Inability to completely empty the bladder, which can be acute (sudden, painful, inability to void) or chronic (gradual, often painless, with overflow incontinence). Causes: benign prostatic hyperplasia, urethral stricture, neurogenic bladder, medications (anticholinergics), and pelvic organ prolapse. Diagnosis: post-void residual >100 mL, ultrasound, cystoscopy. Acute treatment: urethral catheterization. Chronic: alpha-blockers, 5-alpha-reductase inhibitors, and surgery.

Urinary Tract Infection (UTI)

- Inflammatory response of the urothelium to microbial invasion, ranging from lower tract infection (cystitis, urethritis) to upper tract infection (pyelonephritis, renal abscess). Classification: uncomplicated (infection in a healthy, non-pregnant, immunocompetent adult female with normal urinary anatomy) versus complicated (infection associated with factors increasing treatment failure or tissue damage, such as male gender, pregnancy, urinary obstruction, neurogenic bladder, indwelling catheter, immunosuppression, or renal insufficiency).

Escherichia coli causes > 80% of all community-acquired UTIs. Clinical assessment, urinalysis, urine culture, and targeted antimicrobial therapy form the core management strategy.

Urodynamic Testing

- Suite of diagnostic procedures designed to evaluate the physiological function of the lower urinary tract (bladder and urethral sphincter) during filling, storage, and emptying phases. Components: Uroflowmetry (measures urine flow rate and volume), Cystometrogram (CMG—evaluates bladder compliance, sensation, capacity, and involuntary detrusor contractions during saline filling), Pressure-Flow Studies (differentiates bladder outlet obstruction from detrusor muscle underactivity during voiding), Urethral Pressure Profiling, and Electromyography (EMG—assesses sphincter muscle activity and detrusor-sphincter dyssynergia). Indications: neurogenic bladder, refractory urinary incontinence, failed BPH surgery, and complex voiding dysfunction.

Urolithiasis

- Stone formation in the urinary tract (kidneys, ureters, bladder, urethra). Types: calcium oxalate (most common, 60-70%), calcium phosphate (15-20%), struvite (infection-related, 10-15%), uric acid (5-10%), and cystine (1-2%). Risk factors: dehydration, hypercalciuria, hyperoxaluria, hyperuricosuria, hypocitraturia, and urinary tract infections. Ureteral stones present with colicky flank pain radiating to groin, hematuria, nausea/vomiting. Diagnosis: non-contrast CT (gold standard), ultrasound. Treatment: medical expulsive therapy (tamsulosin) for distal <10mm stones; ESWL, ureteroscopy with laser lithotripsy, or PCNL for larger/complex stones.

Urology

- Surgical and medical specialty concerned with the study, diagnosis, and management of diseases affecting the male and female urinary tract (kidneys, ureters, urinary bladder, urethra) and the male reproductive system (prostate, testes, epididymis, seminal vesicles, penis). Subspecialties: urologic oncology, endourology and stone disease, female pelvic medicine and reconstructive surgery (FPMRS), neurourology and urodynamics, andrology and male infertility, pediatric urology, and renal transplantation. Common diagnostic modalities include uri-

nalysys, cystoscopy, ultrasound, CT urography, and urodynamics.

Varicocele

– Abnormal dilation and tortuosity of the pampiniform venous plexus within the spermatic cord, resulting from incompetent or absent venous valves. Occurs in 15% of adolescent and adult males; overwhelmingly common on the left side (> 85%) due to the left testicular vein entering the left renal vein at a right angle (90 degrees) under higher hydrostatic pressure, compared to the right testicular vein entering the inferior vena cava obliquely. Described on physical examination as feeling like a "bag of worms", which decompresses when supine and accentuates during a Valsalva maneuver. Leading treatable cause of male infertility (present in 40% of infertile men), causing hyperthermia, venous stasis, and oxidative stress that impairs spermatogenesis. Treatment: microscopic varicocelectomy or percutaneous embolization for symptomatic pain, testicular atrophy, or abnormal semen parameters.

Vasectomy

– Minor surgical procedure for permanent male contraception involving surgical interruption, occlusion, or excision of a segment of both vasa deferentia, preventing spermatozoa from entering the ejaculate. Performed under local anesthesia using traditional incisional or no-scalpel vasectomy (NSV) techniques. Vas occlusion methods: cauterization, ligation with clips/sutures, or fascial interposition. Contraceptive reliance is not immediate; patients must use alternative contraception until a post-vasectomy semen analysis (PVSA) confirms azoospermia or < 100,000 non-motile sperm/mL, typically evaluated 8–12 weeks and 20 ejaculations post-procedure. Reversal (vasovasostomy) is possible but technically challenging and not guaranteed to restore fertility.

Vesicoureteral Reflux

– Retrograde flow of urine from the bladder into the ureters and potentially the kidneys, most commonly due to incompetent ureterovesical valve. Predisposes to pyelonephritis and renal scarring. More common in children, presenting with recurrent febrile UTIs. Diagnosis: voiding cystourethrogram (VCUG). Grading I–V. Management: observation with prophylactic antibiotics for low-grade, ureteral reimplantation or endoscopic injection for

high-grade.

Xanthogranulomatous Pyelonephritis

– Chronic destructive renal infection with replacement of parenchyma by lipid-laden macrophages. Associated with obstructing stones and *Proteus* infection. Enlarged kidney with scattered low-attenuation areas on CT resembling a bear paw. Treated with nephrectomy as the kidney is non-functional and harbors chronic infection.

Chapter 42

Vascular Surgery & Angiology

Acute Limb Ischemia (ALI)

- Sudden, rapid decrease in lower extremity arterial perfusion threatening limb viability, typically caused by acute arterial embolism (AFib) or in situ thrombosis of an atherosclerotic vessel. Clinical hallmark is the '6 Ps': Pain, Pallor, Pulselessness, Paresthesia, Paralysis, and Poikilothermia. Requires emergency revascularization (surgical embolectomy, catheter-directed thrombolysis, or bypass) within 6 hours to prevent irreversible ischemic neuromuscular damage and amputation.

Ankle-Brachial Index (ABI)

- Non-invasive bedside diagnostic test for peripheral artery disease (PAD), calculated by dividing the highest systolic blood pressure at the ankle (dorsalis pedis or posterior tibial artery) by the highest brachial systolic blood pressure. Interpretation: Normal (1.00–1.40), Borderline (0.91–0.99), Abnormal/PAD (≤ 0.90), Severe PAD (< 0.50 , associated with critical limb ischemia), and Non-compressible/Calcinosis (> 1.40 , seen in severe diabetes or end-stage renal disease due to arterial medial calcification).

Aortic Dissection

- Life-threatening vascular emergency occurring when a tear in the aortic intima allows blood to surge into the aortic media, creating a false lumen that propagates along the aorta. Classified by Stanford system: Type A (involves ascending aorta, requires emergency open surgical repair) and Type B (confined to descending aorta distal to left subclavian origin, managed medically with blood pressure control or endovascular stent repair—TEVAR). Risk factors: severe chronic hypertension, Marfan syndrome, Ehlers-Danlos syndrome, bicuspid aortic valve, and cocaine use. Presentation: sudden onset

of severe, knife-like, tearing or ripping chest pain radiating to the interscapular back. Complications: pericardial tamponade, aortic regurgitation, stroke, and visceral/limb malperfusion.

Arteriovenous Fistula (AVF)

- Abnormal direct communication between an artery and a vein, bypassing the high-resistance capillary bed. Congenital AVFs result from developmental vascular malformations. Acquired AVFs are created surgically (e.g., radiocephalic or brachiocephalic AV fistula in the forearm/arm) as a durable vascular access site for maintenance hemodialysis in end-stage renal disease, or develop traumatically from penetrating vascular injury. Hemodynamic consequences: low resistance causes high flow, palpable thrill, continuous machinery murmur, elevated venous pressure, and potential high-output heart failure or steal syndrome (ischemia of distal tissue).

Arteriovenous Graft (AVG)

- Surgical vascular access for hemodialysis created by interposition of a synthetic conduit (PTFE graft) connecting a peripheral artery (e.g., brachial artery) to a adjacent vein (e.g., basilic vein) when native superficial veins are inadequate for a direct AV fistula.

Atherectomy

- Endovascular interventional technique utilized to mechanically cut, shave, sand (rotational), or vaporize (laser) calcified or heavy atherosclerotic plaque from the lumen of peripheral arteries (e.g., superficial femoral artery) prior to balloon angioplasty or stenting.

Axillofemoral Bypass

- Extra-anatomic arterial bypass procedure performing a subcutaneous graft connection from the axillary artery to the femoral artery; indicated in high-

risk patients with severe aortoiliac occlusive disease or infected aortic prosthetic grafts who cannot tolerate major transabdominal aortic reconstruction.

Buerger Disease (Thromboangiitis Obliterans)

- Non-atherosclerotic, segmental, inflammatory vasculitis affecting small- and medium-sized arteries and veins of the extremities, occurring almost exclusively in young male heavy smokers (< 45 years). Leads to digital ischemia, severe pain, distal claudication, and painful ulcerations/gangrene. Absolute smoking cessation is the only effective intervention.

Carotid Artery Stenting (CAS)

- Endovascular alternative to open carotid endarterectomy, involving transfemoral or transcarotid deployment of a self-expanding metallic stent across a carotid artery stenosis under distal embolic protection device guidance; preferred in patients with high surgical risk, prior neck radiation, or recurrent post-endarterectomy restenosis.

Carotid Endarterectomy (CEA)

- Surgical procedure performed to remove atherosclerotic plaque from the carotid artery bifurcation and internal carotid artery, reducing the risk of ischemic stroke. Indications: symptomatic carotid stenosis (> 50–70% luminal narrowing following TIA or non-disabling stroke) and select asymptomatic stenosis (> 70–80%). Operative technique: longitudinal arteriotomy, meticulous plaque excision, and patch closure (dacron or vein graft) to prevent restenosis. Complications: perioperative stroke, cranial nerve injury (hypoglossal, vagus/recurrent laryngeal, marginal mandibular), hyperperfusion syndrome, and wound hematoma.

Carotid Stenosis

- Atherosclerotic narrowing of the carotid artery, primarily localized at the carotid bifurcation and proximal internal carotid artery. Responsible for 15–20% of all ischemic strokes due to artery-to-artery thromboembolism or hypoperfusion. Symptomatic presentation: transient ischemic attack (TIA), amaurosis fugax (transient monocular blindness described as a "curtain coming down over one eye"), or acute ischemic stroke. Diagnostic modalities: Carotid Duplex Ultrasound (initial screening), CT Angiography (CTA), or MR Angiography (MRA). Management: intensive medical therapy (antiplatelets, high-

intensity statin, blood pressure control) combined with revascularization (Carotid Endarterectomy or Carotid Artery Stenting—CAS) for significant stenosis.

Catheter-Directed Thrombolysis (CDT)

- Minimally invasive endovascular therapy delivering localized thrombolytic agents (tPA, alteplase) directly into a clot via a multi-sidehole infusion catheter placed fluoroscopically within a thrombosed artery or deep vein (e.g., iliofemoral DVT or acute limb ischemia).

Central Venous Stenosis

- Pathological narrowing of central thoracic veins (subclavian, brachiocephalic, or superior vena cava) commonly resulting from previous central venous catheterization, pacemaker leads, or high-flow hemodialysis access. Presents with ipsilateral upper extremity edema, venous engorgement, and hemodialysis access dysfunction.

Chronic Venous Insufficiency (CVI)

- Pathological condition resulting from incompetent venous valves, deep vein thrombosis, or venous outflow obstruction, leading to impaired venous return and sustained ambulatory venous hypertension in the lower extremities. Clinical manifestations (CEAP classification C1–C6): telangiectasias, varicose veins, lower extremity edema, stasis dermatitis (hyperpigmentation from hemosiderin deposition), lipodermatosclerosis (induration of subcutaneous tissue causing "inverted champagne bottle" leg), and non-healing venous stasis ulcers (typically located superior to the medial malleolus). Management: compression therapy (graduated compression stockings), leg elevation, exercise, endovenous thermal ablation (radiofrequency or laser) for superficial reflux, and wound care.

Compartment Syndrome (Vascular)

- Surgical emergency occurring when elevated intracompartmental tissue pressure within a closed osteofascial compartment exceeds capillary perfusion pressure, leading to tissue ischemia and necrosis. Frequently occurs following reperfusion of an acutely ischemic limb. Requires urgent surgical emergency decompressive Fasciotomy.

Critical Limb Ischemia (CLI)

– Advanced, severe stage of peripheral artery disease (PAD) characterized by chronic ischemic rest pain, non-healing ischemic ulcers, or frank gangrene attributable to objectively proven arterial occlusive disease. Rest pain typically affects the distal foot/toes, worsens at night or when elevating the leg, and is transiently relieved by hanging the foot over the edge of the bed. ABI is usually < 0.40 , with ankle systolic pressure < 50 mmHg. Represents an imminent threat of limb loss; requires urgent diagnostic angiography and revascularization (endovascular angioplasty/stenting or surgical bypass) to prevent amputation.

Deep Vein Thrombosis (DVT)

– Formation of a blood clot (thrombus) within a deep vein, most commonly in the deep veins of the lower extremities (popliteal, femoral, iliac veins). Pathophysiology described by Virchow's Triad: (1) Venous stasis (immobility, surgery, travel), (2) Endothelial injury (trauma, catheters), and (3) Hypercoagulability (cancer, factor V Leiden, pregnancy, OCPs). Clinical features: unilateral leg pain, swelling, warmth, erythema, and calf tenderness. Complications: Pulmonary Embolism (PE—life-threatening detachment of clot traveling to pulmonary arteries) and Post-Thrombotic Syndrome (PTS). Diagnosis: D-dimer (high sensitivity, excludes DVT), Compression Ultrasonography (gold standard). Treatment: anticoagulation (DOACs, LMWH, warfarin) for at least 3–6 months.

Endovascular Aneurysm Repair (EVAR)

– Minimally invasive surgical technique for repairing abdominal aortic aneurysms. Under fluoroscopic guidance, a modular bifurcated synthetic stent-graft is delivered via transfemoral catheter access and deployed inside the aneurysmal sac, relining the aorta and excluding the aneurysm from systemic arterial pressure. Advantages: lower perioperative morbidity, shorter hospital stay, and lower 30-day mortality compared to open repair. Limitations: requires favorable aortic anatomy (adequate proximal landing zone neck) and necessitates lifelong imaging surveillance (CT or ultrasound) to monitor for endoleaks (persistent blood flow into the aneurysm sac outside the stent-graft).

Endovenous Laser Therapy (EVLT)

– Minimally invasive thermal ablation procedure for superficial venous reflux (saphenous insufficiency); a laser fiber inserted under ultrasound guidance delivers thermal energy to wall of vein, causing collapse, endothelial destruction, and fibrotic occlusion of the incompetent saphenous vein.

Fasciotomy

– Emergency surgical procedure consisting of longitudinal incisions through skin and underlying deep fascia to relieve abnormally high intracompartmental pressure, used to treat acute compartment syndrome following trauma or revascularization of acute limb ischemia.

Femorofemoral Bypass

– Extra-anatomic arterial bypass graft constructed subcutaneously across the suprapubic space, diverting blood from a healthy donor femoral artery to the contralateral ischemic femoral artery in patients with unilateral iliac artery occlusion.

Femoropopliteal Bypass

– Surgical arterial revascularization procedure by-passing an obstructed superficial femoral artery segment by anastomosing a graft (autologous great saphenous vein or PTFE) from the common femoral artery to the popliteal artery above or below the knee.

Fogarty Catheter Embolectomy

– Surgical technique for emergency extraction of arterial emboli or fresh thrombi; a balloon-tipped Fogarty catheter is passed distally beyond the occlusion, the balloon is inflated, and withdrawn, pulling the occlusive material out through arteriotomy.

Giant Cell Arteritis (Temporal Arteritis)

– Granulomatous vasculitis of large and medium-sized vessels affecting elderly adults (> 50 years), targeting extracranial branches of the carotid artery (temporal artery). Symptoms: headache, jaw claudication, scalp tenderness, and amaurosis fugax. High risk of irreversible blindness due to anterior ischemic optic neuropathy; requires immediate high-dose corticosteroid therapy.

Inferior Vena Cava (IVC) Filter

– Metallic intravascular filter device deployed fluoroscopically into the infrarenal IVC to mechanically

trap large emboli originating from lower extremity deep vein thrombosis, preventing pulmonary embolism. Indicated in patients with acute DVT/PE who have absolute contraindications to anticoagulation or recurrent PE despite adequate anticoagulation.

Intermittent Claudication

– Classic symptomatic manifestation of stable peripheral artery disease (PAD). Characterized by reproducible muscle aching, cramping, pain, or fatigue in the lower extremity (calf, thigh, or buttock) precipitated by physical exertion (walking) and promptly relieved by rest (usually within 2–5 minutes). Site of pain correlates with proximal arterial stenosis: calf claudication indicates superficial femoral or popliteal artery disease; thigh/buttock claudication indicates iliofemoral disease. Pathophysiology: exercise-induced imbalance between skeletal muscle oxygen demand and restricted blood supply. Management: risk factor modification (smoking cessation, statin, antiplatelet), structured exercise therapy, and cilostazol.

Lymphedema

– Accumulation of interstitial fluid and tissue swelling resulting from impaired lymphatic drainage, leading to chronic inflammation, adipose tissue deposition, and progressive subcutaneous fibrosis. Classified into Primary Lymphedema (congenital developmental malformations: Milroy disease, Meige disease) and Secondary Lymphedema (acquired damage to lymph nodes/vessels: surgical lymph node dissection for cancer, radiation therapy, tumor obstruction, or filariasis caused by *Wuchereria bancrofti*—the leading cause worldwide). Clinical features: non-pitting edema of the limb (Stemmer sign positive—inability to pinch a fold of skin at the base of the second toe), hyperkeratosis, and recurrent cellulitis. Management: Complete Decongestive Therapy (CDT: manual lymphatic drainage, multilayer compression bandaging, skin care, and exercise).

May-Thurner Syndrome

– Vascular compression anomaly where the left common iliac vein is chronically compressed against the lumbar spine by the overlying right common iliac artery, resulting in venous stasis, intraluminal fibrous bands, and a markedly increased risk of left

iliofemoral DVT in young females.

Open Aneurysm Repair

– Traditional open surgical technique for abdominal or thoracic aortic aneurysm repair involving a laparotomy or thoracotomy, cross-clamping the aorta, opening the aneurysm sac, and sewing a synthetic prosthetic graft (Dacron or PTFE) in an inlay fashion.

Paget-Schroetter Syndrome (Effort Thrombosis)

– Acute primary deep vein thrombosis of the subclavian-axillary vein resulting from repetitive upper extremity mechanical compression between the clavicle and first rib (thoracic outlet obstruction), classically seen in young competitive athletes performing overhead arm motions (baseball pitchers, swimmers).

Percutaneous Transluminal Angioplasty (PTA)

– Endovascular interventional catheter procedure where a balloon catheter is advanced under fluoroscopy across a focal arterial stenosis and inflated to dilate the lumen by disrupting atherosclerotic plaque; often combined with metallic stent placement.

Peripheral Artery Disease (PAD)

– Systemic atherosclerotic occlusive disease of the arteries supplying the upper and lower extremities (excluding coronary and intracranial circulation). Affects over 200 million people worldwide. Major risk factors: cigarette smoking, diabetes mellitus, hypertension, hyperlipidemia, and advanced age. Clinical spectrum: asymptomatic (50%), atypical leg pain, intermittent claudication, critical limb ischemia (rest pain, non-healing ulcers), and acute limb ischemia (the "6 Ps": Pain, Pallor, Pulselessness, Paresthesia, Paralysis, Poikilothermia). Diagnosis: Ankle-Brachial Index (ABI ≤ 0.90) and CTA/MRA. Treatment: medical therapy (aspirin/clopidogrel, high-intensity statin, ACE inhibitors), exercise therapy, and revascularization (angioplasty/stenting or surgical bypass).

Popliteal Artery Aneurysm

– The most common peripheral artery aneurysm (70–80%), defined as popliteal artery diameter > 2 cm. Strongly associated with abdominal aortic aneurysms (50% co-occurrence). Unlike AAAs

which rupture, popliteal aneurysms present primarily with thromboembolism, causing acute limb ischemia or distal trash feet.

Popliteal Artery Entrapment Syndrome

- Developmental vascular anomaly where the popliteal artery is abnormally compressed by adjacent musculotendinous structures (medial head of gastrocnemius muscle) in the popliteal fossa, leading to exertional leg claudication in young, healthy active individuals.

Post-Thrombotic Syndrome (PTS)

- Chronic venous condition developing in up to 50% of patients following deep vein thrombosis, caused by irreversible venous valve damage and residual venous obstruction. Symptoms include persistent lower extremity swelling, aching pain, heaviness, venous ectasia, hyperpigmentation, and stasis ulceration.

Pulmonary Embolism (PE)

- Occlusion of one or more pulmonary arteries by a thrombus (or less commonly fat, air, or amniotic fluid) that has dislodged from a distant site, overwhelmingly (> 90%) originating from a deep vein thrombosis (DVT) of the lower extremities. Pathophysiology: mechanical obstruction increases right ventricular afterload, risking acute right ventricular failure and cardiogenic shock. Symptoms: sudden dyspnea, pleuritic chest pain, cough, hemoptysis, tachypnea, tachycardia, and apprehension. Diagnosis: Well's score for probability, D-dimer, and CT Pulmonary Angiography (CTPA—gold standard). Management: anticoagulation (LMWH, DOACs), systemic thrombolysis (alteplase) for massive PE with hemodynamic instability, or catheter-directed embolectomy.

Radiofrequency Ablation (Venous)

- Minimally invasive endovascular technique delivering thermal energy generated by high-frequency alternating current via a catheter inserted into an incompetent saphenous vein, causing vein wall contraction, lumen obliteration, and venous reflux elimination.

Raynaud Phenomenon

- Exaggerated vasospastic response of digital arteries and arterioles to cold temperature or emotional stress, causing episodic digital ischemia. Classic

triphasic color response: (1) White (pallor due to intense arterial vasospasm), (2) Blue (cyanosis due to deoxygenated blood accumulation), and (3) Red (rubor due to reactive hyperemia upon rewarming, accompanied by throbbing pain and paresthesias). Primary Raynaud Disease: benign, idiopathic, symmetrical, without underlying disease. Secondary Raynaud Syndrome: associated with underlying systemic autoimmune diseases (systemic sclerosis/scleroderma, lupus, rheumatoid arthritis), occupational vibration injury, or medications. Management: cold avoidance, keeping body warm, and dihydropyridine calcium channel blockers (nifedipine, amlodipine).

Saphenous Vein Stripping

- Surgical procedure for severe superficial venous insufficiency involving ligation of the saphenofemoral junction (flush ligation) and physical avulsion/removal of the great saphenous vein trunk from the leg using a surgical stripper wire.

Subclavian Steal Syndrome

- Hemodynamic phenomenon resulting from severe stenosis or occlusion of the proximal subclavian artery proximal to the vertebral artery origin. Exercise of the ipsilateral arm causes retrograde blood flow down the ipsilateral vertebral artery away from the brainstem, causing vertebrobasilar insufficiency (dizziness, ataxia, syncope) and arm claudication.

Superior Vena Cava (SVC) Syndrome

- Clinical emergency resulting from obstruction of blood flow through the superior vena cava, overwhelmingly (80–90%) caused by malignant compression (small cell lung cancer, non-Hodgkin lymphoma). Features: facial edema, plethora, neck and upper chest vein distension, dyspnea, and headache.

Thoracic Endovascular Aortic Repair (TEVAR)

- Minimally invasive endovascular procedure deploying a flexible fabric-covered stent graft within the thoracic aorta via femoral artery access to treat thoracic aortic aneurysms, Type B aortic dissections, or traumatic aortic transections.

Thoracic Outlet Syndrome (TOS)

- Symptom complex resulting from compression of the neurovascular bundle (brachial plexus, subclavian artery, subclavian vein) at the thoracic outlet

(interscalene triangle, costoclavicular space). Categorized as Neurogenic (95%, pain/numbness in hand), Venous (Paget-Schroetter syndrome), or Arterial (subclavian aneurysm/ischemia).

Thromboangiitis Obliterans

– See Buerger Disease.

Transcranial Doppler (TCD)

– Non-invasive ultrasound modality measuring velocity and direction of blood flow within major basal intracranial arteries through thin skull windows (temporal, orbital); used to monitor cerebral vasospasm after subarachnoid hemorrhage and screen children with sickle cell disease for stroke risk.

Ultrasound-Guided Foam Sclerotherapy

– Minimally invasive venous treatment where a sclerosant liquid (polidocanol) mixed with air to form foam is injected into incompetent varicose veins under ultrasound guidance, displacing blood and producing chemical endovenous inflammation and sclerosis.

Varicose Veins

– Dilated, tortuous, elongated superficial veins ≥ 3 mm in diameter, most commonly affecting the great and small saphenous veins and their tributaries in the lower extremities. Caused by primary valvular incompetence, saphenofemoral junction incompetence, or weakness of the venous wall, leading to retrograde venous reflux and elevated hydrostatic pressure. Risk factors: female gender, pregnancy, prolonged standing, obesity, family history, and advanced age. Symptoms: aching, heaviness, leg fatigue, pruritus, cosmetic concern, and localized phlebitis. Treatment: compression hosiery, conservative measures, endovenous thermal ablation (radiofrequency or endovenous laser therapy—EVLT), ultrasound-guided foam sclerotherapy, or surgical ambulatory phlebectomy / vein stripping.

Vascular Steal Syndrome

– Complication of surgical arteriovenous fistula or graft created for hemodialysis, occurring when the low-resistance AV access diverts ('steals') arterial blood flow away from distal extremity tissue, causing distal hand ischemia, coldness, pain, and sensory loss.

Vascular Surgery & Angiology

– Angiology is the medical subspecialty dedicated

to the study, diagnosis, and non-surgical management of diseases of the circulatory system (arteries, veins, and lymphatic vessels). Vascular Surgery is the surgical specialty focused on open and endovascular interventions for structural, traumatic, inflammatory, and occlusive diseases of the vascular system (excluding intracranial and coronary vessels). Major clinical domains: abdominal/thoracic aortic aneurysms, peripheral artery disease, carotid artery stenosis, deep vein thrombosis, venous insufficiency, vascular access, and vascular trauma.

Vein Graft Failure

– Occlusion or stenosis of an autologous vein bypass graft caused early (< 30 days) by technical error or thrombosis, mid-term (1 month to 2 years) by intimal hyperplasia, or late (> 2 years) by progressive atherosclerosis within graft wall.

Chapter 43

General Medical Terms

Eponym

– A medical term, disease, sign, symptom, or anatomical structure named after a person (usually the physician, surgeon, or scientist who first described it, or occasionally a patient). Examples include Parkinson’s disease, Fallopian tube, and Babinski sign. Modern medical terminology increasingly favors descriptive clinical terms over eponyms to improve clarity and international standardization.

Placebo Effect

– A beneficial physical or psychological health outcome resulting from an inert treatment (such as a sugar pill, saline injection, or sham procedure) that cannot be attributed to the active properties of the treatment itself. Driven by patient expectations, classical conditioning, and the therapeutic doctor-patient relationship. In clinical trials, new therapies must demonstrate efficacy superior to placebo controls.

Quarantine

– The restriction of movement or isolation of individuals, animals, or goods who have been exposed to a contagious disease (or suspected of exposure) to prevent the potential spread of infection to others. Differentiated from isolation, which separates individuals who are already known to be ill and infectious.
