

Medical Dictionary by Specialty

A Comprehensive Reference of Medical Terminology

Chaman Singh Verma

August 1, 2026

Preface

Medical dictionaries have traditionally been organised alphabetically, an arrangement well suited for looking up an unfamiliar term when you already know its name. But medicine is not learned alphabetically, nor is it practised that way. A cardiologist thinking through a differential diagnosis reaches for cardiac terms, not a mixture of cardiology wedged between caesarean section and cataract.

This dictionary is organised by medical specialty for precisely that reason. Each of the 43 chapters corresponds to a recognised clinical or preclinical discipline, with terms listed alphabetically within that chapter. The result is a reference that mirrors the structure of medical knowledge itself: renal terms in Nephrology, antiarrhythmics in Cardiology, autoimmune diseases in Rheumatology. Cross-references redirect the reader from variant names and alternative spellings to the main entry, so “Pertussis” still leads to “Whooping Cough” and “Hepatolenticular Degeneration” points to “Wilson Disease.”

The entries are drawn primarily from Black’s Medical Dictionary (42nd Edition) and supplemented with definitions reflecting contemporary clinical practice. Each entry is written in a concise single-line format, with the term displayed in bold red and automatically indexed. The dictionary runs to over 5,500 entries across 960 pages, covering anatomy, physiology, pathology, pharmacology, clinical medicine, surgery, and the allied health sciences.

This work is a living document. The LaTeX source is designed to be easily extended, corrected, and reorganised. Contributions, corrections, and suggestions are welcome.

Medical Disclaimer

Educational and Reference Purpose Only: This publication, *Medical Dictionary by Specialty*, is prepared and compiled strictly for educational, academic, historical, and reference purposes. It is intended for medical students, healthcare professionals, educators, and researchers.

No Medical Advice: The information contained herein does not constitute professional medical advice, clinical diagnosis, treatment protocols, or formal therapeutic recommendations. It should not be used as a substitute for the professional judgment of qualified physicians, surgeons, or certified healthcare providers.

Clinical Practice Guidelines: Healthcare practitioners must always consult primary evidence-based medical literature, institutional protocols, manufacturer prescribing information, and national clinical guidelines (such as WHO, CDC, NICE, or national medical councils) when making diagnostic or therapeutic decisions for individual patients.

Limitation of Liability: Neither the author nor the publishers accept any legal responsibility or liability for any errors, omissions, or clinical outcomes resulting from the use or application of any information presented in this work.

Chapter 1

Anatomy

Abdominal Aorta

- From diaphragmatic hiatus at T12 to common iliac bifurcation at L4. Major branches: celiac trunk (T12), SMA (L1), IMA (L3), renal arteries (L1-L2), gonadal arteries, lumbar arteries. Anterior to the vertebral column. Abdominal aortic aneurysm is common in elderly males (13th leading cause of death). Rupture causes hypotension, back pain, and pulsatile mass with over 80 percent mortality.

Acetabulum

- Cup-shaped lateral hip socket from fused ilium, ischium, and pubis. Articulates with the femoral head at the ball-and-socket hip joint. The acetabular labrum deepens the socket. Oriented with approximately 15 degrees anteversion and 45 degrees inclination. Fractures are serious high-energy trauma injuries.

Acromion

- Bony process forming the shoulder's highest point, extending laterally from the scapular spine. Articulates with the clavicle at the acromioclavicular joint and arches over the glenohumeral joint. Attachment for deltoid and trapezius. The subacromial space contains the supraspinatus tendon and subacromial bursa. Its shape influences impingement syndrome susceptibility.

Adductor Muscles

- A group of muscles on the medial thigh that adduct (pull toward the midline) the hip: adductor longus, adductor brevis, adductor magnus, gracilis, and pectineus. Innervated by the obturator nerve (L2-L4); adductor magnus also receives tibial nerve (sciatic). Adductor longus is a common site of athletic injury ('groin strain'). Adductor canal (subsartorial) contains the femoral artery, vein, and saphenous nerve.

Adenoids

- Also called the pharyngeal tonsil, lymphoid tissue in the posterior wall and roof of the nasopharynx. Enlarged adenoids (adenoidal hypertrophy) in children cause nasal obstruction, mouth breathing, snoring, obstructive sleep apnea, serous otitis media (eustachian tube obstruction), and facial changes ('adenoid facies'). Inflammation (adenoiditis) is treated medically or with adenoidectomy. The adenoids are part of Waldeyer ring of pharyngeal lymphoid tissue. They enlarge in childhood and atrophy after puberty.

Adrenal Gland

- Paired endocrine glands atop each kidney (suprarenal), composed of cortex and medulla. Cortex (three zones): zona glomerulosa (aldosterone, mineralocorticoids), zona fasciculata (cortisol, glucocorticoids), zona reticularis (androgens). Medulla: chromaffin cells secrete epinephrine and norepinephrine (catecholamines). Regulated by ACTH (cortex) and sympathetic nervous system (medulla). Conditions: Cushing syndrome, Addison disease, pheochromocytoma, Conn syndrome, congenital adrenal hyperplasia.

Alveolus

- The terminal air sac (200-300 microns) where gas exchange occurs. Approximately 300-500 million per lung, providing 70 m² surface area. Wall: type I pneumocytes (95% surface, thin for diffusion), type II pneumocytes (5%, secrete pulmonary surfactant reducing surface tension), alveolar macrophages (dust cells, phagocytosis). Capillary network in close apposition (blood-air barrier: type I pneumocyte, fused basement membrane, capillary endothelium). Surfactant deficiency causes RDS in preterm infants. Conditions: pneumonia, ARDS, pulmonary edema,

emphysema (alveolar destruction), pulmonary fibrosis.

Amygdala

– Almond-shaped nucleus cluster in the anterior medial temporal lobe, part of the limbic system, primarily processing emotions (especially fear/anxiety). Receives thalamic/cortical sensory input; projects to hypothalamus, brainstem, and cortex for autonomic/behavioral fear responses. Essential for emotional memory (fear conditioning) and social signal processing. Lesions (Urbach-Wiethe disease) impair fear recognition. Hyperactive in anxiety disorders and PTSD.

Anal Canal

– The terminal 3-4 cm of the gastrointestinal tract, extending from the anorectal junction (puborectalis/pectinate line) to the anal verge. Above the pectinate line: lined by columnar epithelium, innervated by autonomic nerves, draining to portal system, supplied by superior rectal artery. Below the pectinate line: stratified squamous epithelium, somatic innervation (inferior rectal nerve—pain-sensitive), systemic drainage. Internal anal sphincter (smooth, involuntary, sympathetic/parasympathetic) and external anal sphincter (striated, voluntary, pudendal). Hemorrhoids, fissures, fistulae, and anorectal abscesses occur here.

Anatomical Snuffbox

– Triangular depression on the dorsal wrist, bounded by extensor pollicis longus medially and extensor pollicis brevis/abductor pollicis longus laterally. Floor contains the scaphoid, trapezium, and radial artery. Tenderness after a fall on an outstretched hand suggests scaphoid fracture. The radial artery pulse is palpable here.

Ankle Joint

– Uniaxial hinge synovial joint between distal tibia, lateral malleolus, and superior talus, allowing dorsiflexion/plantarflexion. Medial (deltoid) ligament resists eversion; lateral complex resists inversion. The ankle mortise provides bony stability. Ankle sprains are the most common sports injury (anterior talofibular ligament most commonly affected). Fractures classified by the Weber system.

Antecubital Fossa

– Triangular depression on the anterior elbow, bounded laterally by brachioradialis, medially by

pronator teres, and superiorly by a line connecting the epicondyles. Floor formed by brachialis and supinator. Contains biceps tendon, brachial artery, and median nerve. Primary site for venipuncture and blood pressure measurement.

Anterior Tibial Artery

– Arises from the popliteal artery, passes through the anterior intermuscular septum to the anterior compartment, continuing to the ankle as the dorsalis pedis artery. Supplies anterior leg and dorsal foot muscles. Palpable anterior to the lateral malleolus as the dorsalis pedis pulse. Important for vascular assessment; vulnerable to injury in tibial fractures and anterior compartment syndrome.

Aorta

– Largest artery, from the left ventricle distributing oxygenated blood systemically. Approximately 30 cm long, 2.5 cm diameter. Four segments: ascending aorta, aortic arch (brachiocephalic trunk, left common carotid, left subclavian), descending thoracic aorta, descending abdominal aorta (bifurcating into common iliacs at L4). Three layers: intima, media (elastic tissue), adventitia. Aneurysm and dissection are life-threatening.

Aortic Arch

– Curves from second right sternocostal joint superiorly and left, then posteriorly and inferiorly to T4. From right to left: brachiocephalic trunk, left common carotid, left subclavian. Related to left recurrent laryngeal nerve (hooking under it), trachea, esophagus, left phrenic nerve. Arch aneurysms may cause hoarseness and SVC syndrome.

Aortic Valve

– Semilunar valve between left ventricle and aorta with right, left, and posterior cusps. Each cusp forms a sinus of Valsalva from which coronary arteries originate. Opens during systole; closes during diastole. Aortic stenosis is the most common elderly valvular disease from calcific degeneration, causing a systolic crescendo-decrescendo murmur. Bicuspid aortic valve is the most common congenital valvular abnormality.

Appendix

– A blind-ended tubular diverticulum of the cecum, typically 6-10 cm long, rich in lymphoid tissue. Variable position (retrocecal 65 percent, pelvic, retroileal); located at McBurney's point (one-third

from ASIS to umbilicus). Innervated by T10 (visceral pain initially periumbilical, later localizing to right lower quadrant). Acute appendicitis is the most common surgical emergency in young adults; complications include perforation, abscess, and peritonitis. Appendectomy is definitive treatment.

Arachnoid Mater

– The middle of the three meninges, a delicate avascular membrane lying between the dura mater and pia mater. The subarachnoid space between arachnoid and pia contains cerebrospinal fluid (CSF) and major vessels. Arachnoid granulations (villi) project into the dural venous sinuses and mediate CSF reabsorption. The arachnoid is separated from the dura by the subdural space (site of subdural hematoma). Inflammation (meningitis) or hemorrhage (subarachnoid hemorrhage) in this space has serious consequences.

Artery

– A blood vessel that carries oxygenated blood away from the heart to the tissues, except for the pulmonary arteries which carry deoxygenated blood to the lungs. Arteries have thick, elastic, muscular walls that withstand high pressure and distribute blood throughout the body. The aorta is the largest artery. Arterial structure: tunica intima (endothelium), tunica media (smooth muscle and elastic fibers), tunica adventitia (connective tissue). Arteries branch into smaller arterioles and eventually capillaries. Diseases: atherosclerosis, aneurysms, arteritis, emboli.

Ascending Aorta

– From left ventricle at the aortic valve to the sternal angle (approximately 5 cm), enclosed in pericardium. Gives rise to right/left coronary arteries at the aortic sinuses. Most common site of aneurysm and dissection, especially in Marfan syndrome, bicuspid aortic valve, and hypertension. Aneurysms may compress adjacent structures and cause aortic regurgitation.

Ascending Colon

– Extends from cecum to hepatic flexure below the liver, approximately 15-20 cm, retroperitoneal (fixed to posterior abdominal wall). Anteriorly: abdominal wall. Posteriorly: right kidney. Absorbs water/electrolytes and compacts fecal matter. Tumors may present as a palpable right-sided mass. The right colic flexure marks its transition to the trans-

verse colon.

Atlas (C1)

– First cervical vertebra articulating with occipital condyles at the atlanto-occipital joint for nodding movement. Lacks a body and spinous process; has anterior/posterior arches and lateral masses. Transverse foramina transmit vertebral arteries. The anterior arch has a facet for the axis dens. Commonly fractured in axial loading injuries such as diving accidents.

Atrium

– One of the two upper chambers of the heart that receive blood returning to the heart. The right atrium receives deoxygenated blood from the superior and inferior venae cavae and the coronary sinus; the left atrium receives oxygenated blood from the four pulmonary veins. The interatrial septum separates the two atria; the fossa ovalis marks the site of the fetal foramen ovale. Atrial contraction (atrial kick) contributes 15–25% of ventricular filling. The atrial appendages (auricles) increase atrial capacity. Conditions: atrial fibrillation, atrial septal defect, atrial myxoma.

Axilla

– Pyramidal space between the upper lateral thorax and medial arm. Bounded by anterior fold (pectoralis major/minor), posterior fold (latissimus dorsi/teres major), medial wall (ribs/serratus anterior), and lateral wall (humerus). Contains axillary artery/vein, brachial plexus cords, and lymph nodes. Axillary nodes are significant in breast cancer staging.

Axillary Artery

– The continuation of the subclavian artery, running from the outer border of the first rib to the lower border of teres major, where it becomes the brachial artery. Divided into three parts by the pectoralis minor. Branches (part 1): superior thoracic; (part 2): thoracoacromial, lateral thoracic; (part 3): subscapular, anterior and posterior circumflex humeral. Supplies the shoulder, axilla, and upper limb. Relations: axillary vein (anterior/medial), brachial plexus cords. Site of axillary artery catheterization; injury causes axillary hematoma and upper limb ischemia; circumflex humeral vessels are important to the humeral head blood supply.

Axillary Nerve

- From posterior cord (C5-C6), passing through the quadrangular space with the posterior circumflex humeral artery. Innervates deltoid and teres minor; provides sensation to the regimental badge area (lateral deltoid skin). Vulnerable in anterior shoulder dislocations and surgical neck humeral fractures. Injury causes loss of lateral deltoid sensation and weakness of abduction beyond 15 degrees.

Axis (C2)

- Second cervical vertebra with the dens (odontoid process) projecting superiorly, serving as a pivot for atlas rotation, allowing approximately 50 percent of cervical rotation. Has a large spinous process and flat superior articular facets. Dens fractures (Types I-III) may cause atlanto-axial instability and spinal cord compression, often requiring surgical fixation.

Axon

- The single long process of a neuron that conducts action potentials away from the cell body toward the axon terminal for synaptic transmission. Axons vary in length (microscopic to >1 m for sciatic motor fibers) and are wrapped by Schwann cells (PNS) or oligodendrocytes (CNS) to form myelin, which enables saltatory conduction and speeds transmission. Axons end in synaptic boutons releasing neurotransmitters. Axonal injury in the CNS does not regenerate effectively; Wallerian degeneration occurs distal to injury. Axonal transport (anterograde and retrograde) carries organelles and proteins.

Basal Ganglia

- Deep gray matter nuclei in the cerebral hemispheres for motor control, cognition, and emotion. Key structures: caudate nucleus, putamen, globus pallidus (internal/external segments), subthalamic nucleus, substantia nigra. Direct pathway facilitates movement; indirect inhibits it. Receive cortical/thalamic input, project back to cortex via thalamus. Diseases: Parkinson's (substantia nigra dopamine depletion), Huntington's (caudate atrophy), hemiballismus (subthalamic lesion).

Biceps Brachii Muscle

- Two-headed anterior arm muscle. Long head from supraglenoid tubercle, short head from coracoid process, both inserting on the radial tuberosity. Innervated by musculocutaneous nerve (C5-C6). Most powerful elbow flexor in supination; supinates forearm; weakly flexes shoulder. Distal rupture causes

Popeye deformity. Long head susceptible to tenosynovitis.

Bone

- A rigid, mineralised connective tissue that forms the skeleton, providing structural support, protection of vital organs, hematopoiesis (bone marrow), and mineral storage (calcium, phosphate). Bone composition: organic matrix (90% type I collagen) and inorganic mineral (hydroxyapatite, calcium phosphate). Types: cortical (compact, 80% of bone mass) and cancellous (trabecular, 20%). Cells: osteoblasts (bone formation), osteocytes (mechanosensation), osteoclasts (bone resorption). Ossification: intramembranous (flat bones) and endochondral (long bones). Remodelling: continuous cycle of resorption and formation.

Brachial Artery

- The continuation of the axillary artery, running from the lower border of teres major to the cubital fossa, where it divides into radial and ulnar arteries. Lies medial to the biceps; palpated for blood pressure and brachial pulse. Branches: profunda brachii (deep brachial), superior/inferior ulnar collaterals. Site for blood pressure measurement, arterial access (catheterization), and the median nerve travels alongside. Trauma here causes forearm ischemia; collateral circulation around the elbow (anastomosis) limits ischemic damage.

Brachialis Muscle

- Flat strong muscle deep to the biceps, from distal anterior humerus to ulnar tuberosity and coronoid process. Innervated by musculocutaneous nerve (C5-C6). Primary elbow flexor regardless of forearm position ("workhorse" of elbow flexion). Less visible than biceps but significantly contributes to arm strength.

Brachial Plexus

- Nerve network (C5-T1) formed by roots, trunks, divisions, and cords, giving rise to upper limb nerves. Roots unite into superior/middle/inferior trunks, dividing into anterior/posterior divisions, recombining into lateral/posterior/medial cords. Major branches: musculocutaneous, axillary, radial, median, ulnar. Birth injuries cause Erb's palsy (C5-C6) or Klumpke's palsy (C8-T1). Vulnerable to shoulder trauma and thoracic outlet syndrome.

Brachial Plexus Cords

- Formed by divisions recombining behind the pectoralis minor. Lateral cord (anterior divisions of upper/middle trunks), posterior cord (all three posterior divisions), medial cord (anterior division of lower trunk). Named for relationship to the axillary artery. Lateral cord: lateral pectoral nerve, contributes to median nerve. Posterior cord: subscapular, thoracodorsal, axillary, radial nerves. Medial cord: medial pectoral, cutaneous, and ulnar nerves.

Brachial Plexus Roots

- Ventral rami of C5-T1 emerging from intervertebral foramina, passing between anterior and middle scalene muscles (interscalene triangle). C5-C6 form the upper trunk, C7 continues as middle trunk, C8-T1 form the lower trunk. Root injuries cause specific dermatome/myotome deficits. C5 avulsion causes loss of deltoid/biceps function. Roots are vulnerable in birth trauma, motorcycle accidents, and disc herniation radiculopathy.

Brachial Plexus Trunks

- Formed in the posterior neck triangle. Upper (C5-C6), middle (C7), and lower (C8-T1) trunks each divide into anterior/posterior divisions behind the clavicle. Upper trunk is most commonly injured in birth injuries (Erb-Duchenne palsy), causing waiter's tip position. Lower trunk injury (Klumpke's palsy from upward arm traction) causes claw hand.

Brain

- The central organ of the nervous system, enclosed in the cranial cavity and composed of the cerebrum, cerebellum, and brainstem. The brain receives, processes, and integrates sensory information; initiates and coordinates motor responses; and serves as the seat of cognition, emotion, memory, and consciousness. The cerebrum (largest part) has two hemispheres connected by the corpus callosum, with four lobes (frontal, parietal, temporal, occipital) responsible for higher functions. The cerebellum coordinates movement, balance, and motor learning. The brainstem (midbrain, pons, medulla) controls vital autonomic functions (breathing, heart rate, blood pressure) and contains cranial nerve nuclei. Protected by the skull, meninges (dura, arachnoid, pia), and cerebrospinal fluid. Blood supply via internal carotid and vertebral arteries (circle of Willis). Conditions: stroke, tumor, trauma, neurodegenerative diseases, epilepsy, infection.

Brainstem

- Connects cerebrum to spinal cord, with midbrain (superior), pons (middle), and medulla oblongata (inferior). Contains cranial nerve nuclei (III-XII), ascending/descending tracts, and vital autonomic centers for cardiac, respiratory, and vasomotor function. Reticular formation regulates consciousness and sleep-wake cycles. Contains all brain-spinal cord pathways. Lesions are often devastating and fatal, causing respiratory arrest, cardiac arrhythmias, and bilateral cranial nerve deficits.

Bronchi

- The major airways conducting air from the trachea into the lungs. The trachea bifurcates at the carina (T4-T5) into right and left main bronchi. The right main bronchus is wider, shorter, and more vertical—aspirated foreign bodies preferentially lodge here. Main bronchi divide into lobar (secondary), segmental (tertiary), and progressively smaller bronchi and bronchioles. Bronchi contain cartilage and submucosal glands; bronchioles lack cartilage. Bronchial walls contain smooth muscle (bronchoconstriction in asthma), goblet cells, and ciliated epithelium that clears mucus. Blood supply: bronchial arteries.

Bronchiole

- Small airways (less than 2 mm diameter) without cartilage, branching from segmental bronchi to terminal bronchioles (conducting zone) to respiratory bronchioles (transitional, alveoli bud from walls) to alveolar ducts to alveolar sacs to alveoli. Lined by ciliated simple cuboidal epithelium (Clara cells in terminal bronchioles, secrete surfactant components). No goblet cells, no submucosal glands. Smooth muscle in walls regulates airflow (bronchoconstriction/dilation). Conditions: bronchiolitis, asthma, bronchiolitis obliterans, small airway disease.

Bronchus

- One of the two main branches of the trachea that conduct air into the lungs. The right main bronchus is wider, shorter, and more vertical than the left, making it more susceptible to aspiration. Each main bronchus divides into lobar bronchi (secondary), segmental bronchi (tertiary), and progressively smaller branches (bronchioles). Bronchial walls contain ciliated pseudostratified columnar epithelium, smooth

muscle, cartilage plates, and mucous glands. Bronchoconstriction occurs in asthma. Bronchiectasis is irreversible dilatation. Bronchoscopy allows visualization and biopsy.

Cadaver

– A dead human body used for anatomical dissection, surgical training, and medical research. Cadavers are preserved through embalming (arterial injection of formaldehyde-based fixatives) to prevent decomposition and maintain tissue integrity. Anatomical dissection of cadavers remains a cornerstone of medical education, providing three-dimensional understanding of human anatomy, anatomical variation, and surgical approaches. Whole-body donation programs supply cadavers to medical schools; ethical considerations include informed consent, respectful treatment, and compliance with anatomical gift laws.

Calcaneus

– Largest tarsal bone forming the heel. Articulates with talus proximally and cuboid anteriorly. Lever for the calf muscles via the Achilles tendon on its posterior tuberosity. Predominantly trabecular bone, the most commonly fractured tarsal bone from falls from height. Bohler's angle assesses fractures on lateral radiographs.

Cantlie Line

– Functional liver division extending from the gallbladder fossa to the IVC, corresponding to the middle hepatic vein plane. Unlike the falciform ligament (anatomical division), it represents the true functional blood supply/biliary drainage division. Right hepatic artery and portal vein supply the right half; left supply the left. Basis for anatomic hepatic segmentectomy and liver transplantation.

Capitate

– Largest carpal bone, centrally located in the distal row as the carpal keystone. Rounded head articulates with scaphoid and lunate; distal surface with the third metacarpal. Last carpal bone to ossify. Wrist joint axis, bearing significant axial load. Avascular necrosis may occur with fractures similar to scaphoid injuries.

Carpal Tunnel

– Narrow passageway on the palmar wrist, bounded by carpal bones dorsally and the flexor retinaculum as the roof. Transmits the median nerve and flexor

tendons. Carpal tunnel syndrome causes numbness in the lateral 3.5 digits and thenar weakness. It is the most common entrapment neuropathy, associated with repetitive motion, diabetes, hypothyroidism, and pregnancy.

Cartilage

– A tough, flexible avascular connective tissue found in joints, the ear, nose, rib cage, and intervertebral discs. Composed of chondrocytes embedded in an extracellular matrix of collagen fibers, proteoglycans, and water, providing resilience and compressive strength. Types: hyaline cartilage (most common, covers articular surfaces of joints, costal cartilages), elastic cartilage (ear, epiglottis), and fibrocartilage (intervertebral discs, menisci, pubic symphysis). Cartilage lacks blood vessels, nerves, and lymphatics; it receives nutrition by diffusion from synovial fluid, limiting healing capacity.

Cecum

– First and widest large intestinal part in the right iliac fossa below the ileocecal valve, a blind-ended pouch approximately 6 cm long. Appendix arises from its posteromedial wall approximately 2 cm below the valve, containing abundant lymphoid tissue. Cecal volvulus causes large bowel obstruction. Absorbs water/electrolytes and compacts fecal matter.

Celiac Artery

– The first major ventral branch of the abdominal aorta at T12, arising from the aorta just below the diaphragm and supplying the foregut (stomach, proximal duodenum, liver, gallbladder, spleen, pancreas). It trifurcates into the left gastric, splenic, and common hepatic arteries, with rich collateral circulation between these branches. Occlusion/stenosis can cause chronic mesenteric ischemia. The celiac trunk is encased in the celiac plexus; it is important in vascular surgery (celiac axis clamping) and anatomy of the pancreatic bed.

Celiac Trunk

– First major abdominal aortic branch at T12-L1, the foregut artery. Divides into left gastric (lesser curvature), splenic (spleen, pancreas, greater curvature), and common hepatic (proper hepatic/gastroduodenal) arteries. Surrounded by the celiac plexus. Compression by the median arcuate ligament causes celiac trunk compression syndrome with postprandial pain.

Cell

– The fundamental structural and functional unit of all living organisms. Human cells are eukaryotic, characterized by a nucleus containing DNA and membrane-bound organelles. Major components: cell membrane (phospholipid bilayer with embedded proteins, regulates transport and signaling), cytoplasm (cytosol + organelles), nucleus (chromosomes, nucleolus), mitochondria (ATP production through oxidative phosphorylation), endoplasmic reticulum (protein/lipid synthesis), Golgi apparatus (modification and sorting of proteins), lysosomes (intracellular digestion), peroxisomes (fatty acid oxidation), and cytoskeleton (microfilaments, intermediate filaments, microtubules—maintains shape and enables movement). Cells differentiate into 200 specialized types with distinct functions (neurons, myocytes, hepatocytes, etc.). Cell division occurs via mitosis (somatic cells) and meiosis (gametes). Cell death occurs by apoptosis (programmed) or necrosis (pathologic).

Cerebellum

– Largest brain portion (approximately 10 percent of volume but over 50 percent of neurons) in the posterior cranial fossa behind the brainstem. Two hemispheres and a vermis, divided into vestibulocerebellum (balance, eye movements), spinocerebellum (posture, gait, coordination), and cerebrocerebellum (motor planning, cognition). Receives mossy/climbing fiber input from spinal cord, brainstem, and cortex; outputs via deep nuclei to thalamus/motor cortex. Lesions cause ataxia, dysmetria, intention tremor, nystagmus, and scanning speech.

Cerebral Lobes

– Four lobes divided by sulci. Frontal (anterior to central sulcus): executive function, motor control (precentral gyrus), Broca's area. Parietal (between central and parieto-occipital sulci): somatosensory (postcentral gyrus), spatial awareness. Temporal (below lateral sulcus): auditory processing, memory (hippocampus), Wernicke's area. Occipital (posterior): visual processing. Insula (deep within lateral sulcus): taste, emotion, interoception.

Cerebral Peduncle

– Paired structures of the ventral midbrain carrying descending motor tracts (corticospinal, corticobulbar, corticopontine) connecting the cerebrum to

the pons and below. Lesions produce contralateral hemiparesis; Weber syndrome (peduncle + CN III) causes ipsilateral CN III palsy with contralateral hemiparesis. The peduncles are separated by the interpeduncular fossa and flanked by the substantia nigra (dopaminergic, degenerated in Parkinson disease).

Cerebrum

– The largest part of the brain, comprising two cerebral hemispheres connected by the corpus callosum. Each hemisphere has four lobes: frontal (executive function, motor, Broca's area), parietal (somatosensory, spatial awareness), temporal (auditory, memory, Wernicke's area), occipital (visual processing). Cerebral cortex (gray matter) over white matter (myelinated tracts). Basal ganglia deep within. Lateral ventricles produce CSF. Blood supply: anterior, middle, posterior cerebral arteries (circle of Willis). Conditions: stroke, tumor, dementia, epilepsy, trauma.

Chordae Tendineae

– Thin tendinous cords connecting the papillary muscles to the free edges of the atrioventricular valve leaflets (mitral and tricuspid). They tether the leaflets and, with papillary muscle contraction during ventricular systole, prevent valve prolapse and regurgitation. Rupture (from papillary muscle infarction) causes acute severe mitral regurgitation and cardiogenic shock. Chordal dysfunction contributes to mitral valve prolapse and functional MR.

Choroid

– The vascular layer of the eye between the sclera and retina, part of the uveal tract (with ciliary body and iris). Contains dense capillary network (choriocapillaris) supplying outer retina (photoreceptors). Pigmented (melanin) to absorb stray light. Bruch's membrane separates choroid from retinal pigment epithelium. Conditions: choroidal nevus, melanoma, neovascularization (wet AMD), choroiditis, central serous chorioretinopathy.

Ciliary Body

– Circumferential structure between iris and choroid, with ciliary muscle (accommodation control via zonular fibers) and ciliary processes (aqueous humor production). Part of the uveal tract (iris, ciliary body, choroid). Parasympathetic CN III fibers cause muscle contraction, relaxing zonular fibers

and allowing lens convexity for near vision. Ciliary processes secrete aqueous humor into the posterior chamber, flowing through the pupil to the anterior chamber and draining at the trabecular meshwork and Schlemm's canal.

Clavicle

- Only horizontally oriented long bone, serving as a shoulder-trunk strut. Medial end articulates with the manubrium (sternoclavicular joint); lateral end with the acromion (acromioclavicular joint). Most common fracture at the middle-lateral third junction from falls on an outstretched hand. Protects the underlying brachial plexus and subclavian vessels.

Coccyx

- Terminal vertebral column part with 3-5 fused vertebrae. Articulates with the sacrum, allowing limited flexion important during childbirth. Provides attachment for gluteus maximus, coccygeus, and levator ani (pelvic floor). A common site of pain (coccydynia) following falls, direct trauma, and prolonged sitting.

Cochlea

- Snail-shaped hearing organ in the inner ear, coiled approximately 2.5 turns around the modiolus. Three fluid-filled chambers: scala vestibuli (perilymph), scala media (endolymph, organ of Corti), scala tympani (perilymph). The organ of Corti has inner/outer hair cells transducing mechanical vibrations into electrical signals via stereocilia deflection. Basilar membrane vibrates differentially along its length (tonotopic: high frequencies at base, low at apex). Hair cell damage from noise, ototoxicity, and ageing causes irreversible sensorineural hearing loss, most commonly affecting high frequencies.

Colon

- The largest part of the large intestine, extending from the cecum to the rectum. Anatomically divided into ascending colon (right side), transverse colon (across the abdomen), descending colon (left side), and sigmoid colon (S-shaped, leading to the rectum). Functions: absorption of water and electrolytes, fermentation of undigested carbohydrate by gut microbiota, formation and storage of feces. The colon has a distinct appearance with taeniae coli (three longitudinal muscle bands), haustra (sacculations), and appendices epiploicae (fat appendages). Common diseases: diverticulosis, colitis, colorectal

cancer, irritable bowel syndrome.

Common Iliac Arteries

- Terminal abdominal aortic branches at L4, each approximately 4 cm long, dividing into internal and external iliacs. Supply the pelvis and lower extremities. Right crosses anterior to the right common iliac vein. Aneurysms may occur with AAA and compress ureters causing hydronephrosis. They unite to form the IVC at L5.

Common Peroneal Nerve

- Sciatic division (L4-S2) winding around the fibular neck, the body's most vulnerable major nerve to external compression. Divides into superficial peroneal (peroneus longus/brevis, dorsal foot sensation) and deep peroneal (tibialis anterior, extensors, first web space sensation). Injury causes foot drop (loss of dorsiflexion/eversion) with dorsal foot sensory loss.

Coracoid Process

- Hook-like scapular projection extending anteriorly and laterally. Attachment for 3 muscles (pectoralis minor, coracobrachialis, short head of biceps) and 3 ligaments. Important surgical landmark. Fractures uncommon but may occur with direct trauma or shoulder dislocations.

Cornea

- Transparent, avascular, dome-shaped anterior eye surface providing approximately two-thirds of total refractive power. Five layers: epithelium (stratified squamous, rapidly regenerating), Bowman's membrane, stroma (thickest, regular collagen), Descemet's membrane, endothelium (single cell layer maintaining transparency). Innervated by CN V1 (ophthalmic trigeminal), extremely sensitive. Conditions: abrasion, ulcers, keratoconus (progressive thinning and cone-shaped protrusion). Contact lens wear is a major risk factor for microbial keratitis, which can rapidly lead to corneal ulceration, perforation, and sight loss if not treated promptly.

Corpus Callosum

- Brain's largest white matter tract with approximately 200 million axons connecting left and right hemispheres. Four parts: rostrum, genu, body, splenium. Facilitates interhemispheric communication for sensory, motor, and cognitive integration. Genu connects prefrontal cortices; body connects motor/sensory cortices; splenium connects tempo-

ral/occipital cortices. Callosotomy is a last-resort epilepsy treatment producing split-brain syndromes with disconnection phenomena.

Cranial Nerve

– Twelve paired nerves (CN I-XII) emerging directly from the brain/brainstem, primarily serving head and neck. I Olfactory (smell), II Optic (vision), III Oculomotor (eye movement, pupil), IV Trochlear (superior oblique), V Trigeminal (face sensation, mastication), VI Abducens (lateral rectus), VII Facial (expression, taste anterior 2/3), VIII Vestibulocochlear (hearing, balance), IX Glossopharyngeal (taste posterior 1/3, swallowing), X Vagus (parasympathetic to thorax/abdomen), XI Accessory (SCM, trapezius), XII Hypoglossal (tongue movement). Mnemonics: "Oh, Oh, Oh, To Touch And Feel Very Good Velvet, Ah, Heaven."

Cuboid

– Cube-shaped lateral foot tarsal bone articulating with calcaneus proximally and 4th/5th metatarsals distally. Attachment for the long plantar ligament and peroneus longus tendon. Keystone of the lateral longitudinal arch. Cuboid syndrome (subluxation) is a common lateral foot pain cause in athletes from excessive pronation.

Deltoid Muscle

– Large triangular muscle forming the shoulder contour, from lateral clavicle, acromion, and scapular spine to the deltoid tuberosity. Innervated by the axillary nerve (C5-C6). Anterior fibers flex/medially rotate, middle fibers abduct (primary abductor beyond 15 degrees), posterior fibers extend/laterally rotate. Essential for abduction; common injection site. Axillary nerve injury causes loss of abduction.

Dendrite

– The branched, tapering neuronal processes that receive synaptic input from other neurons and conduct graded potentials toward the cell body. Dendrites contain receptors, ion channels, and postsynaptic densities. Dendritic spines (small protrusions) are major sites of excitatory (glutamatergic) synapse formation; their density and morphology change with learning and are altered in many neuropsychiatric and neurodegenerative conditions (e.g., Down syndrome, schizophrenia). Electrical signals are graded and summate at the axon hillock, where an action potential is generated if threshold is reached.

Dermis

– Thick connective tissue layer beneath the epidermis providing structural support, elasticity, and nourishment. Two layers: papillary (superficial, loose connective tissue with dermal papillae interdigitating with epidermal ridges) and reticular (deep, dense irregular connective tissue). Contains collagen (type I, tensile strength), elastin, fibroblasts, blood vessels, lymphatics, nerves, hair follicles, sebaceous glands, and sweat glands. The dermal-epidermal junction is critical for adhesion; disruption causes blistering disorders such as pemphigus vulgaris and toxic epidermal necrolysis.

Descending Colon

– From splenic flexure to left iliac fossa, approximately 25-30 cm, retroperitoneal and fixed by phrenicocolic ligament. Anteriorly: small intestine. Posteriorly: left kidney. Absorbs water/electrolytes and compacts fecal matter. Left-sided pathology (diverticulitis, cancer) is more common here and in the sigmoid. Narrower than ascending colon, more susceptible to obstruction.

Descending Thoracic Aorta

– From aortic arch at T4 to diaphragm at T12. Gives off bronchial, esophageal, mediastinal, and posterior intercostal arteries. In the posterior mediastinum, initially left of the vertebral column. Related to esophagus, thoracic duct, and azygos vein. Aneurysms are mostly atherosclerotic, treatable with thoracic endovascular aortic repair.

Diaphragm

– Dome-shaped musculotendinous partition separating thoracic/abdominal cavities, primary inspiration muscle. Central tendon with muscular periphery from xiphoid, lower six costal cartilages, and lumbar vertebrae via crura and arcuate ligaments. Innervated by phrenic nerves (C3-C5). Contraction flattens the dome increasing thoracic volume. Three openings: caval (T8), esophageal (T10), aortic (T12). Paralysis causes hemiparesis or paradoxical breathing.

Diaphysis

– The shaft of a long bone, comprising thick cortical (compact) bone surrounding the medullary cavity, which contains bone marrow in children and is largely yellow (fatty) marrow in adults. Enclosed by periosteum; the nutrient artery enters here. Frac-

tures of the diaphysis heal by callus formation (enchondral and intramembranous). Blood supply via nutrient artery (avulsed in displaced shaft fractures, delaying healing). Contrast with epiphysis (ends) and metaphysis (growth zone).

Duodenum

- Shortest first small intestinal segment (25 cm), C-shaped around the pancreatic head. Four parts. Descending part has the major duodenal papilla for bile/pancreatic duct entry via the hepatopancreatic ampulla. Brunner's glands produce alkaline mucus. Most common peptic ulcer site. Primary iron and calcium absorption site.

Dural Venous Sinuses

- Venous channels between dural layers, draining brain blood and CSF from the subarachnoid space into the internal jugular veins. Major sinuses: superior sagittal, transverse, sigmoid, cavernous, straight. Valveless with bidirectional flow possible. Thrombosis (cerebral venous sinus thrombosis) causes increased intracranial pressure, headache, seizures, and focal deficits.

Dura Mater

- The outermost, thickest meningeal layer, a tough fibrous membrane. In the cranium it is two layers: periosteal (outer, adherent to skull) and meningeal (inner), which separate to form dural venous sinuses (e.g., superior sagittal, cavernous). Dural folds: falx cerebri, tentorium cerebelli, falx cerebelli. Cranial dura is pain-sensitive near vessels and at the base. Epidural hematoma (arterial, middle meningeal, lens-shaped) lies outside the dura; subdural hematoma (venous, crescent-shaped) lies between dura and arachnoid.

Ear

- Organ of hearing and balance, divided into external, middle, and inner ear. External: auricle (pinna), external auditory canal, tympanic membrane. Middle: air-filled cavity in temporal bone, auditory ossicles (malleus, incus, stapes), Eustachian tube (to nasopharynx). Inner (bony labyrinth): cochlea (hearing), vestibule (utricle, saccule – linear acceleration), semicircular canals (rotational acceleration). CN VIII (vestibulocochlear). Conditions: otitis media/externa, hearing loss, vertigo, Meniere's disease, acoustic neuroma, cholesteatoma.

Endosteum

- The thin connective tissue membrane lining the inner surface of bone, including the medullary cavity, Haversian canals, and trabeculae. Contains osteoprogenitor cells and osteoblasts, contributing to bone formation, remodeling, and repair (fracture healing). Participates with periosteum in the regulation of bone growth and mineral homeostasis.

Epidermis

- Outermost skin layer, stratified squamous keratinized epithelium approximately 0.1 mm thick, with five layers (superficial to deep): stratum corneum (dead keratinized cells), lucidum (clear layer, thick skin only), granulosum (keratinization begins), spinosum (spiny layer, Langerhans cells), basale (stem cells, melanocytes, Merkel cells). Keratinocytes (80 percent of cells) produce keratin for waterproofing and protection. Avascular, nourished by dermal diffusion. Melanocytes produce melanin for UV protection and skin pigmentation.

Epididymis

- Coiled duct approximately 6 meters long on the posterolateral aspect of each testis, divided into head (caput, receiving efferent tubules from the testis), body (corpus), and tail (cauda, continuing as the vas deferens). Functions include sperm maturation (gaining motility over approximately 12 days), storage (in the tail), and transport. The epididymis is a common site of infection (epididymitis), typically from sexually transmitted organisms in young men or urinary tract organisms in older men.

Epigastric Region

- Central superior region between the hypochondriac regions and above the umbilical region. Overlies the stomach, duodenum, pancreas, and portions of the liver. The aorta and inferior vena cava pass through it. Epigastric pain associates with gastric ulcers, pancreatitis, GERD, and aortic aneurysms. Critical for detecting pulsatile masses and organomegaly.

Epiglottis

- A leaf-shaped elastic cartilage at the base of the tongue that covers the laryngeal inlet during swallowing, directing food and liquid into the esophagus and preventing aspiration into the airway. Elevates during swallowing (with the larynx) under glossopharyngeal/vagal innervation. Acute epiglottitis (traditionally *Haemophilus influenzae* type b, now often viral or other bacteria) causes severe sore

throat, drooling, stridor, and airway obstruction—a medical emergency. Inflamed epiglottis is visible on lateral neck X-ray ('thumb sign').

Epithelium

– One of the four primary tissue types, composed of cells that line the surfaces of the body (skin, mucous membranes, serous membranes) and form glands. Epithelial tissues are classified by cell shape (squamous—flat, cuboidal—cube-shaped, columnar—tall, transitional—variable) and layering (simple—single layer, stratified—multiple layers, pseudostratified—appears layered but all cells contact the basement membrane). Functions: protection (stratified squamous epithelium of skin), absorption (simple columnar of intestinal lining), secretion (glandular epithelium), filtration (simple squamous of capillary endothelium), and sensory reception (olfactory epithelium). Epithelium rests on a basement membrane, is avascular (receives nutrition by diffusion), and has high regenerative capacity. Epithelial-mesenchymal transition is a key process in development and cancer metastasis.

Ethmoid Bone

– Delicate bone between the orbits forming parts of the nasal septum and orbital/nasal roofs. Has the cribriform plate (olfactory nerve filaments), perpendicular plate (superior nasal septum), and labyrinths (nasal conchae, ethmoid air cells). The crista galli provides falx cerebri attachment. Cribriform fractures cause CSF rhinorrhea and anosmia.

Eustachian Tube

– Auditory/pharyngotympanic tube connecting the middle ear to the nasopharynx, approximately 36 mm long in adults. Cartilaginous medial two-thirds and bony lateral third. Functions: equalizing middle ear/atmospheric pressure, draining middle ear secretions, and protecting from nasopharyngeal pathogens. Opens during swallowing, yawning, sneezing via tensor/levator veli palatini muscles. Children have shorter, wider, more horizontal tubes predisposing to otitis media. Dysfunction causes middle ear effusion (glue ear), the most common cause of conductive hearing loss in children.

Extensor Digitorum

– Posterior forearm muscle from lateral epicondyle via the common extensor tendon, dividing into 4 tendons inserting on extensor expansions of dig-

its 2-5. Innervated by posterior interosseous nerve (C7-C8). Extends MCP joints, assists PIP/DIP extension. Lateral epicondylitis (tennis elbow) is an overuse injury of its common origin. Extensor hood coordinates finger movements.

External Auditory Canal

– Tube from the concha to the tympanic membrane, approximately 2.5 cm long in adults. Lateral third is cartilaginous; medial two-thirds are bony (temporal bone). Skin-lined with ceruminous glands (producing cerumen/earwax) and hair follicles. Cerumen has antimicrobial and insect-repellent properties. Innervated by auriculotemporal nerve (V3) laterally and vagus nerve (Arnold's nerve) medially, explaining why canal touching may trigger coughing. Otitis externa (swimmer's ear) is common.

External Iliac Artery

– Larger common iliac terminal branch, continuing as the femoral artery below the inguinal ligament. Gives off inferior epigastric and deep circumflex iliac arteries. Related to external iliac vein medially and ureter anteriorly. Commonly used for cardiac catheterization and endovascular access. Atherosclerosis causes thigh/calf claudication.

External Jugular Vein

– Formed by posterior auricular and retromandibular vein divisions, crossing the sternocleidomastoid superficially to drain into the subclavian vein. Visible through the skin; used for peripheral IV access when other sites are unavailable. Distended in right heart failure and SVC obstruction. A useful physical examination landmark.

External Oblique Muscle

– Most superficial flat abdominal muscle from outer lower eight ribs to linea alba, pubic tubercle, and iliac crest. Innervated by T7-T12. Contralateral trunk rotation and flexion; compresses abdomen. Forms the inguinal ligament from its free inferior border. Superficial inguinal ring is an opening in its aponeurosis. Strains common in twisting athletes.

Extraocular Muscles

– Six muscles controlling eye movement: four rectus (superior, inferior, medial, lateral) and two oblique (superior, inferior). Medial rectus (CN III) adducts; lateral rectus (CN VI) abducts; superior rectus (CN III) elevates/intorts; inferior rectus (CN III) depresses/extorts; superior oblique (CN

IV) depresses/intorts; inferior oblique (CN III) elevates/extorts. Hering's law: yoke muscles receive equal innervation. Sherrington's law: agonist contraction accompanies antagonist relaxation. Paralysis of individual muscles causes characteristic strabismus (squint) and diplopia.

Eye

– The organ of vision, a spherical structure (approximately 24 mm diameter) in the bony orbit. Three layers: fibrous (sclera, cornea), vascular/uveal (choroid, ciliary body, iris), neural (retina). Anterior segment: cornea, anterior chamber (aqueous humor), iris/pupil, lens. Posterior segment: vitreous humor, retina (photoreceptors: rods/cones), optic nerve. Extraocular muscles (6) control movement. Cranial nerves II, III, IV, VI. Conditions: refractive errors, cataract, glaucoma, macular degeneration, retinal detachment, diabetic retinopathy.

Facet Joints

– Zygapophysial joints connecting adjacent vertebral articular processes. Orientation varies: cervical (45 degrees, allowing rotation), thoracic (coronal, allowing rotation but limiting flexion/extension), lumbar (sagittal, allowing flexion/extension but limiting rotation). Innervated by medial branches of dorsal rami. Common source of low back pain treated with facet injections and medial branch blocks.

Fallopian Tube

– The paired muscular tubes (10-12 cm) connecting the ovaries to the uterus, conducting oocytes and sperm and the site of fertilization (usually ampulla). Segments: infundibulum (fimbriae—sweep the oocyte), ampulla, isthmus, intramural. Lined by ciliated columnar epithelium and secretory cells; peristalsis and ciliary action transport the oocyte. Blockage causes infertility; inflammation (salpingitis, from ascending pelvic infection) predisposes to ectopic pregnancy. Tubal ligation is a sterilization procedure.

Fallopian Tubes

– Paired muscular tubes (approximately 10-12 cm long) extending from the uterus to near the ovaries, serving as the site of fertilization. Four parts: infundibulum (with fimbriae sweeping the oocyte), ampulla (widest part, most common fertilization site), isthmus (narrow medial part), and intramural (passing through the uterine wall). The tubal mucosa has

ciliated epithelium propelling the oocyte/embryo toward the uterus. Tubal pathology (infection, adhesions) can cause ectopic pregnancy or infertility.

False Ribs

– Ribs 8-10 not articulating directly with the sternum; their cartilages join rib 7's cartilage forming the costal margin. Greater mobility and flexibility of the lower thoracic wall. More susceptible to fractures at their angles due to greater length and less rigid attachment. The costal margin is an important clinical landmark for abdominal examination.

Femoral Artery

– Continues from external iliac through the femoral triangle and adductor canal to become the popliteal artery. Branches: superficial/deep circumflex femoral, deep femoral (profunda femoris), muscular. Palpable in the femoral triangle; most common site for arterial catheterization. Related to femoral vein medially and nerve laterally. Atherosclerosis causes peripheral arterial disease.

Femoral Nerve

– Largest lumbar plexus nerve (L2-L4), passing through psoas major and entering the thigh under the inguinal ligament lateral to the femoral artery. Innervates quadriceps, sartorius, pectineus; sensation to anterior thigh and medial leg (saphenous nerve). Used for knee surgery nerve block anesthesia. Neuropathy (retroperitoneal hemorrhage, hip surgery) causes quadriceps weakness and loss of knee jerk.

Femoral Triangle

– Upper anterior thigh space bounded superiorly by the inguinal ligament, laterally by sartorius, and medially by adductor longus. Contents from lateral to medial: femoral nerve, artery, vein, and deep inguinal lymph nodes. The femoral artery is used for arterial catheterization. The femoral vein is accessed for central venous lines. Femoral hernias occur through the femoral canal medial to the vein.

Femoral Vein

– The major deep vein of the thigh, continuation of the popliteal vein (through the adductor hiatus), running with the femoral artery in the femoral sheath (medial to artery) through the femoral triangle, becoming the external iliac vein at the inguinal ligament. Receives the great saphenous vein. Site of central venous access (femoral line), femoral

venipuncture, and DVT. The femoral sheath also contains the femoral canal (medial), site of femoral hernia.

Femur

- Longest, heaviest, strongest body bone. Proximal: head, neck, trochanters. Shaft: linea aspera. Distal: condyles, epicondyles. The neck connects head to shaft at approximately 125 degrees. Neck fractures are common in elderly osteoporotic patients with avascular necrosis risk. Bears entire upper body weight during standing.

Fibula

- Slender lateral leg bone, not weight-bearing, serving for muscle attachment and forming the lateral malleolus. Head provides biceps femoris and lateral collateral ligament attachment; the common peroneal nerve wraps around its neck, vulnerable to injury. Lateral malleolus extends more distally and posteriorly than the medial malleolus. Often fractured with tibial fractures.

Flexor Digitorum Profundus

- Deep anterior forearm muscle with ulnar and humeroulnar heads, inserting on distal phalanges bases of digits 2-5. Medial half (digits 4-5) innervated by ulnar nerve; lateral half (digits 2-3) by anterior interosseous nerve (C8-T1). Flexes DIP, PIP, MCP joints, and wrist. Anterior interosseous palsy causes inability to pinch with the index finger.

Flexor Digitorum Superficialis

- Large anterior forearm muscle with humeroulnar, radial, and ulnar heads, inserting on middle phalanges of digits 2-5. Innervated by median nerve (C8-T1). Flexes PIP joints, MCP joints, and wrist. Important for median nerve function assessment. Tendons pass through carpal tunnel, susceptible to stenosing tenosynovitis (trigger finger).

Floating Ribs

- Ribs 11-12 with short costal cartilages terminating in abdominal wall musculature, not articulating with the sternum or other ribs. Most mobile and least protected, susceptible to fracture from direct trauma. Fractures may injure underlying kidneys, requiring hematuria and flank tenderness assessment in trauma.

Fovea Centralis

- Central macular pit (approximately 1.5 mm) with the highest cone density (approximately 200,000

per square millimeter) and no rods, providing the sharpest visual acuity and color vision. Avascular with overlying retinal layers displaced laterally for direct light access to cones. The foveola (central 0.35 mm) has the thinnest retina and highest cone density. Pathology here (macular holes, central serous chorioretinopathy, macular degeneration) severely impairs central vision.

Frontal Bone

- Forms the forehead and superior orbits, with the squama frontalis, orbital plates, and nasal part. Contains frontal sinuses draining into the nasal cavity via the frontonasal duct. Articulates with parietal bones at the coronal suture. The metopic suture fuses by age six. Fractures may cause pneumocephalus or CSF rhinorrhea through the sinuses.

Frontal Lobe

- The largest lobe of the cerebral cortex, lying anterior to the central sulcus, comprising the primary motor cortex (precentral gyrus, Brodmann 4), premotor and supplementary motor areas, prefrontal cortex, and Broca's area (dominant hemisphere, expressive language). Functions: motor planning and execution, executive function, judgment, reasoning, working memory, social behavior, and personality. Lesions cause contralateral hemiparesis (UMN), expressive aphasia (Broca), personality changes, apathy, and executive dysfunction; prefrontal injury (e.g., Phineas Gage) alters behavior. Orbital surface (olfaction).

Ganglion

- A collection of neuronal cell bodies located outside the central nervous system (CNS). Ganglia are classified as: (1) Sensory ganglia (dorsal root ganglia of spinal nerves, cranial nerve ganglia—trigeminal, geniculate, vestibular, spiral, petrosal, nodose), containing pseudounipolar neurons whose peripheral processes receive sensory input and central processes enter the CNS. (2) Autonomic ganglia (sympathetic chain ganglia, prevertebral ganglia—celiac, superior mesenteric, inferior mesenteric, and parasympathetic ganglia—ciliary, pterygopalatine, submandibular, otic, enteric—Auerbach and Meissner plexuses), containing multipolar neurons with efferent output to target organs. (3) Basal ganglia (CNS structures involved in motor control: caudate, putamen, globus pallidus, substantia nigra, subthalamic nucleus—non-

pathological usage differs from peripheral ganglia). Clinically: dorsal root ganglia are sites of latency for herpes zoster; basal ganglia dysfunction causes Parkinson disease, Huntington disease, and dystonia. The term "ganglion" is also used for benign cystic swellings arising from tendon sheaths or joint capsules (ganglion cyst), which contain mucinous fluid and are not neural in origin.

Gastrocnemius Muscle

- Most superficial posterior leg muscle forming the calf prominence, with medial/lateral femoral condyle heads merging with soleus to form the Achilles tendon on the calcaneus. Innervated by tibial nerve (S1-S2). Plantarflexes ankle and flexes knee (two-joint muscle). Active in walking/running/jumping. Achilles tendon is the body's strongest but vulnerable to rupture during explosive activities.

Gland

- An organized group of epithelial cells specialized for secretion. Glands are classified by: (1) Location: exocrine (secrete onto a surface via ducts—sweat, salivary, mammary, sebaceous, lacrimal, pancreatic exocrine) or endocrine (secrete hormones directly into the bloodstream—thyroid, pituitary, adrenal, pancreatic islets, parathyroid, gonads). (2) Number of cells: unicellular (goblet cells) or multicellular. (3) Duct structure: simple (unbranched duct) or compound (branched duct). (4) Secretory unit shape: tubular, acinar (alveolar), or tubuloacinar. (5) Secretion mechanism: merocrine (exocytosis, e.g., salivary, pancreatic), apocrine (apical cell membrane pinches off, e.g., mammary, axillary sweat), holocrine (entire cell disintegrates, e.g., sebaceous). (6) Secretion type: serous (watery, enzyme-rich), mucous (viscous, mucin-rich), mixed (seromucous).

Glenohumeral Joint

- Ball-and-socket synovial joint between humeral head and glenoid cavity. Most mobile body joint allowing flexion, extension, abduction, adduction, medial/lateral rotation, circumduction. Mobility trades for stability, making it the most commonly dislocated joint. Stabilized by glenoid labrum, glenohumeral ligaments, and rotator cuff. Loose, redundant capsule.

Glenoid Cavity

- Shallow pear-shaped depression on the lateral

scapular angle articulating with the humeral head. The glenoid labrum deepens the socket by approximately 50 percent. Due to its shallowness, the glenohumeral joint is the most commonly dislocated joint. Bankart lesions (inferior labral tears) are associated with anterior dislocations and recurrent instability.

Glisson's Capsule

- Thin fibrous connective tissue envelope surrounding the liver, sending septa inward dividing it into lobules. Richly innervated by phrenic and intercostal nerve pain fibers, sensitive to distension and inflammation. Covered by visceral peritoneum except at the bare area. Hepatic injuries may cause subcapsular hematomas that can rupture causing hemoperitoneum.

Globin

- A family of heme-binding proteins involved in oxygen transport and storage. Structure: globin fold (8 alpha-helices arranged in a globular structure), binds one heme molecule (iron-protoporphyrin IX) per subunit. Types: (1) hemoglobin (alpha2-beta2 tetramer in adults, HbA; alpha2-gamma2 in fetal, HbF): transports oxygen in red blood cells. (2) Myoglobin (single subunit): stores oxygen in skeletal and cardiac muscle, facilitates oxygen diffusion. (3) Neuroglobin: expressed in neurons, protects against hypoxia. (4) Cytochrome: expressed in fibroblasts and other tissues, involved in nitric oxide metabolism and oxidative stress. Mutations in globin genes cause haemoglobinopathies: sickle cell disease (beta-globin Glu6Val), thalassaemias (reduced alpha or beta globin chain production).

Globulin

- A group of serum proteins (globular proteins) that are less soluble in water but soluble in dilute salt solutions. On serum protein electrophoresis, globulins migrate in the alpha-1, alpha-2, beta, and gamma regions. Alpha-1 globulins: alpha-1-antitrypsin, alpha-fetoprotein. Alpha-2 globulins: haptoglobin, alpha-2-macroglobulin, ceruloplasmin. Beta globulins: transferrin, beta-2-microglobulin, complement factors (C3, C4). Gamma globulins: immunoglobulins (antibodies). Abnormal globulin levels: polyclonal increase (chronic infection, autoimmune disease, cirrhosis), monoclonal gammopathy (multiple myeloma producing a monoclonal peak, MGUS,

Waldenström macroglobulinaemia), decreased (immunodeficiency, nephrotic syndrome).

Glomerulus

– The tuft of capillaries in the renal corpuscle (Bowman’s capsule) where blood is filtered to form urine. The glomerular filtration barrier consists of: (1) fenestrated endothelium (70-100 nm pores), (2) glomerular basement membrane (GBM, 300-350 nm, type IV collagen network), (3) podocyte foot processes (slit diaphragms formed by nephrin, NEPH1, podocin, and CD2AP). The barrier selectively retains cells and proteins >69 kDa while allowing water and small solutes to pass. Glomerular filtration rate (GFR): 125 mL/min (180 L/day). Mesangial cells support the capillary loops and regulate flow by contraction. Glomerular injury causes proteinuria and haematuria (glomerulonephritis).

Glucagon

– A peptide hormone produced by the alpha cells of the pancreatic islets (Langerhans). Primary function: counter-regulatory hormone to insulin, maintaining blood glucose by: (1) stimulating hepatic glycogenolysis (breakdown of glycogen to glucose), (2) promoting gluconeogenesis (synthesis of glucose from lactate, amino acids, glycerol), (3) inhibiting glycolysis and glycogen synthesis in the liver. Secreted in response to: hypoglycaemia, catecholamines, amino acids (arginine), and vagal stimulation. Secretion inhibited by: glucose, insulin, somatostatin. Glucagon also relaxes smooth muscle in the gastrointestinal tract (used therapeutically as IV glucagon for severe hypoglycaemia and for relaxation of the GI tract during endoscopy or imaging). Glucagonoma: a rare pancreatic neuroendocrine tumor producing glucagon, causing diabetes, weight loss, necrolytic migratory erythema (characteristic rash).

Glucose

– A monosaccharide (C₆H₁₂O₆) that is the primary energy source for cells. Types: D-glucose (dextrose, naturally occurring enantiomer) and L-glucose (synthetic). Routes of entry: dietary carbohydrates (digested to glucose), gluconeogenesis (synthesis from non-carbohydrate precursors), glycogenolysis (breakdown of stored glycogen). Cellular metabolism: glycolysis (cytosol, 2 ATP per glucose), TCA cycle (mitochondria, 36 ATP to

tal), pentose phosphate pathway (generates NADPH and ribose-5-phosphate). Glucose transport into cells: facilitated diffusion via GLUT transporters (GLUT1-4, 12 isoforms; GLUT4 is insulin-sensitive in muscle and adipose tissue). Blood glucose regulation: insulin (lowers), glucagon, cortisol, catecholamines, growth hormone (raise). Clinical significance: hyperglycaemia (diabetes), hypoglycaemia, glucose tolerance test (OGTT) for diabetes diagnosis. Intravenous dextrose is used for treating hypoglycaemia and as a component of parenteral nutrition.

Gluteus Maximus Muscle

– Largest, most superficial gluteal muscle forming the buttock bulk, from posterior iliac gluteal line, sacrum, coccyx, and sacrotuberous ligament to the iliotibial tract and gluteal tuberosity. Innervated by inferior gluteal nerve (L5-S2). Primary hip extensor and lateral rotator. Important for stair climbing, rising from seated, and posture. Common intramuscular injection site.

Gluteus Medius Muscle

– Thick fan-shaped muscle between maximus and minimus, from external ilium to the greater trochanter. Innervated by superior gluteal nerve (L4-S1). Primary hip abductor essential for pelvic stability during single-leg stance. Superior gluteal nerve injury causes Trendelenburg sign with contralateral pelvic drop. Commonly involved in hip pain and trochanteric bursitis.

Gluteus Minimus Muscle

– Smallest, deepest gluteal muscle from external ilium to the greater trochanter. Innervated by superior gluteal nerve (L4-S1). Hip abductor and medial rotator stabilizing the hip during walking. Works synergistically with medius for pelvic stability. Tendinopathy commonly causes lateral hip pain mimicking trochanteric bursitis.

Glycogen

– A branched polysaccharide composed of glucose units linked by alpha-1,4 glycosidic bonds (linear) and alpha-1,6 bonds (branching points, every 8-10 residues). Glycogen serves as the main storage form of glucose in animals. Stored primarily in: liver (up to 100 g, 3-5% wet weight, released as glucose for systemic use) and skeletal muscle (approximately 400 g, 1-2% wet weight, used locally for

exercise). Glycogenesis: synthesis of glycogen from glucose (insulin-stimulated). Glycogenolysis: breakdown of glycogen to glucose-1-phosphate (glucagon-stimulated in liver, epinephrine-stimulated in muscle). Glycogen storage diseases: von Gierke (type I, G6Pase deficiency, severe fasting hypoglycaemia), Pompe (type II, acid alpha-glucosidase deficiency, fatal cardiomyopathy), Cori (type III, debranching enzyme), McArdle (type V, muscle phosphorylase deficiency, exercise intolerance).

Greater Curvature

- Convex lateral stomach border from gastroesophageal junction to pylorus, approximately four times longer than the lesser curvature. Attachment site for the greater omentum. Blood supply from short gastric and left gastroepiploic vessels. Common site for gastric ulcers and cancer. The gastrocolic ligament connects it to the transverse colon.

Greater Trochanter

- Large quadrilateral lateral proximal femoral prominence. Insertion for gluteus medius/minimus and piriformis. Palpable landmark and site of trochanteric bursa. Intertrochanteric fractures between trochanters are extracapsular with lower avascular necrosis risk because periosteal blood supply is preserved.

Hair Follicle

- Complex dermal/hypodermal mini-organ producing hair. Has infundibulum (surface opening), isthmus (from sebaceous duct to arrector pili insertion), and lower segment (bulb with matrix and dermal papilla). Hair cycle: anagen (active growth, 2-7 years), catagen (regression, 2-3 weeks), telogen (resting, 2-3 months). Arrector pili contraction causes hair erection (goosebumps). Androgenetic alopecia results from DHT-induced follicle miniaturization. Alopecia areata is autoimmune follicle destruction.

Hamate

- Wedge-shaped distal row carpal bone on the ulnar side with the hook of the hamate. The hook forms Guyon's canal medial border and serves as flexor retinaculum attachment. Articulates with 4th/5th metacarpals. Hook fractures associated with racquet sports and ulnar nerve compression.

Hamstring Muscles

- Three posterior thigh muscles: biceps femoris

(long/short heads), semitendinosus, semimembranosus, mostly from the ischial tuberosity (short head of biceps from linea aspera). Long head/semimembranosus/semitendinosus innervated by tibial sciatic nerve; short head by common peroneal division. Flex knee, extend hip. Essential for running/deceleration. Strains are among the most common sports injuries.

Heart

- A four-chambered muscular pump (two atria, two ventricles) located in the mediastinum, responsible for circulating blood throughout the body. The right side receives deoxygenated blood from the systemic veins and pumps it to the lungs (pulmonary circulation); the left side receives oxygenated blood from the pulmonary veins and pumps it to the systemic circulation. The heart wall has three layers: epicardium (visceral pericardium), myocardium (cardiac muscle), and endocardium. Valves ensure unidirectional flow: tricuspid, pulmonary, mitral, aortic. Coronary arteries supply the myocardium. Conduction system: SA node (pacemaker), AV node, bundle of His, Purkinje fibers. Conditions: coronary artery disease, heart failure, arrhythmia, valvular disease, cardiomyopathy, congenital defects.

Hepatic Portal System

- The venous network draining blood from the gastrointestinal tract, spleen, and pancreas to the liver before it reaches the systemic circulation. Formed by the union of the superior mesenteric and splenic veins behind the pancreatic neck; receives inferior mesenteric, left gastric, and other tributaries. The portal vein delivers nutrients and toxins to the liver for processing (first-pass metabolism). Portal hypertension (cirrhosis) causes esophageal varices, ascites, splenomegaly, caput medusae, and portosystemic shunting. Portal venous pressure normally 5-10 mmHg.

Hepatic Vein

- Veins draining the liver into the inferior vena cava. The right, middle, and left hepatic veins emerge from the posterior surface of the liver at the bare area and drain into the IVC just below the diaphragm. They carry deoxygenated blood leaving the liver (after the hepatic portal system delivers blood for processing). Hepatic vein occlusion (Budd-Chiari syndrome) causes hepatic congestion, ascites,

and liver failure. Hepatic veins are key reference points for liver resection (segment anatomy) and transplantation.

Hip Joint

– Multiaxial ball-and-socket synovial joint between femoral head and acetabulum. Designed for stability and mobility, bearing entire upper body weight. Acetabular labrum deepens the socket; strong ligaments (iliofemoral, pubofemoral, ischiofemoral) reinforce it. Ligamentum teres contains the femoral head artery. Allows flexion, extension, abduction, adduction, rotation, circumduction. Total hip arthroplasty is a common treatment for osteoarthritis.

Hippocampus

– Curved medial temporal lobe structure, part of the limbic system, critical for new declarative memory formation (episodic and spatial) and short-to-long-term memory conversion. Has dentate gyrus, hippocampus proper (CA1-CA4), subiculum, and entorhinal cortex. One of few adult neurogenesis sites (dentate gyrus). Bilateral damage (herpes simplex encephalitis, bilateral PCA strokes) causes anterograde amnesia. Atrophy is an early Alzheimer's finding.

Humeroradial Joint

– Between capitulum and radial head, allowing flexion-extension and contributing to pronation-supination via radial head rotation. Radial collateral ligament provides lateral stability. Capitulum has articular cartilage only anteriorly. Less stable than humeroulnar joint; more susceptible to dislocation, particularly nursemaid's elbow in children.

Humeroulnar Joint

– Uniaxial hinge between trochlea and trochlear notch of the ulna, allowing only flexion/extension (0 to approximately 145 degrees). Ulnar collateral ligament is the primary valgus restraint. Trochlear notch provides inherent bony stability, making it the most congruent elbow joint. Commonly affected by osteoarthritis and rheumatoid arthritis.

Humerus

– Single upper arm bone, the longest of the upper limb. Proximal end: head, anatomical/surgical necks, tubercles. Shaft: deltoid tuberosity, radial groove, epicondyles. Distal end: trochlea, capitulum, olecranon fossa. The surgical neck is the

common fracture site potentially injuring the axillary nerve. Midshaft fractures may injure the radial nerve in the radial groove.

Hyoid Bone

– U-shaped bone in the anterior neck at C3, unique for not directly articulating with any other bone. Suspended by muscles and the stylohyoid ligament. Provides attachment for suprahyoid (digastric, stylohyoid, mylohyoid, geniohyoid) and infrahyoid (sternohyoid, sternothyroid, thyrohyoid, omohyoid) muscles. Critical for swallowing and speech. Fracture is a classic finding in manual strangulation.

Hypodermis

– Subcutaneous tissue/superficial fascia, the deepest skin layer with loose connective tissue and adipose tissue. Attaches skin to underlying muscles/bones via fibrous septa. Provides thermal insulation, energy storage (fat), mechanical cushioning, and contains blood vessels, lymphatics, and nerves. Subcutaneous injections are administered here. Fat distribution is hormonally influenced (estrogen promotes gynoid; testosterone promotes android). Lipoatrophy may occur from repeated insulin injections, causing subcutaneous fat loss and sometimes requiring rotation of injection sites to prevent dermal scarring.

Hypogastric Region

– Central inferior region below the umbilical region, containing the urinary bladder, sigmoid colon, rectum, and in females the uterus and ovaries. Assessed for bladder distension, uterine enlargement, and pelvic masses. Suprapubic pain may indicate cystitis, calculi, or pelvic pathology.

Hypothalamus

– Small region below the thalamus forming the third ventricle's floor and lower lateral walls, weighing approximately 4 grams, the master homeostasis regulator. Controls autonomic and endocrine systems (via the pituitary through the hypophyseal portal system), temperature, hunger, thirst, sleep-wake cycles, and emotion. Key nuclei: suprachiasmatic (circadian rhythm), arcuate (appetite), supraoptic/paraventricular (ADH/oxytocin), mammillary bodies (memory). Lesions cause diabetes insipidus, hypothalamic dysfunction (temperature dysregulation, appetite disturbance), and endocrine disorders such as hypopituitarism.

Ileum

- Longest distal segment (3.5 m) with thinner walls, shorter villi, and Peyer's patches on the antimesenteric border. Absorbs vitamin B12, bile salts, remaining nutrients. Ileocecal valve prevents colonic backflow. Crohn's disease most commonly affects the terminal ileum; resection may cause B12 deficiency and bile salt malabsorption. Meckel's diverticulum is a vitelline duct remnant here.

Ilium

- Largest hip bone forming the superior portion. Body contributes to acetabulum; wing has a concave iliac fossa. Iliac crest runs ASIS to PSIS, a palpable landmark for lumbar puncture level. Sacroiliac joint articulates with sacrum. Gluteal muscles originate from its external surface; iliacus fills its fossa.

Inferior Mesenteric Artery

- Third major abdominal aortic branch at L3, the hindgut artery. Supplies distal transverse colon through rectum. Branches: left colic, sigmoid, superior rectal. The marginal artery of Drummond provides SMA-IMA collateral circulation. Occlusion may cause ischemic colitis at the splenic flexure watershed (Griffiths' point).

Inferior Vena Cava

- Body's largest vein, formed by common iliac vein union at L5, returning lower body deoxygenated blood to the right atrium. Ascends right of the aorta, pierces the diaphragm at T8, enters the pericardium. Receives hepatic, renal, gonadal, and lumbar veins. IVC thrombosis/compression causes bilateral lower extremity edema and DVT.

Inguinal Canal

- An oblique passage (4 cm) through the anterior abdominal wall, from the deep (internal) inguinal ring to the superficial (external) inguinal ring, transmitting the spermatic cord in males and round ligament in females, plus ilioinguinal and genital branch of genitofemoral nerves. Boundaries: floor (inguinal ligament), roof (internal oblique, transversus abdominis), anterior wall (external oblique aponeurosis), posterior wall (transversalis fascia). Site of indirect (through deep ring, congenital) and direct (through posterior wall/Hesselbach triangle, acquired) inguinal hernias.

Inguinal Region

- Area at the thigh-trunk junction traversed by

the inguinal ligament (ASIS to pubic tubercle). Clinically significant for inguinal hernias: indirect (through deep inguinal ring, most common) and direct (through Hesselbach's triangle). Contains the spermatic cord in males and round ligament in females, along with the inferior epigastric vessels.

Intermediate Cuneiform

- Smallest cuneiform, centrally located between medial and lateral cuneiforms. Articulates with navicular, medial/lateral cuneiforms, and second metatarsal. Forms the transverse arch apex. Relatively fixed, contributing to midfoot stability. Injuries are typically associated with high-energy midfoot trauma.

Internal Iliac Artery

- Smaller common iliac terminal branch (hypogastric), supplying the pelvis, perineum, gluteal region, and medial thigh. Posterior division: iliolumbar, lateral sacral, superior gluteal. Anterior division: inferior gluteal, internal pudendal, obturator, vesical, uterine, vaginal, middle rectal arteries. Primary uterine blood supply, ligated during hysterectomy for hemorrhage. Embolization controls pelvic hemorrhage.

Internal Jugular Vein

- Descends in the carotid sheath with the internal carotid artery and vagus nerve, draining brain, face, and neck. Begins at the jugular foramen as a sigmoid sinus continuation, joining the subclavian vein to form the brachiocephalic vein. Contains backflow-preventing valves. Used for central venous catheterization. JVD assessment indicates right heart failure or elevated central venous pressure.

Internal Oblique Muscle

- Middle flat abdominal layer deep to external oblique, from thoracolumbar fascia, iliac crest, and lateral inguinal ligament to lower ribs, linea alba, and pubic crest. Innervated by T7-T12 and L1. Ipsilateral rotation (opposite of external oblique). Contributes to inguinal canal and abdominal wall integrity.

Iris

- Colored circular muscular diaphragm between cornea and lens, controlling pupil size and light entry. Two muscles: sphincter pupillae (parasympathetic CN III, constricts in bright light) and dilator pupillae (sympathetic, dilates in darkness). Iris root

attaches to the ciliary body. The anterior chamber angle between iris and cornea is where aqueous humor drains. Narrow angles may cause acute angle-closure glaucoma with sudden IOP elevation.

Ischium

- Inferior-posterior hip bone. Ischial tuberosity bears seated weight and serves as hamstring attachment. Ischial spine is a pudendal nerve block landmark and determines pelvic outlet level. Lesser sciatic notch lies between spine and tuberosity.

Jejunum

- Middle segment (2.5 m) with prominent circular folds and tall villi for a velvety appearance. Richer blood supply and thicker walls than the ileum. Primary nutrient absorption site for carbohydrates, amino acids, fatty acids, vitamins, minerals. Fewer Peyer's patches. More commonly affected by Crohn's disease. Robust blood supply preferred for surgical anastomoses.

Joint

- Articulation between two or more bones permitting movement. Structural classification: fibrous (sutures, syndesmoses, gomphoses – immovable/slightly movable), cartilaginous (synchondroses, symphyses – slightly movable), synovial (freely movable – plane, hinge, pivot, condyloid, saddle, ball-and-socket). Synovial joint features: articular cartilage (hyaline), joint capsule (fibrous outer, synovial inner), synovial fluid (lubrication, nutrition), ligaments (stability), menisci/labrum (congruence). Conditions: osteoarthritis, rheumatoid arthritis, septic arthritis, dislocation, sprain.

Jugular Vein

- One of the major veins draining blood from the head, face, and neck. There are two pairs: internal jugular vein (IJV) and external jugular vein (EJV). Internal jugular vein: the larger vessel, runs within the carotid sheath (medial to the carotid artery), descends from the jugular foramen (at the base of the skull) to the brachiocephalic vein. Receives blood from the brain (via dural venous sinuses, sigmoid sinus), face, and superficial neck. The IJV is the preferred site for central venous access (internal jugular central line) because of its straight course, predictable anatomy, and lower risk of pneumothorax compared to the subclavian approach. It is also used for measuring central venous pres-

sure (CVP) and for venous sampling in endocrine testing (inferior petrosal sinus sampling for ACTH-dependent Cushing syndrome). External jugular vein: superficial vein formed by the retromandibular and posterior auricular veins, descends obliquely across the sternocleidomastoid muscle, pierces the deep fascia, and drains into the subclavian vein. Easily visible when it distends (Valsalva, heart failure, superior vena cava obstruction). The EJV is used for peripheral venous access when other sites are compromised. Jugular venous pressure (JVP): the height of the IJV pulsation in the neck reflects right atrial pressure, assessed with the patient at 45 degrees; the a-wave reflects atrial contraction (absent in atrial fibrillation, cannon a-wave in tricuspid atresia, AV dissociation), and the v-wave reflects atrial filling during ventricular systole (giant v-wave in tricuspid regurgitation).

Kidney

- A paired, bean-shaped retroperitoneal organ responsible for filtering blood, excreting waste products as urine, and regulating fluid and electrolyte balance, acid-base homeostasis, and blood pressure (via the renin-angiotensin-aldosterone system). Each kidney contains approximately 1 million nephrons, the functional filtering units. Structure: outer renal cortex, inner renal medulla (organized into renal pyramids), renal pelvis (collecting urine). The renal artery supplies blood; the renal vein drains it. Kidneys also produce erythropoietin (stimulates red blood cell production) and activate vitamin D. Common diseases: chronic kidney disease, nephrolithiasis, glomerulonephritis, pyelonephritis.

Knee Joint

- Largest, most complex joint with three compartments: medial/lateral tibiofemoral and patellofemoral. Tibiofemoral is a modified hinge allowing flexion-extension with rotation when flexed. Stabilized by cruciate (ACL/PCL) and collateral (MCL/LCL) ligaments; menisci cushion and distribute load. The suprapatellar bursa is the body's largest. Common injuries: ACL tears, meniscal tears, patellar dislocations.

Lacrimal Apparatus

- Produces, distributes, and drains tears for corneal moisture and protection. Components: lacrimal gland (superolateral orbit, parasympathetic CN

V1, produces aqueous tear layer), superior/inferior puncta (medial eyelid openings), canaliculi, lacrimal sac (lacrimal groove), and nasolacrimal duct (drains into inferior meatus). Dry eye syndrome (keratoconjunctivitis sicca) from decreased production or excessive evaporation is common. Nasolacrimal duct obstruction causes epiphora and may cause dacryocystitis (lacrimal sac infection) presenting with epiphora and mucopurulent discharge.

Lacrimal Gland

- The paired almond-shaped exocrine glands that secrete the aqueous layer of the tear film, located in the lacrimal fossa of the superior lateral orbit (orbital part) and the upper eyelid (palpebral part). The lacrimal gland is a tubuloacinar serous gland, innervated by parasympathetic fibers from the facial nerve (CN VII) via the pterygopalatine ganglion and the zygomatic and lacrimal nerves. Its secretion is stimulated by corneal irritation, emotional responses, and trigeminal reflexes. Tears drain via the lacrimal puncta (upper and lower) into the lacrimal canaliculi, common canaliculus, lacrimal sac, and nasolacrimal duct, emptying into the inferior meatus of the nasal cavity. The tear film has three layers: lipid (meibomian glands, prevents evaporation), aqueous (lacrimal gland, contains lysozyme, lactoferrin, IgA, electrolytes), and mucin (conjunctival goblet cells, anchors tears to cornea). Diseases: dacryoadenitis (inflammation, usually viral or autoimmune–Sjogren syndrome, sarcoidosis), dacryocystitis (infection of the lacrimal sac, commonly obstructed nasolacrimal duct), and tumors (pleomorphic adenoma most common benign, adenoid cystic carcinoma most common malignant).

Large Intestine

- Final GI segment (approximately 1.5 meters) from ileocecal valve to rectum. Six segments: cecum, ascending, transverse, descending, sigmoid colon, rectum. Absorbs water, electrolytes, and vitamins (K, biotin) from colonic bacteria. Characterized by haustra, taeniae coli, and epiploic appendages. Houses approximately 100 trillion bacteria forming a diverse microbiome essential for metabolism and immunity.

Lateral Cuneiform

- Located between intermediate cuneiform and cuboid, articulating with navicular, intermediate

cuneiform, cuboid, and third metatarsal. Contributes to the transverse arch and lateral foot column. Injuries typically from high-energy midfoot trauma.

Latissimus Dorsi Muscle

- Broadest back muscle forming the posterior axillary wall, from T7-L5 spinous processes, thoracolumbar fascia, iliac crest, and lower ribs to the intertubercular groove floor. Innervated by thoracodorsal nerve (C6-C8). Adducts, medially rotates, extends the arm powerfully in swimming/rowing/climbing. Common reconstructive surgery flap. Susceptible to overhead strain.

Left Atrium

- Receives oxygenated blood from 4 pulmonary veins. Most posterior chamber forming the cardiac base on chest radiography. Smooth walls from absorbed pulmonary veins; small auricle with pectinate muscles. Mitral valve separates it from the left ventricle. Enlargement is common in mitral disease and atrial fibrillation, potentially causing esophageal compression or recurrent laryngeal nerve hoarseness.

Left Hypochondriac Region

- Upper left abdomen lateral to the epigastric region, containing the spleen, stomach fundus, splenic flexure, and pancreatic tail. Important for evaluating splenomegaly, gastric pathology, and splenic infarction. The spleen is normally not palpable below the costal margin; enlargement into this region is a significant finding.

Left Iliac Region

- Lower left abdomen containing the descending colon, sigmoid colon, and left ureter. Important for evaluating diverticulosis and diverticulitis, most commonly affecting the sigmoid colon here. Palpation may reveal masses from inflammatory bowel disease or colorectal cancer.

Left Ventricle

- Thickest cardiac chamber (13-15 mm), pumping oxygenated blood into the aorta for systemic distribution. Generates approximately 120 mmHg systolic pressure. Receives blood through the mitral valve; ejects through the aortic valve. Left ventricular hypertrophy from chronic hypertension or aortic stenosis is a risk factor for heart failure, arrhythmias, and sudden death.

Lens

– Transparent biconvex avascular structure behind the iris/pupil, suspended by zonular fibers from the ciliary body. Provides approximately one-third of refractive power and allows accommodation (focusing on near objects by changing shape). Concentric lens fiber layers from surface epithelium, surrounded by a capsule. Absorbs ultraviolet light. Cataracts (opacification) are the most common cause of reversible blindness worldwide. Accommodation decreases with age (presbyopia).

Lesser Curvature

– Concave medial stomach border from gastroesophageal junction to pylorus. Attachment site for the lesser omentum connecting to the liver, containing right/left gastric arteries. Most common gastric ulcer site. The angular incisure marks the body-antrum junction. Cancer here may cause early obstruction from the narrow lumen.

Lesser Trochanter

– Small conical posteromedial proximal femoral prominence. Insertion for iliopsoas (primary hip flexor). Isolated fractures in adults may indicate pathologic fracture from metastatic disease; in adolescents may result from iliopsoas avulsion. Visible on lateral hip radiographs.

Ligament

– A dense, fibrous connective tissue band that connects bone to bone, providing passive joint stability and guiding joint motion. Ligaments are composed predominantly of type I collagen fibers (parallel orientation, crimped pattern) and elastin fibers (10-20% in some ligaments), arranged in bundles. The collagen fibers give ligaments high tensile strength (up to 30-40 N/mm² for the ACL), while elastin allows elastic recoil. Ligaments have a limited blood supply (attachments are relatively avascular), leading to slow healing after injury. Mechanoreceptors (Ruffini, Pacinian, Golgi-type) within ligaments provide proprioceptive feedback about joint position and tension. The ligament response to injury: acute inflammatory phase (days), proliferative phase (weeks, fibroblast proliferation, collagen deposition, initially type III then type I), and remodelling phase (months-years, orientation of collagen along lines of stress). Classification of ligament injuries (grades): grade 1 (mild stretching, microscopic tears, no instability), grade 2 (partial tear, some laxity),

grade 3 (complete rupture, gross instability). Healing is better in intra-articular ligaments (ACL has poor healing potential, often requires surgical reconstruction) vs extra-articular (MCL heals well non-operatively). Ligaments weaken with age and corticosteroid use, and sprains are common ankle sprain (anterior talofibular ligament most common), ACL tear (knee, pivot sport), MCL tear (knee, valgus stress), and ulnar collateral ligament (thumb, skier's thumb/gamekeeper's thumb).

Linea Aspera

– Prominent longitudinal posterior femoral shaft ridge from converging muscle attachment lines. Insertion for adductor magnus, vastus medialis/lateralis, and short head of biceps femoris. Thickest femoral cortex, resisting bending forces. Diverges distally into supracondylar lines. The profunda femoris artery pierces the adductor magnus near it.

Liver

– The largest internal organ, located in the right upper quadrant of the abdomen beneath the diaphragm. Functions: metabolism of carbohydrates, lipids, and proteins; detoxification of drugs and toxins; synthesis of proteins (albumin, clotting factors, complement); bile production for fat digestion; storage of glycogen, vitamins, and iron; immune function (Kupffer cells). Dual blood supply: hepatic artery (oxygenated) and portal vein (nutrient-rich from intestines). Drains into hepatic veins to IVC. Bile drains via biliary tree to gallbladder and duodenum. Regenerative capacity allows recovery from partial resection. Conditions: hepatitis, cirrhosis, fatty liver, liver cancer, gallstones, drug-induced liver injury.

Liver Lobule

– The functional unit of the liver: a hexagonal structural unit centered on a central (hepatic) venule, with portal triads (portal vein, hepatic artery, bile ductule) at the corners. Hepatocytes arranged in cords radiate from the center; sinusoids (lined by Kupffer cells) receive mixed portal venous and hepatic arterial blood flowing toward the central vein; bile canaliculi flow in the opposite direction. Zones 1-3 differ in oxygen and metabolic function (zone 3 most vulnerable to ischemia/toxins—centrilobular necrosis). Alternative concepts: portal lobule and

hepatic acinus (Rappaport).

Lumbar Vertebrae (L1-L5)

– Largest and strongest mobile vertebrae for weight-bearing. Large kidney-shaped bodies, short hatchet-shaped spinous processes, sagittally-oriented facets allowing primarily flexion/extension. Lordotic curvature. Most common disc herniation site, particularly L4-L5 and L5-S1 causing sciatica. Lumbar puncture performed between L3-L4 or L4-L5.

Lunate

– Crescent-shaped proximal row carpal bone between scaphoid and triquetrum. Most commonly dislocated carpal bone from falls on extended wrists. Dislocation may compress the median nerve causing acute carpal tunnel syndrome. Vulnerable to avascular necrosis (Kienbock disease) from its precarious blood supply.

Lung

– The paired, cone-shaped respiratory organs located in the thoracic cavity, responsible for gas exchange (oxygen uptake, carbon dioxide elimination). Each lung is divided into lobes: the right lung has three (superior, middle, inferior), the left lung has two (superior, inferior) with a cardiac notch accommodating the heart. Structure: trachea branches into bronchi, bronchioles, alveolar ducts, and alveoli (300–500 million, providing a surface area of approximately 70–100 m²). The pleura (visceral and parietal) surrounds each lung. Ventilation is driven by the diaphragm and intercostal muscles. Common diseases: pneumonia, COPD, asthma, lung cancer, pulmonary embolism.

Lymphatic System

– A network of lymphatic vessels, lymph nodes, and lymphoid organs (tonsils, thymus, spleen, Peyer patches) that returns interstitial fluid (lymph) to the bloodstream, transports dietary fat (chyle), and serves as the conduit for immune surveillance. Lymphatic capillaries collect excess tissue fluid; lymph passes through lymph nodes (filtration, antigen presentation), then trunks and ducts (thoracic duct on the left, right lymphatic duct) into the venous system. Dysfunction causes lymphedema; lymphangitic spread is a major route of cancer metastasis.

Lymph Node Structure

– Small bean-shaped lymphoid organs (1-25 mm) distributed along lymphatic vessels, filtering lymph

and mounting immune responses. Each has a cortex (outer, containing B-cell follicles with germinal centers), paracortex (deep cortex, containing T-cells and dendritic cells), and medulla (inner, containing medullary cords and sinuses). Afferent vessels enter the cortex; efferent vessels exit at the hilum (also containing the artery, vein, and efferent lymphatic). Macrophages and dendritic cells within the node process and present antigens to lymphocytes, initiating adaptive immune responses and germinal center formation.

Macula Lutea

– Small oval yellowish central retinal area approximately 5.5 mm in diameter for high-acuity vision. Yellow color from xanthophyll pigments (lutein, zeaxanthin) filtering blue light and protecting photoreceptors. The fovea centralis is the central depression (1.5 mm) with highest cone density and no rods. Fovea is avascular, supplied by underlying choriocapillaris. Age-related macular degeneration is the leading cause of irreversible vision loss in developed countries.

Mammary Gland

– Modified sweat (apocrine) gland in the breast, overlying pectoralis major, with 15-20 lactiferous ducts converging on the nipple. Composed of glandular lobules (alveoli), fibrous stroma (Cooper's ligaments), and fat. Development regulated by estrogen, progesterone, prolactin, and oxytocin (milk let-down). Lymphatic drainage: primarily to axillary nodes (level I-III), also internal mammary and supraclavicular—critical for breast cancer staging. Blood supply: internal thoracic, lateral thoracic, intercostal arteries.

Mandible

– Largest facial bone forming the lower jaw, with horseshoe-shaped body and two rami ending in condylar (TMJ) and coronoid processes. Mental foramen transmits the mental nerve. Mandibular foramen is the entry point for inferior alveolar nerve blocks. Most commonly fractured facial bone, typically at the condyle, angle, or symphysis.

Masseter Muscle

– Thick rectangular muscle of mastication on the mandibular ramus, from the zygomatic arch to mandibular angle/ramus. Innervated by the masseteric nerve (V3). Most powerful masticatory muscle,

elevating the mandible with up to 70 kg force. Involved in bruxism, TM disorders, and myofascial pain. Hypertrophy can widen facial appearance.

Maxilla

– Paired bone forming the upper jaw, central face, and parts of orbit, nasal cavity, and hard palate. Body contains the maxillary sinus (largest paranasal sinus). Four processes: frontal, zygomatic, alveolar (upper teeth), and palatine (anterior hard palate). Fractures classified using the Le Fort system. The infraorbital nerve emerges from its foramen.

Medial Cuneiform

– Largest cuneiform, on the medial foot between navicular and first metatarsal. Insertion for tibialis anterior and posterior tendons supporting the medial longitudinal arch. The first tarsometatarsal joint (Lisfranc joint) is an important landmark; Lisfranc injuries involve fracture-dislocation at this level.

Median Nerve

– From lateral and medial cords (C5-T1), passing through the arm without branching, through the cubital fossa, into the forearm innervating most flexor muscles. In the hand innervates thenar muscles (opponens, abductor brevis, flexor brevis pollicis) and first two lumbricals. Sensation to lateral 3.5 digits. Carpal tunnel syndrome is the most common entrapment, causing thenar wasting and lateral palm/finger sensory loss.

Medulla Oblongata

– Most inferior brainstem segment, continuous with the spinal cord at the foramen magnum. Contains vital autonomic centers: cardiovascular center (heart rate, blood pressure), respiratory center (dorsal/ventral respiratory groups), and area postrema (vomiting center). Houses the pyramidal decussation (corticospinal tracts crossing, explaining contralateral motor control), olives (inferior olivary nuclei for cerebellar motor learning), and cranial nerve IX-XII nuclei. Lesions (Chiari malformation, syringobulbia, lateral medullary syndrome) cause ipsilateral cranial nerve deficits and contralateral long tract signs, often with vertigo, dysphagia, and respiratory compromise.

Melanocytes

– Dendritic pigment-producing neural crest-derived cells in the epidermal basal layer and hair follicles,

comprising approximately 5-10 percent of basal keratinocytes. Produce melanin (eumelanin, brown-black; pheomelanin, yellow-red) in melanosomes, transferred to keratinocytes via dendritic processes for UV protection. Each melanocyte supplies approximately 30-40 keratinocytes (epidermal melanin unit). UV exposure stimulates melanin production (tanning). Cell of origin for melanoma, a potentially fatal skin cancer that metastasises early and requires prompt surgical excision with clear margins.

Meninges

– The three membranes enveloping the brain and spinal cord: dura mater (outermost, tough), arachnoid mater (middle, avascular), and pia mater (innermost, adherent to the CNS surface). The subarachnoid space (between arachnoid and pia) contains cerebrospinal fluid. The epidural and subdural spaces are sites of hemorrhage. Inflammation of the meninges (meningitis) and meningeal carcinomatosis (tumor spread) are serious clinical conditions. Dural reflections form the falx cerebri and tentorium cerebelli; dural venous sinuses lie between dural layers.

Mesentery

– The fan-shaped double layer of peritoneum attaching the small intestine (jejunum and ileum) to the posterior abdominal wall, carrying the superior mesenteric artery, vein, lymphatics, and autonomic nerves between its layers. Root extends from duodenojejunal junction to ileocecal junction. Related mesenteries: transverse mesocolon, sigmoid mesocolon, mesoappendix. Inflammation of the mesentery (mesenteric adenitis, ischemic mesenteric disease) causes abdominal pain; mesenteric ischemia/volvulus is a surgical emergency. The mesentery functions to suspend and provide blood supply to the gut.

Metacarpals

– Five long bones (I-V) forming the palm framework. Each has base, shaft, and head. The first is shortest and most mobile, articulating with the trapezium at a saddle joint for opposition. Second/third are firmly fixed; fourth/fifth more mobile. Bennett's fracture affects the first metacarpal base; boxer's fracture affects the fifth neck.

Metaphysis

– The region of a long bone between the epiphysis

(end) and diaphysis (shaft), containing the epiphyseal growth plate (physis) in children—the zone of active cartilage growth (endochondral ossification). The metaphysis is highly vascularized with abundant trabecular bone; common site of osteomyelitis (sluggish blood flow) and bone tumors (osteosarcoma, Ewing sarcoma) in children. After skeletal maturity, the growth plate closes and the metaphysis fuses with the epiphysis.

Metatarsals

- Five long bones (I-V) forming the forefoot. Each has base, shaft, and head. First is shortest/thickest, bearing approximately one-third of forefoot load. Stress fractures commonly affect the second and third (march fractures). Morton's neuroma typically affects the nerve between 3rd/4th metatarsal heads. MTP joints are condyloid allowing flexion, extension, limited abduction/adduction.

Midbrain

- Most superior brainstem segment connecting pons to diencephalon. Contains cerebral peduncles (corticospinal/corticobulbar tracts), substantia nigra (dopaminergic neurons degenerated in Parkinson's), red nucleus (rubrospinal tract for coordination), and periaqueductal gray (pain modulation). Superior/inferior colliculi on the tectum process visual/auditory reflexes. The cerebral aqueduct connects third/fourth ventricles. Syndromes (Weber's, Benedikt's, Claude's, Nothnagel's) result from vascular lesions affecting specific midbrain regions, producing characteristic combinations of ipsilateral cranial nerve palsy and contralateral hemiplegia or ataxia.

Mitral Valve

- Left atrioventricular (bicuspid) valve with anterior and posterior cusps supported by chordae tendineae and papillary muscles. Anterior cusp is larger and proximate to the aortic valve. Mitral valve prolapse is the most common valvular abnormality. Mitral stenosis (most commonly rheumatic) and regurgitation are significant. Most commonly affected valve in rheumatic heart disease.

Muscle

- A specialized contractile tissue responsible for movement, posture, and heat production. Three types: skeletal muscle (voluntary, striated, attached to bones via tendons, responsible for locomotion), car-

diac muscle (involuntary, striated, found only in the heart, with intercalated discs for synchronized contraction), and smooth muscle (involuntary, non-striated, found in walls of blood vessels, gastrointestinal tract, bladder, uterus). Skeletal muscle structure: epimysium (outer sheath), perimysium (surrounds fascicles), endomysium (surrounds individual fibers). Contraction mechanism: sliding filament theory (actin-myosin cross-bridge cycling, ATP-dependent, calcium-regulated via troponin-tropomyosin).

Musculocutaneous Nerve

- From lateral cord (C5-C7), piercing coracobrachialis, running between biceps and brachialis to supply these muscles and lateral forearm skin (lateral antebrachial cutaneous nerve). Sole motor supply to the anterior arm compartment. Injury causes weakness of elbow flexion/forearm supination with lateral forearm sensation loss. Vulnerable in axillary injuries and proximal humeral fractures.

Myelin Sheath

- The lipid-rich insulating layer around axons formed by Schwann cells (peripheral nervous system) and oligodendrocytes (central nervous system), which wrap the axon in concentric membrane layers. Myelin provides electrical insulation and enables saltatory conduction (action potentials jump between nodes of Ranvier), greatly increasing conduction velocity and reducing energy demands. Damage/demyelination (multiple sclerosis, Guillain-Barre syndrome, vitamin B12 deficiency) slows or blocks conduction, causing weakness, sensory loss, and autonomic dysfunction.

Navicular

- Boat-shaped tarsal bone between talus and three cuneiforms. Navicular tuberosity is a palpable medial prominence serving as posterior tibial tendon insertion, key medial longitudinal arch stabilizer. Central third has a precarious blood supply, susceptible to stress fractures and avascular necrosis (Kohler disease in children). Most commonly fractured midfoot tarsal bone.

Nerve

- A bundle of axons (nerve fibers) surrounded by connective tissue sheaths that transmits electrical impulses between the central nervous system and the periphery. Structure: epineurium (outer layer), per-

ineurium (surrounds fascicles), endoneurium (surrounds individual axons). Types: sensory (afferent, carry impulses toward CNS), motor (efferent, carry impulses away from CNS to muscles/glands), and mixed nerves. Myelinated axons conduct impulses faster (saltatory conduction) than unmyelinated axons. Cranial nerves (12 pairs) arise from the brain; spinal nerves (31 pairs) arise from the spinal cord. Nerve regeneration is limited in the CNS but possible in the PNS.

Neuron

- The fundamental excitable cell of the nervous system specialized for receiving, integrating, and transmitting electrical and chemical signals. Structural components: cell body (soma), dendrites (receptive), axon (conducting), and synaptic terminals (releasing neurotransmitters). Types: sensory, motor, and interneurons; classified by structure (unipolar, bipolar, multipolar) and function. Neurons are highly polarized cells with resting membrane potentials and generate action potentials; they rely on axonal transport and are largely post-mitotic (limited regeneration). Neurotransmitters include glutamate, GABA, dopamine, serotonin, and acetylcholine.

Nose

- The external nasal structure and nasal cavities, the primary organ of olfaction and the entry to the respiratory tract. External nose: bone (nasal bones, frontal process of maxilla) and cartilage (septal, upper/lower lateral cartilages). Nasal cavity: divided by septum, lined by respiratory epithelium (ciliated pseudostratified columnar) and olfactory epithelium (superior turbinate/septum). Turbinates (conchae): superior, middle, inferior (increase surface area, warm/humidify/filter air). Paranasal sinuses drain into nasal cavity (maxillary, frontal, ethmoid, sphenoid). Blood supply: sphenopalatine, greater palatine, facial arteries. Conditions: rhinitis, sinusitis, epistaxis, deviated septum, nasal polyps, olfactory loss.

Obturator

- A structure that occludes an opening. In anatomy, the obturator foramen is a large opening in the pelvic bone, closed by the obturator membrane. The obturator nerve (L2–L4) innervates the adductor muscles of the thigh and provides sensory innervation to the medial thigh. The obturator

artery supplies the adductor compartment. The term also applies to surgical obturators—prosthetic devices used to close palatal defects (cleft palate, post-surgical).

Occipital Bone

- Forms the posterior-inferior cranium surrounding the foramen magnum (spinal cord passage). Has basilar, lateral, and squamous parts. Occipital condyles articulate with C1 for nodding movement. The external occipital protuberance provides muscle attachment. Fractures through the foramen magnum may cause brainstem injury and are life-threatening.

Occipital Lobe

- The most posterior of the four cerebral lobes, located behind the parieto-occipital sulcus and above the tentorium cerebelli. The occipital lobe is the primary visual processing center of the brain. The primary visual cortex (V1, Brodmann area 17) receives input from the lateral geniculate nucleus via the optic radiations; damage causes contralateral homonymous hemianopia or quadrantanopia. Higher-order visual areas (V2–V5) process colour, motion, and object recognition. The lingual gyrus and cuneus are key occipital landmarks. Lesions beyond V1 can cause visual agnosia, alexia without agraphia, and visual hallucinations (peduncular hallucinosis).

Odontoid Process

- Also called the dens, a tooth-like projection superiorly from the body of the axis (C2 vertebra). The odontoid process projects into the atlas (C1) and is held in place by the transverse ligament of the atlas, allowing rotation of the head (the atlantoaxial joint accounts for 50% of cervical rotation). Fractures of the odontoid process (Anderson–D’Alonzo classification types I–III) can cause atlantoaxial instability and spinal cord compression. Type II fractures (at the base of the dens) have the highest non-union rate. Os odontoideum is a congenital variant where the dens is not fused to the axis body.

Olfactory Nerve

- Cranial nerve I (CN I), responsible for the sense of smell. Olfactory receptor neurons in the olfactory epithelium of the nasal roof project axons through the cribriform plate of the ethmoid bone to the olfactory bulb, then via the olfactory tract to the primary olfactory cortex (piriform cortex, amygdala,

entorhinal cortex). Loss of smell (anosmia) can result from head trauma (shearing of fibers at the cribriform plate), viral infections (COVID-19, common cold), nasal polyps, neurodegenerative diseases (Parkinson, Alzheimer, Lewy body dementia), and meningiomas of the olfactory groove. Testing uses the University of Pennsylvania Smell Identification Test (UPSIT) or sniffin' sticks.

Omentum

– A double layer of peritoneum connecting the stomach to other abdominal organs. The greater omentum (gastrocolic omentum) hangs from the greater curvature of the stomach, covers the transverse colon and small intestine, and is rich in fat and immune cells (milky spots—aggregates of macrophages and lymphocytes). It is mobile and can migrate to sites of inflammation to wall off infection (the 'policeman of the abdomen'). The lesser omentum (gastrohepatic omentum) connects the lesser curvature of the stomach and duodenum to the liver, containing the hepatic artery, portal vein, and common bile duct (within the hepatoduodenal ligament). Omentectomy is performed in gastric and ovarian cancer surgery.

Optic Nerve

– CN II exiting through the optic disc (blind spot), passing through the optic canal, and partially decussating at the optic chiasm. Technically a CNS tract with oligodendrocyte myelination and meningeal coverings, making it susceptible to demyelinating disease (optic neuritis in MS). Papilledema (disc swelling from raised ICP) and optic atrophy are important findings. Carries approximately 1.2 million ganglion cell axons.

Ossicles

– Three smallest body bones forming the ossicular chain in the middle ear: malleus (hammer, attached to tympanic membrane), incus (anvil), stapes (stirrup, footplate in oval window). Amplify and transmit sound vibrations from tympanic membrane to inner ear, providing approximately 22-fold amplification (impedance matching between air and fluid). Tensor tympani (CN V3) attaches to the malleus; stapedius (CN VII) to the stapes, forming the acoustic reflex dampening loud sounds. Ossicular erosion or disruption (from chronic otitis media, cholesteatoma, or trauma) causes conductive hearing

loss, often correctable with tympanoplasty or ossicular reconstruction.

Osteoblast

– A bone-forming cell derived from mesenchymal stem cells in the bone marrow. Osteoblasts synthesise and deposit the bone matrix (osteoid), composed primarily of type I collagen and non-collagenous proteins (osteocalcin, osteonectin, alkaline phosphatase). They then regulate matrix mineralisation by releasing matrix vesicles containing calcium and phosphate. Osteoblasts also produce RANKL (receptor activator of nuclear factor kappa-B ligand), which stimulates osteoclast differentiation, and osteoprotegerin (OPG), which inhibits RANKL. Once encased in mineralised matrix, they become osteocytes. Impaired osteoblast function contributes to osteoporosis (uncoupling of bone formation and resorption).

Osteoclast

– A large, multinucleated bone-resorbing cell derived from the monocyte–macrophage lineage (hematopoietic stem cells). Osteoclasts attach to bone surfaces via integrins, form a sealed acidic compartment (ruffled border), and secrete hydrogen ions (dissolve hydroxyapatite) and proteolytic enzymes (cathepsin K, matrix metalloproteinases) to degrade the bone matrix. They are regulated by RANK–RANKL signalling (stimulates differentiation/activity) and calcitonin (inhibits). Overactive osteoclasts cause bone loss in osteoporosis, Paget disease of bone, rheumatoid arthritis, and multiple myeloma. Bisphosphonates, denosumab (RANKL inhibitor), and calcitonin are therapeutic inhibitors of osteoclast activity.

Osteocyte

– The mature, terminally differentiated bone cell embedded within the bone matrix in lacunae, derived from osteoblasts. Osteocytes are connected to each other and to bone surface cells via canaliculi, forming a mechanosensory network that senses mechanical loading and fluid flow. They regulate bone remodeling by secreting signaling molecules (RANKL, osteoprotegerin, sclerostin) that coordinate osteoblast and osteoclast activity. Osteocyte apoptosis with aging reduces bone quality. Sclerostin (osteocyte product) inhibits bone formation; anti-sclerostin antibodies (romosozumab) treat os-

teoporosis.

Ovary

- The female gonad, a paired almond-shaped organ located in the pelvic cavity on each side of the uterus. Functions: production of oocytes (ova) and secretion of female sex hormones (oestrogen, progesterone, and small amounts of androgens). Each ovary contains follicles at various stages of development. Monthly ovulation releases a mature oocyte. After ovulation, the follicle becomes the corpus luteum, which secretes progesterone. Ovarian structure: outer cortex (containing follicles) and inner medulla (containing blood vessels and connective tissue). Common conditions: polycystic ovary syndrome, ovarian cysts, ovarian tumors, premature ovarian insufficiency.

Pancreas

- Retroperitoneal gland (15-20 cm) behind the stomach, spanning from duodenum to spleen. Exocrine function: acinar cells secrete digestive enzymes (amylase, lipase, proteases) and bicarbonate into pancreatic duct to duodenum. Endocrine function: islets of Langerhans secrete insulin (beta cells), glucagon (alpha cells), somatostatin (delta cells), pancreatic polypeptide. Blood supply: splenic artery, superior/inferior pancreaticoduodenal arteries. Conditions: acute/chronic pancreatitis, pancreatic cancer, diabetes mellitus, cystic fibrosis, pancreatic cysts.

Papillary Muscle

- Muscular projections of the ventricular myocardium attached by chordae tendineae to the atrioventricular valve leaflets (anterolateral and posteromedial in the left ventricle; anterior, septal, and posterior in the right ventricle). They contract during ventricular systole to tense the chordae, preventing AV valve prolapse and regurgitation. Papillary muscle rupture (acute MI, especially posteromedial) causes acute severe mitral regurgitation, pulmonary edema, and cardiogenic shock—a surgical emergency.

Parasympathetic Nervous System

- The craniosacral division of the autonomic nervous system mediating 'rest-and-digest' functions. Preganglionic fibers from cranial nerves III, VII, IX, X, and sacral nerves S2-S4 synapse on ganglia near or within target organs (short postganglionic fibers). Neurotransmitter: acetylcholine at both

ganglia (nicotinic) and end organs (muscarinic). Effects: bradycardia, bronchoconstriction, increased GI motility and secretion, miosis, bladder contraction, salivation, and penile erection. Opposes the sympathetic system; tonic balance maintains homeostasis.

Parietal Bones

- Paired curved bones forming the cranial vault roof and sides. Articulate at the sagittal suture, with frontal at coronal, temporal at squamous, and occipital at lambdoid sutures. The pterion (where four bones meet) overlies the middle meningeal artery; fractures here may cause epidural hematomas.

Parietal Lobe

- The cerebral lobe posterior to the central sulcus and above the lateral sulcus, containing the primary somatosensory cortex (postcentral gyrus, Brodmann 3,1,2) processing touch, pain, temperature, and proprioception, plus the somatosensory association cortex. Functions: spatial awareness, body schema, visuospatial processing, and (dominant hemisphere) skilled movements, apraxia; (nondominant) neglect. Lesions cause contralateral sensory loss, agraphesthesia, astereognosis, hemineglect (nondominant), Gerstmann syndrome (dominant: agraphia, acalculia, finger agnosia, left-right confusion), and homonymous hemianopia (optic radiation).

Parotid Gland

- The largest of the three major salivary glands, located in the preauricular region, extending from the zygomatic arch superiorly to the angle of the mandible inferiorly. The parotid gland is encased in the parotid fascia (investing layer of deep cervical fascia). It produces serous saliva (thin, watery, rich in amylase), secreted via Stensen duct (parotid duct), which pierces the buccinator muscle and opens opposite the second upper molar tooth. Structures passing through the parotid gland (from superficial to deep): facial nerve (CN VII—its five branches: temporal, zygomatic, buccal, marginal mandibular, and cervical), retromandibular vein, and external carotid artery (dividing into maxillary and superficial temporal arteries). Clinical: parotitis (mumps—most common cause), Sjögren syndrome, sialolithiasis (parotid duct stones), and parotid tumors (80% benign—pleomorphic adenoma most common; 20% malignant—mucoepidermoid

carcinoma, adenoid cystic carcinoma). Parotidectomy is the surgical treatment; the facial nerve must be identified and preserved.

Patella

- Largest sesamoid bone, embedded in the quadriceps tendon. Articulates with the trochlear groove forming the patellofemoral joint. Increases quadriceps mechanical advantage by approximately 30 percent. Triangular with inferior apex. Covered with the thickest articular cartilage (up to 7 mm). Common conditions: fractures, dislocations, chondromalacia.

Pectoralis Major Muscle

- Thick fan-shaped chest muscle with clavicular and sternocostal heads, inserting on the lateral intertubercular groove lip. Innervated by medial/lateral pectoral nerves (C5-T1). Clavicular head flexes; sternocostal head extends from flexion. Adducts and medially rotates powerfully. Rupture uncommon, may occur during weightlifting at the musculotendinous junction.

Pectoralis Minor Muscle

- Thin triangular muscle deep to pectoralis major, from ribs 3-5 to the coracoid process. Innervated by medial pectoral nerve (C8-T1). Draws scapula anteriorly/inferiorly, stabilizing it against the thorax. Assists forced inspiration. Tightness contributes to rounded shoulder posture and thoracic outlet syndrome.

Pelvis

- Bony ring from 2 hip bones, sacrum, and coccyx. Each hip bone fuses from ilium, ischium, and pubis meeting at the acetabulum. Divided into false (greater, above brim) and true (lesser, below brim) pelvis. Males: narrower, deeper, heart-shaped inlet. Females: wider, shallower, oval inlet for childbirth.

Penis

- The male external genital organ, composed of three erectile columns: two dorsal corpora cavernosa and one ventral corpus spongiosum (containing the urethra, expanding into the glans). Root is attached to the pubic arch (crura and bulb). Erection: parasympathetic (pelvic splanchnic, NO-cGMP) vasodilation filling the corpora; detumescence by sympathetic. Blood supply: deep and dorsal arteries of the penis (from internal pudendal); drainage to superficial/deep dorsal veins. Conditions: phimosis, paraphimosis, Peyronie disease, priapism, penile

fracture, carcinoma.

Pericardium

- The fibroserous sac surrounding the heart and proximal great vessels. Outer fibrous pericardium (anchors to diaphragm, sternum) and inner serous pericardium (parietal layer lining the sac; visceral layer/epicardium on the heart) with the pericardial cavity (15-50 mL serous fluid) between them. Functions: limits cardiac distension, reduces friction, barriers to infection. Pericarditis causes chest pain (relieved by leaning forward), friction rub, and ECG changes; pericardial effusion may cause cardiac tamponade (Beck triad). Pulsus paradoxus in tamponade.

Periosteum

- The dense connective tissue membrane covering the outer surface of bones (except at articular surfaces, which are covered by cartilage). Two layers: outer fibrous (collagen, vessels, nerves) and inner cambium (osteoprogenitor cells, osteoblasts). Supplies blood to bone, provides attachment for tendons/ligaments, and mediates appositional bone growth, callus formation, and fracture healing. Stripping of the periosteum (fracture, surgery) can devascularize the underlying bone. Pain-sensitive, mediating bone pain.

Peripheral Nervous System

- The portion of the nervous system consisting of nerves and ganglia outside the brain and spinal cord. The PNS connects the central nervous system (CNS) to peripheral tissues and organs. Components: (1) Cranial nerves (12 pairs)—emerging from the brain/brainstem, innervating head, neck, and viscera. (2) Spinal nerves (31 pairs)—emerging from the spinal cord via dorsal and ventral roots, each dividing into dorsal and ventral rami. (3) Autonomic nervous system—sympathetic (thoracolumbar, 'fight or flight') and parasympathetic (craniosacral, 'rest and digest'), regulating involuntary functions. Peripheral nerves are composed of axons bundled into fascicles by connective tissue layers: endoneurium (surrounds individual axons), perineurium (surrounds fascicles—blood-nerve barrier), and epineurium (outer layer). Myelination (by Schwann cells in the PNS) enables saltatory conduction. Peripheral nerve injury is classified by Seddon (neuropathia—conduction block,

axonotmesis—axon disrupted but sheath intact, neurotmesis—complete transection) or Sunderland (grades I–V). Peripheral neuropathy (polyneuropathy, mononeuritis multiplex) has many causes.

Peritoneum

– The serous membrane lining the abdominal cavity and covering the abdominal organs. Parietal peritoneum lines the abdominal wall (innervated by somatic nerves—pain is well-localized); visceral peritoneum covers organs (innervated by visceral afferents—pain is dull, poorly localized). The peritoneal cavity (potential space) contains serous fluid. Mesenteries, omenta, and ligaments are peritoneal folds. Peritonitis (infection/inflammation) causes abdominal rigidity, rebound tenderness, and ileus. Peritoneal dialysis uses this membrane. Ascites is fluid accumulation in the peritoneal cavity.

Phalanges

– 14 finger bones. Thumb: 2 (proximal, distal). Each other finger: 3 (proximal, middle, distal). MCP joints are condyloid allowing flexion, extension, abduction, adduction, circumduction. IP joints are hinge joints allowing only flexion/extension. Mallet finger and jersey finger are common tendon avulsion injuries.

Pharynx

– A muscular tube extending from the base of the skull (clivus) to the level of the cricoid cartilage (C6), where it continues as the esophagus. The pharynx is divided into three parts: nasopharynx (posterior to the nasal cavity, contains the pharyngeal tonsil/adenoids, Eustachian tube openings), oropharynx (posterior to the oral cavity, contains the palatine tonsils, lingual tonsil, base of tongue, soft palate), and laryngopharynx/hypopharynx (posterior to the larynx, extends from the hyoid bone to the cricoid cartilage, leads to esophagus and larynx). The pharynx functions in swallowing (deglutition—voluntary oral phase followed by involuntary pharyngeal phase, coordinated by the swallowing center in the medulla), breathing (conducts air from nasal/oral cavities to the larynx), and speech (resonance). The pharyngeal constrictor muscles (superior, middle, inferior) contract sequentially in peristalsis to propel the bolus. The pharynx is innervated by the pharyngeal plexus (CN IX and X).

Phrenic Nerve

– Primarily from C4 (with C3 and C5: "C3, 4, 5 keeps the diaphragm alive"), traveling between anterior and middle scalene muscles, descending anterior to the anterior scalene across the first rib. Right phrenic passes anterior to the lung root; left passes anterior and lateral. Innervates the ipsilateral diaphragm and provides sensory innervation to central diaphragmatic pleura, pericardium, and peritoneum. Injury causes ipsilateral hemidiaphragm paralysis reducing vital capacity. Phrenic nerve palsy causes ipsilateral hemidiaphragmatic paralysis, detected as an elevated hemidiaphragm on chest radiograph with paradoxical movement on fluoroscopic sniff test.

Pia Mater

– The innermost meningeal layer, a delicate vascularized membrane firmly adherent to the surface of the brain and spinal cord, following all gyri and sulci. It carries blood vessels that penetrate the CNS and forms the tela choroidea, contributing to the choroid plexus (CSF production). The pia and the spinal cord are anchored by the denticulate ligaments. Inflammation (meningitis) involves all meninges; subpial hemorrhages occur in some conditions.

Pinna

– Visible external ear portion, elastic cartilage covered by skin, shaped to funnel sound into the external auditory canal. Key features: helix (outer rim), antihelix (inner ridge), tragus (canal prominence), antitragus, concha (canal-leading depression), lobule (earlobe, only non-cartilaginous part). Blood supply: superficial temporal and posterior auricular arteries. Innervated by great auricular nerve (C2–C3) and auriculotemporal nerve (V3). Perichondritis can cause permanent deformity.

Pisiform

– Small pea-shaped sesamoid bone in the flexor carpi ulnaris tendon, in the proximal row. Articulates only with the triquetrum. Forms the medial border of Guyon's canal (ulnar nerve/artery passage). Only sesamoid carpal bone, subcutaneous and easily palpable on the ulnar palm.

Pituitary Gland

– Pea-sized "master gland" in the sella turcica, connected to hypothalamus by infundibulum. Anterior

pituitary (adenohypophysis): GH, TSH, ACTH, FSH, LH, prolactin. Posterior pituitary (neurohypophysis): ADH (vasopressin), oxytocin (from hypothalamus). Regulates other endocrine glands and bodily functions. Conditions: pituitary adenoma, hypopituitarism, acromegaly, Cushing disease, diabetes insipidus, prolactinoma.

Pleura

- The serous membrane covering the lungs (visceral pleura) and lining the thoracic cavity (parietal pleura: costal, mediastinal, diaphragmatic, cervical/cupola). The pleural cavity is a potential space containing a thin film of serous fluid that couples the lung to the chest wall during ventilation. Parietal pleura is pain-sensitive (innervated by intercostal and phrenic nerves); visceral pleura is not. Pleural effusion, pneumothorax, hemothorax, empyema, and pleurisy (pleuritic chest pain) are pleural disorders. Pleural fluid analysis distinguishes transudates from exudates (Light criteria).

Pons

- Middle brainstem segment with prominent anterior bulge containing pontine nuclei (relaying cortical input to cerebellum), corticospinal fibers, and cranial nerve V, VI, VII, and VIII nuclei. Fourth ventricle floor is partly formed by the pons. Pneumotaxic center (parabrachial nucleus) regulates breathing pattern. Bilateral ventral pontine infarction causes locked-in syndrome with preserved consciousness and vertical eye movements but complete paralysis.

Popliteal Artery

- Continues from femoral artery at the adductor hiatus, dividing into anterior/posterior tibial arteries at the lower popliteus border. Deepest popliteal fossa structure, related anteriorly to vein and tibial nerve. Palpable at the fossa's inferior margin. Popliteal aneurysms are the most common peripheral arterial aneurysms, frequently bilateral and associated with AAA. Vulnerable to injury in knee dislocations.

Popliteal Fossa

- Diamond-shaped space on the posterior knee, bounded by hamstrings superiorly and gastrocnemius heads inferiorly. Contains popliteal artery/vein, tibial nerve, and common peroneal nerve. The popliteal pulse is palpated at the inferior margin. Significant for evaluating aneurysms, Baker's cysts, and vascular status in peripheral

artery disease.

Portal System

- Venous network draining the GI tract, spleen, and pancreas to the liver via the portal vein (formed by superior mesenteric and splenic vein union behind the pancreatic neck). Carries nutrient-rich deoxygenated blood for hepatic processing before systemic entry. Receives left gastric, right gastric, cystic, and paraumbilical veins. Portal hypertension (cirrhosis) causes esophageal varices, caput medusae, and ascites.

Portal Vein

- The vein carrying nutrient-rich blood from the gastrointestinal tract, spleen, pancreas, and gallbladder to the liver, formed behind the pancreatic neck by the union of the superior mesenteric and splenic veins. It enters the porta hepatis with the hepatic artery and bile duct. Within the liver it ramifies, delivering blood to sinusoids for processing (first-pass metabolism). Portal hypertension (cirrhosis) leads to esophageal varices, ascites, splenomegaly, and portosystemic shunting; portal vein thrombosis causes portal hypertension without cirrhosis.

Posterior Tibial Artery

- Arises from the popliteal artery, courses deep in the posterior leg, palpable behind the medial malleolus. Divides into medial/lateral plantar arteries for the sole. Supplies posterior leg muscles. Important for peripheral vascular disease assessment. The pedal pulse behind the medial malleolus is a key clinical examination component.

Prostate

- Walnut-sized gland (approximately 20 g) surrounding the urethra just below the bladder, producing approximately 30 percent of seminal fluid. It has peripheral, central, and transition zones. The peripheral zone is the most common site of prostate cancer; the transition zone enlarges in benign prostatic hyperplasia (BPH), compressing the urethra and causing urinary obstruction. The prostate secretes prostate-specific antigen (PSA), citric acid, and zinc. The ejaculatory ducts pass through the prostate and open at the verumontanum in the prostatic urethra.

Proximal Radioulnar Joint

- Pivot synovial joint between radial head circumference and ulnar radial notch, held by the annular

ligament. Allows pronation/supination with approximately 150 degrees range. Parallel bones in supination; radius crosses ulna in pronation. Significant in radial head fractures, Monteggia fracture-dislocations, and nursemaid's elbow.

Pubis

- Anterior-inferior hip bone with body, superior ramus, and inferior ramus. Two pubic bones meet at the pubic symphysis (cartilaginous joint widening in childbirth). Pubic tubercle is the lateral inguinal ligament attachment. Direct hernias emerge medial to inferior epigastric vessels near it.

Pulmonary Valve

- Semilunar valve between right ventricle and pulmonary trunk with three cusps. Most superiorly located cardiac valve with thinner cusps than the aortic valve. Pulmonic stenosis is a congenital defect causing right ventricular hypertrophy. Less commonly affected by endocarditis than mitral/aortic valves. A systolic ejection murmur at the left upper sternal border suggests pulmonic stenosis.

Pulmonary Vein

- The four veins (two from each lung) returning oxygenated blood from the lungs to the left atrium, a unique exception in the venous system (carrying oxygenated blood). Superior and inferior pulmonary veins enter the left atrium posteriorly. Anomalous drainage (partial or total anomalous pulmonary venous return) causes left-to-right shunt/cyanosis. Pulmonary vein isolation (ablation) is a treatment for atrial fibrillation because ectopic foci in the pulmonary vein sleeves trigger AF. Pulmonary vein stenosis complicates ablation.

Pupil

- Central round iris aperture for light entry, size controlled by sphincter pupillae (CN III parasympathetic, constricts to 2-3 mm) and dilator pupillae (sympathetic, dilates to 8 mm). The pupillary light reflex tests CN II (afferent) and CN III (efferent): light in one eye causes bilateral constriction (direct and consensual). Argyll Robertson pupils (small, irregular, Accommodate but do not React) suggest neurosyphilis. Fixed dilated pupils may indicate CN III compression from uncal herniation.

Quadriceps Femoris Muscle

- Four-muscle anterior thigh group: rectus femoris, vastus lateralis, vastus medialis, vastus intermedius,

all inserting on the tibial tuberosity via the patellar ligament. Innervated by femoral nerve (L2-L4). Primary knee extensor for walking, running, rising from seated. VMO is important for patellar tracking. Weakness common after knee injury, surgery, and aging.

Radial Artery

- The smaller terminal branch of the brachial artery, arising at the cubital fossa, running laterally along the radius to the wrist (palpable at the anatomical snuffbox) and hand. Supplies the lateral forearm and the thumb side of the hand; forms the deep palmar arch. Clinical importance: radial artery pulse, Allen test (collateral circulation before radial artery cannulation or CABG conduit harvest), arterial blood gas sampling, and coronary angiography access. The radial artery is a preferred conduit for coronary bypass grafting.

Radial Nerve

- From posterior cord (C5-T1), the plexus's largest branch. In the arm runs in the radial groove with the profunda brachii artery, innervating triceps and anconeus. At the elbow divides into superficial (sensory to dorsal hand) and deep (posterior interosseous) branches. Deep branch innervates forearm/hand extensors. Midshaft humeral fracture palsy causes wrist drop with preserved grip strength.

Radius

- Lateral forearm bone in the anatomical position. Proximal end: head, neck, radial tuberosity. Shaft. Distal end: styloid process, articular surfaces. The radial head articulates with the capitulum and ulnar notch, allowing pronation/supination. Bears approximately 80 percent of wrist axial load. Colles' fracture (distal radius with dorsal displacement) is among the most common fractures.

Rectus Abdominis Muscle

- Long flat vertical anterior abdominal wall muscle from pubic symphysis to xiphoid process/costal cartilages 5-7, divided by tendinous intersections ("six-pack"). Innervated by T7-T12. Flexes trunk, compresses abdomen, increases intra-abdominal pressure. Diastasis recti common in pregnancy/obesity. Common TRAM flap donor site for breast reconstruction.

Reflex Arc

- The neural pathway that mediates a reflex ac-

tion, bypassing conscious brain processing for rapid, automatic responses. A reflex arc consists of five components: (1) Receptor—sensory nerve ending detecting a stimulus (e.g., pain, stretch). (2) Sensory (afferent) neuron—carries the signal from the receptor to the spinal cord (dorsal root ganglion). (3) Integration center—a single synapse (monosynaptic reflex, e.g., patellar reflex) or multiple interneurons (polysynaptic reflex, e.g., withdrawal reflex) within the spinal cord gray matter. (4) Motor (efferent) neuron—carries the signal from the spinal cord to the effector organ. (5) Effector—muscle or gland that executes the response. Examples: monosynaptic—stretch reflex (patellar reflex, testing L3–L4 nerve root). Polysynaptic—flexor withdrawal reflex (pain causes limb withdrawal), crossed extensor reflex (opposite limb extends to maintain posture), and superficial reflexes (abdominal, cremasteric, plantar—Babinski sign). The reflex arc is the functional unit of the nervous system and is assessed in the neurological examination to localise lesions.

Renal Cortex

- Outer kidney portion between capsule and medulla. Granular tissue with glomeruli, convoluted tubules, and cortical collecting ducts. Extends between pyramids as renal columns. Receives approximately 90 percent of renal blood flow; primary filtration site. Cortical nephrons (85 percent) have cortical glomeruli; juxtamedullary (15 percent) are near the corticomedullary junction. Essential for GFR regulation and erythropoietin production.

Renal Medulla

- Inner kidney with 8-18 renal pyramids containing loops of Henle, vasa recta, and medullary collecting ducts in countercurrent arrangement for urine concentration. Pyramid bases face cortex; apices (papillae) project into minor calyces. Lower blood flow (approximately 10 percent) and higher osmolality (up to 1200 mOsm/kg at papillary tip). Corticomedullary gradient is critical for ADH-mediated water reabsorption. More susceptible to ischemic injury than cortex.

Reticular Formation

- A network of interconnected nuclei in the brainstem (midbrain, pons, medulla) that regulates arousal, consciousness, sleep-wake transitions, and alertness

(ascending reticular activating system), as well as muscle tone, posture, cardiovascular and respiratory control (vasomotor and respiratory centers), pain modulation, and attention. Damage to the ARAS causes coma or reduced consciousness; certain sedatives and anesthetics act here. Collateral projections from sensory pathways activate the ARAS.

Retina

- Innermost eye layer, a thin neural tissue layer lining the posterior two-thirds of the globe for phototransduction (light to neural signals). Ten layers, with photoreceptors (rods for low-light vision, cones for color vision) in the outer nuclear layer. Macula lutea is the central high-acuity area; fovea centralis has the highest cone density and sharpest vision. Supplied by the central retinal artery; drained by the central retinal vein. Conditions: retinal detachment, diabetic retinopathy, age-related macular degeneration (ARMD), retinal vein occlusion, and retinitis pigmentosa.

Retroperitoneum

- Space posterior to the peritoneum. Primary retroperitoneal (never intraperitoneal): kidneys, adrenals, ureters, aorta, IVC. Secondary (originally intraperitoneal): duodenum 2nd-4th parts, pancreas head/body, ascending/descending colon. Divided into anterior pararenal, perirenal, and posterior pararenal spaces. Contains retroperitoneal fibrosis, hematomas, and tumors.

Rib

- One of 12 paired, curved bones forming the thoracic cage, protecting the heart, lungs, and great vessels. True ribs (1–7) attach directly to the sternum via costal cartilage. False ribs (8–10) attach indirectly to the sternum via the costal cartilage of rib 7. Floating ribs (11–12) have no anterior attachment. Each rib has a head, neck, tubercle, shaft, and costal groove (housing the intercostal neurovascular bundle). Intercostal muscles occupy the spaces between ribs and are essential for respiration. Rib fractures are common and can cause pneumothorax or haemothorax.

Right Atrium

- Receives deoxygenated blood from superior vena cava, inferior vena cava, and coronary sinus. Smooth posterior part (sinus venosus) and rough anterior auricle with pectinate muscles. The fossa ovalis

is the fetal foramen ovale remnant. The SA node pacemaker is near the superior vena cava opening. Contracts to fill the right ventricle through the tricuspid valve.

Right Hypochondriac Region

– One of nine abdominal regions in the upper right abdomen, bounded medially by the right midclavicular line and superiorly by the right costal margin. Contains the cecum, appendix, ascending colon, and inferior right liver lobe. Pain here may indicate appendicitis (McBurney's point), cecal pathology, or hepatic disease. Important for assessing hepatomegaly and gallbladder referred pain.

Right Iliac Region

– Lower right abdomen containing the cecum, appendix, and terminal ileum. McBurney's point (junction of lateral and middle thirds from umbilicus to ASIS) is critical for appendicitis diagnosis. Also significant for evaluating inguinal and femoral hernias, and the right ureter's course.

Right Lymphatic Duct

– Short lymphatic vessel (approximately 1.5 cm) draining lymph from the right upper quadrant: right arm, right side of the head and neck, and right thorax. Formed by the junction of right jugular, subclavian, and bronchomediastinal trunks, emptying into the right venous angle (junction of right internal jugular and subclavian veins). Blockage may cause right-sided chylothorax, though this is less common than left-sided from thoracic duct injury.

Right Ventricle

– Receives deoxygenated blood from the right atrium through the tricuspid valve, pumping into the pulmonary trunk via the pulmonary valve. Thinner walls (3–5 mm) than the left ventricle due to low pulmonary resistance. Features: trabeculae carneae, 3 papillary muscles with tricuspid chordae tendineae, moderator band with right bundle branch. Pressure overload from pulmonary hypertension causes hypertrophy and failure.

Sacroiliac Joint

– The synovial joint between the sacrum and the ilium (auricular surfaces), forming the connection between the axial skeleton and the pelvis. The sacroiliac joint is reinforced by strong ligaments (anterior, interosseous, and posterior sacroiliac ligaments, sacrotuberous and sacrospinous ligaments).

It has limited mobility (2–4 degrees of rotation, 1–2 mm of translation) and functions primarily to transmit weight from the upper body to the lower limbs and provide stability. Sacroiliac joint dysfunction (sacroiliitis) is a common cause of low back pain, often referred to the buttock, groin, and posterior thigh. Causes: inflammatory (ankylosing spondylitis, psoriatic arthritis, reactive arthritis, inflammatory bowel disease-associated arthropathy), degenerative (osteoarthritis), pregnancy and postpartum (hormonally-mediated ligamentous laxity), trauma, and infection (septic arthritis, rare). Diagnosis: clinical examination (FABER test, Gaenslen sign, compression/distraction), imaging (X-ray, CT, MRI with STIR sequences for inflammation), and diagnostic intra-articular injection. Treatment: physiotherapy (core strengthening, pelvic stabilisation), NSAIDs, local corticosteroid injection, and radiofrequency ablation for refractory pain.

Sacrum

– Large triangular bone from 5 fused sacral vertebrae between the hip bones. Articulates with L5 superiorly and coccyx inferiorly. The sacral promontory is an obstetric landmark. Contains 4 pairs of sacral foramina. Forms the posterior pelvic wall. Sacroiliac joints are important for force transmission between spine and lower limbs.

Salivary Glands

– Exocrine glands that produce saliva. Three pairs of major salivary glands: parotid glands (largest, located preauricularly, secrete serous saliva via Stensen duct), submandibular glands (located in the submandibular triangle, secrete mixed serous and mucous saliva via Wharton duct), and sublingual glands (smallest, located in the floor of the mouth, secrete predominantly mucous saliva via multiple ducts of Rivinus). Numerous minor salivary glands (600–1000) are scattered throughout the oral mucosa, palate, pharynx, and lips. Saliva (1–1.5 L/day) contains water (99%), electrolytes, amylase (starch digestion), mucus (lubrication), lysozyme and IgA (antimicrobial), and lingual lipase (fat digestion). Salivary secretion is controlled by the autonomic nervous system: parasympathetic (CN VII and IX—profuse, watery secretion) and sympathetic (scanty, viscous secretion).

Scaphoid

- Largest proximal carpal row bone on the radial wrist side. Most commonly fractured carpal bone from falls on an outstretched hand. Unique distal blood supply makes waist fractures prone to proximal fragment avascular necrosis. Anatomical snuffbox tenderness is characteristic. Initial radiographs may be negative, requiring repeat imaging or MRI.

Scapula

- Flat triangular bone on the posterior thorax between ribs 2-7. Key features: acromion, coracoid process, glenoid cavity, spine, supraspinous/infraspinous fossae. Stabilized by 17 muscles and serves as rotator cuff attachment. Has 3 borders, 3 angles, and 2 surfaces. Fractures are uncommon, usually from high-energy trauma.

Sciatic Nerve

- Body's largest nerve (L4-S3), formed from the lumbosacral plexus, exiting via the greater sciatic foramen below the piriformis. Descends in the posterior thigh, dividing into tibial and common peroneal nerves at the popliteal fossa. Innervates hamstrings and provides lower leg/foot motor/sensory innervation via its branches. Sciatica is pain radiating along its distribution, commonly from L4-L5 or L5-S1 disc herniation.

Sclera

- Dense fibrous opaque outer eye coat providing structural integrity and extraocular muscle attachment. White, covering approximately five-sixths of the globe. Continuous with cornea anteriorly (limbus) and dura mater posteriorly through the optic nerve sheath. May appear yellowish in elderly or with jaundice (icterus). Scleritis (inflammation) is associated with autoimmune diseases like rheumatoid arthritis and may be sight-threatening.

Scrotum

- Pouch of skin and superficial fascia containing the testes, epididymides, and lower spermatic cords. The scrotal wall has multiple layers reflecting the abdominal wall layers. The dartos muscle (smooth muscle in the superficial fascia) and cremaster muscle (skeletal muscle from the internal oblique) regulate testicular temperature by contracting (bringing testes closer to the body in cold) or relaxing (lowering them in warmth). The scrotum is divided by a median septum into two compartments, each

containing one testis with its epididymis and the lower portion of the spermatic cord.

Sebaceous Glands

- Holocrine glands associated with hair follicles (pilosebaceous units) secreting sebum (triglycerides, wax esters, squalene, cholesterol). Lubricate and waterproof skin/hair, have antimicrobial properties (fatty acids), and maintain skin barrier function. Most numerous on the face and scalp. Hyperactivity contributes to acne vulgaris; hypoactivity causes dry skin. Stimulated by androgens (explaining puberty acne). Fordyce spots are ectopic glands on oral mucosa and genitalia.

Semicircular Canals

- Three fluid-filled (endolymph) loops in each inner ear, oriented approximately orthogonally to detect angular (rotational) acceleration in three planes: horizontal (lateral), anterior (superior), and posterior. Each has an ampulla with a crista containing hair cells embedded in a gelatinous cupula. Head rotation deflects the cupula, bending stereocilia and stimulating hair cells. Horizontal canal excitatory direction is ampullopetal flow. BPPV results from displaced otoconia entering the canals, causing benign paroxysmal positional vertigo with brief episodes of spinning provoked by head movement.

Seminal Vesicle

- Paired accessory sex glands posterior to the bladder that secrete a fructose-rich, alkaline seminal fluid (approximately 60-70 percent of semen volume) providing energy for sperm and neutralizing vaginal acidity. Ducts join the vas deferens to form the ejaculatory duct, emptying into the prostatic urethra. Seminal fluid contains prostaglandins, seminal vesicle-specific antigen (SVSA), and fibrinogen. Absence or dysfunction causes low-volume ejaculate and male infertility. Seminal vesicle involvement by prostate cancer (T3b) worsens prognosis.

Seminal Vesicles

- Paired lobulated glands behind the bladder and anterior to the rectum, each approximately 5 cm long, producing approximately 60-70 percent of seminal volume. The secretion is alkaline (neutralizing vaginal acidity), rich in fructose (energy source for sperm), prostaglandins (stimulating female reproductive tract contractions), and clotting proteins (causing semen coagulation after ejaculation). Each

seminal vesicle duct joins the vas deferens to form the ejaculatory duct. Seminal vesicle pathology (infection, cysts, or invasion by prostate cancer) may affect ejaculate volume, cause haemospermia, and impair male fertility.

Serratus Anterior Muscle

- Fan-shaped muscle from ribs 1-8/9 to the medial scapular border. Innervated by long thoracic nerve (C5-C7). Protracts scapula, upwardly rotates glenoid for overhead elevation, stabilizes against thorax. Long thoracic nerve injury causes medial scapular winging, especially visible during wall push-ups. Commonly injured in breast surgery.

Sigmoid Colon

- S-shaped segment from descending colon to rectum in the left iliac fossa, approximately 40-50 cm, with complete mesentery (intraperitoneal, mobile). Most common diverticular disease site from narrow lumen and high pressure. Common volvulus site, particularly in elderly/institutionalized patients. Second most common colorectal cancer site. Transition between water-absorbing colon and rectal storage.

Sinuses

- Air-filled cavities within the skull bones lined by respiratory mucosa, connected to the nasal cavity via ostia. Four paired paranasal sinuses: maxillary (largest, in maxilla, drains to middle meatus), frontal (in frontal bone, drains to middle meatus), ethmoid (3-18 cells in ethmoid bone, anterior/middle/posterior groups), sphenoid (in sphenoid bone, drains to sphenoethmoidal recess). Functions: lighten skull, resonate voice, humidify air, crumple zones for trauma. Conditions: sinusitis (acute/chronic), mucocele, polyps, fungal sinusitis, osteomeatal complex obstruction.

Skin

- The largest organ of the body (approximately 1.5–2 m²), forming a protective barrier against physical injury, pathogens, UV radiation, and water loss. Layers: epidermis (stratified squamous epithelium, keratinocytes, melanocytes, Langerhans cells, Merkel cells), dermis (connective tissue with collagen and elastin fibers, blood vessels, nerves, hair follicles, sweat and sebaceous glands), and hypodermis (subcutaneous fat). Functions: thermoregulation (sweating, vasodilation/vasoconstriction), sensation (touch, pain, temperature), vitamin D synthesis,

immune surveillance. Common diseases: dermatitis, psoriasis, skin cancer (basal cell, squamous cell, melanoma), acne, infections.

Skull

- Bony framework of the head with 22 bones: cranium (8: frontal, 2 parietal, 2 temporal, occipital, sphenoid, ethmoid) and facial (14). Joined by sutures: coronal, sagittal, lambdoid, squamous. The skull base has foramina for cranial nerves and vessels. Protects the brain and provides attachment for muscles of mastication and facial expression.

Small Intestine

- Longest GI segment (approximately 6 meters) from pylorus to ileocecal valve. Primary nutrient digestion and absorption site. Three segments: duodenum (25 cm, chyme/bile/pancreatic enzymes), jejunum (2.5 m, prominent folds/villi for absorption), ileum (3.5 m, Peyer's patches for immunity). Specialized for absorption via plicae circulares, villi, and microvilli. Ileocecal valve prevents colonic back-flow.

Soleus Muscle

- Broad flat deep posterior leg muscle from posterior tibia, fibula, and tendinous arch to the calcaneus via the Achilles tendon. Innervated by tibial nerve (S1-S2). Powerful ankle plantarflexor, the primary anti-gravity muscle for upright posture. One-joint muscle. High slow-twitch fiber proportion for fatigue-resistant sustained postural activities and walking.

Sphenoid Bone

- Butterfly-shaped bone at the skull base, with body (sphenoid sinuses), greater/lesser wings, and pterygoid processes. The sella turcica houses the pituitary gland. Important foramina include the optic canal (CN II, ophthalmic artery), superior orbital fissure (CN III, IV, V1, VI), foramen rotundum (V2), ovale (V3), and spinosum (middle meningeal artery). Articulates with most cranial bones.

Spinal Cord

- The cylindrical bundle of nerve fibers extending from the medulla oblongata (at the foramen magnum) to the conus medullaris (L1–L2 in adults), surrounded by the vertebral column and meninges (dura mater, arachnoid mater, pia mater). The spinal cord is divided into 31 segments: 8 cervical, 12 thoracic, 5 lumbar, 5 sacral, and 1 coccygeal. Each

segment gives rise to a pair of spinal nerves (dorsal root—sensory, ventral root—motor). Internal structure: central gray matter (butterfly-shaped—dorsal horn: sensory; ventral horn: motor; lateral horn: autonomic) surrounded by white matter (ascending tracts—spinothalamic, dorsal columns, spinocerebellar; descending tracts—corticospinal, reticulospinal, vestibulospinal). The spinal cord conducts sensory information from the periphery to the brain, carries motor commands from the brain to muscles, and mediates spinal reflexes (stretch, withdrawal). Spinal cord injury causes paralysis, sensory loss, and autonomic dysfunction below the level of the lesion.

Spine

- See Spinal Cord and Vertebral Column.

Spleen

- Largest lymphoid organ in the left upper quadrant under ribs 9-11, approximately 12 cm long and 150-200 g. Red pulp filters blood (removing old/damaged RBCs and platelets); white pulp mounts immune responses (lymphoid follicles and periarteriolar lymphoid sheaths). Enclosed by a fibroelastic capsule with trabeculae. Connected to the stomach by the gastrosplenic ligament. The splenic hilum is where vessels enter and exit. Asplenia (congenital or surgical) increases infection risk from encapsulated bacteria, particularly *Streptococcus pneumoniae*, *Neisseria meningitidis*, and *Haemophilus influenzae*.

Spleen Hilum

- Concave medial surface where the tortuous splenic artery (celiac trunk branch) enters and splenic vein exits, with lymphatics and nerves. Artery divides into 5 segmental branches at the hilum (basis for partial splenectomy). Splenic vein joins the superior mesenteric vein forming the portal vein. Attaches the splenorenal ligament containing vessels and pancreatic tail. Pancreatic pathology may involve splenic vessels here.

Sternocleidomastoid Muscle

- Strap-like anterior neck muscle from manubrium and medial clavicle to the mastoid process. Innervated by CN XI and C2-C3. Divides neck into anterior/posterior triangles. Unilaterally: laterally flexes to opposite side, rotates face to same side. Bilaterally: flexes neck, assists forced inspiration. Key examination landmark; commonly affected by

congenital torticollis.

Sternum

- Flat bone in the anterior midline thorax, with manubrium, body, and xiphoid process. The sternal angle (of Louis) at the manubriosternal junction is a key landmark at the 2nd costal cartilage, T4-T5, and tracheal bifurcation. Common site for bone marrow biopsy. Median sternotomy is the standard cardiac surgical approach.

Stomach

- J-shaped muscular organ in the left upper quadrant, connecting esophagus to duodenum. Regions: cardia, fundus, body, antrum, pylorus. Functions: food storage, mechanical churning, chemical digestion (pepsin, HCl), intrinsic factor secretion (B12 absorption). Mucosa has rugae (folds) allowing expansion. Blood supply: celiac trunk branches (left/right gastric, left/right gastroepiploic, short gastric). Venous drainage to portal system. Nerve supply: vagus (parasympathetic), celiac plexus (sympathetic). Conditions: gastritis, peptic ulcer, gastric cancer, gastroparesis, obstruction.

Subclavian Artery

- The artery supplying the upper limb, arising on the right from the brachiocephalic trunk and on the left directly from the aortic arch, passing over the first rib and becoming the axillary artery. Branches: vertebral, internal thoracic, thyrocervical trunk, costocervical trunk. The subclavian is a site of central venous/arterial access (subclavian line) and is compressed in thoracic outlet syndrome and by cervical ribs. Occlusion causes upper limb ischemia; subclavian steal syndrome (vertebral reversal) causes vertebrobasilar symptoms with arm exercise.

Submandibular Gland

- One of the three paired major salivary glands, located in the submandibular triangle beneath the mandible. Mixed gland (predominantly serous) secreting saliva via Wharton's duct opening at the sublingual caruncle (floor of mouth). Saliva contains amylase, mucins, lysozyme, IgA. Submandibular stones (sialolithiasis) are common (Wharton's duct is long and gravity-dependent); causes painful swelling with eating. Enlargement on palpation bimanually. Blood supply: facial and lingual arteries; innervation: parasympathetic via chorda tympani/submandibular ganglion.

Superior Mesenteric Artery

- Second major abdominal aortic branch at L1, the midgut artery. Supplies distal duodenum through proximal two-thirds of transverse colon. Branches: inferior pancreaticoduodenal, jejunal, ileal, ileocolic, right colic, middle colic. Arises anterior to the pancreatic uncinate process, crosses the third duodenal part. Occlusion causes acute mesenteric ischemia with severe pain disproportionate to examination. SMA syndrome compresses the duodenum.

Superior Vena Cava

- Formed by brachiocephalic vein junction at the first right costal cartilage, returning upper body deoxygenated blood to the right atrium. Approximately 7 cm, valveless. Related to right lung/pleura, right phrenic nerve, and azygos vein. SVC syndrome from compression (commonly lung cancer) causes facial swelling, plethora, and upper extremity edema.

Synovium

- The inner layer of the joint capsule in synovial joints, composed of synovial lining cells (type A macrophage-like, type B fibroblast-like) on a vascularized connective tissue base. Produces synovial fluid (hyaluronic acid, lubricin, proteinases) for lubrication and chondrocyte nutrition. Two layers: intimal (1-3 cells thick) and subintimal (vascularized connective tissue). Inflammation (synovitis) causes joint swelling, pain, and destruction in rheumatoid arthritis, gout, infection.

Talus

- Second largest tarsal bone articulating with tibia/fibula proximally at the ankle. Approximately 60 percent of its surface is articular cartilage with no muscular attachments. Transmits entire body weight to the calcaneus. Talar neck fractures may disrupt blood supply causing avascular necrosis in up to 50 percent. Also participates in the subtalar joint for inversion/eversion.

Tarsus

- The collection of seven bones forming the posterior part of the foot, between the tibia/fibula and the metatarsals. The tarsal bones: talus (articulates with tibia and fibula at the ankle joint), calcaneus (heel bone—largest tarsal bone, insertion of Achilles tendon), navicular (medial midfoot), cuboid (lateral midfoot), and three cuneiforms (medial, intermediate, lateral—articulate with the metatarsals). The

tarsus transmits body weight from the leg to the foot, provides a flexible arch, and permits inversion/eversion movements at the subtalar and midtarsal joints. Tarsal coalition (congenital fusion of two or more tarsal bones—calcaneonavicular and talocalcaneal most common) causes peroneal spastic flatfoot and limited subtalar motion. Tarsal tunnel syndrome: compression of the posterior tibial nerve beneath the flexor retinaculum (medial ankle), causing burning pain, paraesthesia, and numbness on the plantar surface of the foot.

Temporal Bones

- Paired bones forming the cranial floor and lateral wall, with squamous, petrous, mastoid, tympanic, and styloid parts. Contain the external auditory canal, middle and inner ear, and foramina: carotid canal (internal carotid), jugular foramen (CN IX-XI, IJV), and foramen lacerum. Fractures may cause hearing loss, facial nerve palsy, and CSF otorrhea.

Temporomandibular Joint

- Synovial ginglymoarthrodial joint between mandibular condyle and temporal bone's mandibular fossa, separated by an articular disc. Only bilateral body joint, allowing hinge and sliding movements. Disc divides into superior/inferior compartments. Temporomandibular disorders cause pain, clicking, limited movement, common with bruxism.

Tendon

- Dense regular connective tissue connecting muscle to bone, composed primarily of type I collagen fibers arranged in parallel bundles. Transmits muscle force to bone to produce movement. Poor vascularity (slower healing). Enclosed in tendon sheath (synovial) at friction points. Common injuries: tendinitis (inflammation), tendinosis (degeneration), rupture (Achilles, rotator cuff, biceps). Examples: Achilles tendon (gastrocnemius/soleus to calcaneus), patellar tendon (quadriceps to tibial tuberosity), rotator cuff tendons.

Testis (Testicle)

- The male gonad, a paired ovoid organ (4–5 cm × 2–3 cm, weight 15–20 g) located in the scrotum, responsible for sperm production (spermatogenesis) and testosterone secretion. Each testis is covered by the tunica vaginalis (peritoneal remnant) and tunica albuginea (dense fibrous capsule). Internally: 200–300 lobules, each containing 1–4 seminiferous

tubules (site of spermatogenesis—60–70 days), lined by Sertoli cells (support, nourishment, and regulation of spermatogenesis; produce inhibin B, anti-Müllerian hormone) and containing germ cells (spermatogonia → primary spermatocytes → secondary spermatocytes → spermatids → spermatozoa). Leydig cells (interstitial cells) in the connective tissue between tubules produce testosterone (regulated by LH). The testis develops in the abdomen and descends into the scrotum at 28–32 weeks gestation under the influence of androgens, guided by the gubernaculum. Undescended testis (cryptorchidism) increases the risk of infertility and testicular cancer. The testis is innervated by the genitofemoral nerve (L1–L2) and supplied by the testicular artery.

Thalamus

– Bilateral ovoid gray matter structure forming the third ventricle's lateral walls, the brain's relay station for nearly all sensory (except olfaction), motor, and limbic information to the cortex. Numerous nuclei: VPL (spinothalamic, dorsal column), VPM (trigeminal), LGN (visual), MGN (auditory), VL/VA (motor). Lesions cause contralateral sensory loss, Dejerine-Roussy thalamic pain syndrome, and cognitive impairment.

Thoracic Duct

– Body's largest lymphatic vessel, approximately 40 cm long, draining lymph from the entire body below the diaphragm and left side above it (approximately 75 percent of total lymph). Begins at the cisterna chyli (abdominal lymphatic sac) at the L1–L2 level, ascends through the aortic hiatus, through the posterior mediastinum between the aorta and azygos vein, and empties into the junction of the left internal jugular and left subclavian veins. Blocked or damaged thoracic duct causes chylothorax (leakage of chyle into the pleural space), typically on the left side, manifesting as a milky pleural effusion rich in triglycerides.

Thoracic Vertebrae (T1–T12)

– Have costal facets on bodies and transverse processes for rib articulation. Heart-shaped bodies, long downward spinous processes, coronally-oriented facets allowing rotation and lateral flexion but limiting flexion/extension. Small circular vertebral foramen. Most rigid vertebral region due to the rib cage, least affected by disc herniations.

Thymus

– Primary lymphoid organ in the anterior mediastinum, largest in childhood, involutes with age. Site of T-cell maturation (thymopoiesis): thymocytes undergo positive and negative selection to produce self-tolerant, MHC-restricted T cells. Epithelial cells produce thymic hormones (thymosin, thymopoietin). Blood supply: internal thoracic arteries. Conditions: thymoma, myasthenia gravis, DiGeorge syndrome, thymic hyperplasia, thymic carcinoma.

Thymus Gland

– A bilobed lymphoid organ located in the superior mediastinum, posterior to the sternum and anterior to the great vessels. The thymus is the primary lymphoid organ for T-cell development and maturation. It is largest relative to body size in infancy (weighs 20–30 g at birth), continues to grow until puberty (peak 30–40 g), then progressively involutes with age, replaced by adipose tissue (involution—60–80% loss by age 50). Structure: each lobe is divided into lobules by fibrous septa; each lobule has an outer cortex (immature T-lymphocytes / thymocytes, epithelial reticular cells, macrophages) and an inner medulla (mature T-cells, Hassall corpuscles—concentric whorls of epithelial cells, site of negative selection). T-cell development: bone marrow-derived lymphoid progenitors enter the thymus at the corticomedullary junction, undergo positive selection (cortex—T-cells with functional T-cell receptors that recognise self-MHC molecules are retained) and negative selection (medulla—T-cells that react strongly with self-antigens are deleted by apoptosis, mediated by AIRE gene expression), producing a self-tolerant, self-MHC-restricted T-cell repertoire. Disorders: thymic hyperplasia (myasthenia gravis—associated with thymoma or hyperplasia), thymoma (benign or malignant epithelial tumor, associated with autoimmune diseases—myasthenia gravis, pure red cell aplasia, hypogammaglobulinaemia), DiGeorge syndrome (22q11.2 deletion—thymic aplasia/hypoplasia, T-cell deficiency, recurrent infections).

Thyroid Gland

– An endocrine gland located in the anterior neck, consisting of two lobes (right and left) connected by an isthmus, lying anterior to the trachea between the

cricoid cartilage and the suprasternal notch. The thyroid produces tri-iodothyronine (T_3) and thyroxine (T_4)—iodinated tyrosine derivatives that regulate metabolism, growth, and development—and calcitonin (produced by parafollicular/C-cells, regulates calcium metabolism). Thyroid hormone synthesis: iodide is actively transported into follicular cells (NIS/sodium-iodide symporter), oxidised by thyroid peroxidase (TPO), and iodinated to tyrosine residues on thyroglobulin (Tg) to form MIT and DIT, which couple to form T_3 and T_4 . Secretion is regulated by the hypothalamic–pituitary–thyroid axis (TRH → TSH → thyroid hormone → negative feedback). Disorders: hyperthyroidism (Graves disease, toxic nodular goitre, thyroiditis), hypothyroidism (Hashimoto thyroiditis, iodine deficiency, post-surgical/radioiodine), thyroid nodules and thyroid cancer (papillary—most common, follicular, medullary, anaplastic), goitre, and thyroiditis. The thyroid gland develops from the foramen cecum at the base of the tongue (week 4 of gestation) and descends to its final position; thyroglossal duct remnants can form midline neck cysts.

Tibia

– Larger leg bone, the main weight-bearer transmitting body weight from knee to ankle. Proximal: tibial plateau (medial/lateral condyles) and tibial tuberosity (patellar ligament insertion). Shaft: sharp subcutaneous anterior border. Distal: medial malleolus articulating with the talus at the ankle. Tibial plateau fractures are common in high-energy trauma.

Tibialis Anterior Muscle

– Superficial anterior leg muscle from lateral tibial condyle and shaft to medial cuneiform and first metatarsal base. Innervated by deep peroneal nerve (L4–L5). Primary dorsiflexor for foot clearance during gait swing phase; inverts foot. Weakness causes foot drop with steppage gait. Commonly affected by anterior compartment syndrome and shin splints.

Tibialis Posterior Muscle

– Deepest posterior leg muscle from posterior tibia, fibula, and interosseous membrane to navicular tuberosity, medial cuneiform, and sustentaculum tali. Innervated by tibial nerve (L4–L5). Plantarflexes and inverts foot; primary dynamic medial longitudinal arch stabilizer. Dysfunction causes

adult-acquired flatfoot with arch flattening, hind-foot valgus, and medial ankle pain.

Tibial Nerve

– Sciatic division (L4–S3) continuing from posterior thigh through the popliteal fossa into the deep posterior leg, innervating gastrocnemius, soleus, tibialis posterior, flexor digitorum longus, and flexor hallucis longus. Passes behind the medial malleolus as the tarsal tunnel, dividing into medial/lateral plantar nerves for the foot. Sensation to the sole. Tarsal tunnel syndrome causes burning pain and paresthesias in the sole.

Tonsils

– Aggregated lymphoid tissue forming Waldeyer’s ring at the pharyngeal entrance. Pharyngeal tonsils (adenoids) in the nasopharynx, palatine tonsils at the oropharyngeal pillars, lingual tonsils at the tongue base, and tubal tonsils near the Eustachian tube orifices. They are the first line of defense against inhaled or ingested pathogens. Palatine tonsils are most commonly infected (tonsillitis) and surgically removed (tonsillectomy) for recurrent infections or obstructive sleep apnoea. The tonsils are part of Waldeyer’s ring, a protective lymphoid barrier at the pharyngeal inlet that samples inhaled and ingested antigens, with maximal activity in early childhood.

Trachea

– The windpipe, a 10–12 cm fibrocartilaginous tube from the larynx (C6) to the carina (T4/T5) where it bifurcates into main bronchi. Sixteen to twenty C-shaped hyaline cartilage rings (open posteriorly, completed by trachealis muscle) maintain patency. Lined by ciliated pseudostratified columnar epithelium with goblet cells (mucociliary escalator). Relations: thyroid isthmus (anterior), esophagus (posterior), recurrent laryngeal nerves (tracheoesophageal groove). Blood supply: inferior thyroid arteries. Conditions: tracheitis, tracheal stenosis, tracheomalacia, tracheoesophageal fistula, tracheostomy.

Transverse Colon

– Longest, most mobile colonic segment from hepatic to splenic flexure, approximately 45 cm, with complete mesentery (transverse mesocolon). Crosses anterior to duodenum, pancreas, and major vessels. Splenic flexure is the highest colon point and common gas trapping site. Most common diverticular

disease site along with the sigmoid.

Transversus Abdominis Muscle

- Deepest flat abdominal muscle with horizontal fibers, from inguinal ligament, iliac crest, thoracolumbar fascia, and inner lower six costal cartilages. Innervated by T7-T12 and L1. Compresses abdomen without trunk movement, providing core stability and increased intra-abdominal pressure during coughing, lifting, Valsalva. Key for core stability exercises and low back pain rehabilitation.

Trapezium

- Saddle-shaped distal row carpal bone on the radial side, articulating with the first metacarpal at the CMC joint of the thumb. This saddle joint allows thumb opposition essential for grip and fine motor function. Basal joint arthritis is common in postmenopausal women, causing pinch grip pain and weakness.

Trapezius Muscle

- Large triangular muscle from occipital bone and C7-T12 spinous processes to clavicle, acromion, and scapular spine. Innervated by CN XI and C3-C4. Upper fibers elevate scapula, middle fibers retract, lower fibers depress. Essential for shoulder stability and scapulothoracic motion. CN XI injury causes scapular winging and difficulty with abduction above 90 degrees.

Trapezoid

- Smallest distal row carpal bone between trapezium and capitate, articulating with the second metacarpal. Wedge shape provides stability for the firmly fixed second metacarpal. Fractures rare (less than 1 percent of carpal fractures). Contributes to the radial column wrist stability.

Triceps Brachii Muscle

- Three-headed posterior arm muscle. Long head from infraglenoid tubercle, lateral head from posterior humerus above radial groove, medial head below. All insert on the olecranon. Innervated by radial nerve (C7-C8). Primary elbow extensor; assists shoulder extension/adduction. Triceps reflex (C7) tests radial nerve/spinal cord integrity.

Tricuspid Valve

- Right atrioventricular valve with anterior, posterior, and septal cusps supported by chordae tendineae and three papillary muscles. Largest cardiac valve. Most commonly affected in IV drug use-associated

endocarditis. Tricuspid regurgitation from right ventricular dilation, endocarditis, or carcinoid. Stenosis is rare, mostly rheumatic. Thinner and more delicate than the mitral valve.

Trigeminal Nerve

- Cranial nerve V (CN V), the largest cranial nerve, providing sensory innervation to the face and anterior scalp (ophthalmic V_1 , maxillary V_2 , mandibular V_3 divisions) and motor innervation to the muscles of mastication (masseter, temporalis, medial and lateral pterygoids, tensor veli palatini, tensor tympani, mylohyoid, anterior belly of digastric). The trigeminal nerve emerges from the lateral pons as a large sensory root (trigeminal ganglion/semilunar/Gasserian ganglion in Meckel cave) and a smaller motor root. Sensory distribution: V_1 (ophthalmic)—forehead, scalp, upper eyelid, cornea, nasal tip; V_2 (maxillary)—cheek, lower eyelid, side of nose, upper lip, upper teeth and gums, palate; V_3 (mandibular)—lower lip, chin, lower teeth and gums, anterior two-thirds of tongue (general sensation), floor of mouth, temporal region. Motor: V_3 supplies the muscles of mastication, tensor veli palatini, tensor tympani, mylohyoid, and anterior belly of digastric. Reflexes: corneal reflex (afferent V_1 , efferent CN VII), jaw jerk (afferent and efferent V_3 —monosynaptic). Lesions: trigeminal neuralgia (V_2/V_3), trigeminal schwannoma, cavernous sinus syndrome, and brainstem stroke.

Triquetrum

- Pyramidal proximal row carpal bone on the ulnar side, articulating with lunate, hamate, pisiform, and TFCC. Second most commonly fractured carpal bone. Contributes to proximal carpal row and ulnar wrist stability. Pisiform articulates with its volar surface.

True Ribs

- Ribs 1-7 articulating directly with the sternum via their own costal cartilages. Each has a head, neck, tubercle, and shaft. The first two are short and strongly curved for neck/shoulder muscle attachment. Costal cartilages provide thoracic cage elasticity for respiratory expansion. Less commonly fractured than false ribs due to shorter length and more protected position.

Tympanic Membrane

- Thin translucent cone-shaped membrane separat-

ing external and middle ear, approximately 10 mm diameter. Three layers: outer cutaneous, middle fibrous, inner mucous. Malleus handle is visible through it. Light reflex (cone of light) in the anteroinferior quadrant indicates normal position. Perforation from trauma, infection (otitis media), or barotrauma. Myringotomy and tympanostomy tube placement treat chronic otitis media with effusion. Vibrates in response to sound, transmitting energy to the ossicular chain and ultimately to the cochlear fluid for auditory transduction.

Ulna

– Medial forearm bone, longer than the radius. Proximal end: trochlear notch, olecranon, coronoid process. Shaft. Distal end: head, styloid process. The trochlear notch articulates with the trochlea forming the primary elbow hinge. Bears approximately 20 percent of wrist axial load. The olecranon is the bony elbow prominence and triceps insertion. Serves as the forearm rotation axis.

Ulnar Artery

– The larger terminal branch of the brachial artery at the cubital fossa, running medially down the forearm to the wrist (palpable medial to the pisiform) and hand. Supplies the medial forearm and ulnar side of the hand; forms the superficial palmar arch. Provides the common interosseous artery. Clinical: ulnar artery pulse, Allen test for collateral circulation, and ulnar artery cannulation. The ulnar nerve travels with the artery at the wrist (Guyon canal); ulnar artery occlusion causes hypothenar pain and digital ischemia.

Ulnar Nerve

– From medial cord (C8-T1), passing behind the medial epicondyle (cubital tunnel), into the forearm innervating flexor carpi ulnaris and medial FDP half. In the hand innervates hypothenar muscles, interossei, medial two lumbricals, and adductor pollicis. Sensation to medial 1.5 digits. Injury (elbow trauma, Guyon's canal compression) causes claw hand (MCP hyperextension with IP flexion of digits 4-5) and loss of grip/pinch strength.

Umbilical Region

– Central region around the umbilicus containing small intestine, transverse colon, and great vessels. The umbilicus is a landmark for assessing ascites, caput medusae in portal hypertension, and umbil-

ical hernias. Percussion and auscultation here are essential components of the abdominal examination.

Umbilicus (Navel)

– The scar on the anterior abdominal wall marking the site of attachment of the umbilical cord in fetal life, located at the level of the L3-L4 intervertebral disc, approximately midway between the xiphoid process and the pubic symphysis. The umbilicus is a remnant of fetal structures: the umbilical vein (ligamentum teres hepatis, running to the liver), the umbilical arteries (medial umbilical ligaments), and the urachus (median umbilical ligament, running to the bladder apex). It is a common site of hernia (umbilical hernia) and is used as a laparoscopic port entry site (Hasson technique, Veress needle insertion for pneumoperitoneum). Dermatome supply is T10. The aorta is palpable at the level of the umbilicus, and the iliac bifurcation lies at the L4 level, approximately 1 cm below it.

Ureter

– The paired muscular tubes (25-30 cm) conveying urine from the renal pelvis to the urinary bladder, crossing the pelvic brim at the pelvic inlet. Three anatomical narrowings (pelviureteric junction, pelvic brim, vesicoureteric junction) are common sites of ureteric stone impaction. Peristalsis propels urine; valves (oblique intramural passage) prevent reflux. Blood supply: segmental (renal, gonadal, iliac, vesical arteries). Ureteric obstruction (stones, tumor, compression) causes hydronephrosis and renal colic. Ureteroscopy/ureteric stents are used in management.

Urethra

– The tube conveying urine from the bladder to the exterior. Male urethra (18-20 cm): prostatic, membranous, and spongy (penile) parts; carries urine and semen; longer and more tortuous than female. Female urethra (3-4 cm): short, straight, predisposing to ascending urinary tract infections. The external urethral sphincter (striated, voluntary) provides continence; internal sphincter (smooth). Male urethral trauma occurs with pelvic fracture (membranous) and straddle injuries (bulbar). Urethral strictures cause obstructive voiding symptoms.

Uterus

– Hollow muscular organ in the pelvis between the bladder and rectum, approximately 7.5 cm long

in adult females, responsible for menstruation, implantation, and fetal development during pregnancy. Three layers: endometrium (inner mucosa, cyclically shed during menstruation), myometrium (middle smooth muscle layer, contracts during labor), and perimetrium (outer serous coat). The uterus has a fundus (superior portion above the tube openings), body, and cervix (lower portion protruding into the vagina. The cervix has an internal and external os, with the endocervical canal being a common site for cervical cancer screening via smear tests.

Vagina

– Muscular fibromembranous canal extending from the cervix to the vulva, approximately 7-9 cm long in adult females. Functions include receiving the penis during intercourse, serving as the birth canal, and channeling menstrual flow. The vaginal walls have rugae (transverse folds allowing distension) and are lined with stratified squamous epithelium (non-keratinized, responding to estrogen by producing glycogen). Lactobacilli in the vaginal flora metabolize glycogen to lactic acid, maintaining an acidic environment (pH 4-5) that protects against pathogenic colonisation by opportunistic organisms.

Vas Deferens

– Muscular duct (approximately 45 cm long) transporting sperm from the epididymal tail to the ejaculatory duct. It ascends through the spermatic cord, passes through the inguinal canal, enters the pelvis, crosses over the ureter, and joins the seminal vesicle duct to form the ejaculatory duct (in the prostate). The vas deferens has thick smooth muscle walls providing peristaltic propulsion of sperm. It is the structure cut during vasectomy (male sterilization), typically at the scrotal level where it is easily palpable through the scrotal skin, allowing reliable identification and division with minimal morbidity.

Vein

– A blood vessel that carries deoxygenated blood toward the heart (except pulmonary veins, which carry oxygenated blood). Veins have thinner walls and larger lumens than arteries, with less smooth muscle and elastic tissue. Many veins contain one-way valves (especially in the legs) that prevent backflow and assist venous return against gravity. Venous return is facilitated by the skeletal muscle pump, respiratory pump, and cardiac suction. Venous sys-

tem: superficial veins (subcutaneous), deep veins (accompany arteries), and perforating veins (connect superficial and deep systems). Conditions: varicose veins, deep vein thrombosis, chronic venous insufficiency.

Vena Cava

– The two largest systemic veins returning deoxygenated blood to the right atrium. Superior Vena Cava (SVC): formed by brachiocephalic veins, drains head, neck, upper limbs, thorax (no valves). Inferior Vena Cava (IVC): formed by common iliac veins at L5, drains abdomen, pelvis, lower limbs (receives hepatic, renal, gonadal, lumbar veins). SVC syndrome: obstruction causes facial/upper body swelling, dyspnea, distended neck veins. IVC filter for PE prevention.

Ventricle

– One of the two lower, thicker-walled chambers of the heart that pump blood out of the heart. The right ventricle pumps deoxygenated blood into the pulmonary artery (low-pressure system); the left ventricle pumps oxygenated blood into the aorta (high-pressure system, generating systemic blood pressure). The left ventricular wall is 3-4 times thicker than the right. The interventricular septum separates the ventricles. Ventricular contraction (systole) ejects blood; ventricular relaxation (diastole) allows filling. Conditions: ventricular hypertrophy, ventricular failure, ventricular septal defect, ventricular tachycardia/fibrillation. Also refers to the four fluid-filled cavities within the brain (two lateral ventricles, third, and fourth ventricles) that produce and circulate cerebrospinal fluid (CSF).

Ventricle (Brain)

– The interconnected system of fluid-filled cavities within the brain producing and containing cerebrospinal fluid: two lateral ventricles (cerebrum), third ventricle (diencephalon), and fourth ventricle (pons/medulla, continuous with the central canal). CSF is produced by the choroid plexus, flows through the interventricular foramina (Monro), cerebral aqueduct (Sylvius), and median/lateral apertures (Magendie/Luschka) to the subarachnoid space. Obstruction (e.g., aqueductal stenosis, tumor) causes hydrocephalus with raised intracranial pressure. Ependymal lining.

Vertebra

– The individual bone of the vertebral column (33 vertebrae: 7 cervical, 12 thoracic, 5 lumbar, 5 sacral fused, 4 coccygeal). Parts: vertebral body, vertebral arch (pedicles, laminae), spinous and transverse processes, articular processes/facets, and vertebral foramen (spinal canal). Regional variations: cervical (transverse foramina, bifid spine), thoracic (costal facets for ribs, long downward spinous processes), lumbar (large bodies). Vertebral bodies articulate via intervertebral discs. Fractures, spondylolisthesis, and disc herniation are common clinical conditions.

Vertebral Column

– 33 vertebrae: 7 cervical, 12 thoracic, 5 lumbar, 5 fused sacral, 4 fused coccygeal. Protects the spinal cord, supports the head/trunk, provides muscle/rib attachment. Each typical vertebra has a body, vertebral arch, and 7 processes. Intervertebral discs (nucleus pulposus/annulus fibrosus) provide cushioning. Four curvatures: cervical lordosis, thoracic kyphosis, lumbar lordosis, sacral kyphosis.

Vestibule

– Central bony labyrinth between cochlea and semicircular canals, containing utricle (horizontal linear acceleration and head tilt detection) and saccule (vertical linear acceleration detection). Each has a macula with hair cells covered by gelatinous membrane embedded with otoconia (calcium carbonate crystals). Forces deflect otoconia, bending stereocilia and generating nerve impulses. The vestibular system works with visual and proprioceptive systems for balance. Vestibular neuritis and labyrinthitis cause acute vertigo, nystagmus, and balance disturbance, while Ménière's disease involves episodic vertigo with tinnitus and hearing loss.

Viscera

– The internal organs of the body, particularly those within the thoracic and abdominal cavities. The thoracic viscera include the heart, lungs, esophagus, trachea, and thymus. The abdominal viscera are divided into the digestive organs (stomach, small intestine, large intestine, liver, gallbladder, pancreas), the urinary organs (kidneys, ureters, bladder), and the reproductive organs (uterus, ovaries in females; prostate, seminal vesicles in males). Visceral pain is poorly localised, vague, and referred to dermatomes that share the same spinal cord level (e.g., cardiac ischemic pain referred to the left arm and jaw, gall-

bladder pain referred to the right shoulder). Visceral peritoneum covers the abdominal organs; the mesentery suspends the intestines and carries blood vessels, lymphatics, and nerves. The viscera receive dual autonomic innervation: sympathetic (fight or flight) and parasympathetic (rest and digest, primarily via the vagus nerve).

Vulva

– External female genitalia, including the mons pubis (fatty mound over the pubic symphysis), labia majora (outer fatty folds covered with hair), labia minora (inner hairless folds), clitoris (erectile tissue homologous to the penis, with the glans being the most sensitive erogenous zone), vestibular glands (Bartholin's glands lubricating the vaginal opening), and the urethral and vaginal openings. The vulva is innervated by the pudendal nerve. Vulvar skin conditions include lichen sclerosus, vulvar intraepithelial neoplasia (VIN), and vulvovaginitis, each presenting with pruritus, irritation, and visible changes to the vulvar skin and mucosa.

Wrist Joint

– Condylodisc synovial joint between distal radius and articular disc proximally and scaphoid/lunate/triquetrum distally. Allows flexion, extension, radial/ulnar deviation, circumduction. The triangular fibrocartilage complex absorbs ulnar side load. Commonly affected by rheumatoid arthritis, osteoarthritis, and traumatic injuries including scaphoid fractures and Colles' fractures.

Zygoma (Zygomatic Bone)

– The cheekbone, a paired, quadrangular bone of the facial skeleton (viscerocranium) that forms the prominence of the cheek and the lateral wall and floor of the orbit. The zygomatic bone articulates with four bones: the maxilla (at the zygomaticomaxillary suture, forming the infraorbital rim), the temporal bone (at the zygomaticotemporal suture, forming the zygomatic arch, which is completed posteriorly by the temporal process of the zygomatic bone and anteriorly by the zygomatic process of the temporal bone), the frontal bone (at the zygomaticofrontal suture, forming the lateral orbital margin), and the sphenoid bone (at the zygomaticosphenoid suture). The zygomatic bone has three surfaces: lateral (facial, for attachment of the zygomaticus major

and minor muscles), orbital (forming the lateral and inferior orbital walls, containing the zygomaticofacial and zygomaticotemporal foramina for the corresponding nerves), and temporal (forming part of the temporal fossa). The zygomatic nerve (branch of V2, maxillary division of the trigeminal nerve) runs through the zygomatic bone, providing sensory innervation. Zygomatic fractures (tripod/trimalar fracture, zygomaticomaxillary complex fracture) are the second most common facial fracture (after nasal bone fractures) and cause flattening of the malar prominence, periorbital ecchymosis, subconjunctival hemorrhage, trismus (from impingement of the coronoid process of the mandible), and infraorbital nerve paraesthesia (numbness of the cheek, upper lip, and lateral nose).

Chapter 2

Anesthesiology

Airway Management

– Airway management encompasses techniques and devices used to maintain ventilation and oxygenation in patients with compromised airways. The modified Mallampati classification predicts difficult laryngoscopy based on oropharyngeal anatomy visible with mouth open: Class I (soft palate, uvula, fauces, pillars visible), Class II (soft palate, uvula, fauces visible), Class III (soft palate and uvula visible), Class IV (only hard palate visible). Other predictors of difficult intubation include reduced mouth opening (less than 3 cm), reduced thyromental distance (less than 6.5 cm), limited neck extension (less than 35 degrees), and obesity; equipment including the difficult airway trolley should be immediately available when difficulty is anticipated.

Anaphylaxis During Anesthesia

– A rare but life-threatening IgE-mediated hypersensitivity reaction, with incidence of 1 in 5,000 to 20,000 anesthetics. Most common triggers are neuromuscular blocking agents (rocuronium, succinylcholine), latex, and antibiotics (vancomycin, piperacillin-tazobactam). Latex allergy is less common with modern latex-free operating rooms. Signs include hypotension, tachycardia, bronchospasm, cutaneous manifestations (urticaria, flushing), and elevated end-tidal CO₂ in the immediate diagnosis and management of anaphylaxis; treatment follows the ABCDE approach with removal of the suspected trigger, administration of 100% oxygen, intravenous fluids, and adrenaline (epinephrine) as the first-line drug at a dose of 50-100 mcg IV titrated to effect; second-line agents include antihistamines and corticosteroids, though their role in acute management is limited.

Anesthesia

– The use of medications to prevent sensation, particularly pain, during medical procedures or surgery. Types: general anesthesia (reversible loss of consciousness and sensation, involving hypnotics, analgesics, and muscle relaxants), regional anesthesia (blocking sensation in a specific body region, e.g., epidural, spinal, brachial plexus block), local anesthesia (numbing a small area, e.g., infiltration, topical), and sedation (reduced consciousness while maintaining airway reflexes and spontaneous ventilation). General anesthesia involves three components: hypnosis (loss of consciousness, propofol, volatile anesthetics), analgesia (pain relief, opioids, ketamine, lidocaine), and muscle relaxation (neuromuscular blocking agents). Monitoring: ECG, BP, SpO₂, end-tidal CO₂, anesthetic gas concentration, and temperature.

Anesthesia for Coagulopathy

– Coagulopathy increases bleeding risk during surgery. Assessment includes history, physical examination, and laboratory tests (INR, PT, aPTT, platelet count, fibrinogen). INR greater than 1.5 or aPTT greater than 1.5 times control increases bleeding risk. Platelet count less than 50,000 for major surgery or less than 100,000 for neurosurgery requires platelet transfusion. Fibrinogen less than 150 mg/dL requires cryoprecipitate or fibrinogen concentrate. Fresh frozen plasma (15 to 20 mL/kg) corrects coagulopathy effectively. Vitamin K (10 mg IV slow push, 30 minutes onset) is used for warfarin reversal. Prothrombin complex concentrate (PCC) is preferred over FFP for urgent reversal (INR correction in 15 minutes). Antifibrinolytics (tranexamic acid 1 g IV) reduce bleeding in trauma and cardiac surgery.

Anesthesia for Epilepsy

– Patients with epilepsy require continuation of antiepileptic drugs perioperatively. Missed doses increase seizure risk. Propofol and benzodiazepines are anticonvulsant. Sevoflurane in high concentrations may lower seizure threshold. Hyperventilation and hypocapnia provoke seizures. Avoid meperidine (normeperidine is proconvulsant). Tramadol lowers seizure threshold. Postoperative pain and sleep deprivation are seizure triggers. Ensure antiepileptic drugs are given on schedule. Status epilepticus requires immediate treatment with benzodiazepines (lorazepam 4 mg IV, midazolam, or diazepam 20 mg IV) and escalation of care.

Anesthesia for Hemophilia

– Hemophilia A (factor VIII deficiency) and Hemophilia B (factor IX deficiency) require factor replacement before surgery. Mild cases: desmopressin (DDAVP 0.3 mcg/kg IV) releases stored factor VIII and von Willebrand factor. Moderate to severe cases: factor concentrate (factor VIII or IX) to achieve 80 to 100 percent factor level. Dosing: factor VIII 40 units/kg raises level by 80 percent; factor IX 50 units/kg raises by 100 percent. Repeat dosing every 12 to 24 hours. Avoid intramuscular injections and intramuscular injections; avoid neuraxial blockade if factor levels are not normalised. Monitor for bleeding postoperatively.

Anesthesia for Neurosurgery

– Neuroanesthesia aims to maintain cerebral perfusion pressure (CPP = mean arterial pressure minus intracranial pressure), optimize brain relaxation, and minimize secondary brain injury. Induction agents (propofol, etomidate) reduce cerebral metabolic rate and intracranial pressure. Volatile anesthetics increase cerebral blood flow at concentrations greater than 1 MAC. Hyperventilation (PaCO₂ 30 to 35 mmHg) causes cerebral vasoconstriction and reduces intracranial pressure acutely. Mannitol (0.5 to 1 g/kg IV) reduces intracranial pressure through osmotic diuresis. Maintain CPP at 60 to 70 mmHg. Avoid hypotension and hypoxia. Emergence should be smooth to prevent coughing and hypertension. Postoperative neurological assessment is essential.

Anesthesia for Pheochromocytoma

– Pheochromocytoma is a catecholamine-secreting tumor causing episodic hypertension, tachycardia,

headache, sweating, and pallor. Preoperative alpha-blockade (phenoxybenzamine 10 to 14 days) is essential before beta-blockade (propranolol) to prevent unopposed alpha stimulation. Blood pressure and heart rate variability requires aggressive hemodynamic monitoring (arterial line, central venous pressure). Induction and intubation cause massive catecholamine release. Tumor manipulation causes hypertensive episodes intraoperatively; resection causes hypotension from catecholamine withdrawal. Postoperative management requires continued alpha and beta blockade.

Anesthesia for Porphyrria

– Acute intermittent porphyria is a metabolic disorder of heme synthesis causing abdominal pain, neuropathy, psychiatric symptoms, and dark urine. Certain anesthetics are porphyrinogenic (triggering attacks): barbiturates, sulfonamides, carbamazepine, and possibly volatile anesthetics (though sevoflurane is considered safe). Safe agents include propofol, opioids, benzodiazepines (low dose), succinylcholine, and non-depolarizing neuromuscular blockers. Porphyrria-safe drug databases should be consulted and porphyria-safe drug lists verified before administering any anesthetic agent.

Anesthesia Gas Analyzers

– Anesthesia gas analyzers monitor delivered and exhaled gas concentrations. Oxygen analyzer (paramagnetic or fuel cell) is required on every anesthesia machine and provides continuous SpO₂ and FiO₂ monitoring. Capnography (infrared CO₂ analyzer) measures end-tidal CO₂, confirming endotracheal tube position, ventilation adequacy, and detecting esophageal intubation immediately. End-tidal CO₂ normally equals arterial CO₂ within 5 mmHg. Pulse oximetry (spectrophotometry) measures hemoglobin oxygen saturation. Temperature monitoring (nasopharyngeal or oesophageal) detects malignant hyperthermia early. Neuromuscular monitoring (TOF) guides muscle relaxant dosing. Invasive arterial pressure is indicated for major cases, haemodynamic instability, and patients with cardiorespiratory disease. Central venous pressure and cardiac output monitoring (pulmonary artery catheter, TTE/TEE, FloTrac, LiDCO) are used for major surgery and sick patients.

Anesthesia Informatics

– Anesthesia informatics integrates electronic health records, decision support systems, and data analytics into clinical practice. Automated documentation reduces charting time. Clinical decision support alerts for drug interactions and dosing errors. Big data analytics identify patterns in anesthesia outcomes.

Anesthesia Machine

– The anesthesia machine delivers precise mixtures of oxygen, air, and volatile anesthetics to the patient. Components include gas cylinders (E-cylinder oxygen contains 660 liters at 2000 psi), pipeline supplies (hospital oxygen at 50 psi), pressure regulators, fail-safe valve (oxygen pressure below 25 psi shuts off nitrous oxide), vaporizers (variable-bypass sevoflurane, desflurane uses heated pressurized system), scavenging system (removes waste anesthetic gases), and breathing circuit (Circle system) comprises fresh gas inlet, inspiratory and expiratory valves, reservoir bag, CO₂ absorber, adjustable pressure limiting valve, and ventilator. The circle system reduces gas consumption and heat loss. Safety features include oxygen failure alarm, hypoxia prevention system, and vapouriser interlock (prevents simultaneous use of two volatile agents).

Anesthesia Monitoring

– Anesthesia monitoring encompasses continuous assessment of patient physiology during surgery. Standard ASA monitoring includes electrocardiography (detecting arrhythmias and ischemia), pulse oximetry (continuous SpO₂ measurement), non-invasive blood pressure (oscillometric every 3 to 5 minutes), end-tidal CO₂ (confirming tube position and ventilation adequacy), temperature monitoring, and inspired oxygen concentration. Invasive arterial pressure monitoring provides beat-to-beat blood pressure and allows precise vasopressor management. Central venous pressure and cardiac output monitoring are used in high-risk patients. Neuromuscular monitoring (train-of-four) is used for muscle relaxant management. Temperature monitoring is essential for detecting malignant hyperthermia and hypothermia. The goal is to maintain physiological parameters within acceptable ranges and detect abnormalities early.

Anesthesia Pharmacogenomics

– Anesthesia pharmacogenomics studies genetic vari-

ations affecting drug response. Pseudocholinesterase deficiency causes prolonged succinylcholine paralysis. CYP2D6 polymorphisms affect codeine metabolism to morphine. Malignant hyperthermia susceptibility is linked to RYR1 gene mutations. Pharmacogenomic testing guides personalized anesthesia.

Aspiration Pneumonitis

– Chemical lung injury caused by inhalation of gastric contents, characterized by bronchospasm, hypoxemia, pulmonary edema, and atelectasis. Risk factors include full stomach, emergency surgery, obesity, pregnancy, gastroesophageal reflux, bowel obstruction, and decreased consciousness. Prevention includes rapid sequence induction with cricoid pressure (Sellick maneuver), endotracheal intubation, and preoperative fasting. Treatment includes suctioning the airway, bronchoscopy, and supportive care with mechanical ventilation if needed. Most cases resolve within 24-48 hours with appropriate management.

Atropine

– A competitive muscarinic antagonist used to treat symptomatic bradycardia, reduce secretions, and reverse cholinergic side effects of neostigmine. Atropine blocks parasympathetic effects on the heart, increasing heart rate. Dose for bradycardia is 0.5 mg IV, repeat every 3 to 5 minutes, maximum 3 mg. Preoperative dose is 0.4 mg IV or IM. Atropine crosses the blood-brain barrier at high doses, causing central anticholinergic syndrome (confusion, hallucinations, agitation). Side effects include dry mouth, blurred vision, urinary retention, and tachycardia. Atropine is contraindicated in angle-closure glaucoma, obstructive uropathy, and myasthenia gravis. It is a tertiary amine that freely crosses the blood-brain barrier, unlike glycopyrrolate, producing central anticholinergic effects (agitation, confusion, hallucinations) at high doses.

Autologous Blood Donation

– Autologous blood donation involves preoperative collection and storage of the patient's own blood for intraoperative or postoperative transfusion. It eliminates risks of alloimmune reactions, transfusion-transmitted infections, and immune modulation. Indications include rare blood types, multiple alloantibodies, elective orthopedic surgery, and religious objections to allogeneic transfusion. Preoperative

donation requires hemoglobin greater than 11 g/dL and at least 3 weeks before surgery. Intraoperative cell salvage and acute normovolaemic haemodilution reduce allogeneic transfusion requirements. Complications include bacterial contamination, clerical error, and fluid overload.

Awake Fiberoptic Intubation

– The gold standard for anticipated difficult airways, performed with the patient conscious and cooperatively maintaining spontaneous ventilation. Topical anesthesia is achieved through lidocaine nebulization, nerve blocks (glossopharyngeal, superior laryngeal, transtracheal), and spray-as-you-go technique. Sedation with dexmedetomidine or remifentanyl provides anxiolysis while maintaining respiratory drive. The fiberoptic bronchoscope is passed through the vocal cords, and the endotracheal tube is passed over the bronchoscope into the trachea. Awake fiberoptic intubation is used in patients with known difficult airway, limited neck mobility (cervical spine injury, rheumatoid arthritis), head and neck tumours, and morbid obesity. Contraindications include patient refusal, severe hypoxia, and bleeding diathesis.

Awareness Under Anesthesia

– Unintended recall of events during general anesthesia, most commonly occurring during procedures where neuromuscular blockade prevents movement. Incidence: 0.1-0.2% of all general anesthetics, higher in cardiac, trauma, and cesarean section. Presents with postoperative recall of conversations, surgical sounds, or pain (worst outcomes). Risk factors: inadequate anesthesia (planned light anesthesia, hemodynamic instability), equipment failure, and certain drugs (ketamine, etomidate, nitrous oxide). Prevention: adequate dosing, volatile anesthetic end-tidal monitoring (MAC >0.7), BIS monitoring (target 40-60), and pre-oxygenation with a protocol. Management: documented debriefing, apology, psychological support, and referral to post-traumatic stress disorder services.

Blood Products

– Blood products used in anesthesia include packed red blood cells (increase oxygen-carrying capacity, each unit raises hemoglobin by approximately 1 g/dL), fresh frozen plasma (contains all coagulation factors, used for warfarin reversal, massive transfusion, and coagulopathy), platelets (prevent

or treat thrombocytopenia, 1 apheresis unit raises count by 30,000 to 60,000), cryoprecipitate (rich in fibrinogen, factor VIII, von Willebrand factor, used for fibrinogen deficiency), and whole blood (is indicated for massive hemorrhage with specific ratios of PRBC:FFP:platelets (1:1:1)). Transfusion reactions include acute haemolytic reaction, febrile non-haemolytic reaction, allergic reaction, transfusion-associated circulatory overload (TACO), transfusion-related acute lung injury (TRALI), and transfusion-transmitted infections.

Brain Monitoring

– Brain monitoring during anesthesia assesses the depth of hypnosis and neurological function. Bispectral index (BIS) processes the frontal EEG into a number from 0 (isoelectric) to 100 (fully awake), with 40 to 60 recommended for general anesthesia. BIS monitoring reduces awareness risk and may reduce anesthetic requirements. Entropy monitoring (state and response entropy) is an alternative. Processed EEG is less reliable in patients with brain pathology, hypothermia, and certain anesthetics (ketamine and nitrous oxide). Monitoring raw EEG waveforms is valuable for detecting cerebral ischaemia and epileptiform activity in patients undergoing neurosurgery and vascular surgery.

Bronchospasm

– Involuntary constriction of bronchial smooth muscle causing airway obstruction, wheezing, and increased airway pressures. Triggers include airway manipulation, volatile anesthetics (sevoflurane is bronchodilating; desflurane can cause bronchospasm), histamine-releasing drugs (morphine, atracurium), and reactive airway disease. Treatment includes deepening anesthesia with sevoflurane, beta-2 agonists (albuterol nebulized), epinephrine (10 to 100 mcg IV), and corticosteroids (hydrocortisone 100 mg IV). Volatile anesthetics may need to be reduced or switched to intravenous agents (propofol) to permit effective bronchodilator therapy, and severe cases may require intravenous adrenaline infusion and magnesium sulphate (2 g IV).

Bupivacaine

– A long-acting amide local anesthetic with onset of 5 to 15 minutes and duration of 2 to 4 hours for peripheral nerve blocks, 1 to 2 hours for epidural. It is available in 0.25 percent, 0.5 percent, and 0.75

percent concentrations. Bupivacaine provides dense sensory and motor blockade. Maximum dose is 2.25 mg/kg (170 mg for 75 kg adult). Bupivacaine is cardiotoxic in overdose, causing refractory ventricular arrhythmias and cardiac arrest. Lipid emulsion therapy (20 percent Intralipid) 1.5 mL/kg bolus followed by infusion is the specific antidote for bupivacaine cardiotoxicity. Bupivacaine is contraindicated for intravenous regional anesthesia (Bier block) due to risk of systemic toxicity.

Cannot Intubate Cannot Oxygenate

– The most critical airway emergency — inability to intubate the trachea and inability to oxygenate the patient by face mask or supraglottic airway despite optimal efforts. CICO is a life-threatening situation requiring immediate surgical airway access. Signs: SpO₂ decreasing despite 100% O₂, absent end-tidal CO₂, no chest rise. Management (CICO algorithm): declare CICO, call for surgical airway, perform scalpel cricothyroidotomy (vertical skin incision, horizontal membrane incision, tracheal hook, insert endotracheal tube or bougie). Alternative: needle cricothyroidotomy with jet ventilation (temporizing). Prevention: early recognition of difficult airway, awake techniques, and capnography confirmation of every intubation.

Carbon Dioxide Absorber

– The carbon dioxide absorber in the Circle breathing system contains soda lime or baralyme, which chemically reacts with exhaled CO₂ to form calcium carbonate and water, allowing gas recycling. Soda lime contains calcium hydroxide with sodium hydroxide and potassium hydroxide as activators, and phenolphthalein as indicator (turns purple with CO₂ absorption and desiccation). Desiccated CO₂ absorbers react with sevoflurane to produce Compound A, a fluorinated vinyl compound nephrotoxic in rats. Clinical significance in humans is uncertain, but fresh gas flows below 2 L/min should be avoided with sevoflurane. Baralyme is more reactive than soda lime and is no longer available in most regions.

Chronic Pain

– Pain persisting longer than three months or beyond normal tissue healing time, often lacking an ongoing identifiable cause. It involves complex interactions between biological, psychological, and

social factors that can amplify pain signaling in the nervous system. Management is multimodal, combining medications, physical therapy, cognitive behavioral therapy, nerve blocks, and complementary approaches.

Chronic Pain Management

– Chronic pain management extends beyond the perioperative period. Opioid therapy for chronic pain requires careful patient selection, informed consent, and regular reassessment. Multimodal approach includes NSAIDs, acetaminophen, gabapentinoids, antidepressants (SNRIs, TCAs), topical agents (lidocaine patches, capsaicin), and interventional procedures (nerve blocks, radiofrequency ablation, spinal cord stimulation). Opioid rotation (switching to a different opioid) is used for tolerance or side effects; methadone is used for both pain and opioid use disorder due to its long half-life (24-36 hours) and NMDA receptor antagonism, which may reduce tolerance. Buprenorphine is a partial mu-opioid agonist with ceiling effect on respiratory depression, making it safer in overdose but with a theoretical risk of precipitating withdrawal. Adjuvant therapies include physical therapy, cognitive behavioural therapy, and neuromodulation (spinal cord stimulation, peripheral nerve stimulation). Long-term opioid use carries risks of hypogonadism, immunosuppression, and opioid-induced hyperalgesia.

Colloids

– Solutions containing large molecules that remain in the intravascular space, providing greater volume expansion per milliliter than crystalloids. Albumin (5 percent, 25 percent) is a natural plasma protein used for volume expansion and specific indications (cirrhosis with paracentesis, nephrotic syndrome). Synthetic colloids include hydroxyethyl starch (HES), which is associated with acute kidney injury, coagulopathy, and increased mortality, leading to restricted use. Dextran (40 and 70 kDa) and dextran 70 (70 kDa) — are associated with anaphylactic reactions, interference with blood cross-matching, and impaired platelet function. Gelatin (succinylated gelatin, polygeline) is a colloid with lower molecular weight and shorter duration of action, rarely used due to risk of anaphylactoid reactions. The SAFE study demonstrated no mortality benefit of albumin over saline in ICU patients, and albumin

use is limited to specific indications due to its cost and lack of proven benefit over crystalloids in most clinical settings.

Cricoid Pressure

- Cricoid pressure (Sellick maneuver) applies posterior displacement of the cricoid cartilage against the cervical vertebrae, occluding the esophagus and reducing aspiration risk during rapid sequence intubation. The technique involves applying 30 N pressure (20 N once consciousness is lost) with the thumb and forefinger on the cricoid cartilage. Evidence for effectiveness is mixed, with some studies showing no reduction in aspiration and potential difficulty with laryngoscopy. Recent guidelines suggest individualising cricoid pressure and considering alternative techniques (laryngeal mask airway, video laryngoscopy, suction-assisted laryngoscopy) in difficult situations.

Crystalloids

- Aqueous solutions of mineral salts that distribute between intravascular and interstitial compartments. Normal saline (0.9 percent NaCl) has 154 mEq/L each of sodium and chloride, pH 5.4, and is associated with hyperchloremic metabolic acidosis at large volumes. Lactated Ringer's contains sodium 130, potassium 4, calcium 3, chloride 109, and lactate 28 mEq/L, with pH 6.5. Lactate is metabolized to bicarbonate, making it physiologically balanced. Balanced crystalloids are preferred over normal saline for large-volume resuscitation (>2 L) to reduce the risk of hyperchloraemic metabolic acidosis and acute kidney injury, though isotonic saline remains the most widely available crystalloid worldwide and is appropriate for most clinical situations.

Delayed Emergence

- Prolonged time to regain consciousness after discontinuation of anesthetic agents. Failure to regain consciousness within 30-60 minutes of completing surgery. Causes: anesthetic drug overdose, residual volatile anesthetic (closed circuit, long duration), synergistic sedative effects (benzodiazepines, opioids), residual neuromuscular blockade, metabolic (hypoglycemia, hyponatremia, hypothermia, hypoxia, hypercarbia), and CNS injury (stroke, cerebral edema, seizure). Workup: ABCs, check TOF, end-tidal gas, temperature, glucose, electrolytes, and arterial blood gas. CT head and EEG for sus-

pected neurologic injury.

Delirium in Anesthesia

- Delirium is an acute confusional state characterized by fluctuating consciousness, inattention, disorganized thinking, and altered level of awareness. Postoperative delirium occurs in 15 to 50 percent of elderly surgical patients, with higher rates in hip fracture and cardiac surgery. Risk factors include advanced age, preexisting cognitive impairment, sensory deprivation, sleep disruption, pain, opioids, anticholinergic drugs, and metabolic derangements. Delirium increases length of stay, complications, and mortality; prevention focuses on early recognition of at-risk patients, optimisation of pain and sleep, minimising use of anticholinergic medications, providing sensory aids (glasses, hearing aids), early mobilisation, and family involvement in care.

Desflurane

- A volatile inhalation anesthetic with the lowest blood-gas partition coefficient (0.42) among commonly used agents, providing the fastest induction and emergence of all volatile anesthetics. MAC is 6 percent at sea level. Desflurane causes airway irritation and can trigger sympathetic stimulation (tachycardia, hypertension) if inspired concentration exceeds 1.3 MAC abruptly. It is not suitable for inhalation induction in adults due to pungency. Desflurane is metabolized minimally (0.02 percent) and is the most resistant volatile to biodegradation, with negligible metabolism and no known organ toxicity, though it is a potent greenhouse gas.

Dexmedetomidine

- A highly selective alpha-2 adrenergic agonist providing sedation, anxiolysis, and analgesic sparing effects without significant respiratory depression. It produces cooperative sedation (patients can be aroused and followed commands) resembling natural sleep. Dexmedetomidine is used for procedural sedation, ICU sedation, and as an adjunct to general anesthesia. Dose: loading dose 1 mcg/kg over 10 minutes, then maintenance 0.2 to 0.7 mcg/kg/hour. Side effects include bradycardia, hypotension, and dry mouth. Bradycardia is the most common adverse effect, typically responding to dose reduction or anticholinergic agents (glycopyrrolate, atropine). Dexmedetomidine is unique among sedatives in providing sedation with minimal respiratory depression

while maintaining a patent airway and spontaneous ventilation, making it particularly useful in the intensive care unit for patients requiring sedation during mechanical ventilation.

Difficult Airway

– A clinical situation in which a trained anesthesiologist or emergency physician encounters difficulty with bag-mask ventilation, supraglottic airway placement, laryngoscopy, or endotracheal intubation. Difficult mask ventilation: inability to maintain SpO₂ >92% using 100% oxygen and positive pressure with a mask. Difficult laryngoscopy: Cormack-Lehane grade III or IV view (only epiglottis or no glottic structures visible). Difficult intubation: >3 attempts or >10 minutes required. Predictors: LEMON (Look, Evaluate, Mallampati, Obstruction, Neck mobility), 3-3-2 rule, upper lip bite test, obesity, and OSA. Management: ASA difficult airway algorithm; call for help, optimize position, use video laryngoscope, bougie, and consider awake fiberoptic intubation for anticipated difficult airway.

Difficult Intubation

– Inability to perform direct laryngoscopy or endotracheal intubation despite appropriate expertise and equipment. Predictors include Mallampati Class III or IV, limited mouth opening (less than 3 cm), limited neck mobility, short thyromental distance (less than 6.5 cm), obesity, beard, facial trauma, and prior difficult intubation. The difficult airway algorithm emphasizes preoperative assessment, preparation, and sequential approach: preoxygenation, direct laryngoscopy with Macintosh blade, bougie, video laryngoscopy, supraglottic airway (intubating LMA, i-gel), and surgical airway (cricothyroidotomy). The cannot intubate, cannot oxygenate (CICO) situation requires immediate surgical airway access.

Emergence Agitation

– A state of confusion, restlessness, and inconsolable crying during emergence from anesthesia, occurring in 10 to 80 percent of pediatric patients and 5 to 10 percent of adults. Risk factors include sevoflurane induction, short procedures, parental separation, and preexisting behavioral disorders. Prevention includes gentle handling, parental presence during emergence, adequate analgesia, and

minimizing stimulation. Treatment involves ensuring adequate oxygenation, adequate analgesia, and minimal stimulation. Treatment may require pharmacological intervention with propofol (0.5-1 mg/kg), midazolam (0.05 mg/kg), or dexmedetomidine (0.5 mcg/kg) in severe cases.

Epidural Analgesia

– Epidural analgesia provides segmental pain relief by infusing local anesthetic (bupivacaine 0.1 to 0.2 percent) with or without opioids (fentanyl 2 to 4 mcg/mL, hydromorphone 10 to 20 mcg/mL) through an epidural catheter. Indications include major abdominal, thoracic, and orthopedic surgery, and labor analgesia. Epidural analgesia reduces postoperative pulmonary complications, ileus, and thromboembolic events. Side effects include hypotension (sympathetic blockade), urinary retention, pruritus (opioid-related), and motor blockade. Epidural hematoma and abscess are rare but serious complications requiring urgent neurosurgical consultation. Contraindications include coagulopathy, local infection at insertion site, increased intracranial pressure, patient refusal, and severe hypovolaemia.

Epidural Anesthesia

– A regional anesthetic technique involving injection of local anesthetic and/or opioid into the epidural space (the potential space between the dura mater and the ligamentum flavum within the spinal canal), producing segmental analgesia and sympathetic blockade. Indications: labor analgesia (most common use), major abdominal, thoracic, and orthopedic surgery (provides intraoperative and postoperative analgesia), and chronic pain management. Common local anesthetics: bupivacaine 0.0625–0.125%, ropivacaine 0.1–0.2%, lidocaine 1–2%. Opioids (fentanyl, morphine) are added to enhance analgesia and reduce local anesthetic dose. Side effects: hypotension (sympathetic blockade), motor blockade, urinary retention, pruritus (opioid-related), nausea. Serious complications: epidural hematoma (risk increased with anticoagulation), epidural abscess, post-dural puncture headache, and nerve injury. Contraindicated in coagulopathy, infection at the insertion site, increased intracranial pressure, and patient refusal.

Esmolol

– An ultra-short-acting cardioselective beta-1 adrenergic blocker with onset of 1 to 2 minutes and half-life of 9 minutes, metabolized by red blood cell esterases. It is administered as IV infusion (loading dose 500 mcg/kg over 1 minute, then 50 to 300 mcg/kg/min) for titratable heart rate and blood pressure control. Esmolol is used for intraoperative tachycardia, hypertension, arrhythmias, and prevention of extubation-induced sympathetic response. It is ideal for patients requiring rapid emergence and recovery, making it suitable for short procedures, day-case surgery, and patients undergoing procedures where rapid neurological assessment is needed.

Etomidate

– An intravenous induction agent with rapid onset (30 seconds) and short duration of action. It is hemodynamically neutral, making it the induction agent of choice in hemodynamically unstable patients, trauma, and sepsis. Etomidate acts as a GABA-A receptor agonist producing unconsciousness without significant cardiovascular effects. It decreases cerebral metabolic rate and intracranial pressure. Etomidate suppresses adrenal steroidogenesis by inhibiting 11-beta-hydroxylase, reducing cortisol and aldosterone levels for 12-24 hours after a single induction dose, which may be clinically significant in septic patients and those with adrenal insufficiency; this has led to controversy about its use in septic shock and increased preference for ketamine as an alternative in haemodynamically unstable patients.

Extubation Criteria

– Extubation requires the patient to meet specific criteria: fully awake and following commands, adequate tidal volume and respiratory rate, strong cough and gag reflex, adequate oxygenation (SpO₂ greater than 95 percent on room air or baseline), hemodynamic stability, and return of neuromuscular function (TOF ratio greater than 0.9, sustained head lift for 5 seconds). Extubation should be performed at light anesthesia or fully awake. Awake extubation is preferred in difficult airway, obese, or high risk of aspiration (obstetric patients, obesity, gastro-oesophageal reflux disease, full stomach). Complications of extubation include laryngospasm, bronchospasm, aspiration, airway edema, and hy-

poxemia. Use of airway exchange catheters is recommended in patients with a known difficult airway to allow re-intubation if needed.

Failed Intubation

– Inability to successfully place an endotracheal tube after multiple attempts. In the operating room, a failed intubation algorithm is followed: call for help, maintain oxygenation (face mask, supraglottic airway), and decide to wake the patient (if non-emergent) or proceed with a supraglottic airway (if surgery is urgent). In the emergency department or ICU: difficult airway cart, video laryngoscopy, bougie, and surgical airway (cricothyroidotomy) if cannot intubate and cannot oxygenate. Failed intubation is more common in obstetric anesthesia (1 in 200-300) due to airway changes in pregnancy.

Fasting Guidelines

– Preoperative fasting guidelines minimize aspiration risk while reducing patient discomfort and catabolism. Clear liquids (water, clear juice without pulp, black coffee, sports drinks) are allowed up to 2 hours before surgery. Breast milk up to 4 hours. Infant formula up to 6 hours. Light meal (toast and clear liquid) up to 6 hours. Heavy/fatty meal up to 8 hours. The American Society of Anesthesiologists (ASA) fasting guidelines are evidence-based. Preoperative carbohydrate loading (clear carbohydrate drink) 2-3 hours before surgery reduces perioperative insulin resistance, thirst, and hunger without increasing aspiration risk, supporting enhanced recovery after surgery protocols.

Fentanyl

– A synthetic opioid analgesic with potency 50 to 100 times that of morphine, rapid onset (30 seconds IV), and short duration of action (30 to 60 minutes). It is lipid-soluble, allowing rapid brain penetration. Fentanyl is used for intraoperative analgesia, patient-controlled analgesia, and regional analgesia (epidural or intrathecal). It causes dose-dependent respiratory depression, bradycardia, and chest wall rigidity at rapid high-dose administration. Fentanyl does not cause histamine release, making it haemodynamically stable. Intraoperative doses are 1-2 mcg/kg IV; patient-controlled analgesia bolus is 10-20 mcg IV with lockout of 6-10 minutes.

Fentanyl Derivatives

– Opioid derivatives used in anesthesia include fentanyl (most common, 50 to 100 mcg IV), sufentanil (5 to 10 times more potent than fentanyl, 5 to 10 mcg IV, used in cardiac anesthesia), remifentanyl (ultra-short-acting, metabolized by esterases, 0.1 to 0.5 mcg/kg/min infusion), alfentanil (shorter duration than fentanyl, used for brief procedures), and carfentanyl (10,000 times more potent than fentanyl, used for wildlife immobilization). All opioids cause dose-dependent respiratory depression, histamine release, hypotension, and bradycardia at high doses and rapid administration. Fentanyl is lipid-soluble, allowing rapid brain penetration and making it suitable for transdermal delivery (fentanyl patch) for chronic pain. Fentanyl causes chest wall rigidity at rapid high-dose administration (greater than 150 mcg IV bolus), requiring positive pressure ventilation or neuromuscular blockade to overcome.

General Anesthesia

– A controlled, reversible state of unconsciousness, analgesia, amnesia, and muscle relaxation induced by pharmacologic agents, enabling surgical procedures without patient awareness or pain. The components of general anesthesia are induction (rapid onset of unconsciousness), maintenance (sustained anesthetic state), and emergence (recovery of consciousness). Induction agents include propofol (1.5 to 2.5 mg/kg IV, onset 15 to 30 seconds, duration 5 to 10 minutes, the most common induction agent), etomidate (0.2-0.3 mg/kg, haemodynamically neutral), and ketamine (1-2 mg/kg, dissociative anesthetic producing sympathetic stimulation and bronchodilation). Maintenance: volatile anesthetics (sevoflurane, isoflurane, desflurane) or total intravenous anesthesia (TIVA) with propofol and remifentanyl infusions. Muscle relaxation can be achieved with depolarizing (succinylcholine) or non-depolarizing (rocuronium, vecuronium, atracurium) neuromuscular blocking agents. Emergence involves discontinuing anesthetics, reversing muscle relaxation, and extubating the patient once criteria are met.

Glycopyrrolate

– An anticholinergic agent used to counteract muscarinic side effects of neostigmine and other cholinesterase inhibitors. It does not cross the blood-brain barrier, unlike atropine, producing fewer cen-

tral side effects. Glycopyrrolate is administered at 0.2 to 0.4 mg IV for each 1 mg of neostigmine. It causes dry mouth, urinary retention, and tachycardia. Glycopyrrolate is also used preoperatively to reduce secretions and prevent bradycardia during vagal stimulation. It has a slower onset of action compared to atropine (2-3 minutes IV). It does not effectively cross the placenta and has minimal effect on fetal heart rate, making it preferred for obstetric anesthesia.

Hypertension in Anesthesia

– Hypertension during anesthesia causes increased bleeding, myocardial ischemia, and stroke risk. Common causes include light anesthesia, pain, hypercarbia, hypoxia, bladder distension, shivering, and drug withdrawal (beta-blockers, clonidine). Treatment involves deepening anesthesia, providing analgesia (fentanyl, remifentanyl), and antihypertensive agents (esmolol for tachycardia-associated hypertension, labetalol, nicardipine, nitroglycerin). In neurosurgery, blood pressure control prevents cerebral perfusion pressure management and avoidance of hypertension-induced bleeding.

Hyperthermia in Anesthesia

– Perioperative hyperthermia (temperature greater than 38 degrees Celsius) has multiple causes. Malignant hyperthermia (discussed separately) is the most urgent. Sepsis, thyroid storm, serotonin syndrome, neuroleptic malignant syndrome, and central fever are other causes. Fever increases metabolic rate by 10 to 13 percent per degree Celsius, increasing oxygen consumption and carbon dioxide production. Treatment involves identifying and addressing the underlying cause. Antipyretics (acetaminophen, and NSAIDs) are used. Cooling measures include forced air warming (paradoxically), cold intravenous fluids, ice packs, and cooling blankets. Avoid shivering if possible (meperidine 12.5-25 mg IV, dexmedetomidine). Identify and treat the underlying cause: dantrolene for malignant hyperthermia, beta-blockers for thyroid storm, cyproheptadine for serotonin syndrome.

Hypotension in Anesthesia

– Mean arterial pressure less than 65 mmHg or a decrease greater than 20 percent from baseline during anesthesia. Causes include anesthetic depth (volatile agents, propofol, opioids), hypovolemia

(fasting, blood loss, third spacing), vasodilation (neuraxial blockade, sepsis, anaphylaxis), and cardiac dysfunction (myocardial depression, arrhythmias). Treatment involves identifying and addressing the cause: reducing anesthetic depth, fluid resuscitation, vasopressors (phenylephrine 50-100 mcg IV, ephedrine 5-10 mg IV, norepinephrine infusion), and inotropic support (epinephrine, dobutamine) if cardiac dysfunction is suspected or confirmed.

Hypothermia in Anesthesia

– Hypothermia (core temperature less than 36 degrees Celsius) occurs in 50 to 80 percent of surgical patients due to anesthetic-induced thermoregulatory dysfunction and heat redistribution. Initial phase (first 30 to 60 minutes) involves core-to-peripheral heat redistribution causing 0.5 to 1.5 degree Celsius drop. Prolonged surgery causes heat loss through radiation, convection, evaporation, and conduction. Hypothermia increases surgical site infection risk, prolongs drug metabolism, causes coagulopathy, and increases transfusion requirements. Prevention includes forced-air warming blankets, warmed intravenous fluids, and maintaining operating room temperature above 21 degrees Celsius.

Inotropes in Anesthesia

– Inotropes increase myocardial contractility. Dobutamine is a beta-1 and beta-2 agonist increasing cardiac output with minimal effect on heart rate. Dose: 2 to 20 mcg/kg/min infusion. Milrinone is a phosphodiesterase-3 inhibitor increasing contractility and causing vasodilation. Dose: loading dose 50 mcg/kg over 10 minutes, then 0.375 to 0.75 mcg/kg/min. Epinephrine has potent beta-1 inotropic effects at low doses and alpha effects at high doses. Dose: 0.01 to 0.5 mcg/kg/min. Inotropes are used for cardiac dysfunction (myocardial depression, heart failure) and vasodilatory shock (sepsis, anaphylaxis). Adverse effects of inotropes include arrhythmias, increased myocardial oxygen consumption, and tolerance with prolonged use.

Intraoperative Blood Transfusion

– Intraoperative blood transfusion replaces lost blood volume and maintains oxygen-carrying capacity during major surgery. Indications include hemoglobin less than 7 g/dL in stable patients, less than 8 g/dL in cardiac disease, or active hemorrhage with hemodynamic instability. Packed red blood cells are the

most commonly transfused component, with each unit increasing hemoglobin by approximately 1 g/dL. Massive transfusion protocol (greater than 10 units in 24 hours or greater than 4 units in 1 hour) involves predefined ratios of PRBC, FFP, and platelets (1:1:1). Complications of massive transfusion include hypothermia, acidosis, hypocalcaemia (citrate toxicity), hyperkalemia, and dilutional coagulopathy. Point-of-care testing (TEG, ROTEM) guides component therapy in real time.

Intraoperative Neuromonitoring

– Intraoperative neuromonitoring (IONM) uses electrophysiological techniques to monitor neural pathway integrity during surgery. Somatosensory evoked potentials (SSEP) monitor sensory pathways. Motor evoked potentials (MEP) monitor motor pathways. Electromyography (EMG) monitors cranial nerves and spinal roots. IONM is used in spine surgery (decompressive procedures, scoliosis correction), vascular surgery (carotid endarterectomy, aortic aneurysm repair), and skull base surgery. Changes in IONM signals require prompt communication with the surgical team to guide intervention (e.g., reducing retraction, altering surgical approach, or completing resection). anesthetic management must be tailored to IONM requirements, avoiding neuromuscular blocking agents during MEP monitoring and using total intravenous anesthesia (propofol and remifentanyl) to minimise interference with evoked potential monitoring.

Intraoperative Temperature Monitoring

– Core temperature monitoring is essential during prolonged or major surgery. Sites include esophageal (most accurate for cardiac surgery), nasopharyngeal, bladder (with continuous irrigation), tympanic, and pulmonary artery (gold standard, requires PA catheter). Skin temperature (forehead, axilla) reflects peripheral temperature and is inaccurate for core estimation. Temperature probes are placed before induction for baseline measurement. Continuous monitoring allows early detection of hypothermia, which is common in prolonged surgery. Forced-air warming blankets are the most effective active warming method. Maintaining normothermia is essential for patient comfort, wound healing, and coagulation.

Isoflurane

– A volatile inhalation anesthetic with blood-gas partition coefficient of 1.4 and MAC of 1.15 percent. It was the most commonly used volatile anesthetic for many years but has been largely replaced by sevoflurane and desflurane. Isoflurane causes dose-dependent vasodilation and myocardial depression, maintaining cardiac output relatively well. It increases cerebral blood flow and intracranial pressure. Isoflurane is metabolized approximately 0.2 percent by CYP2E1 to inorganic fluoride (free fluoride ion) and trifluoroacetic acid, but hepatic metabolism is not clinically significant at usual doses. Isoflurane preserves hepatic and renal blood flow. It is a bronchodilator and is suitable for patients with reactive airway disease.

Ketamine

– A dissociative anesthetic acting as a non-competitive NMDA receptor antagonist, producing profound analgesia and amnesia while maintaining airway reflexes and spontaneous ventilation. It causes sympathetic stimulation, increasing heart rate, blood pressure, and cardiac output, making it ideal for hypotensive or traumatized patients. Ketamine is a bronchodilator and is used in asthmatic patients. It increases cerebral blood flow and intracranial pressure, limiting use in neurosurgery. Ketamine increases cerebral blood flow and intracranial pressure, limiting its use in neurosurgery. It is also used for treatment-resistant depression, acute and chronic pain, and as a bronchodilator in status asthmaticus. Psychotomimetic effects (emergence phenomena, hallucinations) are reduced in children and with benzodiazepine co-administration.

Laryngospasm

– A protective reflex causing violent adduction of the vocal cords, resulting in complete airway obstruction. It is most common during light anesthesia, emergence, and in pediatric patients. Triggers include secretions, blood, airway manipulation, and suctioning. Signs include paradoxical chest-abdominal movement, suprasternal retractions, and absent air entry. Treatment includes positive pressure ventilation with 100 percent oxygen via face mask, jaw thrust, and deepening anesthesia with propofol (0.5-1 mg/kg IV) or succinylcholine (0.1-0.5

mg/kg IV). If oxygenation fails, cricothyroidotomy or tracheostomy is required. Prevention includes maintaining adequate depth of anesthesia before airway manipulation and avoiding airway stimulation during light planes of anesthesia.

Lidocaine

– An amide local anesthetic and Class IB antiarrhythmic drug. As a local anesthetic, it is used for infiltration, nerve blocks, epidural, and spinal anesthesia (onset 5 to 10 minutes, duration 60 to 120 minutes). It is often combined with epinephrine (1:200,000) to prolong duration and reduce systemic absorption. Maximum dose is 4.5 mg/kg without epinephrine and 7 mg/kg with epinephrine. Lidocaine reduces intraocular pressure and is used to blunt airway reflexes during laryngoscopy (11.5 mg/kg IV prior to laryngoscopy). Lidocaine undergoes hepatic metabolism by CYP3A4 and has an elimination half-life of 1.5-2 hours which is prolonged in heart failure and hepatic disease. Toxicity (perioral numbness, metallic taste, tinnitus, seizures, arrhythmias) occurs at plasma concentrations greater than 5 mcg/mL, progressing to CNS depression and cardiovascular collapse at levels greater than 10 mcg/mL.

Lipid Emulsion Therapy

– The antidote for local anesthetic systemic toxicity. The mechanism involves the lipid sink theory (lipid phase sequesters lipophilic local anesthetics from neural and cardiac tissue) and metabolic theory (lipid provides fatty acid substrate to ischemic myocardium). Dosing: bolus 1.5 mL/kg (approximately 100 mL for 70 kg adult) over 1 minute, followed by infusion 0.25 mL/kg/min. If cardiovascular instability persists, repeat bolus every 3 to 5 minutes, up to maximum 10 mL/kg. Continue infusion until haemodynamic stability is restored. Lipid emulsion is effective for bupivacaine and other lipophilic local anesthetics. Prepare lipid emulsion immediately when performing regional anesthesia with high-risk agents. Propofol (lipid emulsion vehicle) is not a substitute for Intralipid therapy as it delivers insufficient lipid volume.

Local Anesthetic

– A medication that causes reversible loss of sensation in a specific, localized area of the body without affecting consciousness. Local anesthet-

ics block voltage-gated sodium channels in nerve cell membranes, preventing action potential generation and propagation. The non-ionized (lipophilic) form crosses the nerve sheath; the ionized form binds to the sodium channel intracellularly, stabilizing it in the inactivated state. Small nerve fibers (A-delta and C, pain and temperature) are blocked before larger fibers (A-beta, touch and motor). Types: amides (lidocaine, bupivacaine, ropivacaine, prilocaine — metabolized in the liver) and esters (procaine, tetracaine, benzocaine — metabolized by plasma pseudocholinesterases). Maximum safe doses: lidocaine 4.5 mg/kg without epinephrine, 7 mg/kg with epinephrine; bupivacaine 2.25 mg/kg. Contraindications include allergy to same class, severe hepatic impairment (amides), and pseudocholinesterase deficiency (esters). Toxicity presents with CNS symptoms (perioral numbness, metallic taste, tinnitus, seizures, coma) followed by cardiovascular collapse (hypotension, arrhythmias, cardiac arrest). Treatment: stop injection, airway support, benzodiazepines for seizures, and Intralipid 20% for cardiovascular toxicity. Addition of epinephrine prolongs duration and reduces systemic absorption.

Local Anesthetic Systemic Toxicity

– A life-threatening complication caused by elevated plasma concentration of local anesthetic, most commonly from inadvertent intravascular injection or rapid absorption. Presents with progressive CNS symptoms (perioral numbness, metallic taste, tinnitus, agitation, seizures) followed by cardiovascular effects (arrhythmias, bradycardia, hypotension, cardiac arrest). Cardiovascular collapse typically precedes CNS symptoms with bupivacaine (highly cardiotoxic). Prevention: test dose, incremental injection, aspiration, and ultrasound guidance. Treatment: STOP injection, call for help, airway management, lipid emulsion therapy (Intralipid 20%: 1.5 mL/kg bolus, then 0.25 mL/kg/min infusion). Avoid vasopressin and calcium channel blockers. Continue CPR until lipid levels are therapeutic.

Malignant Hyperthermia

– A rare, life-threatening pharmacogenetic disorder of skeletal muscle triggered by volatile inhalation anesthetics and succinylcholine, with incidence of approximately 1 in 15,000 to 50,000 anesthetics. The pathophysiology involves a defect in the ryanodine

receptor (RYR1) on the sarcoplasmic reticulum, causing uncontrolled calcium release and sustained muscle contraction. Early signs include rising end-tidal CO₂ (the earliest and most sensitive sign), tachycardia, masseter muscle rigidity (masseter spasm), hyperthermia (late and fulminant sign), and metabolic acidosis. Treatment: discontinue all triggering agents immediately, hyperventilate with 100% oxygen, administer dantrolene (2.5 mg/kg IV bolus, repeated as needed, up to 10 mg/kg), active cooling, correct metabolic acidosis, treat hyperkalemia with insulin and glucose, and monitor end-tidal CO₂ and core temperature. Dantrolene inhibits calcium release from the sarcoplasmic reticulum by blocking the ryanodine receptor. Post-crisis monitoring in intensive care for 24-48 hours is mandatory as recurrence can occur.

Mechanical Ventilation

– Mechanical ventilation provides respiratory support by delivering controlled or spontaneous breaths through an endotracheal tube or tracheostomy. Ventilator modes include volume-controlled ventilation (delivers set tidal volume regardless of airway pressure), pressure-controlled ventilation (delivers breaths at set inspiratory pressure, tidal volume varies based on compliance), pressure support ventilation (spontaneous breaths augmented by set pressure level), and synchronized intermittent mandatory ventilation (SIMV) which delivers set mandatory breaths between spontaneous breaths. Lung-protective ventilation uses low tidal volumes (6-8 mL/kg ideal body weight), plateau pressure less than 30 cmH₂O, positive end-expiratory pressure (PEEP 5-10 cmH₂O), and permissive hypercapnia. Driving pressure (plateau pressure minus PEEP) greater than 15 cmH₂O is associated with increased mortality in ARDS.

Mendelson Syndrome

– See Aspiration Pneumonitis. Mendelson syndrome is a historical eponym for aspiration pneumonitis, originally described in obstetric patients.

Midazolam

– A water-soluble benzodiazepine with rapid onset and short duration of action, used for anxiolysis, sedation, amnesia, and seizure control. It acts on GABA-A receptors producing dose-dependent sedation. Midazolam is commonly used for procedural

sedation, premedication, and continuous sedation in intensive care. It causes dose-dependent respiratory depression, particularly when combined with opioids. Midazolam is metabolized hepatically by CYP3A4 to active metabolite 1-hydroxymidazolam, which has sedative activity contributing to its effects, particularly in patients with hepatic impairment and the elderly. Flumazenil is the specific benzodiazepine antagonist.

Monitored Anesthesia Care

– A distinct service where an anesthesia professional provides premedication, administration of analgesics and/or sedatives, continuous monitoring of the patient's cardiorespiratory status, and intervention for any emergent or unavoidable complications that may arise during a diagnostic or therapeutic procedure. MAC is used for endoscopy, colonoscopy, interventional radiology, and minor surgical procedures. The patient may progress from moderate sedation to deep sedation, where airway intervention may be required. MAC requires at least one qualified anesthesia professional continuously present to monitor vital signs, administer sedation and analgesia, and be prepared to manage the airway and haemodynamic emergencies at any time during the procedure.

Neostigmine

– An acetylcholinesterase inhibitor used to reverse non-depolarizing neuromuscular blockade. It prevents breakdown of acetylcholine at the neuromuscular junction, restoring neuromuscular transmission. Neostigmine is administered with an anticholinergic agent (glycopyrrolate or atropine) to prevent muscarinic side effects (bradycardia, salivation, bronchospasm). Dose is 0.04 to 0.07 mg/kg IV, maximum 5 mg. Neostigmine is ineffective against depolarizing blockade (succinylcholine) and should not be used for routine reversal of rocuronium due to the availability of sugammadex, which provides faster and more predictable reversal without muscarinic side effects.

Neuromuscular Junction

– The neuromuscular junction is the synapse between motor neuron and skeletal muscle fiber, where acetylcholine released from presynaptic terminals binds to nicotinic acetylcholine receptors on the postsynaptic motor end plate, causing depolarization and muscle

contraction. Acetylcholinesterase in the synaptic cleft breaks down acetylcholine, terminating the signal. Neuromuscular blocking agents interfere with this process: depolarizing agents (succinylcholine) cause persistent depolarization, while non-depolarizing agents (rocuronium, vecuronium, atracurium) competitively block acetylcholine binding, producing flaccid paralysis that can be reversed with anticholinesterases or sugammadex.

Nitrous Oxide

– A volatile inhalation anesthetic with blood-gas partition coefficient of 0.47 and MAC of 105 percent, meaning it cannot produce surgical anesthesia alone. It is typically used as an adjunct to other anesthetics, reducing the requirement for volatile agents by 30 to 40 percent. Nitrous oxide has analgesic properties at subanesthetic concentrations and is widely used in obstetric analgesia and dentistry. It diffuses into air-filled cavities, expanding trapped gas volumes and increasing the risk of tension pneumothorax, bowel distension, and expansion of air emboli. Nitrous oxide causes diffusion hypoxia upon emergence, where nitrous oxide rapidly exits the blood into the alveoli, diluting alveolar oxygen; this is prevented by administering 100% oxygen during emergence. Chronic exposure causes vitamin B12 oxidation and inactivation of methionine synthase, leading to megaloblastic anaemia and peripheral neuropathy with prolonged use.

Opioid Reversal

– Achieved with naloxone, a competitive mu-opioid receptor antagonist. Dose: 0.04 to 0.1 mg IV, titrated to effect, repeat every 2 to 3 minutes. Maximum typical dose is 2 to 4 mg. Naloxone has shorter half-life (30 to 80 minutes) than most opioids, risking recurrent respiratory depression. Continuous infusion (2 to 4 mg/hour diluted in 500 mL saline) may be needed for long-acting opioids (methadone, sustained-release formulations). Nalmefene and naltrexone are longer-acting oral antagonists with half-lives of 4-10 hours and 4 hours respectively. Long-acting reversal agents should be used post-operatively and in monitored settings. Opioid reversal can precipitate acute withdrawal syndrome in opioid-dependent patients, characterized by agitation, hypertension, tachycardia, vomiting, and diarrhoea. Partial agonists and mixed agonist-

antagonists (buprenorphine, nalbuphine) have ceiling effects on respiratory depression but can precipitate withdrawal in opioid-dependent patients.

Other Pain Conditions

– Other pain types encompass pain conditions not primarily classified as nociceptive (somatic or visceral) or classic neuropathic pain, including nociplastic pain (altered nociception without clear tissue or nerve damage, such as fibromyalgia, chronic tension-type headache, temporomandibular disorders, and chronic pelvic pain), complex regional pain syndrome (CRPS Type I and II—persistent regional pain disproportionate to inciting event with autonomic and motor features), central pain syndromes (post-stroke pain, spinal cord injury pain), and chronic visceral pain syndromes (interstitial cystitis/bladder pain syndrome, irritable bowel syndrome, chronic pancreatitis, endometriosis). These conditions share mechanisms of central sensitization, dysfunctional descending modulation, and psychologic contributors. Diagnosis is clinical, often requiring exclusion of alternative pathology. Management is multimodal: patient education, physical therapy, cognitive-behavioral therapy, medications (tricyclic antidepressants, gabapentinoids, SNRIs), and neuromodulation; opioids are generally ineffective and not recommended for chronic non-cancer pain.

Pain

– An unpleasant sensory and emotional experience associated with actual or potential tissue damage, serving as a protective alerting system but becoming maladaptive when chronic (lasting >3 months). The biopsychosocial model recognizes nociception (tissue damage), pain perception (sensory-discriminative, affective-motivational, cognitive-evaluative dimensions), and pain behaviors influenced by genetics, psychology, social context, and comorbidities. Classification: nociceptive (somatic—well-localized, aching; visceral—diffuse, cramping), neuropathic (nerve injury—burning, shooting, allodynia), and nociplastic (altered nociception without clear lesion—fibromyalgia). Acute pain resolves with healing; chronic pain affects 20% of adults and is a leading cause of disability. Assessment: PQRST (provoking/palliating, quality, region/radiation, severity, timing), functional impact, and psychologic screening (depression, catastrophizing, kinesiopho-

bia). Management requires an individualized multimodal approach.

Pain Assessment Scales

– Pain assessment uses standardized scales to quantify pain intensity. Numeric rating scale (NRS) asks patients to rate pain from 0 (no pain) to 10 (worst pain imaginable). Visual analog scale (VAS) is a 10 cm line with anchors. Faces pain scale (Wong-Baker FACES) uses facial expressions for children and cognitively impaired patients. FLACC scale (Face, Legs, Activity, Cry, Consolability) assesses pain in non-verbal children. Critical-care Pain Observation Tool (CPOT) assesses pain in mechanically ventilated patients in the intensive care unit. PAINAD (Pain Assessment in Advanced Dementia) assesses pain in elderly patients with dementia. Pain should be assessed at rest and with movement. Standardized scales improve pain documentation, treatment consistency, and outcomes. The goal is to maintain pain scores below 3-4 out of 10, allowing the patient to function and participate in recovery.

Pain Relief (Analgesia)

– Achieved through pharmacologic, interventional, physical, and psychologic modalities targeting nociceptive transmission and pain perception. Pharmacologic: World Health Organization (WHO) analgesic ladder recommends non-opioids (acetaminophen, NSAIDs) for mild pain, weak opioids (tramadol, codeine) for moderate pain, and strong opioids (morphine, oxycodone, hydromorphone, fentanyl) for severe pain, with adjuvant medications (antidepressants, anticonvulsants, local anesthetics) for neuropathic pain. Interventional procedures: nerve blocks (facet, epidural, peripheral nerve), radiofrequency ablation, spinal cord stimulation, intrathecal pumps. Physical modalities: ice/heat, transcutaneous electrical nerve stimulation (TENS), physical therapy, massage, acupuncture. Psychologic: cognitive-behavioral therapy, biofeedback, relaxation techniques, mindfulness meditation. Opioid prescribing requires careful risk-benefit assessment given addiction potential (especially with chronic use), respiratory depression, tolerance, and opioid-induced hyperalgesia. Multimodal analgesia—combining agents with different mechanisms—improves efficacy and reduces opioid requirements (opioid-sparing effect).

Patient-Controlled Analgesia

– Patient-controlled analgesia (PCA) allows patients to self-administer small doses of analgesic medication within preset safety limits. IV PCA typically uses morphine (demand 1 mg, lockout 6 to 10 minutes, hourly limit 4 mg), hydromorphone (demand 0.2 mg, lockout 6 to 10 minutes), or fentanyl (demand 10 to 20 mcg, lockout 6 to 10 minutes). PCA provides more consistent pain control than nurse-administered boluses and gives patients a sense of control. Basal infusion is controversial and increases the risk of respiratory depression, especially in opioid-naïve patients and those with obstructive sleep apnea. PCA by proxy (family members or nurses activating the button) is dangerous and should be avoided. Contraindications include patient inability to understand the device (cognitive impairment, age <5 years), allergy, and opioid tolerance. Epidural PCA (PCEA) combines a background infusion with patient-controlled boluses and is used for postoperative and labour analgesia.

Pediatric Anesthesia

– Pediatric anesthesia requires age-appropriate dosing, equipment, and techniques. Children have higher metabolic rates, increased oxygen consumption, smaller functional residual capacity, and higher risk of desaturation. Airway anatomy differs (larger tongue, more anterior larynx, narrower subglottic area). Induction is commonly performed via inhalation (sevoflurane in oxygen) or intravenous. Dosing is based on weight (mg/kg) with adjustments for neonates and infants. Temperature management is critical in neonates and infants due to high surface area-to-volume ratio. Emergence delirium is more common in children (sevoflurane) and is managed with propofol, dexmedetomidine, or gentle awakening. Postoperative nausea and vomiting is also common and treated with ondansetron, dexamethasone, and total intravenous anesthesia.

Peripheral Nerve Blocks

– Peripheral nerve blocks provide targeted anesthesia and analgesia for specific surgical sites. Ultrasound-guided blocks improve success rates and reduce complications. Common blocks include interscalene (shoulder surgery), supraclavicular (arm surgery), infraclavicular (arm and hand), axillary (hand surgery), femoral (knee surgery), adductor canal

(knee surgery with preserved quadriceps function), sciatic (foot and ankle), popliteal (foot and ankle), and ilioinguinal/iliohypogastric (inguinal hernia repair). Local anesthetics (bupivacaine 0.25-0.5%, ropivacaine 0.2-0.5%, lidocaine 1-2%) are used with or without epinephrine to prolong block duration and reduce systemic absorption. Ultrasound guidance has become the standard of care, reducing the risk of inadvertent vascular puncture, intraneural injection, and pneumothorax while improving block success rates and reducing local anesthetic volume requirements.

Postanesthesia Care Unit

– The postanesthesia care unit (PACU) is a monitored recovery area where patients are observed during the immediate postoperative period. Admission assessment includes vital signs, level of consciousness, pain assessment, and surgical site evaluation. The Aldrete scoring system assesses recovery criteria: activity, respiration, circulation, consciousness, and oxygen saturation. Common PACU problems include postoperative nausea and vomiting (treated with ondansetron), pain (treated with PCA or regional pain management). Modified Aldrete scoring system uses 5 criteria: activity (2: moves all extremities; 1: moves 2 extremities; 0: moves 0), respiration (2: deep breaths/cough; 1: dyspnea; 0: apnea), circulation (2: BP $\pm$ 20 of preop; 1: $\pm$ 20-50; 0: $\pm$ >50), consciousness (2: fully awake; 1: arousable; 0: unresponsive), and oxygen saturation (2: >92% on RA; 1: >92% with O₂; 0: <92% with O₂). Total score >9 indicates readiness for discharge. Discharge criteria include stable vital signs, adequate oxygenation, controlled pain, minimal nausea/vomiting, and ability to void (for spinal/epidural).

Post-Dural Puncture Headache

– A positional headache occurring after accidental dural puncture during epidural placement or lumbar puncture, caused by cerebrospinal fluid leakage and intracranial hypotension. Symptoms include frontal or occipital headache worse when upright and relieved when supine, neck stiffness, tinnitus, photophobia, and nausea. Incidence is 1 to 2 percent with 25 gauge pencil-point needles, 5 to 10 percent with 22 gauge cutting needles. Treatment includes conservative: bed rest, hydration, caffeine (500 mg

IV or oral), and analgesics. Invasive: epidural blood patch (15–20 mL of autologous blood injected into the epidural space at the level of the dural puncture), which is highly effective (80–95% success rate). Prevention: use of pencil-point (Whitacre, Sprotte) instead of cutting needles (Quincke), small gauge (25–27 G), and orientation of the needle bevel parallel to the dural fibers.

Postoperative Cognitive Dysfunction

– Decline in cognitive function (memory, concentration, executive function) after surgery and anesthesia, more common in elderly patients. POCD can be early (weeks to months) or persistent (>1 year). Incidence: 25–40% in elderly patients at hospital discharge, 10–15% at 3 months. Risk factors: age, lower education level, preoperative cognitive impairment, prolonged surgery, respiratory complications, and postoperative delirium. Pathophysiology: neuroinflammation (surgical stress response, cytokines), anesthetics (GABAergic drugs), and microemboli. Prevention: minimize depth and duration of anesthesia, avoid anticholinergic drugs, early mobilization, and cognitive stimulation. Management: neuropsychological evaluation and cognitive rehabilitation.

Postoperative Delirium

– A common complication after major surgery, particularly in elderly patients. It is categorized as hyperactive (agitation, restlessness, hallucinations), hypoactive (lethargy, withdrawal, decreased responsiveness), or mixed. Hypoactive delirium is the most common and most missed form. The Confusion Assessment Method (CAM) is the standard diagnostic tool. Postoperative delirium is associated with increased mortality, longer hospital stay, and accelerated cognitive decline that may persist for months to years. Prevention includes comprehensive geriatric assessment, preoperative cognitive screening, multidisciplinary team approach, and avoidance of high-risk medications (anticholinergics, benzodiazepines, meperidine). Management includes non-pharmacological measures (reorientation, family presence, early mobilization, sleep hygiene, sensory aids) and, if needed, low-dose antipsychotics (haloperidol 0.5–1 mg oral/IM, olanzapine, quetiapine) for hyperactive symptoms causing safety concerns.

Postoperative Nausea and Vomiting

– Nausea, retching, or vomiting occurring within 24–48 hours after surgery. PONV is one of the most common and distressing complications. Risk factors (Apfel score): female gender, non-smoker, history of motion sickness/PONV, and postoperative opioids. 0–1 risk factors: 10–20% incidence; 2: 40%; 3: 60%; 4: 80%. Prophylaxis: multimodal approach — 5-HT₃ antagonists (ondansetron 4 mg), dexamethasone 4–8 mg, droperidol 0.625 mg, scopolamine patch, and total intravenous anesthesia with propofol. Treatment: 5-HT₃ antagonist + dexamethasone + droperidol for rescue; consider NK₁ antagonists (aprepitant) for high-risk patients.

Postoperative Pain Management

– Postoperative pain management uses multimodal analgesia combining pharmacologic and regional techniques. Opioids (morphine, hydromorphone, fentanyl) provide potent analgesia but cause respiratory depression, nausea, and ileus. Acetaminophen (1000 mg IV every 6 hours) provides baseline analgesia. NSAIDs (ketorolac, celecoxib) reduce opioid requirements. Gabapentinoids (gabapentin, pregabalin) address neuropathic pain. Local anesthetic wound infiltration and regional blocks provide targeted analgesia. Regional techniques (epidural, spinal, peripheral nerve blocks) provide superior analgesia for specific surgical sites. Multimodal analgesia reduces opioid requirements and opioid-related side effects by targeting different pain pathways. The goal of postoperative pain management is to facilitate early mobilization, reduce pulmonary complications, and improve patient satisfaction.

Post-Surgical Pain

– Acute pain following operative procedures, caused by tissue incision, retraction, dissection, and inflammation, mediated by nociceptors sensitized by prostaglandins, bradykinin, and cytokines. Intensity varies by procedure (thoracotomy, joint replacement, and laparotomy produce more severe pain). Uncontrolled post-surgical pain increases risk of chronic postsurgical pain (CPSP, prevalence 10–50% depending on procedure), promotes complications (atelectasis, immobilization, thromboembolism, ileus, delayed wound healing), and prolongs hospital stay. Assessment: numeric rating

scale (0–10) at rest and with movement. Multimodal analgesia (opioid-sparing): regional anesthesia (nerve blocks, neuraxial anesthesia, local infiltration), NSAIDs/acetaminophen (around-the-clock), gabapentinoids, ketamine (for opioid-tolerant patients), and patient-controlled analgesia (PCA) with opioids for moderate-severe pain. Enhanced Recovery After Surgery (ERAS) protocols integrate multimodal analgesia, early mobilization, and patient education.

Preoperative Assessment

– Preoperative assessment evaluates surgical risk and optimizes medical conditions before anesthesia. It includes medical history, physical examination, airway assessment, cardiovascular risk stratification (Revised Cardiac Risk Index), pulmonary function assessment, and laboratory testing based on clinical indication. The ASA Physical Status Classification System grades patient fitness: ASA I (healthy), ASA II (mild systemic disease), ASA III (severe systemic disease), ASA IV (life-threatening disease (ASA IV), moribund patient not expected to survive 24 hours (ASA V), and brain-dead organ donor (ASA VI). The ASA class correlates with perioperative mortality: class I (<0.1%), II (0.2%), III (1.8%), IV (7.8%), and V (9.4%). Preoperative testing should be guided by patient age, comorbidities, surgery type, and anesthesia technique rather than routine batteries; focused testing based on clinical indication is more cost-effective and avoids unnecessary interventions.

Propofol

– The most widely used intravenous induction and maintenance agent, acting as a GABA-A receptor agonist producing rapid onset (30 to 40 seconds) and short duration of action (5 to 10 minutes). It causes dose-dependent hypotension through vasodilation and decreased cardiac output, and is contraindicated in patients with propofol allergy (egg or soybean oil hypersensitivity). Propofol has antiemetic properties and is used for total intravenous anesthesia (TIVA) when combined with remifentanyl infusion. Propofol infusion syndrome (rare but fatal) is associated with prolonged high-dose infusions (>4–5 mg/kg/hour for >48 hours) in children and critically ill patients, presenting as metabolic acidosis, rhabdomyolysis, renal failure, and cardiac failure.

Propofol is formulated in a lipid emulsion (soybean oil, egg lecithin, glycerol) providing 1.1 kcal/mL and requiring aseptic handling to prevent infection.

Rapid Sequence Induction

– An intubation technique designed to minimize aspiration risk in patients with full stomach. Steps include preoxygenation with 100 percent oxygen for 3 to 5 minutes (8 vital capacity breaths or 3 minutes), application of cricoid pressure, administration of induction agent (propofol 2 mg/kg or etomidate 0.3 mg/kg) followed immediately by succinylcholine (1.5 mg/kg) or rocuronium (1.2 mg/kg), and intubation without bag-mask ventilation. If rocuronium is used, sugammadex (16 mg/kg) is available as a rescue reversal agent, providing rapid and complete reversal of rocuronium-induced neuromuscular blockade. RSI is indicated in full stomach, emergency surgery, obesity, pregnancy, gastrointestinal obstruction, and severe gastro-oesophageal reflux disease.

Regional Anesthesia

– Regional anesthesia involves the administration of local anesthetic agents to specific nerves or nerve plexuses to provide surgical anesthesia and postoperative analgesia for a defined body region. Spinal anesthesia involves injection of local anesthetic (bupivacaine 0.5 percent, 7.5 to 15 mg) into the subarachnoid space at the L3–L4 or L2–L3 interspace, producing rapid onset of dense motor, sensory, and sympathetic blockade below the level of injection. Epidural anesthesia involves placement of a catheter into the epidural space, allowing continuous infusion of local anesthetic with or without opioids for surgical anesthesia and postoperative analgesia, with the advantage of titratable block level and duration. Contraindications to regional anesthesia include coagulopathy, infection at insertion site, patient refusal, increased intracranial pressure (dural puncture), and severe hypovolaemia.

Remifentanyl

– An ultra-short-acting synthetic opioid analgesic metabolized by non-specific plasma and tissue esterases, producing context-sensitive half-time of approximately 3 to 10 minutes regardless of infusion duration. This makes it ideal for total intravenous anesthesia (TIVA) combined with propofol, and for procedures requiring rapid emergence. Remifentanyl

is 200 to 300 times more potent than morphine. It causes dose-dependent respiratory depression and bradycardia. Remifentanyl-induced bradycardia and hypotension at bolus doses greater than 1 mcg/kg, and postoperative hyperalgesia at high infusion rates (>0.3 mcg/kg/min), requiring careful dose selection to balance opioid-induced hyperalgesia against inadequate analgesia.

Rocuronium

– A non-depolarizing aminosteroid neuromuscular blocking agent with onset of 60 to 90 seconds and duration of 30 to 45 minutes at intubating dose. It is the primary alternative to succinylcholine for rapid sequence intubation when administered at 1.2 mg/kg, providing comparable intubating conditions. Rocuronium does not cause histamine release, hyperkalemia, or malignant hyperthermia. It is metabolized hepatically and excreted in bile. Reversal is achieved with sugammadex (2 to 4 mg/kg) depending on depth of blockade. Sugammadex has largely replaced neostigmine for rocuronium reversal due to faster onset, predictable reversal regardless of blockade depth, and absence of muscarinic side effects. Rocuronium causes minimal cardiovascular effects and does not cause histamine release.

Ropivacaine

– A long-acting amide local anesthetic with sensory-motor dissociation, providing effective analgesia with less motor blockade than bupivacaine. It is used for epidural analgesia (0.2 percent), peripheral nerve blocks, and postoperative pain management. Ropivacaine is less cardiotoxic than bupivacaine and has a safer toxicity profile. Maximum dose is 3 mg/kg. Onset is 5 to 15 minutes, duration is 2 to 4 hours. Ropivacaine is available in 0.2 percent, 0.5 percent, and 1 percent concentrations. Ropivacaine is the least cardiotoxic amide local anesthetic and is preferred for high-volume peripheral nerve blocks and epidural infusions, particularly in ambulatory surgery where rapid recovery of motor function is desirable.

Scavenging System

– The anesthesia gas scavenging system collects and removes waste anesthetic gases from the operating room environment to protect staff from chronic exposure. Active scavenging uses negative pressure from vacuum source; passive scavenging vents to

exhaust through gravity. The interface between the anesthesia machine and scavenging system includes a positive pressure relief valve (to prevent barotrauma) and negative pressure relief valve (to prevent excessive suction). Occupational exposure limits for nitrous oxide are 25 ppm (time-weighted average over 8 hours) and for volatile agents 0.5-2 ppm depending on the agent. Proper scavenging is a critical occupational health and safety requirement in all anaesthetising locations, with periodic environmental monitoring to verify adequate system function and compliance with exposure limits.

Sedation Levels

– Defined by the ASA continuum: minimal sedation (anxiolysis, normal response to verbal commands), moderate sedation (response to verbal or light tactile stimulation, airway patent, spontaneous ventilation adequate), deep sedation (purposeful response after repeated or painful stimulation, airway may require assistance, spontaneous ventilation inadequate), and general anesthesia (unarousable even with painful stimulus, airway intervention often required, spontaneous ventilation may be inadequate). The ASA recommends that practitioners be able to rescue patients from the level of sedation immediately above that intended. Sedation is administered by qualified anesthesia professionals or trained non-anesthesia personnel under appropriate supervision with monitoring of oxygen saturation, heart rate, blood pressure, and level of consciousness.

Sevoflurane

– A volatile inhalation anesthetic with low blood-gas partition coefficient (0.65), providing rapid induction and emergence. It is non-pungent and widely used for inhalation induction in pediatric patients. Minimum alveolar concentration (MAC) is 2 percent in adults, 2.5 percent in children. Sevoflurane causes dose-dependent myocardial depression and vasodilation. It is metabolized minimally (2 to 5 percent) by CYP2E1 to inorganic fluoride. Compound A is formed when sevoflurane reacts with desiccated CO₂ absorbents (soda lime, baralyme), producing Compound A, a vinyl ether that is nephrotoxic in rats at high concentrations, though clinical significance in humans at low fresh gas flows (>2 L/min) is debated; this concern has limited the use of low-flow anesthesia with sevoflurane.

Spinal Analgesia

- Spinal analgesia involves single-shot injection of local anesthetic and/or opioid into the subarachnoid space for rapid, dense sensory and motor blockade. Bupivacaine 0.5 percent (10 to 15 mg) provides surgical anesthesia lasting 2 to 4 hours. Intrathecal morphine (0.1 to 0.3 mg) provides postoperative analgesia for 12 to 24 hours but carries risk of delayed respiratory depression, particularly in obese or elderly patients. Spinal analgesia is used for lower extremity surgery, cesarean section, and urological procedures, and provides rapid onset and reliable blockade. Hypotension from sympathetic blockade is the most common complication, treated with intravenous fluids and vasopressors (phenylephrine, ephedrine). Post-dural puncture headache is a risk, particularly with larger-gauge or cutting needles.

Succinylcholine

- A depolarizing neuromuscular blocking agent with rapid onset (30 to 60 seconds) and short duration of action (5 to 10 minutes), making it the drug of choice for rapid sequence intubation. It acts by binding to nicotinic acetylcholine receptors at the neuromuscular junction, causing persistent depolarization and initial fasciculations followed by paralysis. Succinylcholine is metabolized by plasma pseudocholinesterase. Adverse effects include hyperkalemia (contraindicated in burns, major trauma, neuromuscular disease (muscle atrophy), and malignant hyperthermia susceptibility. Succinylcholine causes increased intraocular, intragastric, and intracranial pressure. Fasciculations can be prevented by a small priming dose of a non-depolarizing muscle relaxant (defasciculating dose). Prolonged paralysis occurs in patients with pseudocholinesterase deficiency (genetic variant or acquired).

Sugammadex

- A selective relaxant binding agent that reverses aminosteroid neuromuscular blockers (rocuronium and vecuronium) by encapsulating them in a cyclodextrin molecule, forming a 1:1 complex that is renally excreted. Onset of action is within 2 to 3 minutes. Dosing: 2 mg/kg for moderate reversal (second dose of rocuronium), 4 mg/kg for rapid reversal (3 minutes after rocuronium), and 16 mg/kg for immediate reversal (within 3 minutes of rocuronium). Sugammadex eliminates the need for anti-

cholinesterase drugs (neostigmine) for aminosteroid reversal, as it encapsulates the steroid molecule directly without affecting acetylcholinesterase, avoiding muscarinic side effects. Anaphylactic reactions to sugammadex have been reported but are rare. Sugammadex is the reversal agent of choice for rapid sequence intubation with rocuronium, providing reliable and complete reversal within 3 minutes at the 16 mg/kg dose.

Supraglottic Airway Devices

- Supraglottic airway devices (SADs) sit above the vocal cords, providing a seal around the laryngeal inlet without tracheal intubation. First-generation SADs (classic LMA, i-gel) provide airway seal but do not protect against aspiration. Second-generation SADs (LMA ProSeal, LMA Supreme, i-gel) include a gastric drainage port and higher sealing pressures, allowing ventilation and aspiration protection. SADs are used for short procedures, as rescue airway devices, and in difficult airway algorithm-algorithms. SAD complications include airway obstruction, laryngospasm, and aspiration. Correct placement is confirmed by chest rise, capnography, and no leak. Contraindications include full stomach, reduced pulmonary compliance, and pharyngeal pathology.

Target-Controlled Infusion

- A computerized infusion pump system that maintains a predetermined drug concentration in plasma or effect site using pharmacokinetic modeling. TCI systems use three-compartment pharmacokinetic models to calculate infusion rates that achieve and maintain target concentration. Propofol TCI models include Marsh (plasma-targeted) and Schnider (effect-site targeted). Remifentanyl TCI uses the Minto model. TCI provides more stable anesthetic depth compared to manual manual infusion techniques by maintaining a stable predicted concentration, reducing haemodynamic variability and anesthetic waste. Limitations include the accuracy of pharmacokinetic models in individual patients (obesity, elderly, paediatrics, organ dysfunction), variability in drug potency, and the potential for infusion pump programming errors.

Total Intravenous Anesthesia

- Total intravenous anesthesia (TIVA) uses intravenous agents exclusively for induction and main-

tenance of anesthesia, avoiding volatile inhalation agents. The most common TIVA regimen combines propofol infusion (50 to 200 mcg/kg/min) with remifentanyl infusion (0.1 to 0.5 mcg/kg/min). TIVA advantages include rapid emergence, reduced postoperative nausea and vomiting, suitability for patients with malignant hyperthermia risk, and use in procedures requiring volatile anesthetic avoidance. TIVA disadvantages include the need for dedicated infusion pumps, risk of propofol infusion syndrome with prolonged high-dose infusions, and the lack of an end-tidal volatile anesthetic concentration monitor to confirm anesthetic depth; BIS or entropy monitoring is typically used with TIVA to assess depth of anesthesia and reduce the risk of intraoperative awareness.

Train-of-Four Monitoring

- Train-of-four (TOF) monitoring assesses neuromuscular blockade by delivering four supramaximal electrical stimuli at 2 Hz to a peripheral nerve (usually ulnar nerve at the wrist). The ratio of the fourth twitch height to the first twitch height indicates the degree of blockade. TOF ratio of 0 indicates complete blockade, 0.25 indicates profound blockade, 0.5 indicates moderate blockade, and 0.7 to 0.9 indicates partial recovery. A TOF ratio greater than 0.9 is required for adequate neuromuscular recovery before extubation, and for prevention of residual neuromuscular blockade. Residual blockade (TOF ratio <0.9) occurs in 20-40% of patients receiving non-depolarizing neuromuscular blockers and is associated with increased risk of postoperative pulmonary complications, hypoxemia, and aspiration, making objective TOF monitoring essential before extubation.

Tranexamic Acid

- An antifibrinolytic agent that inhibits plasminogen activation, reducing fibrinolysis and blood loss. TXA is used in trauma (CRASH-2 trial: 1 g IV over 10 minutes, then 1 g infusion over 8 hours), cardiac surgery (reduces re-exploration and transfusion), orthopedic surgery (joint replacement reduces blood loss by 30 to 50 percent), and heavy menstrual bleeding. Dose is 10 to 20 mg/kg IV. TXA is contraindicated in active intravascular clotting, history of thromboembolism, thromboembolism, and subarachnoid hemorrhage. Side effects are rare but

include seizures, thrombotic events, and anaphylaxis. Routine use in cardiac surgery is supported by evidence, but its use in trauma beyond the first 3 hours is not recommended.

Vasopressors in Anesthesia

- Vasopressors maintain blood pressure during anesthesia-induced vasodilation. Phenylephrine is a pure alpha-1 agonist causing vasoconstriction without cardiac effects, used for pure vasodilatory hypotension. Dose: bolus 50 to 100 mcg IV or infusion 0.05 to 0.5 mcg/kg/min. Ephedrine stimulates alpha and beta receptors, increasing both heart rate and blood pressure. Dose: 5 to 10 mg IV bolus. Norepinephrine is a potent alpha-1 and beta-1 agonist, used for refractory hypotension and septic shock. Dose: 0.05 to 0.5 mcg/kg/min infusion. Dopamine acts on dopamine, beta, and alpha receptors in a dose-dependent manner: low dose (1-5 mcg/kg/min) mainly acts on dopamine receptors dilating renal and mesenteric vessels; intermediate dose (5-10 mcg/kg/min) acts on beta-1 receptors increasing contractility and heart rate; high dose (>10 mcg/kg/min) acts on alpha-1 receptors causing vasoconstriction.

Video Laryngoscopy

- Video laryngoscopy uses a camera-equipped blade to visualize the glottis on a screen, providing indirect laryngoscopy with improved glottic exposure. Common devices include GlideScope, C-MAC, and McGrath. Video laryngoscopy is particularly useful in Mallampati Class III or IV patients, limited neck mobility, and obesity. It provides a magnified, well-illuminated view of the vocal cords. The line-of-sight principle differs from direct laryngoscopy, requiring different technique (lifting anteriorly and superior glottic view on screen). Video laryngoscopy is rapidly becoming the standard of care for both anticipated and unexpected difficult airways, and for routine intubation in many institutions due to its improved first-pass success rate and reduced oesophageal intubation rate compared to direct laryngoscopy.

Chapter 3

Biochemistry

Acid

– A substance that donates protons (H^+) or accepts electron pairs (Lewis acid). In aqueous solution, acids increase H^+ concentration ($pH < 7$). Strong acids (HCl , H_2SO_4 , HNO_3) dissociate completely; weak acids (acetic acid, carbonic acid H_2CO_3 , phosphate, amino acid side chains) partially dissociate (K_a , pK_a). In biochemistry, key acids include: carbonic acid (H_2CO_3 , from $CO_2 + H_2O$, major blood buffer with bicarbonate), lactic acid (anaerobic glycolysis), ketone bodies (acetoacetate, beta-hydroxybutyrate, diabetic ketoacidosis), uric acid (purine catabolism, gout), fatty acids, amino acids (carboxyl group, $pK_a \approx 2$), and nucleotide phosphates. Acid-base balance is maintained by respiratory (CO_2) and renal (H^+ , HCO_3^-) compensation. Anion gap = $[Na^+] - ([Cl^-] + [HCO_3^-])$ identifies unmeasured anions.

Active Site

– The specific three-dimensional region of an enzyme where substrate binding and catalysis occur. Formed by amino acid residues that may be distant in primary sequence but brought together by protein folding. The active site provides a unique microenvironment (specific pH, hydrophobicity, electrostatics) that stabilizes the transition state, lowering activation energy. Substrate binding follows induced fit (conformational change) or lock-and-key models. Active site residues directly participate in catalysis (acid-base, covalent, metal ion catalysis).

ADP (Adenosine Diphosphate)

– A nucleotide composed of adenine, ribose, and two phosphate groups. Formed by hydrolysis of ATP ($ATP \rightarrow ADP + Pi$, $\Delta G^\circ = -30.5 \text{ kJ/mol}$). Serves as the immediate precursor for ATP synthesis via oxidative phosphorylation (mitochondrial ATP

synthase), substrate-level phosphorylation (glycolysis, TCA cycle), and photophosphorylation. The ADP/ATP ratio regulates cellular energy state: high ADP stimulates catabolic pathways (glycolysis, beta-oxidation, TCA cycle) and inhibits anabolic pathways.

Albumin

– The most abundant plasma protein (35-50 g/L, 60% of total protein), synthesized in the liver. A single polypeptide (66.5 kDa, 585 amino acids) with high negative charge at physiological pH. Functions: (1) Maintains colloid osmotic pressure (oncotic pressure, 75% of total), retaining fluid in vasculature; (2) Transport: binds and transports fatty acids, bilirubin, hormones (thyroxine, cortisol), drugs (warfarin, penicillins), calcium, and metal ions; (3) Antioxidant: free thiol (Cys34) scavenges reactive oxygen species; (4) Buffering: contributes to plasma buffering capacity. Low albumin (hypoalbuminemia) causes edema, reduced drug binding, and is a marker of malnutrition, liver disease, nephrotic syndrome, inflammation, or protein-losing enteropathy. Albumin infusion used for volume expansion in specific settings.

Amino Acid

– The building blocks of proteins, 20 standard L- α -amino acids sharing a central carbon (α -carbon) bonded to an amino group ($-NH_2$), carboxyl group ($-COOH$), hydrogen, and a unique side chain (R group). Classification by side chain properties: nonpolar (glycine, alanine, valine, leucine, isoleucine, proline, methionine, phenylalanine, tryptophan), polar uncharged (serine, threonine, cysteine, asparagine, glutamine), acidic (aspartate, glutamate), basic (lysine, arginine, histidine). Nine essential amino acids (cannot synthesize): histi-

dine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, valine. Amino acids undergo transamination (PLP-dependent), deamination, and decarboxylation. Carbon skeletons feed into glycolysis/TCA (glucogenic: pyruvate, oxaloacetate, fumarate, succinyl-CoA, α -ketoglutarate; ketogenic: acetyl-CoA, acetoacetate; both: isoleucine, phenylalanine, tyrosine, tryptophan). Branched-chain amino acids (BCAA: leucine, isoleucine, valine) are primarily metabolized in muscle. Branched-chain ketoacid dehydrogenase deficiency causes maple syrup urine disease.

AMP (Adenosine Monophosphate)

– A nucleotide composed of adenine, ribose, and a single phosphate group. Formed by hydrolysis of ADP ($\text{ADP} \rightarrow \text{AMP} + \text{Pi}$) or directly from ATP via adenylate kinase ($2 \text{ ADP} \leftrightarrow \text{ATP} + \text{AMP}$). AMP is a key allosteric signal of low energy status: activates AMPK (AMP-activated protein kinase), phosphorylase kinase (glycogenolysis), and PFK-1 (glycolysis). Degraded to IMP by AMP deaminase in purine catabolism. The ATP:ADP:AMP ratio (energy charge) regulates metabolic flux.

Anabolism

– The set of metabolic pathways that construct complex molecules from simpler precursors, requiring energy input (ATP, reducing equivalents NADPH). Examples: protein synthesis from amino acids, glycogen synthesis (glycogenesis), fatty acid synthesis (lipogenesis), cholesterol synthesis, nucleotide synthesis, gluconeogenesis. Anabolic pathways are typically stimulated by insulin and inhibited by glucagon, epinephrine, and AMPK. They share intermediates with catabolic pathways but use distinct regulated enzymes (reciprocal regulation).

Anticodon

– A three-nucleotide sequence at one end of transfer RNA that base-pairs with a complementary messenger RNA codon during translation, ensuring the correct amino acid is incorporated into the growing polypeptide. Wobble pairing at the first anticodon position permits one tRNA to recognize multiple synonymous codons, explaining codon degeneracy.

Apoenzyme

– The protein component of an enzyme without its required cofactor or coenzyme. Inactive or minimally active until the cofactor binds. The complete,

catalytically active complex of apoenzyme + cofactor is called the holoenzyme. Many enzymes require metal ions (Zn^{2+} , Mg^{2+} , $\text{Fe}^{2+}/\text{Fe}^{3+}$, Cu^{2+} , Mn^{2+}) or organic cofactors (NAD^+ , FAD, coenzyme A, TPP, PLP, biotin) for activity. Apoenzyme folding may depend on cofactor binding.

ATP (Adenosine Triphosphate)

– The primary energy currency of the cell, composed of adenine, ribose, and three phosphate groups. Hydrolysis of the terminal phosphoanhydride bond releases $\Delta G^\circ = -30.5 \text{ kJ/mol}$ (-7.3 kcal/mol), driving endergonic cellular processes such as muscle contraction, active transport, and biosynthesis. Generated via substrate-level phosphorylation (glycolysis, TCA cycle) and oxidative phosphorylation in mitochondria.

Base

– A substance that accepts protons (H^+) or donates electron pairs (Lewis base). In aqueous solution, bases increase OH^- concentration ($\text{pH} > 7$). Strong bases (NaOH , KOH) dissociate completely; weak bases (NH_3 , HCO_3^- , protein side chains) partially. In biochemistry, key bases include: bicarbonate (HCO_3^- , major blood buffer), phosphate (HPO_4^{2-}), amino acid side chains (histidine imidazole, lysine, arginine), and nucleotide bases (adenine, guanine, cytosine, thymine, uracil). Base excess/deficit quantifies metabolic acid-base disturbance.

Base Excision Repair

– The repair pathway for small, non-helix-distorting base lesions including oxidized bases (8-oxoguanine), deaminated bases (uracil from cytosine deamination), alkylated bases, and abasic (AP) sites. Steps: (1) a specific DNA glycosylase recognizes and removes the damaged base by hydrolyzing the N-glycosidic bond, creating an AP (apurinic/apyrimidinic) site. Different glycosylases recognize different lesions: uracil-DNA glycosylase (UNG) removes uracil from DNA; OGG1 removes 8-oxoguanine; MPG (methylpurine DNA glycosylase) removes alkylated bases. After glycosylase action, AP endonuclease 1 (APE1) nicks the DNA backbone 5' to the AP site, DNA polymerase β replaces the missing nucleotide, and DNA ligase seals the nick.

Beriberi

– A nutritional deficiency disease caused by inade-

quate thiamine (vitamin B1), occurring in two forms. Wet beriberi presents with high-output heart failure, peripheral vasodilation, edema, and tachycardia due to impaired cardiac energy metabolism. Dry beriberi presents with peripheral neuropathy (symmetric sensory and motor deficits, paresthesias, muscle wasting). Risk factors: polished rice as dietary staple, alcoholism, malabsorption, and pregnancy. Treatment: thiamine supplementation (parenteral initially for severe cases). Wernicke-Korsakoff syndrome is the neuropsychiatric manifestation of thiamine deficiency in alcoholism.

Beta-Oxidation

– The catabolic process by which fatty acid molecules are broken down in the mitochondria (and peroxisomes) to generate acetyl-CoA, NADH, and FADH₂. Fatty acids are activated to acyl-CoA by acyl-CoA synthetase, transported into the mitochondrial matrix via the carnitine shuttle, and undergo a four-step repeating cycle: oxidation, hydration, oxidation, and thiolysis. Yields 106 ATP net per molecule of palmitate (16-carbon fatty acid).

Biomolecule

– Any organic molecule produced by living organisms, essential for structure, function, and regulation of biological processes. Four major classes: (1) Proteins (amino acid polymers—enzymes, structural, transport, signaling); (2) Nucleic acids (DNA, RNA—genetic information storage and expression); (3) Carbohydrates (sugars, polysaccharides—energy, structure); (4) Lipids (fats, phospholipids, steroids—membranes, energy storage, signaling). Biomolecules are built from a small set of elements (C, H, O, N, P, S) and share universal metabolic pathways across life.

Buffer

– A solution that resists pH change upon addition of acid or base, composed of a weak acid and its conjugate base (or weak base and conjugate acid). Buffer capacity is maximal when $\text{pH} = \text{pK}_a \pm 1$. Major physiological buffers: (1) Bicarbonate/carbonic acid ($\text{HCO}_3^-/\text{H}_2\text{CO}_3$, pK_a 6.1, primary blood buffer, linked to respiratory CO_2 elimination); (2) Phosphate ($\text{H}_2\text{PO}_4^-/\text{HPO}_4^{2-}$, pK_a 7.2, intracellular and urinary buffer); (3) Protein buffers (hemoglobin, albumin, pK_a 6.8–7.8, major intracellular and plasma buffer); (4) Ammonia/ammonium ($\text{NH}_3/\text{NH}_4^+$, re-

nal buffer). Henderson-Hasselbalch equation: $\text{pH} = \text{pK}_a + \log([\text{base}]/[\text{acid}])$.

Carbohydrate

– A class of organic compounds composed of carbon, hydrogen, and oxygen (general formula $\text{C}_m(\text{H}_2\text{O})_n$), serving as the primary energy source for the body. Classification: monosaccharides (glucose, fructose, galactose—single sugar units), disaccharides (sucrose, lactose, maltose—two units), oligosaccharides (3–10 units), and polysaccharides (starch, glycogen, cellulose, fiber—many units). Glucose is the essential fuel for the brain and red blood cells. The body stores limited glycogen (liver 100 g, muscle 400 g). Dietary carbohydrates are digested to monosaccharides, absorbed in the small intestine, and metabolized via glycolysis, the TCA cycle, and oxidative phosphorylation to produce ATP. Excess carbohydrate is converted to fat (lipogenesis). The glycemic index ranks foods by their effect on blood glucose.

Catabolism

– The set of metabolic pathways that break down complex molecules into simpler units, releasing energy captured as ATP, NADH, FADH₂, NADPH. Examples: glycolysis, beta-oxidation, proteolysis, glycogenolysis, nucleotide catabolism. Catabolic pathways converge on central intermediates (acetyl-CoA, pyruvate, TCA cycle intermediates) and are typically stimulated by glucagon, epinephrine, cortisol, and AMPK; inhibited by insulin. The energy released drives anabolic processes, ion gradients, and mechanical work.

Catalyst

– A substance that increases the rate of a chemical reaction without being consumed, by lowering the activation energy (providing an alternative reaction pathway). Enzymes are biological catalysts (proteins or ribozymes). Catalysts do not alter the reaction equilibrium (ΔG), only the kinetics. They accelerate both forward and reverse reactions equally. Enzyme catalysis mechanisms: proximity/orientation, acid-base, covalent, metal ion, electrostatic stabilization, and strain/distortion.

Cholesterol

– A 27-carbon sterol essential for cell membrane structure (modulates fluidity), precursor of steroid hormones (cortisol, aldosterone, sex hormones), bile acids, and vitamin D. Synthesized de novo (1 g/day,

primarily liver) from acetyl-CoA via the mevalonate pathway (HMG-CoA reductase is rate-limiting, targeted by statins). Obtained from diet (animal products). Transported in blood as lipoproteins (LDL, HDL). Cellular uptake via LDL receptor (endocytosis). Excess cholesterol is esterified (ACAT) for storage or effluxed to HDL (ABCA1) for reverse cholesterol transport.

Cholesterol Synthesis

– Occurs in all nucleated cells (primarily liver and intestine, approximately 1 g/day production), using acetyl-CoA as the precursor through approximately 30 enzymatic steps. Key stages: (1) two acetyl-CoA condense to acetoacetyl-CoA, then to HMG-CoA (3-hydroxy-3-methylglutaryl-CoA); (2) HMG-CoA reductase (ER-membrane enzyme, the rate-limiting step) reduces HMG-CoA to mevalonate using 2 NADPH. This step is inhibited by statins (competitive inhibitors, the most widely prescribed cholesterol-lowering drugs). After mevalonate, isopentenyl pyrophosphate (IPP) is formed, and six IPP molecules condense to form squalene, which is cyclized to lanosterol and then converted through nineteen additional steps to cholesterol.

Citric Acid Cycle (Krebs Cycle)

– A central metabolic pathway occurring in the mitochondrial matrix that oxidizes acetyl-CoA (derived from carbohydrates, lipids, and proteins) into CO_2 , generating 3 NADH, 1 FADH_2 , and 1 GTP (ATP) per turn. Rate-limiting enzyme: isocitrate dehydrogenase (inhibited by ATP and NADH; activated by ADP). Also serves an amphibolic role by providing precursors for amino acids, heme, and fatty acid synthesis.

Coenzyme

– A non-protein organic molecule that binds to an enzyme (apoenzyme) and is required for its catalytic activity. Coenzymes often act as transient carriers of specific chemical groups or electrons. Many are vitamin-derived: $\text{NAD}^+/\text{NADP}^+$ (niacin, B3), FAD/FMN (riboflavin, B2), coenzyme A (pantothenic acid, B5), thiamine pyrophosphate/TPP (B1), pyridoxal phosphate/PLP (B6), biotin (B7), tetrahydrofolate (B9), cobalamin (B12). Coenzymes may be tightly bound (prosthetic groups, e.g., FAD in succinate dehydrogenase) or loosely bound (co-substrates, e.g., NAD^+ in dehydrogenases).

Cofactor

– A non-protein chemical compound or metallic ion required for an enzyme's catalytic activity. Cofactors include: (1) Metal ions (Mg^{2+} , Zn^{2+} , $\text{Fe}^{2+}/\text{Fe}^{3+}$, Cu^{2+} , Mn^{2+} , Ca^{2+} , Mo, Se) that stabilize structure, participate in redox, or act as Lewis acids; (2) Coenzymes (organic cofactors, often vitamin-derived). The complete active enzyme (apoenzyme + cofactor) is the holoenzyme. Cofactor deficiency causes metabolic dysfunction (e.g., Zn^{2+} for carbonic anhydrase, Mg^{2+} for kinases, Fe^{2+} for cytochromes).

CRISPR-Cas9 Gene Editing

– A revolutionary genome editing technology adapted from the bacterial adaptive immune system. Bacteria store fragments of invading phage DNA in CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) arrays, which are transcribed and processed into guide RNAs (crRNAs) that direct Cas nucleases to cleave matching foreign DNA. The engineered system uses: a guide RNA (gRNA = crRNA + tracrRNA, or a single guide RNA/sgRNA) complementary to the target DNA sequence (approximately 20 nucleotides). The Cas nuclease (most commonly Cas9 from *Streptococcus pyogenes*) creates a double-strand break (DSB) at the target site, which is repaired by non-homologous end joining (NHEJ, causing insertions/deletions and gene knock-out) or homology-directed repair (HDR, enabling precise edits using a donor template).

Deficiency Diseases

– Diseases caused by a lack of specific essential nutrients in the diet, including vitamins, minerals, or macronutrients. Examples: scurvy (vitamin C deficiency–gingival hypertrophy, perifollicular hemorrhages, impaired wound healing), beriberi (thiamine deficiency–wet: heart failure, dry: neuropathy), pellagra (niacin deficiency–dermatitis, diarrhea, dementia), rickets (vitamin D deficiency in children–bowing deformities, growth retardation), osteomalacia (vitamin D deficiency in adults–bone pain, fractures), kwashiorkor (protein deficiency–edema, hepatomegaly), marasmus (calorie deficiency–wasting, growth failure), iron deficiency anemia, and vitamin B12 deficiency. Treatment: replacement of the deficient nutrient and treatment of the underlying cause.

Deoxyribonucleic Acid (DNA)

– The molecule that carries the genetic instructions used in the development, functioning, and reproduction of all living organisms. DNA is a double-stranded helix composed of nucleotides, each containing a deoxyribose sugar, a phosphate group, and one of four nitrogenous bases: adenine (A), thymine (T), guanine (G), and cytosine (C). Base pairing is specific: A pairs with T (two hydrogen bonds), G pairs with C (three hydrogen bonds). The sequence of bases encodes genetic information. DNA is organized into chromosomes within the nucleus (nuclear DNA, 3 billion base pairs in humans) and is also present in mitochondria (mtDNA, 16,569 base pairs). DNA replication is semiconservative. The human genome contains 20,000 protein-coding genes. DNA analysis techniques (PCR, sequencing, microarray) are fundamental to modern medicine.

DNA Replication: Semi-Conservative

– The mechanism of DNA duplication producing two identical daughter molecules, each containing one original (parental) strand and one newly synthesized strand. The Meselson-Stahl experiment (1958) demonstrated semi-conservative replication using nitrogen isotopes ($^{15}\text{N}/^{14}\text{N}$) and density gradient centrifugation. Replication begins at origins of replication (single *oriC* in *E. coli*; multiple origins in eukaryotic chromosomes, allowing timely replication of large genomes). Key enzymes and steps: (1) helicase unwinds the DNA at the origin; (2) single-strand binding proteins stabilise the separated strands; (3) primase synthesises short RNA primers to provide a free 3'-OH group; (4) DNA polymerase III (prokaryotes) or DNA polymerase delta/epsilon (eukaryotes) extends the primer, synthesising the new strand in the 5' to 3' direction; (5) on the lagging strand, discontinuous Okazaki fragments are joined by DNA ligase after primer removal by DNA polymerase I (prokaryotes) or RNase H and FEN1 (eukaryotes).

Electrolyte

– An ion (charged particle) in solution that conducts electricity. Essential for fluid balance, nerve impulse transmission, muscle contraction, pH regulation, and enzyme function. Major cations: Na^+ (extracellular, 135-145 mEq/L), K^+ (intracellular,

3.5-5.0 mEq/L), Ca^{2+} , Mg^{2+} . Major anions: Cl^- (extracellular), HCO_3^- , PO_4^{3-} , proteins (intracellular). Electrolyte disorders: hyponatremia, hypernatremia, hypokalemia, hyperkalemia, hypocalcemia, hypercalcemia. Measured by serum chemistry panel; regulated by kidneys (renin-angiotensin-aldosterone, ADH), hormones (PTH, vitamin D), and acid-base status.

Electron Transport Chain

– A series of four inner mitochondrial membrane protein complexes (Complex I to IV) plus electron carriers (coenzyme Q, cytochrome c) that transfer electrons from NADH and FADH_2 to molecular oxygen (O_2), reducing it to H_2O . The electron transfer drives proton pumping (H^+) from the matrix into the intermembrane space, creating an electrochemical gradient (proton-motive force).

Enzyme Kinetics (Michaelis-Menten)

– The quantitative study of enzyme-catalyzed reaction rates. Characterized by the Michaelis constant (K_m , the substrate concentration at half-maximal velocity V_{max}) and V_{max} (the maximum rate when enzyme is saturated). Lineweaver-Burk plot ($1/v$ vs. $1/[S]$) linearizes kinetics: competitive inhibitors increase K_m without altering V_{max} ; non-competitive inhibitors decrease V_{max} without altering K_m .

Enzymes

– Proteins (or occasionally RNA molecules—ribozymes) that act as biological catalysts, accelerating chemical reactions by lowering activation energy without being consumed in the process. Enzymes are highly specific, typically catalyzing a single reaction or class of reactions. Nomenclature: substrate + -ase (e.g., lactase breaks down lactose). Classification (EC system): oxidoreductases, transferases, hydrolases, lyases, isomerases, and ligases. Factors affecting enzyme activity: temperature, pH, substrate concentration, and inhibitors. Clinically important enzymes: cardiac troponin (myocardial infarction), creatine kinase (muscle injury), alanine transaminase (liver injury), lipase (pancreatitis), alkaline phosphatase (bone/liver disease), and lactate dehydrogenase (tissue damage). Therapeutic enzymes: tissue plasminogen activator (thrombolysis), asparaginase (leukemia), and pancreatic enzyme

replacement.

Essential Amino Acid

- Any of nine standard amino acids that humans cannot synthesize *de novo* and must obtain from the diet: histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, and valine. Deficiency impairs protein synthesis, producing negative nitrogen balance, muscle wasting, and growth failure. The branched-chain members are catabolized in skeletal muscle.

FAD (Flavin Adenine Dinucleotide)

- A redox coenzyme derived from riboflavin (vitamin B2), composed of flavin mononucleotide (FMN) linked to AMP. Exists as oxidized FAD, semiquinone $\text{FADH}^\bullet$, and reduced FADH_2 . Serves as prosthetic group in flavoproteins: succinate dehydrogenase (Complex II, TCA cycle), acyl-CoA dehydrogenase (beta-oxidation), xanthine oxidase (purine catabolism), and monoamine oxidases. FADH_2 donates electrons to the electron transport chain via Complex II (1.5 ATP equivalent). FAD is also a component of the pyruvate dehydrogenase and alpha-ketoglutarate dehydrogenase complexes.

Fatty Acid

- A carboxylic acid with a long hydrocarbon chain (typically 4-28 carbons), the building block of lipids. Classification: saturated (no double bonds, solid at room temp, e.g., palmitic C16:0, stearic C18:0), monounsaturated (one double bond, e.g., oleic C18:1), polyunsaturated (multiple double bonds, e.g., linoleic C18:2 n-6, alpha-linolenic C18:3 n-3). Essential fatty acids (must obtain from diet): linoleic acid (omega-6) and alpha-linolenic acid (omega-3). Fatty acids are activated to acyl-CoA (ATP-dependent) for beta-oxidation (energy), esterification into triglycerides/phospholipids, or signaling (eicosanoids from arachidonic acid).

Feedback Inhibition

- A regulatory mechanism in which the end product of a biosynthetic pathway inhibits an upstream enzyme, typically the first committed step, balancing production with cellular demand. The inhibitor usually binds an allosteric site, lowering catalytic activity. Examples include isoleucine inhibiting threonine deaminase and cholesterol inhibiting HMG-CoA reductase.

Fructose

- A ketohexose monosaccharide ($\text{C}_6\text{H}_{12}\text{O}_6$), an isomer of glucose. Found in fruits, honey, and as half of sucrose (table sugar). Metabolized primarily in the liver via fructokinase to fructose-1-phosphate, then split by aldolase B to glyceraldehyde and dihydroxyacetone phosphate (entering glycolysis). Unlike glucose, fructose bypasses PFK-1 (the main glycolytic regulatory step), promoting lipogenesis when consumed in excess. Hereditary fructose intolerance (aldolase B deficiency) causes hypoglycemia, liver/kidney damage after fructose ingestion.

Galactose

- A monosaccharide ($\text{C}_6\text{H}_{12}\text{O}_6$) that is an epimer of glucose (differing at the C4 position). Galactose is produced from the hydrolysis of lactose (milk sugar) in the small intestine by lactase. It is converted to glucose via the Leloir pathway: galactose to galactose-1-phosphate to UDP-galactose to UDP-glucose to glucose-1-phosphate. Deficiency of enzymes in this pathway causes galactosemia (GALT, GALK, or GALE deficiency). Galactose is also a component of glycoproteins, proteoglycans, and glycolipids (including blood group antigens).

Galactosemia

- Inborn errors of galactose metabolism, with three main types. Classic galactosemia (GALT deficiency, most severe, autosomal recessive): galactose-1-phosphate uridylyltransferase converts galactose-1-phosphate to glucose-1-phosphate. Deficiency causes accumulation of galactose-1-phosphate (toxic to liver, kidney, brain, and lens) and galactitol (from reduction of galactose by aldose reductase, accumulating in the lens causing osmotic cataracts). Newborns present after milk feeding (lactose = glucose + galactose) with vomiting, diarrhea, failure to thrive, hypoglycemia, jaundice, and hepatomegaly. Long-term complications include cataracts, intellectual disability, and premature ovarian failure.

Globulin

- A family of globular proteins in blood plasma, distinct from albumin. Classified by electrophoresis: alpha-1 (alpha-1-antitrypsin, alpha-fetoprotein), alpha-2 (haptoglobin, ceruloplasmin), beta (transferrin, complement C3), and gamma (immunoglobulins/IgG, IgA, IgM, IgD, IgE). Functions: transport (transferrin for iron, haptoglobin for hemoglobin,

ceruloplasmin for copper), immune defense (immunoglobulins, complement), enzyme inhibition (alpha-1-antitrypsin protects against proteases), and acute phase response (CRP, fibrinogen). A/G ratio (albumin/globulin) is a clinical indicator of protein status.

Glucose

- The primary monosaccharide fuel for cellular metabolism ($C_6H_{12}O_6$, aldohexose). Blood glucose (70-100 mg/dL fasting) is tightly regulated by insulin (lowers) and glucagon/epinephrine/cortisol (raise). Glucose enters cells via GLUT transporters (GLUT1-4, tissue-specific). Metabolic fates: glycolysis (ATP), glycogen synthesis (storage), pentose phosphate pathway (NADPH, ribose-5-P), glucuronidation (detoxification), and protein glycosylation. The brain and RBCs are obligate glucose users. Hypoglycemia (<70 mg/dL) causes neuroglycopenia; hyperglycemia (>126 mg/dL fasting) defines diabetes.

Glycogen

- The storage polysaccharide of glucose in animals, a branched polymer of alpha-1,4-linked glucose with alpha-1,6 branches every 8-12 residues. Synthesized (glycogenesis) in liver (100 g, maintains blood glucose) and muscle (400 g, local energy) via glycogen synthase (UDP-glucose donor) and branching enzyme. Degraded (glycogenolysis) by glycogen phosphorylase (alpha-1,4 cleavage, Pi-dependent) and debranching enzyme. Liver glycogenolysis releases free glucose (glucose-6-phosphatase); muscle lacks this enzyme, produces glucose-6-phosphate for local glycolysis. Glycogen storage diseases (von Gierke, Pompe, Cori, McArdle) result from enzyme deficiencies.

Glycogenesis

- The synthesis of glycogen from glucose for energy storage in the liver (approximately 100 g, maintaining blood glucose) and skeletal muscle (approximately 400 g, local energy). Two key enzymes: glycogen synthase adds glucose residues from UDP-glucose to the non-reducing ends of glycogen via alpha-1,4-glycosidic bonds (the rate-limiting step, activated by dephosphorylation and allosteric activation by glucose-6-phosphate); branching enzyme (amylo-1,4 to 1,6 transglucosidase) creates alpha-1,6 branch points, allowing glycogen to be more soluble

and providing multiple non-reducing ends for rapid glucose release.

Glycogenolysis

- The breakdown of glycogen to glucose, occurring in the liver (to maintain blood glucose) and muscle (for local ATP generation). Key enzyme: glycogen phosphorylase, which cleaves alpha-1,4-glycosidic bonds by phosphorolysis (using inorganic phosphate rather than water), producing glucose-1-phosphate. The debranching enzyme has two activities: transferase (moves a trisaccharide segment from a branch to the main chain) and alpha-1,6-glucosidase (cleaves the remaining branch-point glucose, releasing free glucose). Glycogen phosphorylase is activated by phosphorylation (cascade involving glucagon and epinephrine) and allosterically by AMP; inactivated by insulin and glucose.

Glycolysis

- The metabolic pathway converting one molecule of glucose (6-carbon) to two molecules of pyruvate (3-carbon) in the cytoplasm, occurring in all cells. Ten enzymatic steps in two phases: the energy investment phase (steps 1-5, consuming 2 ATP) and the energy payoff phase (steps 6-10, producing 4 ATP and 2 NADH). Step 1: hexokinase (or glucokinase in the liver) phosphorylates glucose to glucose-6-phosphate (G6P), trapping it in the cell. Step 3: phosphofructokinase-1 (PFK-1) converts fructose-6-phosphate to fructose-1,6-bisphosphate, the committed step and primary regulatory point, allosterically activated by AMP and fructose-2,6-bisphosphate, inhibited by ATP and citrate. (4) Aldolase cleaves fructose-1,6-bisphosphate into dihydroxyacetone phosphate (DHAP) and glyceraldehyde-3-phosphate. (5) Triose phosphate isomerase interconverts DHAP and G3P. The energy payoff phase follows with substrate-level phosphorylation producing ATP and NADH.

HDL (High-Density Lipoprotein)

- The "good cholesterol" lipoprotein (density >1.063 g/mL, smallest, 7-10 nm), synthesized in liver and intestine as nascent discoidal particles (ApoA-I primary apolipoprotein). Functions in reverse cholesterol transport: accepts free cholesterol from peripheral cells via ABCA1, esterifies it via LCAT (lecithin-cholesterol acyltransferase), and delivers cholesterol esters to liver via SR-B1 receptor or to

VLDL/LDL via CETP (cholesteryl ester transfer protein). High HDL (>60 mg/dL) is cardioprotective; low HDL (<40 mg/dL men, <50 mg/dL women) increases cardiovascular risk. ApoA-I Milano variant confers enhanced atheroprotection.

Hemoglobin

– A tetrameric oxygen-transport protein in erythrocytes (two alpha and two beta globin chains, each with a heme prosthetic group containing Fe^{2+}). Binds four O_2 molecules cooperatively (sigmoidal O_2 dissociation curve, P_{50} 26 mmHg). Bohr effect: decreased pH and increased CO_2 shift curve rightward (enhanced O_2 unloading in tissues). 2,3-BPG (bisphosphoglycerate) stabilizes deoxy (T) state, reducing affinity. Variants: HbA (adult, 97%), HbA₂ (2.5%), HbF (fetal, $\alpha_2\gamma_2$, higher O_2 affinity). Mutations cause sickle cell (HbS, Glu6Val beta), thalassemias (globin chain imbalance), methemoglobinemia (Fe^{3+}). Clinical: HbA1c (glycated Hb, 3-month glucose average), anemia (low Hb), polycythemia (high Hb).

Holoenzyme

– The complete, catalytically active enzyme complex consisting of the apoenzyme (protein) plus its required cofactor(s) or coenzyme(s). Many enzymes function only as holoenzymes (e.g., pyruvate dehydrogenase complex requires TPP, lipoamide, CoA, FAD, NAD^+). Removal of cofactor yields inactive apoenzyme. Holoenzyme assembly can be regulated (e.g., phosphorylation of PDH inactivates the complex). Prosthetic groups are tightly bound cofactors (FAD in succinate dehydrogenase, heme in cytochromes); cosubstrates dissociate during catalysis (NAD^+ , CoA).

Inhibitor

– A molecule that decreases enzyme activity by binding to the enzyme (reversible) or covalently modifying it (irreversible). Reversible inhibition types: (1) Competitive: binds active site, competes with substrate (increases apparent K_m , V_{max} unchanged); e.g., statins (HMG-CoA reductase), methotrexate (DHFR). (2) Non-competitive: binds allosteric site, reduces V_{max} , K_m unchanged; e.g., heavy metals. (3) Uncompetitive: binds only enzyme-substrate complex (decreases both V_{max} and K_m). (4) Mixed: binds both free enzyme and ES complex with different affinities. Irreversible inhibitors: covalent

modification of active site residues (aspirin acetylates COX, organophosphates phosphorylate acetylcholinesterase). Clinically: many drugs are enzyme inhibitors (ACE inhibitors, beta-blockers, protease inhibitors).

JAK-STAT Signaling

– The Janus kinase-signal transducer and activator of transcription pathway mediates signaling for cytokines, interferons, and interleukins whose receptors lack intrinsic enzymatic activity. Mechanism: (1) cytokine binding induces receptor dimerization; (2) associated JAKs (JAK1, JAK2, JAK3, TYK2) are activated by trans-phosphorylation; (3) activated JAKs phosphorylate tyrosine residues on the receptor cytoplasmic domain; (4) STAT proteins (STAT1-6) are recruited to the phosphorylated receptor via their SH2 domains; (5) recruited STATs are phosphorylated by JAKs; (6) phosphorylated STATs form homo- or heterodimers and translocate to the nucleus; (7) STAT dimers bind gamma-interferon activation site (GAS) or interferon-stimulated response element (ISRE) DNA sequences, regulating gene transcription.

Ketogenesis

– Hepatic synthesis of ketone bodies (acetoacetate, beta-hydroxybutyrate, acetone) during prolonged fasting, starvation, uncontrolled diabetes, or very low carbohydrate diets. When oxaloacetate is depleted for gluconeogenesis, accumulated acetyl-CoA cannot enter the TCA cycle and is diverted to ketogenesis in the mitochondrial matrix. Key steps: (1) two acetyl-CoA condense to acetoacetyl-CoA by thiolase; (2) HMG-CoA synthase (the rate-limiting enzyme for ketogenesis, activated by fasting, inhibited by insulin and succinyl-CoA) converts acetoacetyl-CoA to HMG-CoA; (3) HMG-CoA lyase cleaves HMG-CoA to acetoacetate and acetyl-CoA. Acetoacetate is reduced to beta-hydroxybutyrate by beta-hydroxybutyrate dehydrogenase (using NADH) or spontaneously decarboxylated to acetone.

Ketone Bodies

– Water-soluble fuels (acetoacetate, beta-hydroxybutyrate, and acetone) produced by the liver from acetyl-CoA during fasting or uncontrolled diabetes. The brain uses them as an alternative energy substrate when glucose is scarce, since it cannot oxidize fatty acids. Excess

production, especially in insulin deficiency, causes ketoacidosis by depleting bicarbonate.

Kilocalorie

- The unit of energy used in nutrition, defined as the energy required to raise one kilogram of water by one degree Celsius, equal to 4184 joules. The dietary Calorie is a kilocalorie. Macronutrients yield approximately 4 kcal/g for carbohydrate and protein, 9 kcal/g for fat, and 7 kcal/g for alcohol.

Lactose

- A disaccharide composed of galactose (β -1,4) glucose, the principal sugar in mammalian milk (4-5% in human milk, 4-6% in cow's milk). Hydrolyzed in the small intestine by lactase (β -galactosidase, encoded by LCT gene) to glucose and galactose for absorption. Lactase deficiency (primary: developmental downregulation after weaning, common in Asian, African, Native American populations; secondary: intestinal injury) causes lactose intolerance: osmotic diarrhea, bloating, flatulence, abdominal pain after dairy consumption. Congenital lactase deficiency (rare, autosomal recessive) presents in neonates. Lactose is also a substrate for bacterial fermentation (lactic acid production) and a drug excipient.

LDL (Low-Density Lipoprotein)

- The major cholesterol-carrying lipoprotein (density 1.019-1.063 g/mL, 22 nm, ApoB-100 primary apolipoprotein). Delivers cholesterol to peripheral cells via LDL receptor (apoB-100 binding, clathrin-mediated endocytosis). Hepatic LDL receptors clear 70% of plasma LDL. Elevated LDL is the primary atherogenic lipoprotein; LDL receptor deficiency causes familial hypercholesterolemia. Oxidized LDL (oxLDL) is taken up by macrophage scavenger receptors, forming foam cells. LDL lowering (statins, ezetimibe, PCSK9 inhibitors) is the cornerstone of atherosclerotic cardiovascular disease prevention.

Lipid

- A diverse group of hydrophobic organic compounds that are essential components of cell membranes and serve as energy storage, signalling molecules, and structural components. Lipids are broadly classified into: (1) Fatty acids: saturated (no double bonds, e.g., palmitic, stearic—solid at room temperature), unsaturated (monounsaturated—oleic; polyunsaturated—linoleic acid, omega-3 fatty acids

such as eicosapentaenoic EPA, docosahexaenoic DHA; essential fatty acids that must be obtained from diet: linoleic acid and alpha-linolenic acid). (2) Triglycerides (triacylglycerols): esters of glycerol with three fatty acids, stored in adipose tissue, the main form of energy storage. (3) Phospholipids: glycerol backbone with two fatty acids and a phosphate group linked to a polar head group (choline, ethanolamine, serine, inositol); the major component of cell membranes (phosphatidylcholine, phosphatidylethanolamine, phosphatidylserine, phosphatidylinositol, sphingomyelin). (4) Sterols: cholesterol (cell membrane stability, precursor of steroid hormones, bile acids, vitamin D). (5) Sphingolipids: ceramide, sphingomyelin, glycosphingolipids (cerebrosides, gangliosides—abundant in the nervous system). (6) Eicosanoids: prostaglandins, thromboxanes, leukotrienes, prostacyclin—short-lived signalling molecules derived from arachidonic acid (omega-6) via cyclooxygenase (COX) and lipoxygenase pathways. Clinical significance: hyperlipidemia (elevated cholesterol and/or triglycerides, major risk factor for atherosclerosis, coronary artery disease, stroke), lipid-lowering therapy (statins, ezetimibe, PCSK9 inhibitors, fibrates).

Lipogenesis

- The anabolic synthesis of fatty acids (principally palmitate) from acetyl-CoA in the cytosol, stimulated by insulin after carbohydrate-rich meals. Acetyl-CoA carboxylase catalyzes the rate-limiting conversion to malonyl-CoA, and fatty acid synthase performs the NADPH-dependent condensation. The product is esterified into triglycerides for storage in adipose tissue.

Lipoprotein

- A complex of lipids (cholesterol, triglycerides, phospholipids) and apolipoproteins that transports hydrophobic lipids through the aqueous bloodstream. Lipoproteins are classified into five major classes based on density: chylomicrons, VLDL, IDL, LDL, and HDL.

Lipoprotein Metabolism

- Lipoproteins are spherical particles with a hydrophobic core (triglycerides and cholesterol esters) and amphipathic surface (phospholipids, free cholesterol, apolipoproteins) for transporting lipids in aqueous plasma. Five classes: chylomicrons (largest,

least dense; ApoB-48; from intestine; transport dietary triglycerides; acted on by lipoprotein lipase on capillary endothelium). VLDL (from liver; ApoB-100; transport endogenous triglycerides; converted to IDL by lipoprotein lipase). LDL (from VLDL metabolism by hepatic lipase, ApoB-100, the major cholesterol carrier, taken up by LDL receptors on hepatocytes and peripheral cells; elevated LDL is the primary atherogenic lipoprotein, and LDL receptor deficiency causes familial hypercholesterolaemia). HDL (from liver and intestine, ApoA-I, reverse cholesterol transport, the "good" cholesterol; protective against atherosclerosis).

Macronutrient

- A dietary nutrient required in gram quantities that supplies metabolic energy and serves as biosynthetic substrate: carbohydrate, protein, and fat. Energy yields are approximately 4 kcal/g for carbohydrate and protein and 9 kcal/g for fat; alcohol provides 7 kcal/g. Recommended distribution is 45-65 percent carbohydrate, 10-35 percent protein, 20-35 percent fat.

Messenger RNA (mRNA)

- The single-stranded RNA transcribed from a protein-coding gene that carries genetic information from DNA to ribosomes for translation into protein. In eukaryotes the primary transcript undergoes processing before export to the cytoplasm. Each consecutive triplet codon specifies an amino acid or stop signal, read 5' to 3' by the ribosome.

Metabolism

- The sum of all chemical reactions in a living organism, organized into catabolic pathways (breakdown, energy release) and anabolic pathways (synthesis, energy consumption). Metabolic pathways are interconnected networks (glycolysis, TCA cycle, oxidative phosphorylation, pentose phosphate pathway, fatty acid oxidation/synthesis, amino acid metabolism, nucleotide metabolism) regulated by substrate availability, allosteric effectors (ATP, ADP, AMP, citrate, acetyl-CoA), covalent modification (phosphorylation by kinases/phosphatases), and hormonal signals (insulin, glucagon, epinephrine, cortisol, thyroid hormone). Compartmentalization (mitochondria, cytosol, ER, peroxisomes, nucleus) separates incompatible pathways and allows independent regulation.

Methylmalonic Acidemia

- An inborn error of organic acid metabolism caused by deficiency of methylmalonyl-CoA mutase (MUT, requiring adenosylcobalamin/B12 as cofactor) or defects in adenosylcobalamin synthesis. The enzyme converts methylmalonyl-CoA to succinyl-CoA (linking odd-chain fatty acid and branched-chain amino acid catabolism to the TCA cycle). Deficiency causes accumulation of methylmalonic acid and other organic acids, leading to metabolic acidosis with elevated anion gap, ketonuria, hyperammonemia (from secondary inhibition of the urea cycle by accumulated organic acids), and neurological deterioration. Treatment includes protein restriction, carnitine supplementation, and vitamin B12 therapy for responsive subtypes.

NADH

- The reduced form of NAD^+ , carrying a hydride (2 electrons + H^+) from substrate oxidation. Produced in glycolysis (glyceraldehyde-3-P dehydrogenase), pyruvate dehydrogenase, TCA cycle (isocitrate, α -ketoglutarate, malate dehydrogenases), and beta-oxidation. Mitochondrial NADH enters ETC at Complex I (2.5 ATP/NADH); cytosolic NADH uses shuttles (malate-aspartate: 2.5 ATP; glycerol-3-phosphate: 1.5 ATP). NADH/ NAD^+ ratio regulates TCA cycle, glycolysis, and gluconeogenesis (inhibits pyruvate dehydrogenase, isocitrate DH, α -ketoglutarate DH; stimulates lactate dehydrogenase).

NAD^+ (Nicotinamide Adenine Dinucleotide)

- A redox coenzyme derived from niacin (vitamin B3), composed of two nucleotides (adenine + nicotinamide riboside) linked by phosphates. Exists as oxidized NAD^+ and reduced NADH. Primary electron carrier in catabolism: accepts 2 electrons + H^+ (hydride) to form NADH during glycolysis, pyruvate dehydrogenase, TCA cycle, and beta-oxidation. NADH donates electrons to Complex I of ETC (2.5 ATP equivalent). NAD^+ /NADH ratio reflects cellular redox state; high NAD^+ stimulates catabolism (sirtuins, PARPs). Also consumed by ADP-ribosylation reactions (PARPs, sirtuins, CD38). Regenerated from NADH by mitochondrial ETC or fermentation (lactate dehydrogenase).

NADPH

– The reduced form of NADP^+ , primarily an anabolic reducing equivalent. Produced by: pentose phosphate pathway (G6PD, 6-phosphogluconate dehydrogenase), malic enzyme (cytosolic), isocitrate dehydrogenase (cytosolic, NADP^+ -dependent), and folate cycle. Used for: fatty acid synthesis (7 NADPH /palmitate), cholesterol synthesis (18 NADPH /cholesterol), nucleotide synthesis (ribonucleotide reductase), glutathione reduction (antioxidant defense, glutathione reductase), cytochrome P450 reactions (detoxification), and nitric oxide synthesis. $\text{NADPH}/\text{NADP}^+$ ratio (typically $>100:1$) maintains reducing environment for biosynthesis and redox defense.

Nucleic Acid

– Linear polymers of nucleotides that store, transmit, and express genetic information, comprising deoxyribonucleic acid (DNA) and ribonucleic acid (RNA). Each nucleotide consists of a nitrogenous base, a pentose sugar, and a phosphate group joined by phosphodiester bonds between the 3' and 5' carbons. Named for their acidic phosphate groups and nuclear location.

Nucleotide

– The building block of nucleic acids (DNA, RNA), composed of a nitrogenous base (purine: adenine, guanine; pyrimidine: cytosine, thymine, uracil), a pentose sugar (ribose in RNA, deoxyribose in DNA), and one or more phosphate groups (mono-, di-, triphosphate). Nucleoside = base + sugar (no phosphate). Nucleotides serve as: genetic information carriers (DNA, RNA), energy currency (ATP, GTP), signaling molecules (cAMP, cGMP, ADP-ribose), enzyme cofactors (NAD^+ , FAD, CoA), and allosteric regulators. Synthesis: de novo (purines from PRPP, pyrimidines from carbamoyl phosphate) and salvage pathways. Degradation: purines to uric acid; pyrimidines to beta-alanine/beta-aminoisobutyrate.

Nucleotide Excision Repair

– The primary repair pathway for bulky, helix-distorting DNA lesions such as UV-induced pyrimidine dimers (cyclobutane pyrimidine dimers and 6-4 photoproducts), bulky chemical adducts (benzo[a]pyrene-guanine from cigarette smoke), and intrastrand crosslinks. In eukaryotes: (1) the XPC-RAD23B complex recognizes the distortion; (2) TFIIH (with XPD helicase) opens the DNA around

the lesion; (3) XPA verifies the damage; (4) RPA stabilizes the single-stranded DNA; (5) XPF-ERCC1 endonuclease makes a 5' incision; (6) XPG endonuclease makes a 3' incision; (7) the oligonucleotide fragment (approximately 24-32 nucleotides) containing the lesion is excised; (8) DNA polymerase delta/epsilon resynthesizes the gap using the complementary strand as a template; (9) DNA ligase I seals the nick. Deficiencies cause xeroderma pigmentosum (extreme UV sensitivity, skin cancer predisposition) and Cockayne syndrome.

Osmolality

– The concentration of osmotically active particles per kilogram of solvent ($\text{mOsm/kg H}_2\text{O}$). Measured by freezing point depression or vapor pressure osmometry. Independent of temperature and pressure (unlike osmolarity). Plasma osmolality (normal 285-295 mOsm/kg) is calculated: $2[\text{Na}^+] + \text{glucose}/18 + \text{BUN}/2.8$. Increased in dehydration, hyperglycemia, azotemia, hyponatremia; decreased in overhydration, hyponatremia, SIADH. The osmolar gap (measured - calculated) detects unmeasured osmoles (ethanol, methanol, ethylene glycol, mannitol).

Osmolarity

– The concentration of osmotically active particles per liter of solution (mOsm/L). Temperature- and pressure-dependent (volume changes). Clinically approximated by calculated osmolality for dilute body fluids. Tonicity (effective osmolality) considers only solutes that cannot cross cell membranes (Na^+ , glucose, urea freely crosses). Isotonic solutions (0.9% NaCl, 5% dextrose) have same tonicity as plasma. Hypotonic/hypertonic solutions cause cell swelling/shrinking.

Oxidative Deamination

– The removal of the amino group from glutamate, catalyzed by glutamate dehydrogenase (GDH) in the mitochondrial matrix, producing free ammonia (NH_4^+) and alpha-ketoglutarate. This reaction is the primary route for amino group disposal, collecting amino groups from all transamination reactions (since most aminotransferases funnel amino groups to glutamate). GDH is a versatile enzyme that can use either NAD^+ or NADP^+ as a cofactor and is allosterically activated by ADP (indicating energy need) and inhibited by GTP and ATP (indicating

energy sufficiency), linking amino acid catabolism to cellular energy status.

Oxidative Phosphorylation

- The production of ATP using energy derived from the redox reactions of the electron transport chain. Driven by ATP synthase (Complex V), which utilizes the proton-motive force across the inner mitochondrial membrane as protons flow back into the matrix. Uncoupling proteins (e.g., thermogenin in brown adipose tissue) dissipate the proton gradient as heat.

Pantothenic Acid

- Vitamin B5, a water-soluble vitamin that is the essential precursor of coenzyme A and of the acyl carrier protein prosthetic group. Coenzyme A carries acyl groups in fatty acid oxidation and synthesis, the citric acid cycle, and steroid synthesis. Deficiency is rare because pantothenic acid is widely distributed in foods.

Passive Transport

- Movement of solutes across a membrane down their electrochemical gradient without expenditure of metabolic energy. Simple diffusion crosses the lipid bilayer directly or via channels; facilitated diffusion uses carrier proteins or channels for polar or larger molecules such as glucose. Because movement is down gradient, it does not consume ATP.

Peptide

- A short chain of amino acids linked by peptide bonds (amide bonds between the carboxyl group of one amino acid and the amino group of the next, with water elimination). Dipeptide (2), tripeptide (3), oligopeptide (2-20), polypeptide (>20, typically called a protein). Peptide bond has partial double-bond character (planar, rigid, trans configuration favored). N-terminus (free amino group) and C-terminus (free carboxyl group) define directionality. Biologically active peptides: hormones (insulin, glucagon, ACTH, oxytocin), neuropeptides (endorphins, substance P), antibiotics (granicidin, vancomycin), and signaling molecules (angiotensin, bradykinin). Peptide synthesis: ribosomal (translation) or non-ribosomal (NRPS, e.g., penicillin, cyclosporine).

pH

- The negative logarithm of hydrogen ion activity: $\text{pH} = -\log_{10}[\text{H}^+]$. Measures acidity/alkalinity of a

solution. Neutral $\text{pH} = 7.0$ (at 25°C , $[\text{H}^+] = [\text{OH}^-] = 10^{-7} \text{ M}$). Arterial blood pH : 7.35-7.45 (tightly regulated by respiratory CO_2 elimination and renal $\text{H}^+/\text{HCO}_3^-$ handling). Intracellular pH 7.2. Gastric pH 1.5-3.5. $\text{pH} < 7.35$ = acidemia; $\text{pH} > 7.45$ = alkalemia. Henderson-Hasselbalch equation: $\text{pH} = 6.1 + \log([\text{HCO}_3^-]/0.03 \times \text{PaCO}_2)$. pH determines protein conformation, enzyme activity, ion distribution, and drug ionization.

Phospholipid

- A lipid with a glycerol (or sphingosine) backbone, two fatty acid chains (hydrophobic tails), and a phosphate group linked to a polar head group (hydrophilic). Major membrane phospholipids: phosphatidylcholine (PC, lecithin, 50%), phosphatidylethanolamine (PE, 25%), phosphatidylserine (PS, 10%, inner leaflet, apoptosis signal), phosphatidylinositol (PI, signaling precursor), sphingomyelin (SM, sphingosine backbone). Phospholipids self-assemble into bilayers in aqueous environments (hydrophobic effect). Phospholipases (A1, A2, C, D) hydrolyze specific bonds, generating second messengers (DAG, IP_3 , arachidonic acid, lysophospholipids). Deficiencies cause hemolytic anemia (PNH, PIGA mutation).

Polypeptide

- A linear chain of amino acids linked by peptide bonds, generally referring to chains longer than about 20 residues that fold into functional proteins (shorter chains are termed peptides). The amino acid sequence, encoded by a gene, constitutes the primary structure and determines higher-order folding. Many proteins assemble from one or more polypeptide chains.

Proteins

- Large, complex macromolecules composed of amino acids linked by peptide bonds, essential for virtually all biological processes. Proteins are polymers of 20 standard L- α -amino acids, each with a central carbon bonded to an amino group, carboxyl group, hydrogen atom, and a unique side chain (R group). Amino acids are classified as essential (must be obtained from diet—histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, valine) and non-essential (synthesized in the body). Protein structure has four levels: primary (linear sequence of amino acids), secondary (α -helices and

β -pleated sheets stabilized by hydrogen bonds), tertiary (three-dimensional folding stabilized by disulfide bonds, hydrophobic interactions, ionic bonds, hydrogen bonds), and quaternary (assembly of multiple polypeptide subunits—e.g., hemoglobin is a tetramer of two α and two β globin chains). Protein functions: enzymes (catalyze biochemical reactions), structural (collagen, keratin, actin, tubulin), transport (hemoglobin, albumin, transferrin), signalling (hormones, receptors, cytokines), immune defence (antibodies, complement), and gene regulation (transcription factors). Protein synthesis: transcription (DNA $\rightarrow$ mRNA in the nucleus), translation (mRNA $\rightarrow$ protein on ribosomes in the cytoplasm), and post-translational modification (folding, glycosylation, phosphorylation, ubiquitination). Recommended dietary allowance (RDA): 0.8 g/kg body weight/day.

Ribonucleic Acid (RNA)

– A nucleic acid composed of ribonucleotides (adenine, guanine, cytosine, uracil) linked by phosphodiester bonds, with a ribose sugar backbone. RNA is transcribed from DNA by RNA polymerase and serves multiple functions in gene expression and regulation. Main types: (1) Messenger RNA (mRNA)—carries the genetic code from DNA to ribosomes for protein synthesis (translation). Pre-mRNA undergoes splicing (removal of introns, joining of exons), 5' capping, and 3' polyadenylation. (2) Transfer RNA (tRNA)—adaptor molecules that bring specific amino acids to the ribosome during translation; each tRNA has an anticodon complementary to the mRNA codon. (3) Ribosomal RNA (rRNA)—structural and catalytic component of ribosomes (28S, 18S, 5.8S, 5S in eukaryotes), undergoes site-specific methylation and pseudouridylation. (4) Small nuclear RNA (snRNA)—components of the spliceosome (U1, U2, U4, U5, U6), catalyzes pre-mRNA splicing. (5) MicroRNA (miRNA, 22 nucleotides)—regulates gene expression post-transcriptionally by binding complementary mRNA sequences, leading to translational repression or mRNA degradation. (6) Small interfering RNA (siRNA)—mediates RNA interference (RNAi), gene silencing. (7) Long non-coding RNA (lncRNA, >200 nucleotides)—regulates gene expression, chromatin remodeling, and X-inactivation (XIST). RNA is also the genetic material of RNA viruses (retroviruses—HIV, influenza, SARS-CoV-2).

Scurvy

– A disease caused by severe vitamin C (ascorbic acid) deficiency. Vitamin C is a cofactor for proline and lysine hydroxylation in collagen synthesis, and a potent antioxidant. Scurvy is rare in developed countries but occurs in people with severely restricted diets (elderly, alcoholism, eating disorders, autism with food selectivity, malabsorption, homelessness). Symptoms develop 8-12 weeks after vitamin C depletion: fatigue, malaise, lethargy, joint and muscle pain, follicular hyperkeratosis (perifollicular haemorrhages), ecchymoses, gingival swelling and bleeding (hypertrophic, spongy gums), impaired wound healing, corkscrew hairs, and anemia. Advanced disease: haemarthrosis, subperiosteal hemorrhage (painful, especially in children), jaundice, edema, and sudden death. Diagnosis: clinical (dietary history, physical exam) and low serum ascorbic acid ($<11 \mu\text{mol/L}$). Treatment: vitamin C 100 mg PO TID for 1 week, then 100 mg daily (higher doses IV for severe disease). Symptoms improve within 24-48 hours; gingival bleeding resolves in 2-3 days; complete recovery in weeks. Prevention: dietary vitamin C (citrus fruits, berries, kiwi, tomatoes, broccoli, peppers).

Substrate

– The specific molecule upon which an enzyme acts. Binds to the enzyme's active site, forming an enzyme-substrate (ES) complex. Substrate specificity arises from complementary shape, charge, and hydrophobicity between active site and substrate. The enzyme stabilizes the transition state, lowering activation energy. Substrate concentration $[S]$ determines reaction velocity (Michaelis-Menten kinetics: $v = V_{max}[S]/(K_m + [S])$). At low $[S]$, v is proportional to $[S]$; at saturating $[S]$, $v = V_{max}$. Multiple substrates may bind sequentially (ordered, random) or in a ping-pong mechanism. Products are released after catalysis.

Tay-Sachs Disease

– A fatal lysosomal storage disease caused by deficiency of hexosaminidase A (Hex A, composed of alpha and beta subunits encoded by HEXA and HEXB genes, respectively), leading to accumulation of GM2 ganglioside in neurons of the central nervous system. Classic infantile Tay-Sachs (HEXA mutations, autosomal recessive): normal at birth,

progressive neurodegeneration begins at 3-6 months with hypotonia, followed by an exaggerated startle response (to loud noises), loss of acquired motor skills, progressive loss of vision (cherry-red macula on fundoscopic examination due to lipid accumulation in retinal ganglion cells), macrocephaly from neuronal lipid storage, seizures, and death by age 4. Carrier frequency is approximately 1 in 30 in Ashkenazi Jewish populations, where HEXA mutations include the common 4-base-pair insertion in exon 11.

Thyroid Hormone

– Iodinated amino acid derivatives produced by the thyroid gland that regulate basal metabolic rate and development, comprising active triiodothyronine (T3) and the more abundant prohormone thyroxine (T4). Thyroid peroxidase iodates tyrosine residues on thyroglobulin to form T3 and T4. T4 is converted peripherally to active T3 by deiodinases.

Transamination

– The transfer of an amino group from an amino acid to an alpha-keto acid, catalyzed by aminotransferases (transaminases) requiring pyridoxal phosphate (PLP, vitamin B6) as a cofactor. The reaction proceeds through a ping-pong mechanism: PLP accepts the amino group from the donor amino acid, becoming pyridoxamine phosphate (PMP), then transfers it to the acceptor alpha-keto acid, regenerating PLP. ALT (alanine aminotransferase, formerly SGPT): transfers the amino group from alanine to alpha-ketoglutarate, forming glutamate and pyruvate. AST (aspartate aminotransferase, formerly SGOT): transfers the amino group from aspartate to alpha-ketoglutarate, forming glutamate and oxaloacetate. These enzymes are clinically important markers of hepatocellular injury.

Transfer RNA (tRNA)

– A small adaptor RNA (70-90 nucleotides) that delivers a specific amino acid to the ribosome during translation. The cloverleaf secondary structure folds into an L-shaped tertiary structure, positioning the anticodon to decode the messenger RNA codon while the CCA 3' end carries the amino acid. Each tRNA is charged by a specific aminoacyl-tRNA synthetase.

Triglycerides

– The main form of stored energy in the body,

composed of a glycerol backbone esterified with three fatty acid chains. Triglycerides are synthesized in the liver (from excess carbohydrates and fatty acids) and stored in adipose tissue. They are transported in the blood as part of very-low-density lipoproteins (VLDL) and chylomicrons. Normal fasting serum triglyceride level: <1.7 mmol/L (<150 mg/dL). hypertriglyceridemia: mild (1.7-5.6 mmol/L)–associated with increased cardiovascular risk; severe (>5.6 mmol/L)–risk of acute pancreatitis (risk increases exponentially with levels >10 mmol/L). Causes: obesity, metabolic syndrome, type 2 diabetes, excessive alcohol intake, hypothyroidism, chronic kidney disease, and genetic disorders (familial hypertriglyceridemia, familial combined hyperlipidemia, lipoprotein lipase deficiency). Management: lifestyle modification (weight loss, reduced carbohydrate and alcohol intake, increased exercise), statins (if LDL also elevated), fibrates (fenofibrate, bezafibrate–first-line for severe hypertriglyceridemia), omega-3 fatty acids (fish oil–4 g/day), and icosapent ethyl (EPA–REDUCE-IT trial: reduced cardiovascular events). Niacin is rarely used due to side effects.

Urea Cycle

– A liver pathway that converts toxic ammonia (NH₃), derived from amino acid catabolism, into nontoxic urea excreted in urine. Spans mitochondria and cytosol. Rate-limiting enzyme: carbamoyl phosphate synthetase I (CPS I), activated by N-acetylglutamate (NAG). Deficiencies (e.g., ornithine transcarbamylase deficiency) lead to hyperammonemia, cerebral edema, and lethargy.

Vitamin B2: Riboflavin

– Riboflavin (vitamin B2) is a water-soluble vitamin that serves as the precursor for two essential coenzymes: flavin mononucleotide (FMN) and flavin adenine dinucleotide (FAD). FMN and FAD are prosthetic groups in flavoproteins (flavoenzymes), accepting and donating electrons (as reduced FADH₂ and FMNH₂) in oxidation-reduction reactions. Key flavoenzymes include: succinate dehydrogenase (Complex II of the ETC, converting succinate to fumarate), NADH dehydrogenase (Complex I), acyl-CoA dehydrogenase (fatty acid oxidation), and xanthine oxidase (purine metabolism). Riboflavin deficiency (ariboflavinosis) causes angu-

lar stomatitis, cheilitis, glossitis, seborrheic dermatitis, and corneal vascularization.

Vitamin B7: Biotin

– Biotin (vitamin B7) is a water-soluble vitamin that serves as a prosthetic group (covalently bound via an amide bond to lysine residues) for five carboxylases in humans: (1) pyruvate carboxylase (pyruvate to oxaloacetate, anaplerosis of the TCA cycle and gluconeogenesis); (2) acetyl-CoA carboxylase (acetyl-CoA to malonyl-CoA, the rate-limiting step of fatty acid synthesis); (3) propionyl-CoA carboxylase (propionyl-CoA to methylmalonyl-CoA, in odd-chain fatty acid and branched-chain amino acid catabolism); and (5) 3-methylcrotonyl-CoA carboxylase (leucine catabolism). Biotin deficiency is rare but can occur from excessive raw egg consumption (avidin in egg white binds biotin, preventing absorption), causing dermatitis, alopecia, neurological symptoms, and metabolic acidosis.

VLDL (Very-Low-Density Lipoprotein)

– A triglyceride-rich lipoprotein (density <1.006 g/mL, 30-80 nm, ApoB-100) synthesized in the liver to transport endogenous triglycerides. VLDL particles acquire ApoC-II and ApoE in circulation. Lipoprotein lipase (LPL, activated by ApoC-II) hydrolyzes VLDL triglycerides on capillary endothelium, releasing free fatty acids for tissue uptake. VLDL remnants (IDL, intermediate-density lipoprotein) are either taken up by liver (ApoE-mediated) or further processed to LDL by hepatic lipase. Elevated VLDL (hypertriglyceridemia) contributes to atherogenic remnant particles and reduced HDL.

Western Blot Analysis

– An immunodetecting technique for identifying and quantifying specific proteins in complex biological samples (cell lysates, tissue homogenates, serum). Steps: (1) sample preparation: cells/tissues are lysed in buffer (containing protease inhibitors, phosphatase inhibitors, detergents) to extract proteins; protein concentration is measured (Bradford, BCA, or Lowry assay); (2) SDS-PAGE: proteins are denatured by heating with SDS (sodium dodecyl sulfate, an anionic detergent that coats proteins uniformly with a negative charge proportional to their mass, allowing separation by size through gel electrophoresis); (3) transfer (blotting): separated proteins are

transferred from the gel to a membrane (nitrocellulose or PVDF) by electroblotting; (4) blocking: non-specific binding sites on the membrane are blocked with a protein solution (BSA, milk, or serum); (5) primary antibody incubation: a specific antibody against the target protein is applied; (6) secondary antibody incubation: an enzyme-conjugated antibody targeting the primary antibody is applied; (7) detection: a chemiluminescent or chromogenic substrate is added, producing a signal proportional to protein quantity that is visualized by film exposure or digital imaging.

Chapter 4

Cardiology

4.1 Ischemic Heart Disease & Acute Coronary Syndromes

Afterload

- The resistance against which the ventricles must eject blood during systole. Left ventricular afterload is primarily determined by systemic vascular resistance (SVR); right ventricular afterload is determined by pulmonary vascular resistance (PVR). Afterload is estimated by blood pressure or calculated as wall stress. Increased afterload (as in hypertension or aortic stenosis) reduces stroke volume and increases myocardial oxygen demand.

Angina Pectoris

- Chest discomfort caused by myocardial ischemia without infarction. Stable angina occurs predictably with exertion and resolves with rest. Unstable angina occurs at rest or with minimal exertion and is an acute coronary syndrome. Prinzmetal (variant) angina occurs at rest due to coronary vasospasm. Diagnosis involves ECG (may show ST depression during episodes) and stress testing. Treatment includes nitrates, beta-blockers, and revascularization when indicated.

Aortic Aneurysm

- Permanent dilation of the aorta exceeding 50% of normal diameter. Abdominal aortic aneurysm (AAA) is more common than thoracic aortic aneurysm and is usually caused by atherosclerosis. AAA >5.5 cm or rapid expansion (>0.5 cm/year) warrants surgical repair (open or endovascular). Thoracic aortic aneurysms may be caused by Marfan syndrome, bicuspid aortic valve, or hypertension. Screening ultrasound is recommended for men aged 65-75 who have ever smoked.

Aortic Stenosis

- Narrowing of the aortic valve opening, obstructing left ventricular outflow. It is the most common valvular disease in developed countries, usually caused by calcific degeneration. Symptoms include angina, syncope, and heart failure (SAD triad). Murmur: crescendo-decrescendo systolic murmur at the right upper sternal border radiating to the carotids. Severe AS (valve area <1.0 cm²) requires aortic valve replacement (surgical or TAVR).

Arrhythmia

- Any abnormality of cardiac rate, rhythm, or site of impulse origin, arising through enhanced automaticity, reentry, or triggered activity. Classified by rate as tachyarrhythmia or bradyarrhythmia and by site as supraventricular or ventricular. Diagnosis rests on the 12-lead ECG and ambulatory monitoring when intermittent. Management follows ACLS algorithms and ranges from drugs and ablation to cardioversion, defibrillation, and pacing.

Arteriosclerosis

- See Atherosclerosis.

Atherosclerosis

- Chronic inflammatory disease of medium and large arteries characterized by accumulation of lipids, inflammatory cells, and fibrous tissue within the arterial wall, forming atherosclerotic plaques. Initiating event is endothelial dysfunction from risk factors (hypertension, smoking, diabetes, dyslipidemia). Progression involves LDL oxidation, monocyte recruitment, foam cell formation, and smooth muscle proliferation. Complicated plaques may rupture, causing acute thrombosis and ischemic events (myocardial infarction, stroke, or peripheral ischemia).

Atrial Fibrillation Ablation

- Catheter-based procedure to eliminate atrial fibril-

lation by creating pulmonary vein isolation (PVI), electrically disconnecting the pulmonary veins from the left atrium. Indicated for symptomatic AFib refractory to or intolerant of antiarrhythmic drugs. Success rates: 70-80% for paroxysmal AFib, 50-60% for persistent AFib. Complications include pulmonary vein stenosis, pericardial tamponade, atrio-esophageal fistula (rare but life-threatening), and stroke. Anticoagulation is continued post-procedure.

Atrioventricular Node

- Located in the posterior-inferior region of the interatrial septum near the coronary sinus. It receives impulses from the SA node via internodal pathways and delays them by approximately 120-200 milliseconds before transmitting them to the ventricles. This delay allows atrial contraction to complete before ventricular contraction. The AV node is the backup pacemaker with an intrinsic rate of 40-60 beats per minute.

Calcium Channel Blockers

- Agents that block L-type calcium channels, reducing calcium influx into cardiac and smooth muscle cells. Dihydropyridines (amlodipine, nifedipine) cause vasodilation and are used for hypertension and angina. Non-dihydropyridines (verapamil, diltiazem) reduce heart rate and contractility, used for rate control in atrial fibrillation and angina. Side effects include peripheral edema, constipation (verapamil), and bradycardia. Non-dihydropyridines are contraindicated in HFrEF.

Cardiac Arrest Survival

- Overall survival to discharge for out-of-hospital cardiac arrest is approximately 10%. For witnessed VF/pVT with early defibrillation, survival can exceed 50%. Chain of survival: early recognition and activation of EMS, high-quality CPR, early defibrillation, advanced life support, and post-arrest care. Targeted temperature management (32-36 degrees C) for 24 hours improves neurological outcomes. Coronary angiography should be considered for all comatose survivors.

Cardiac Catheterization

- Invasive procedure involving insertion of catheters into the heart via peripheral arteries or veins. Diagnostic catheterization measures intracardiac pressures, saturations, and performs coronary angiogra-

phy. Indications include evaluation of CAD, valvular disease, cardiomyopathy, and congenital heart disease. Therapeutic catheterization includes PCI, valvuloplasty, and device closure. Complications include bleeding, vessel injury, arrhythmias, and contrast-induced nephropathy.

Cardiac CT Angiography

- Noninvasive imaging using CT to visualize coronary arteries and cardiac structures. It has high negative predictive value for excluding coronary artery disease, making it useful for low-to-intermediate risk patients with chest pain. Calcium scoring quantifies coronary artery calcification as a marker of atherosclerosis. Limitations include heart rate control requirements, radiation exposure, and inability to assess hemodynamic significance of stenosis. It also evaluates aortic and congenital heart disease.

Cardiac Metastases

- More common than primary cardiac tumors. Most frequent sources: lung cancer, breast cancer, melanoma, lymphoma, and renal cell carcinoma. Most commonly involve the pericardium (effusion, tamponade), but can affect myocardium and endocardium. Presentation depends on location: pericardial effusion, heart failure, arrhythmias, or embolic events. Diagnosis by echocardiography, cardiac MRI, or CT. Treatment focuses on systemic cancer therapy; cardiac surgery rarely indicated.

Cardiac PET Imaging

- Positron emission tomography using radiotracers (Rb-82, N-13 ammonia, O-15 water) for quantitative myocardial perfusion assessment. Advantages over SPECT: superior resolution, shorter scan time, attenuation correction, and absolute myocardial blood flow quantification (mL/g/min). FDG PET identifies hibernating myocardium (viable but ischemic tissue that may benefit from revascularization). Used for viability assessment, sarcoidosis evaluation, and cardiac infection imaging.

Cardiac Radiation Injury

- Late complication of mediastinal radiation therapy (Hodgkin lymphoma, breast cancer, lung cancer). Manifestations include pericardial disease (constrictive pericarditis, effusion), coronary artery disease (accelerated atherosclerosis), valvular disease (fibrosis), myocardial fibrosis, and conduction abnormalities. Risk increases with higher radiation doses and

larger treatment fields. Long-term surveillance with echocardiography is recommended for survivors.

Cardiac Sarcoidosis

– Infiltrative disease characterized by non-caseating granulomas in the myocardium, affecting 25-30% of patients with systemic sarcoidosis. Presentation includes conduction abnormalities (AV block), ventricular arrhythmias, and heart failure. Diagnosis requires cardiac MRI showing late gadolinium enhancement (typically basal septal and epicardial), PET showing active inflammation, or endomyocardial biopsy. Treatment: corticosteroids for active inflammation, ICD for arrhythmia prevention.

Cardiac Stress Testing

– Assessment of cardiac function under physiological or pharmacological stress to detect ischemia. Exercise stress testing involves treadmill or bicycle exercise with continuous ECG monitoring. Pharmacological stress (dobutamine, adenosine, regadenoson) is used when patients cannot exercise. Stress testing combined with imaging (nuclear perfusion, echocardiography, cardiac MRI) improves sensitivity and specificity. Indications include evaluation of chest pain, preoperative risk assessment, and prognosis.

Cardiology

– The branch of medicine devoted to the study, diagnosis, and treatment of disorders of the heart and circulatory system. Cardiologists manage conditions including coronary artery disease, heart failure, valvular heart disease, arrhythmias, cardiomyopathy, pericardial disease, congenital heart disease, and hypertension. Diagnostic tools: electrocardiography, echocardiography, cardiac catheterization, stress testing, cardiac MRI, CT angiography, and nuclear cardiac imaging. Interventional cardiology performs percutaneous coronary intervention and structural heart procedures (TAVR, MitraClip). Electrophysiology manages rhythm disorders with ablation and device therapy (pacemakers, ICDs). Preventive cardiology focuses on risk factor modification for cardiovascular disease.

Cardiomyopathy Classification

– The MOGE(S) classification system provides phenotypic and genotypic description: M (morpho-functional phenotype), O (organ/system involvement), G (genetic inheritance), E (etiology), S (func-

tional status/NYHA class). This replaces older descriptive classifications and provides more precise characterization for prognosis and family counseling. Each cardiomyopathy can be classified as primary (genetic or acquired) or secondary (due to systemic disease).

Cardiorenal Syndrome

– Dysfunction of the heart and kidneys where acute or chronic failure of one organ contributes to dysfunction of the other. Type 1: acute cardiac dysfunction causing acute kidney injury (e.g., cardiogenic shock). Type 2: chronic cardiac dysfunction causing progressive CKD. Type 3: acute kidney injury causing cardiac dysfunction. Type 4: chronic kidney disease causing cardiac dysfunction. Type 5: systemic conditions affecting both organs. Management is challenging and requires coordinated care.

Cardiovascular System

– The organ system comprising the heart and blood vessels (arteries, arterioles, capillaries, venules, veins) responsible for circulating blood throughout the body. Functions: delivery of oxygen and nutrients to tissues, removal of carbon dioxide and metabolic wastes, transport of hormones and immune cells, thermoregulation, and maintenance of fluid and electrolyte homeostasis. The heart is a four-chambered muscular pump (two atria, two ventricles) that generates the pressure gradient for blood flow. The vascular system forms a closed circuit: systemic circulation (oxygenated blood from left heart to body, deoxygenated blood returns to right heart) and pulmonary circulation (deoxygenated blood from right heart to lungs, oxygenated blood returns to left heart).

Carotid Bruit

– An audible systolic (sometimes continuous) murmur over the carotid artery due to turbulent flow, most commonly from atherosclerotic carotid stenosis. A carotid bruit raises concern for significant stenosis (≥ 50 percent), which confers increased stroke risk. However, sensitivity and specificity are limited; the finding prompts confirmation with carotid duplex ultrasound. Management depends on stenosis severity and symptoms: aggressive risk factor modification, antiplatelets, and carotid endarterectomy or stenting for symptomatic high-grade stenosis.

Chest Pain

– A cardinal symptom with cardiac and non-cardiac causes requiring urgent distinction. Cardiac: acute coronary syndrome (angina, MI), pericarditis, aortic dissection, myocarditis. Pulmonary: pulmonary embolism, pneumothorax, pneumonia, pleurisy. GI: GERD, esophageal spasm, peptic ulcer. Musculoskeletal and psychogenic causes also common. Evaluation: history (character, radiation, aggravating/relieving factors, risk factors), ECG, troponin, chest X-ray, and risk stratification; rule-out algorithms (HEART score, serial troponins) guide disposition.

Cholesterol

– A waxy, fat-like substance produced by the liver and obtained from food that is essential for cell membrane structure, hormone synthesis, and vitamin D production. It circulates in the blood bound to lipoproteins: low-density lipoprotein LDL carries cholesterol to tissues and can contribute to artery plaque, while high-density lipoprotein HDL helps remove excess cholesterol. Elevated LDL cholesterol is a major modifiable risk factor for cardiovascular disease.

Cholesterol and Lipids

– Fatty substances in the blood, including LDL cholesterol, HDL cholesterol, and triglycerides, that play critical roles in cellular function and energy metabolism. Abnormal lipid levels, particularly high LDL and triglycerides with low HDL, promote atherosclerosis and increase the risk of heart attack and stroke. Management includes dietary modification, exercise, and statins or other lipid-lowering medications.

Chronic Venous Insufficiency

– Impaired venous return from the lower extremities due to venous valve incompetence or obstruction. Leads to venous hypertension, edema, skin changes (lipodermatosclerosis, hyperpigmentation), and venous stasis ulcers (medial malleolus). Risk factors: varicose veins, DVT, obesity, prolonged standing. Diagnosis: clinical, venous duplex ultrasound. Treatment: compression therapy (graded stockings), leg elevation, exercise, and wound care. Severe cases: endovenous ablation, venous stenting, or surgical reconstruction.

Circumflex Artery

– A branch of the left coronary artery that travels in the left atrioventricular groove. It supplies the lateral wall of the left ventricle, the left atrium, and in left-dominant systems, the inferior wall and posteromedial papillary muscle. Circumflex artery occlusion causes lateral wall myocardial infarction, which may be missed on standard ECG leads.

Class IB Antiarrhythmics

– Sodium channel blockers that shorten the action potential duration and are preferentially taken up by ischemic tissue. Examples include lidocaine and mexiletine. Lidocaine is used for ventricular tachycardia and ventricular fibrillation, particularly in the setting of acute myocardial infarction. It has minimal effect on normal myocardium. Side effects include CNS toxicity (seizures, confusion) and cardiac depression.

Clopidogrel

– An antiplatelet agent that irreversibly inhibits the P2Y₁₂ ADP receptor on platelets, preventing platelet aggregation. It is a prodrug requiring CYP2C19 activation. Used in acute coronary syndromes, post-PCI, and stroke prevention. Clopidogrel resistance is associated with CYP2C19 poor metabolizer status. Dual antiplatelet therapy (aspirin + clopidogrel) is standard after ACS and PCI. Ticagrelor and prasugrel are alternatives with more rapid onset.

Coarctation of the Aorta

– A congenital narrowing of the aorta, typically near the ductus arteriosus. Presents with upper extremity hypertension, diminished femoral pulses, and a blood pressure gradient between arms and legs. Associated with bicuspid aortic valve and other congenital heart defects. Repair is via surgical resection or balloon angioplasty with stent placement.

Cocaine Cardiotoxicity

– Cocaine blocks norepinephrine and dopamine reuptake, causing sympathomimetic effects: tachycardia, hypertension, and coronary vasospasm. Acute myocardial infarction can occur even with normal coronary arteries due to vasospasm, accelerated atherosclerosis, and prothrombotic effects. Treatment: benzodiazepines for sympatholysis. Beta-blockers are contraindicated (unopposed alpha stimulation worsens vasospasm). Calcium channel blockers and nitroglycerin for vasospasm.

Collateral Circulation

- Alternative vascular pathways that develop when coronary arteries become chronically narrowed. Collaterals connect different coronary artery territories and can partially compensate for stenosis. They develop gradually in response to ischemia and are more prominent in patients with chronic coronary artery disease. Well-developed collaterals can reduce infarct size during acute occlusion.

Congestive Heart Failure

- A clinical syndrome in which the heart cannot pump enough blood to meet metabolic demands, causing fluid congestion and reduced tissue perfusion. Causes: ischemic heart disease, hypertension, valvular disease, cardiomyopathy. Types: heart failure with reduced ejection fraction (HFrEF, <40 percent) and preserved EF (HFpEF, >50 percent); left vs. right failure. Features: dyspnea on exertion, orthopnea, paroxysmal nocturnal dyspnea, fatigue, peripheral edema, JVP elevation, pulmonary crackles, S3 gallop. Diagnosis: BNP/NT-proBNP, echocardiography. Management: diuretics, ACE inhibitors/ARBs (or ARNI), beta-blockers, mineralocorticoid antagonists, SGLT2 inhibitors; implantable devices and transplant in advanced disease.

Contrast Echocardiography

- Use of microbubble contrast agents to enhance endocardial border definition and assess myocardial perfusion. Indicated for suboptimal non-contrast echo images and assessment of myocardial viability. Microbubbles remain entirely within the intravascular space, making them ideal for perfusion assessment. First-pass perfusion imaging detects areas of reduced myocardial blood flow. Contraindicated with intracardiac shunts (risk of paradoxical embolism).

Coronary Angiography

- The invasive imaging of coronary arteries via contrast injection and X-ray fluoroscopy, performed by catheterizing the femoral, radial, or brachial artery and advancing a catheter to the coronary ostia. Gold standard for assessing coronary artery disease, stenosis severity, and anatomy before revascularization (PCI or CABG). May include ventriculography and pressure measurements (FFR). Complications: contrast nephropathy, bleeding, dissection, arrhythmia, MI, stroke, and access-site injury.

Invasive; CTA is a noninvasive alternative.

Coronary Artery Disease

- Narrowing or occlusion of coronary arteries, usually due to atherosclerosis, reducing blood flow to the myocardium. Risk factors include hypertension, diabetes, hyperlipidemia, smoking, family history, and obesity. CAD can present as stable angina, acute coronary syndromes (unstable angina, NSTEMI, STEMI), or sudden cardiac death. Diagnosis includes ECG, stress testing, and coronary angiography. Treatment involves lifestyle modification, medications, and revascularization.

Coronary Calcium Score

- A CT-based measurement of coronary artery calcification, quantified as the Agatston score. A score of 0 indicates very low risk of cardiovascular events; >400 indicates high burden and significant atherosclerosis. It is used for cardiovascular risk stratification in asymptomatic individuals and may guide statin therapy decisions. It does not visualize coronary stenosis directly but reflects total atherosclerotic burden.

Coronary Circulation

- The vascular system supplying blood to the myocardium. The left coronary artery (LCA) divides into the left anterior descending (LAD) and circumflex (LCx) arteries. The right coronary artery (RCA) supplies the right ventricle, SA node (in 60% of people), and inferior left ventricular wall. Coronary arteries branch into arterioles, capillaries, and drain into coronary veins and the coronary sinus.

Coronary Dominance

- Determined by which artery gives rise to the posterior descending artery (PDA). Right coronary dominance (85% of people): RCA gives rise to PDA. Left coronary dominance (8%): LCx gives rise to PDA. Codominance (7%): both RCA and LCx contribute. Dominance affects which territories are supplied by each artery and influences the pattern of myocardial infarction.

Coronary Microvascular Dysfunction

- Impairment of the small coronary arteries and arterioles causing impaired coronary flow reserve despite normal epicardial coronary arteries. Common in women, patients with diabetes, and hypertension.

Causes chest pain (angina equivalent) and may contribute to heart failure with preserved ejection fraction. Diagnosis: coronary flow reserve measurement during invasive angiography or by PET/MRI. Treatment: statins, ACE inhibitors, ranolazine, and risk factor modification.

Coronary Thrombosis

- See Myocardial Infarction (Heart Attack).

Diastole

- The phase of the cardiac cycle when the heart muscle relaxes, allowing the chambers to fill with blood. Ventricular diastole begins with isovolumetric relaxation (all valves closed, pressure falls), followed by rapid ventricular filling, slow filling (diastasis), and atrial contraction (atrial kick, contributing 20% of ventricular filling in normal hearts). During diastole, coronary blood flow to the left ventricular myocardium occurs (systolic compression of coronary arteries prevents flow during contraction). Diastolic dysfunction (impaired relaxation or reduced compliance) is a hallmark of heart failure with preserved ejection fraction (HFpEF) and restrictive cardiomyopathy.

Dobutamine Stress Echocardiography

- Pharmacological stress test using dobutamine (beta-1 agonist) to increase heart rate, contractility, and myocardial oxygen demand. New or worsening wall motion abnormalities indicate ischemia. Preferred when patients cannot exercise. Beta-blockers should be held before testing. Sensitivity 80-85% and specificity 80-88% for detecting significant coronary artery disease. Additional atropine may be administered if target heart rate not achieved.

Dressler Syndrome

- A delayed pericarditis occurring 2-10 weeks after myocardial infarction or cardiac surgery. It is an autoimmune-mediated inflammation caused by antibodies against myocardial antigens released during tissue injury. Symptoms include fever, pleuritic chest pain, and pericardial friction rub. ECG may show diffuse ST elevation. Treatment includes NSAIDs, colchicine, and avoidance of anticoagulants if possible. It is a type of post-cardiac injury syndrome.

Drug Bioavailability

- The fraction of an administered drug that reaches

systemic circulation unchanged. Oral bioavailability is affected by first-pass metabolism, absorption, and drug formulation. IV administration has 100% bioavailability. Bioavailability influences drug dosing and route selection. Drugs with low oral bioavailability (e.g., morphine 25%) require higher oral doses compared to IV doses. Food can increase or decrease bioavailability depending on the drug.

Dual Antiplatelet Therapy

- The combination of aspirin and a P2Y₁₂ inhibitor (clopidogrel, prasugrel, or ticagrelor) for prevention of thrombotic events after acute coronary syndrome and percutaneous coronary intervention. Duration varies: 1 month after bare-metal stent, 6-12 months after drug-eluting stent, and 12 months after ACS. Prasugrel is more potent but increases bleeding risk; ticagrelor is reversible but requires twice-daily dosing. DAPT score guides duration of therapy.

Dyspnea on Exertion

- Shortness of breath precipitated by physical activity, a cardinal symptom of cardiac and pulmonary disease. Cardiac causes: heart failure, coronary artery disease (angina equivalent), valvular disease; pulmonary: COPD, asthma, ILD, anemia, deconditioning. Quantified by NYHA functional class (heart failure) and mMRC scale (dyspnea). Evaluation: history (onset, associated symptoms), physical exam, ECG, chest X-ray, echo, spirometry, and exercise testing. The symptom reflects the demand/supply mismatch of oxygen delivery.

Electrocardiogram (ECG / EKG)

- A recording of the heart's electrical activity using electrodes placed on the body surface. A standard 12-lead ECG provides views of the heart from different angles: limb leads (I, II, III, aVR, aVL, aVF) and precordial leads (V1-V6). ECG is used to diagnose arrhythmias, conduction disturbances, myocardial ischemia/infarction, chamber hypertrophy, electrolyte abnormalities, and drug effects.

Endocarditis

- Infection of the endocardial surface of the heart, most commonly involving the valves. Acute bacterial endocarditis: Staph aureus (most common in IV drug users and prosthetic valves), rapid destruction. Subacute: viridans group streptococci (pre-existing valve disease). Symptoms: fever, heart murmur, petechiae, splinter hemorrhages, Janeway lesions,

Osler nodes, Roth spots. Diagnosis: modified Duke criteria, blood cultures (2-3 sets), echocardiography (transthoracic and transesophageal). Complications: valvular regurgitation, heart failure, embolic phenomena (stroke, septic emboli), perivalvular abscess. Treatment: prolonged IV antibiotics based on organism and sensitivity; surgical valve replacement for severe regurgitation, persistent infection, or large vegetations.

Endocarditis Surgical Indications

- Surgery indicated for: heart failure from valve dysfunction, uncontrolled infection (abscess, fistula, vegetation >10 mm with persistent emboli), fungal endocarditis, prosthetic valve dehiscence, and large vegetations (>15 mm) with embolic events. Timing: urgent (within days) for heart failure or uncontrolled infection; emergent (immediate) for acute aortic regurgitation with heart failure or ruptured mycotic aneurysm.

Exercise Stress Test

- A noninvasive cardiac diagnostic test that evaluates the cardiovascular response to graded physical exertion, primarily used to diagnose coronary artery disease, assess functional capacity, and guide prognosis. The test is most commonly performed using a treadmill (Bruce protocol: graded increase in speed and incline every 3 minutes) or stationary bicycle ergometer, following the standard Bruce or modified Bruce protocol. During the test, continuous 12-lead ECG monitoring records heart rate, rhythm, and ST-segment changes.

Familial Hypercholesterolemia

- An autosomal dominant genetic disorder causing severely elevated LDL cholesterol from birth, most commonly due to LDL receptor mutations. Heterozygous FH affects 1 in 250 people, causing premature coronary artery disease (MI in 40s-50s). Diagnosis: LDL >190 mg/dL in adults, or >160 mg/dL in children. Treatment: high-intensity statins, ezetimibe, PCSK9 inhibitors. Cascade screening of family members is essential. Lipoprotein apheresis may be needed for severe cases.

First-Degree AV Block

- A conduction delay in which every atrial impulse reaches the ventricles but with a prolonged PR interval (>0.20 seconds). It is caused by delayed conduction through the AV node or His-Purkinje system.

First-degree block is usually benign and asymptomatic. Causes include increased vagal tone, drugs (beta-blockers, calcium channel blockers, digoxin), inferior myocardial infarction, and fibrotic degeneration. Treatment of the underlying cause is usually sufficient.

First-Pass Metabolism

- The metabolism of a drug by the liver before it reaches systemic circulation after oral administration. Drugs with high first-pass metabolism (e.g., morphine, nitroglycerin, lidocaine) have low oral bioavailability and may require alternative routes (sublingual, transdermal, IV). First-pass metabolism can be affected by liver disease, enzyme induction, and enzyme inhibition. Prodrugs (e.g., enalapril) require hepatic activation during first-pass metabolism.

Fractional Flow Reserve

- An invasive physiological measurement during coronary catheterization using a pressure wire to assess the hemodynamic significance of a coronary stenosis. $FFR = Pa/Pd$ (aortic pressure / distal coronary pressure) during maximal hyperemia (adenosine). Normal FFR is 1.0; $FFR \leq 0.80$ indicates ischemia-producing stenosis warranting revascularization. The FAME and FAME 2 trials demonstrated that FFR-guided PCI improves outcomes compared to angiography-guided PCI.

HDL

- High-density lipoprotein; the 'good' cholesterol that mediates reverse cholesterol transport, removing cholesterol from peripheral tissues and arterial walls and returning it to the liver for excretion. High HDL is associated with reduced cardiovascular risk; low HDL (<40 mg/dL men, <50 mg/dL women) is a risk factor. Levels are increased by exercise, weight loss, and moderate alcohol; pharmacologic elevation (niacin) does not reduce events. Measured in lipid panel; clinical focus is on overall risk and LDL lowering.

Heart

- The muscular organ responsible for pumping blood through the circulatory system. The human heart is a four-chambered, two-sided pump: the right heart (right atrium receiving deoxygenated blood from the body via superior and inferior vena cava, right ventricle pumping to the pulmonary circulation via the

pulmonary artery) and the left heart (left atrium receiving oxygenated blood from the lungs via four pulmonary veins, left ventricle pumping to the systemic circulation via the aorta). The heart wall consists of three layers: epicardium (visceral pericardium), myocardium (cardiac muscle with intercalated discs, gap junctions for electrical coupling, and desmosomes for mechanical coupling), and endocardium (lining the chambers and valves). The heart is enclosed in the pericardium (fibrous outer sac with serous inner layer; 10-50 mL of pericardial fluid lubricates). The cardiac skeleton (fibrous rings around valves and membranous septum) provides structural support and electrical insulation between atria and ventricles. Blood supply: left main coronary artery (LCA, divides into left anterior descending–LAD–and circumflex–LCx) and right coronary artery (RCA, posterior descending artery–PDA–in right-dominant circulation). Venous drainage: coronary sinus (receives the great, middle, and small cardiac veins) emptying into the right atrium. Dimensions: approximately 12 x 9 x 6 cm, weight 250-350 grams. The heart beats approximately 100,000 times per day (2.5 billion times in a 70-year lifetime) and pumps about 5 litres/minute at rest (up to 25 litres/minute during exercise).

Heart Attack (Myocardial Infarction)

– Also known as myocardial infarction, the death of heart muscle tissue due to sudden blockage of a coronary artery, typically by a blood clot. It presents with chest pain or pressure, shortness of breath, nausea, and diaphoresis, though symptoms may be atypical in women and diabetics. Emergency treatment includes reperfusion therapy via angioplasty or thrombolytics, followed by long-term medications and lifestyle changes.

Heart Block

– A delay or interruption in the conduction of cardiac impulses from the atria to the ventricles through the atrioventricular (AV) node and His-Purkinje system. Classification: first-degree AV block: PR interval >200 ms, each atrial impulse conducts to the ventricles, typically asymptomatic. Second-degree AV block: Mobitz type I (Wenckebach): progressive PR prolongation then a dropped QRS, usually benign, localised to AV node. Mobitz type II: constant PR

interval with intermittent dropped QRS, indicates disease below the AV node (His-Purkinje), risk of progression to complete heart block. Third-degree (complete) AV block: no atrial impulses conducted to ventricles; atria and ventricles beat independently (AV dissociation). Ventricular escape rhythm (wide QRS, rate 30-50 bpm) or junctional escape (narrow QRS, rate 40-60 bpm). Causes: idiopathic fibrosis (Lenegre-Lev disease, most common), ischemic heart disease, myocardial infarction (inferior MI–AV nodal block, usually transient; anterior MI–infranodal block, often permanent, poor prognosis), cardiomyopathy, drugs (beta-blockers, calcium channel blockers, digoxin), electrolyte abnormalities (hyperkalaemia), Lyme disease, Chagas disease, endocarditis (aortic valve abscess), post-cardiac surgery, and infiltrative diseases (sarcoidosis, amyloidosis). Symptoms: syncope, presyncope, dizziness, fatigue, dyspnea, angina (see Stokes-Adams attacks). Treatment: urgent pacing for symptomatic or high-grade AV block (type II second-degree or third-degree). Temporary pacing: transcutaneous (external) or transvenous. Permanent pacemaker: dual-chamber (DDD) preferred for sinus node function, single-chamber (VVI) for atrial fibrillation with AV block. Dual-chamber pacing maintains AV synchrony and reduces atrial fibrillation and heart failure risk.

Heartburn

– A burning sensation, typically retrosternal (behind the sternum), that may radiate to the throat and is often associated with regurgitation of sour or bitter-tasting fluid into the mouth. Despite its name, heartburn is a symptom of gastro-oesophageal reflux disease (GORD), not a cardiac symptom. It is caused by reflux of acidic gastric contents into the lower esophagus, stimulating chemoreceptors in the oesophageal mucosa. Exacerbating factors: large meals, fatty or spicy foods, chocolate, caffeine, alcohol, smoking, bending forward, lying supine after eating, pregnancy, obesity, and hiatus hernia. Patients often self-medicate with antacids (aluminium/magnesium hydroxide), alginates (Gaviscon), H₂ antagonists (ranitidine, famotidine), or proton pump inhibitors (omeprazole). Heartburn can be confused with: cardiac chest pain (myocardial ischemia/infarction–pressure, tightness, radiation to left arm/jaw, shortness of breath, diaphoresis),

oesophageal spasm (painful, may mimic angina), peptic ulcer disease, and biliary colic. Red flags requiring investigation: dysphagia, odynophagia, weight loss, GI bleeding, anaemia, age >55, family history of oesophageal or gastric cancer. ECG is indicated when cardiac ischemia cannot be distinguished on history alone.

Heart Disease

– A broad term encompassing various conditions affecting the heart and blood vessels, most commonly coronary artery disease, heart failure, arrhythmias, and valvular heart disease. Atherosclerosis, the buildup of plaque in the arteries, is the underlying cause of most cardiovascular events. Risk factors include hypertension, hyperlipidemia, smoking, diabetes, obesity, and physical inactivity.

Heart Failure with Reduced Ejection Fraction (HFrEF)

– A clinical syndrome of heart failure characterized by left ventricular systolic dysfunction with a reduced ejection fraction ($\leq 40\%$). Causes: ischemic heart disease (prior MI, 60-70%), dilated cardiomyopathy, hypertension, valvular heart disease. Pathophysiology: eccentric remodeling, progressive ventricular dilation, neurohormonal activation (RAAS, sympathetic nervous system). Clinical features: fatigue, dyspnea, orthopnea, PND, bibasilar rales, S3 gallop, elevated JVP, peripheral edema. Diagnosis: echocardiogram (LVEF $\leq 40\%$), elevated BNP/NT-proBNP. Guideline-Directed Medical Therapy (GDMT 4 pillars): ARNI (sacubitril/valsartan) or ACEi/ARB, beta-blocker (carvedilol, metoprolol succinate, bisoprolol), mineralocorticoid receptor antagonist (spironolactone, eplerenone), and SGLT2 inhibitor (dapagliflozin/empagliflozin). Device therapy: ICD for primary prevention if LVEF $\leq 35\%$ despite ≥ 3 months GDMT; CRT for LBBB with QRS ≥ 150 ms.

Heart Surgery

– Surgical procedures performed on the heart or great vessels to treat structural or functional cardiac conditions. Common operations include coronary artery bypass grafting (CABG), valve repair or replacement, and repair of congenital heart defects. Surgical approaches range from traditional open-heart surgery with sternotomy to minimally

invasive and robot-assisted techniques.

Heart Valves

– The four cardiac valves ensure unidirectional blood flow through the heart. Atrioventricular valves: mitral valve (bicuspid, between left atrium and left ventricle, two leaflets — anterior and posterior, attached via chordae tendineae to papillary muscles preventing prolapse) and tricuspid valve (between right atrium and right ventricle, three leaflets). Semilunar valves: aortic valve (between left ventricle and aorta, three cusps — left coronary, right coronary, non-coronary) and pulmonary valve (between right ventricle and pulmonary artery, three cusps). Valve dysfunction: stenosis (failure to open fully, causing pressure overload) and regurgitation (failure to close fully, causing volume overload). Common pathologies: aortic stenosis (calcific, bicuspid valve, rheumatic), mitral regurgitation (mitral valve prolapse, ischemic, rheumatic), and infective endocarditis (vegetations on valve leaflets, typically *Streptococcus viridans*, *Staphylococcus aureus*). Clinical assessment: auscultation (heart sounds and murmurs), echocardiography (transthoracic and transoesophageal) for anatomy and hemodynamics.

Hyperlipidemia

– Elevated levels of lipids in the blood—total cholesterol, LDL, triglycerides, and/or reduced HDL—a major modifiable risk factor for atherosclerosis and cardiovascular disease. Primary (genetic: familial hypercholesterolemia) or secondary (hypothyroidism, diabetes, nephrotic syndrome, obesity, alcohol). Screening: fasting lipid panel; risk calculators (ASCVD) guide treatment. Management: lifestyle modification, statins (first-line), ezetimibe, PCSK9 inhibitors, fibrates/omega-3 for triglycerides. Targets depend on cardiovascular risk category.

Hypertension

– Persistently elevated blood pressure, defined as systolic BP >130 mmHg or diastolic BP >80 mmHg (ACC/AHA guidelines). It is the most common modifiable risk factor for cardiovascular disease, stroke, heart failure, and chronic kidney disease. Most cases (90-95%) are essential (primary) hypertension; 5-10% are secondary (renal, endocrine, renovascular). Treatment includes lifestyle modifications (diet, exercise, weight loss) and pharmacotherapy

(ACE inhibitors, ARBs, CCBs, thiazide diuretics).

Hypertensive Emergency

– Severe hypertension (SBP >180 or DBP >120) with acute target organ damage. Organs involved: brain (hypertensive encephalopathy, stroke), heart (acute coronary syndrome, acute pulmonary edema, aortic dissection), kidneys (acute kidney injury), and eyes (papilledema). Requires immediate BP reduction with IV antihypertensives (nicardipine, labetalol, nitroprusside) and ICU monitoring. Goal: reduce MAP by 10-20% in the first hour, then cautious further reduction.

Hypoplastic Left Heart Syndrome

– A severe congenital heart defect where the left heart structures (mitral valve, left ventricle, aortic valve, ascending aorta) are underdeveloped and unable to support systemic circulation. The right ventricle pumps blood to both the pulmonary and systemic circulations via a patent ductus arteriosus. Presents in the first days of life with cyanosis, tachypnea, and cardiovascular collapse when the ductus closes. Diagnosis: echocardiography shows a tiny left ventricle, hypoplastic ascending aorta, and ductal-dependent systemic circulation. Staged surgical palliation: Norwood procedure (stage 1, neonatal), Glenn shunt (stage 2, 4-6 months), and Fontan completion (stage 3, 2-4 years). Prognosis has improved significantly but remains guarded. Without surgery, it is uniformly fatal.

Impella Device

– Percutaneous microaxial left ventricular assist device that actively pumps blood from the LV into the aorta, reducing LV workload and increasing cardiac output. Types: Impella 2.5 (up to 2.5 L/min), Impella CP (up to 3.7 L/min), Impella 5.0 (up to 5 L/min, surgically placed). Used in cardiogenic shock, high-risk PCI, and as bridge to decision. Complications: hemolysis, limb ischemia, device malposition, bleeding.

Infective Endocarditis

– Infection of the endocardial surface of the heart, most commonly affecting the heart valves. It is diagnosed using the Duke criteria, which include major criteria (positive blood cultures, echocardiographic evidence of vegetations) and minor criteria (predisposing heart condition, fever, vascular phenomena, immunologic phenomena). Treatment requires pro-

longed IV antibiotic therapy (4-6 weeks). Surgery is indicated for complications including heart failure, persistent infection, and embolic events.

Intra-Aortic Balloon Pump

– A mechanical circulatory support device that increases myocardial perfusion and reduces afterload. The balloon inflates during diastole (augmenting coronary perfusion) and deflates during systole (reducing afterload). Inserted percutaneously into the femoral artery. Indications include cardiogenic shock, mechanical complications of MI (papillary muscle rupture, VSD), and high-risk PCI. IABP provides modest hemodynamic support and is being replaced by more effective devices.

Intravascular Ultrasound

– Catheter-based imaging using a miniature ultrasound probe inside coronary arteries to visualize vessel wall layers, plaque composition, and stent deployment. Provides more detailed information than angiography alone, including vessel remodeling, plaque burden, and true vessel diameter. Used to optimize stent deployment (apposition, expansion) and assess intermediate angiographic lesions. OCT (optical coherence tomography) provides higher resolution imaging.

Ischemic Cardiomyopathy

– Dilated cardiomyopathy resulting from extensive myocardial infarction with significant scar burden. EF is typically severely reduced (<35%). The infarcted myocardium is replaced by fibrotic scar tissue, impairing contractile function and promoting ventricular arrhythmias. Viability testing (PET, dobutamine echo, cardiac MRI) may identify hibernating myocardium that could benefit from revascularization. Treatment includes standard heart failure therapy, ICD for arrhythmia prevention, and revascularisation when viable myocardium is present.

Killip Classification

– A clinical classification system for assessing the severity of myocardial infarction based on physical examination findings. Class I: no heart failure signs. Class II: mild heart failure (crackles, S3 gallop, elevated JVD). Class III: pulmonary edema. Class IV: cardiogenic shock. The Killip class correlates with in-hospital mortality: Class I (6%), Class II (17%), Class III (38%), Class IV (81%). It guides initial

management intensity.

LDL

– Low-density lipoprotein; the 'bad' cholesterol that transports cholesterol to peripheral tissues and is the principal driver of atherosclerosis. Elevated LDL is a major modifiable cardiovascular risk factor; guidelines target LDL levels based on global risk (statin intensity). Measurement: direct or Friedewald equation ($\text{LDL} = \text{total cholesterol} - \text{HDL} - \text{triglycerides}/5$). Management: lifestyle (diet, exercise), statins, ezetimibe, PCSK9 inhibitors, bempedoic acid. Each 1 mmol/L (39 mg/dL) LDL reduction lowers major events 20-25 percent.

Left Bundle Branch

– A continuation of the bundle of His that divides into anterior and posterior fascicles. The anterior fascicle supplies the anterior and superior left ventricular wall; the posterior fascicle supplies the inferior and posterior wall. Left bundle branch block (LBBB) causes delayed left ventricular activation and is commonly associated with hypertension, coronary artery disease, and cardiomyopathy. LBBB on ECG shows widened QRS with notched R waves in lateral leads.

Left Ventricle

– The lower left chamber and most muscular chamber of the heart, responsible for pumping oxygenated blood into the aorta for systemic distribution. Its walls are 8-15 mm thick and generate systolic pressures of 100-140 mmHg. The left ventricle is the primary chamber affected in systolic heart failure, hypertension, and coronary artery disease. Its function is assessed by ejection fraction (normally 55-70%).

Mitral Regurgitation

– Incomplete closure of the mitral valve allowing blood to flow backward from the left ventricle to the left atrium during systole. Causes include mitral valve prolapse, papillary muscle dysfunction, rheumatic disease, and ischemic heart disease. Murmur: pansystolic (holosystolic) blowing murmur at the apex radiating to the axilla. Chronic MR leads to left atrial and ventricular dilation. Severe MR requires surgical repair or replacement.

Myocardial Perfusion Imaging

– Nuclear cardiology technique using radiotracers (^{99m}Tc sestamibi, Tl-201) to assess blood flow to the

myocardium. Performed at rest and during stress (exercise or pharmacological) to detect reversible ischemia (stress defect with rest redistribution) or fixed defects (scar from prior MI). SPECT (single-photon emission CT) and PET (positron emission tomography) are the modalities used. PET also quantifies myocardial blood flow and can detect balanced ischemia.

Myocarditis

– Inflammation of the myocardium, most commonly caused by viral infections (coxsackievirus, adenovirus, SARS-CoV-2). Presents with chest pain, dyspnea, arrhythmias, and elevated troponin. Diagnosis: ECG, echocardiography, cardiac MRI with Lake Louise criteria, and endomyocardial biopsy. Treatment: supportive care, heart failure management, and immunosuppression for specific causes.

Myocarditis Diagnosis

– Cardiac MRI (Lake Louise criteria) shows myocardial edema (T2-weighted imaging), late gadolinium enhancement (typically epicardial/mid-wall in non-ischemic distribution), and increased myocardial T1/T2 mapping values. Endomyocardial biopsy (Dallas criteria: inflammatory infiltrate + myocyte necrosis) remains the gold standard but is reserved for unclear cases. Blood tests: elevated troponin, ESR, CRP. Viral serology may identify causative agent.

Myocardium

– The thick muscular middle layer of the heart wall composed of cardiac muscle cells (cardiomyocytes). The myocardium is responsible for the contractile function of the heart. It contains intercalated discs with gap junctions that allow electrical coupling between cells. The left ventricular myocardium is significantly thicker (8-15 mm) than the right ventricle (3-5 mm) due to higher pressure demands of systemic circulation.

NSTEMI

– Non-ST-elevation myocardial infarction: acute myocardial necrosis (elevated cardiac troponin) without persistent ST-segment elevation on ECG, caused by subtotal occlusion or distal embolization of a coronary artery. Features: chest pain, ECG changes (ST depression, T-wave inversion), elevated troponin. Management: antiplatelet (aspirin + P2Y12 inhibitor), anticoagulant, nitrates, beta-blockers,

statins; risk stratification (GRACE score)—early invasive angiography for high risk, ischemia-guided for low risk. Distinguish from STEMI (transmural, needs immediate reperfusion).

Percutaneous Coronary Intervention

– A catheter-based procedure to open blocked coronary arteries, typically involving balloon angioplasty and stent placement. Indications include acute STEMI (primary PCI), NSTEMI (early invasive strategy), and stable CAD with significant stenosis. Drug-eluting stents have reduced restenosis rates compared to bare-metal stents. Dual antiplatelet therapy is required after stent placement. PCI can be performed via radial or femoral artery access.

Pericardiocentesis

– A procedure to aspirate fluid from the pericardial space, performed emergently for cardiac tamponade or diagnostically for pericardial effusion. The subxiphoid approach is most commonly used, with the needle directed toward the left shoulder under echocardiographic guidance. Complications include myocardial puncture, coronary artery injury, and pneumothorax. Pericardial fluid can be analyzed for cytology, culture, and chemistry to determine the cause of effusion.

Peripartum Cardiomyopathy Prognosis

– Approximately 50% of patients recover normal ventricular function within 6 months. Predictors of poor recovery include: persistent LV dilation, severe LV dysfunction at diagnosis, African American race, and delayed diagnosis. Patients who recover should be counseled regarding risk of recurrence in subsequent pregnancies (30-50% risk of deterioration). ACE inhibitors and beta-blockers should be continued for at least 1 year after diagnosis, even if EF recovers.

Peripheral Arterial Disease

– Atherosclerotic occlusive disease of arteries supplying the lower limbs, causing reduced blood flow. Features: claudication (exertional calf pain relieved by rest), rest pain, diminished pulses, cool pale skin, ulcers/gangrene; chronic critical limb ischemia is limb-threatening. Risk factors: smoking (strongest), diabetes, hypertension, hyperlipidemia, age. Diagnosis: ankle-brachial index (ABI <0.9), duplex

ultrasound, CTA/MRA. Management: risk factor control, exercise, antiplatelets, statins, revascularization (angioplasty/stent, bypass); associated with high cardiovascular morbidity (MI, stroke).

Peripheral Edema

– Swelling due to accumulation of fluid in the interstitial space of the limbs, most commonly the lower extremities. Causes: increased hydrostatic pressure (heart failure, venous insufficiency, deep vein thrombosis), reduced oncotic pressure (hypoalbuminemia—liver disease, nephrotic syndrome, malnutrition), lymphatic obstruction (lymphedema), and sodium/fluid retention (renal failure). Usually bilateral with pitting in cardiac/renal disease; unilateral suggests venous or lymphatic cause. Diagnosis: history, exam (pitting vs. non-pitting), and targeted tests (BNP, albumin, renal, DVT imaging).

Peripheral Vascular Disease

– Narrowing of peripheral arteries, most commonly due to atherosclerosis, causing reduced blood flow to extremities. Risk factors include smoking, diabetes, hypertension, and hyperlipidemia. Symptoms include claudication (exercise-induced leg pain), rest pain, and non-healing ulcers. Ankle-brachial index (ABI) <0.90 indicates PVD. Severe PVD (critical limb ischemia) may require revascularization (angioplasty/stenting or bypass surgery) to prevent amputation.

Post-Cardiac Arrest Management

– Comprehensive care after ROSC: hemodynamic optimization (MAP >65 mmHg, avoid hypotension), ventilation management (target PaCO₂ 35-45 mmHg), targeted temperature management, coronary angiography for STEMI or high suspicion for ischemia, seizure monitoring and treatment, and neurological prognostication (clinical exam, SSEPs, EEG, MRI at 3-5 days). Withdrawal of care based on multimodal prognostication when no evidence of meaningful recovery.

Premature Atrial Contraction

– A premature beat arising from an ectopic focus in the atria, producing an early P wave (often abnormal morphology) followed by a normal QRS; common and usually benign, increasing with age and caffeine/stress. ECG: early abnormal P wave, normal PR and QRS, followed by a compensatory pause. May trigger atrial fibrillation; generally

asymptomatic but can cause palpitations. Treatment: reassurance, avoidance of triggers; antiarrhythmics or ablation if symptomatic or frequent.

Pulmonary Embolism Treatment

– Anticoagulation: DOACs preferred (rivaroxaban, apixaban) or LMWH bridging to warfarin. Duration: 3 months for provoked (reversible risk factor), indefinite for unprovoked or recurrent. Massive PE: systemic thrombolysis (alteplase 100 mg IV over 2 hours) or surgical catheter-directed embolectomy. Submassive PE: catheter-directed thrombolysis may reduce RV strain. IVC filter: for contraindication to anticoagulation or recurrent PE despite therapy.

Pulseless Electrical Activity

– A cardiac arrest rhythm organized electrical activity without a detectable pulse. PEA has many reversible causes (5 H's and 5 T's): hypovolemia, hypoxia, hydrogen ion (acidosis), hypo/hyperkalemia, hypothermia; tension pneumothorax, tamponade (cardiac), toxins, thrombosis (pulmonary), thrombosis (coronary). Treatment focuses on identifying and reversing the underlying cause while performing CPR and administering epinephrine.

QRS Complex

– The deflection representing ventricular depolarization, consisting of a Q wave (initial downward deflection), R wave (upward deflection), and S wave (downward deflection after R). Normal duration is 0.06-0.10 seconds (1.5-2.5 small boxes). Widened QRS (>0.12 s) indicates bundle branch block, ventricular rhythm, or hyperkalemia. Abnormal Q waves indicate prior myocardial infarction.

Regadenoson Pharmacological Stress

– Selective A_{2A} adenosine receptor agonist used as a pharmacological vasodilator for nuclear myocardial perfusion imaging. Single IV bolus injection produces coronary vasodilation with fewer side effects than adenosine (less bronchospasm, AV block). Contraindicated in severe asthma or COPD requiring oxygen. Advantages: selective coronary vasodilation, no need for dose adjustment, and simpler administration than adenosine infusion.

Regurgitation

– The backward flow of blood through a heart valve that fails to close properly (valvular incompetence or insufficiency). Regurgitation can affect any of

the four heart valves: mitral regurgitation (most common—systolic murmur at apex radiating to axilla, caused by mitral valve prolapse, ischemic heart disease, rheumatic heart disease, dilated cardiomyopathy), aortic regurgitation (diastolic murmur at left sternal edge—chronic causes: bicuspid aortic valve, aortic root dilation, rheumatic, syphilis; acute causes: infective endocarditis, aortic dissection), tricuspid regurgitation (systolic murmur at left lower sternal edge—functional from right ventricular dilation, pulmonary hypertension, or primary from endocarditis, carcinoid), and pulmonic regurgitation (diastolic murmur at left upper sternal edge—usually benign from pulmonary hypertension). Chronic regurgitation allows compensatory ventricular dilation and eccentric hypertrophy, maintaining cardiac output for years before symptoms develop (exertional dyspnea, fatigue, palpitations). Acute severe regurgitation (e.g., flail mitral leaflet, chordal rupture) causes sudden volume overload, pulmonary edema, and cardiogenic shock. Diagnosis: echocardiography (colour Doppler—quantifies severity by jet area, vena contracta, PISA radius, and regurgitant volume). Treatment: medical therapy for chronic disease (vasodilators, diuretics), surgical repair or replacement for severe symptomatic regurgitation or when ventricular dysfunction develops.

Right Atrium

– The upper right chamber that receives deoxygenated blood from the superior and inferior vena cava and the coronary sinus. It contains the sinoatrial (SA) node in its wall near the junction with the superior vena cava. The right atrium has thin walls (2 mm) and contracts to fill the right ventricle through the tricuspid valve. Pressure in the right atrium is normally 2-8 mmHg.

Right Coronary Artery

– Arises from the right aortic sinus and travels in the right atrioventricular groove. It supplies the right atrium, right ventricle, SA node (60% of individuals), AV node (85% of individuals), and the inferior wall of the left ventricle. RCA occlusion causes inferior myocardial infarction, which may be associated with bradycardia and heart block due to AV nodal involvement.

Right Heart Failure

– Failure of the right ventricle to adequately pump

blood to the lungs, causing systemic venous congestion. Causes include left heart failure (most common), pulmonary hypertension, right ventricular infarction, pulmonary embolism, and constrictive pericarditis. Signs include elevated JVD, peripheral edema, hepatomegaly, and ascites. Treatment focuses on addressing the underlying cause and managing volume overload with diuretics. Inotropes (dobutamine, milrinone) may be needed for RV failure.

Single Ventricle

– A group of congenital heart defects where one functional ventricle supports both the systemic and pulmonary circulations. Includes tricuspid atresia, mitral atresia, double inlet left ventricle, hypoplastic left heart syndrome, and unbalanced AV canal. Pulmonary and systemic blood flow must be balanced by restrictive or non-restrictive shunts. Presents with cyanosis, heart failure, or a combination depending on pulmonary blood flow. All single ventricle patients undergo staged Fontan palliation: stage 1 (neonatal: BT shunt, PA band, or Norwood), stage 2 (4-6 months: Glenn shunt — SVC to PA), and stage 3 (2-4 years: Fontan completion — IVC to PA). Long-term complications: Fontan failure, protein-losing enteropathy, plastic bronchitis, thromboembolism, and arrhythmias.

Splinter Hemorrhages

– Linear hemorrhages under the nail bed, oriented longitudinally. In infective endocarditis, they are caused by septic microemboli to the nail bed capillaries. They are a minor Duke criterion. Splinter hemorrhages can also result from trauma, psoriasis, and systemic vasculitis. Multiple splinter hemorrhages in several nails are more suggestive of endocarditis than a single lesion from trauma.

STEMI

– ST-elevation myocardial infarction: transmural myocardial necrosis from acute total occlusion of a coronary artery, an emergency requiring immediate reperfusion. ECG: ST-segment elevation in contiguous leads (or new LBBB); troponin elevated. Complications: cardiogenic shock, arrhythmias (VF), pump failure, papillary muscle rupture, pericarditis. Management: primary PCI within 90 minutes (or fibrinolysis within 30 min if PCI unavailable), antiplatelet, anticoagulant, nitrates, beta-blockers,

statins, oxygen if hypoxic; time is myocardium. Outcomes improved by early reperfusion.

ST Segment

– The isoelectric period between ventricular depolarization (QRS) and repolarization (T wave). It corresponds to the plateau phase of ventricular action potentials. ST segment elevation (>1 mm in limb leads or >2 mm in precordial leads) suggests acute myocardial infarction, pericarditis, or early repolarization. ST depression indicates ischemia, digoxin effect, or hypokalemia. ST segment changes are critical for diagnosing acute coronary syndromes.

Syncope (Fainting)

– A transient loss of consciousness (TLOC) due to global cerebral hypoperfusion, characterized by rapid onset, short duration, and spontaneous complete recovery. Syncope is common (lifetime prevalence 40%). Three main categories: (1) Reflex (neurally mediated) syncope—vasovagal syncope (most common, triggered by emotion, pain, prolonged standing, fear, venepuncture, heat; prodrome: nausea, sweating, pallor, lightheadedness), situational syncope (micturition, defecation, cough, swallowing, post-exercise), and carotid sinus syncope (head turning, tight collars). (2) Orthostatic hypotension—syncope upon standing due to autonomic failure (Parkinson, diabetes, pure autonomic failure), volume depletion, or medications (α -blockers, diuretics, vasodilators). (3) Cardiac syncope—arrhythmias (bradyarrhythmias—sick sinus syndrome, AV block; tachyarrhythmias—VT, SVT), structural heart disease (aortic stenosis, hypertrophic cardiomyopathy, atrial myxoma, pulmonary embolism, myocardial infarction). Red flags for cardiac syncope: syncope during exertion, supine syncope, associated chest pain or palpitations, family history of sudden cardiac death, abnormal ECG. Evaluation: history (witness account key), ECG, orthostatic BP measurement, echocardiogram, and Holter/event monitor if arrhythmia suspected. Tilt-table testing for recurrent vasovagal syncope. Management: reassurance and trigger avoidance for vasovagal syncope; volume expansion, compression stockings, and fludrocortisone/midodrine for orthostatic hypotension; pacemaker for symptomatic bradycardia; ICD for VT/VF.

Systemic Vascular Resistance

- The resistance against which the left ventricle must pump, calculated as $(\text{MAP} - \text{CVP}) / \text{CO} \times 80$. Normal: 800-1200 dynes/sec/cm⁵. Elevated SVR occurs in cardiogenic shock (compensatory vasoconstriction), aortic stenosis, and systemic hypertension. Decreased SVR occurs in septic shock, anaphylaxis, and cirrhosis. SVR guides vasopressor and vasodilator therapy in critical care settings.

Takotsubo Cardiomyopathy

- Also known as stress cardiomyopathy or broken heart syndrome, characterized by transient left ventricular apical ballooning resembling a Japanese octopus trap (takotsubo). It is typically triggered by emotional or physical stress. ECG may show ST elevation mimicking STEMI. Coronary angiography shows no obstructive disease. Most patients recover normal ventricular function within weeks. Treatment is supportive with beta-blockers and ACE inhibitors.

Targeted Temperature Management

- Controlled therapeutic hypothermia for comatose survivors of cardiac arrest. Target: 32-36 degrees C for 24-72 hours followed by gradual rewarming. Mechanism: reduces metabolic demand, limits reperfusion injury, and reduces free radical generation. TTM2 trial showed 33 degrees C was not superior to 36 degrees C. Active cooling methods: cold IV saline, surface cooling devices, endovascular cooling catheters. Complications: infection, electrolyte disturbances, coagulopathy.

Total Anomalous Pulmonary Venous Return

- A cyanotic congenital heart defect where all four pulmonary veins drain into the systemic venous circulation (right atrium or its tributaries) rather than the left atrium. Supracardiac (most common, 45%): pulmonary veins drain via a vertical vein into the left innominate vein or SVC. Cardiac (25%): drain directly into the coronary sinus or right atrium. Infracardiac (20%): drain via a descending vein into the portal vein or IVC (most obstructed type). Mixed (10%). Obstruction presents with severe cyanosis and respiratory distress in the newborn period. Non-obstructed TAPVR presents with mild cyanosis and right heart volume overload. An obligatory right-to-left shunt via an ASD is required for survival.

Diagnosis: echocardiography shows pulmonary veins not connecting to the left atrium. Treatment: surgical reimplantation of the pulmonary veins to the left atrium, closure of the ASD. Emergency surgery for obstructed TAPVR.

Troponins

- Cardiac-specific proteins (troponin I and T) released into the bloodstream during myocardial cell injury. They are the most sensitive and specific biomarkers for myocardial infarction. High-sensitivity troponin assays can detect very low levels, allowing early diagnosis. Troponins rise within 3-6 hours of injury, peak at 12-24 hours, and remain elevated for 7-14 days. Serial measurements are used to diagnose acute MI.

Unstable Angina

- Myocardial ischemia at rest, new-onset severe angina, or a crescendo pattern (more frequent, longer, lower-threshold) without evidence of myocardial necrosis (normal troponin). Pathophysiology: acute plaque rupture with thrombosis causing transient severe coronary obstruction. Part of acute coronary syndrome; features similar to NSTEMI but without biomarker elevation. Management: hospitalization, antiplatelets (aspirin, P2Y₁₂), anticoagulation, nitrates, beta-blockers, statins; risk stratification and coronary angiography with revascularization as indicated.

Vasovagal Syncope

- Reflex syncope mediated by increased vagal tone and withdrawal of sympathetic activity, causing bradycardia and/or vasodilation resulting in transient cerebral hypoperfusion. Triggers: prolonged standing, heat, pain, emotional stress. Preceded by prodrome (lightheadedness, nausea, diaphoresis, visual tunneling). Characterized by brief loss of consciousness with spontaneous recovery. Diagnosis: clinical history, tilt-table testing. Treatment: education, lifestyle modifications, and rarely, pacemaker implantation.

Venous Thrombosis

- The formation of a blood clot (thrombus) within a vein, most commonly in the deep veins of the lower extremities (deep vein thrombosis, DVT). Pathophysiology (Virchow triad): venous stasis (immobility, surgery, long-haul travel, obesity), hypercoagulability (pregnancy, malignancy, thrombophilia

— factor V Leiden, prothrombin gene mutation, antithrombin deficiency, protein C/S deficiency, antiphospholipid syndrome), and endothelial injury (trauma, surgery, central venous catheters). DVT presents with unilateral leg pain, swelling, warmth, erythema, and Homan sign (calf pain on dorsiflexion, unreliable). Complications: pulmonary embolism (PE, the most dangerous complication, causing dyspnea, chest pain, haemoptysis, and sudden death) and post-thrombotic syndrome (chronic venous insufficiency from venous valve damage). Diagnosis: D-dimer (elevated, sensitive but not specific) and compression ultrasound (non-compressible vein is diagnostic). Ventilation-perfusion (V/Q) scan or CT pulmonary angiography for PE. Treatment: anticoagulation (heparin/LMWH bridging to warfarin or DOAC — rivaroxaban, apixaban, edoxaban, dabigatran) for minimum 3-6 months; compression stockings to prevent post-thrombotic syndrome. Duration: unprovoked DVT may require indefinite anticoagulation. Prevention (prophylaxis): early mobilisation, compression devices, and prophylactic anticoagulation in hospitalised at-risk patients.

Ventricular Fibrillation

– Rapid, chaotic ventricular electrical activity resulting in no effective cardiac output, leading to cardiac arrest. ECG shows irregular, disorganized waveforms with no identifiable QRS complexes. VFib is a medical emergency requiring immediate defibrillation. Causes include acute myocardial infarction, electrolyte imbalances, drug toxicity, and electrical injury. Survival decreases approximately 10% for each minute without defibrillation.

Ventricular Tachycardia

– A wide-complex tachycardia (QRS >0.12 s) originating from the ventricles, with a rate of 100-250 bpm. Monomorphic VT has uniform QRS complexes; polymorphic VT has varying QRS morphology. VT is life-threatening and may degenerate to ventricular fibrillation. Causes include coronary artery disease, cardiomyopathy, electrolyte abnormalities, and drugs. Treatment includes cardioversion for unstable VT, amiodarone for stable VT, and implantable cardioverter-defibrillator for prevention.

4.2 Heart Failure & Cardiomyopathies

Alcoholic Cardiomyopathy

– Dilated cardiomyopathy caused by chronic excessive alcohol consumption, one of the most common reversible causes of dilated cardiomyopathy. Direct toxic effect of ethanol and its metabolite acetaldehyde on cardiomyocytes. Presentation is identical to other dilated cardiomyopathies. Abstinence is the cornerstone of treatment and can lead to significant recovery of LV function. Other treatments follow standard heart failure guidelines.

Anticoagulant Monitoring

– Unfractionated heparin is monitored with aPTT (target 1.5-2.5 x control). Low molecular weight heparins generally do not require monitoring. Warfarin is monitored with INR (target 2-3 for most indications, 2.5-3.5 for mechanical mitral valve). DOACs (rivaroxaban, apixaban, dabigatran) have predictable pharmacokinetics and do not require routine monitoring, though anti-Xa levels can be measured for rivaroxaban/apixaban and dilute thrombin time for dabigatran.

Aortic Dissection

– A tear in the intima of the aorta allowing blood to dissect through the media, creating a false lumen. It is classified as Stanford Type A (ascending aorta involvement, requiring emergency surgery) or Type B (descending aorta only, managed medically unless complicated). Risk factors include hypertension, Marfan syndrome, Ehlers-Danlos syndrome, bicuspid aortic valve, and aortic instrumentation. Symptoms include sudden, severe, tearing chest pain radiating to the back.

Aortic Regurgitation

– Incomplete closure of the aortic valve allowing blood to flow backward from the aorta to the left ventricle during diastole. Causes include bicuspid aortic valve, endocarditis, aortic root dilation, hypertension, and connective tissue disorders. Murmur: early diastolic decrescendo murmur at the left sternal border. Signs include wide pulse pressure, bounding pulses, and de Musset sign. Severe AR requires aortic valve replacement.

Aortic Regurgitation Murmur

– Early diastolic decrescendo murmur heard best at

the left sternal border with the patient sitting up and leaning forward in end-expiration. Wide pulse pressure, water-hammer pulses (Corrigan pulse), de Musset sign (head bobbing with each pulse), and Duroziez sign (femoral bruit with compression). Severity correlates with murmur duration and pulse pressure width. Severe AR requires aortic valve replacement before irreversible LV dysfunction develops.

Aortic Stenosis Grading

- Severity grading: mild (valve area >1.5 cm², mean gradient <20 mmHg), moderate (valve area 1.0-1.5 cm², mean gradient 20-40 mmHg), severe (valve area <1.0 cm², mean gradient >40 mmHg). Very severe (valve area <0.6 cm², mean gradient >60 mmHg) indicates critical stenosis. Grading guides timing of intervention. Echocardiography is the primary modality for assessment, with hemodynamic data from cardiac catheterization when echocardiographic data is inconclusive.

ARB-Neprilysin Inhibitor (ARNI)

- Sacubitril/valsartan combines an ARB with a neprilysin inhibitor, increasing natriuretic peptide levels while blocking the renin-angiotensin system. The PARADIGM-HF trial demonstrated superior reduction in cardiovascular death and heart failure hospitalization compared to enalapril. ARNI is now a cornerstone of HFrEF therapy, recommended as replacement for ACE inhibitors in patients who remain symptomatic on optimal medical therapy.

Artificial Pacemaker

- See Cardiac Pacemaker.

Aspirin

- An antiplatelet agent that irreversibly inhibits cyclooxygenase-1 (COX-1), reducing thromboxane A₂ production and platelet aggregation. Low-dose aspirin (81 mg daily) is used for secondary prevention of cardiovascular events. In acute MI, a loading dose of 162-325 mg is chewed for rapid absorption. Aspirin is also used for pain, inflammation, and fever. Side effects include GI bleeding, tinnitus, and aspirin-exacerbated respiratory disease.

Atrial Fibrillation

- The most common sustained cardiac arrhythmia, characterized by rapid, irregular atrial activity (350-600 bpm) with irregular ventricular response. ECG shows absent P waves, irregularly irregular RR in-

tervals, and narrow QRS complexes (unless aberrant conduction). AFib increases stroke risk 5-fold due to atrial stasis and thrombus formation, particularly in the left atrial appendage. Treatment targets rate control, rhythm control, and anticoagulation.

Atrial Flutter

- A rapid, regular atrial rhythm (typically 250-350 bpm) caused by a macro-reentrant circuit, most commonly in the right atrium. ECG shows sawtooth flutter waves best seen in leads II, III, and aVF, with regular or irregular ventricular response depending on AV conduction ratio (commonly 2:1 or 4:1). Atrial flutter carries similar stroke risk to AFib and requires anticoagulation. Treatment includes cardioversion and catheter ablation.

Atrial Septal Defect

- Congenital opening in the interatrial septum allowing left-to-right shunting of blood. Small defects may close spontaneously. Larger defects cause right heart volume overload, right atrial and ventricular dilation, pulmonary hypertension, and eventually right heart failure. Paradoxical embolism may occur with right-to-left shunting. Systolic crescendo-decrescendo murmur at left upper sternal border with fixed split S₂. Echocardiography confirms diagnosis and assesses shunt magnitude. Transcatheter closure is indicated for moderate-to-large defects.

Austin Flint Murmur

- A mid-diastolic, low-pitched rumbling murmur heard at the apex, caused by the regurgitant jet from severe aortic regurgitation striking the anterior mitral leaflet. This functional murmur can mimic mitral stenosis but is distinguished by the absence of an opening snap, presence of wide pulse pressure, and early diastolic decrescendo murmur of aortic regurgitation. It resolves after aortic valve replacement.

Balloon Aortic Valvuloplasty

- Catheter-based procedure using balloon inflation to dilate a stenotic aortic valve. Provides temporary hemodynamic improvement in severe AS but restenosis is common within 6-12 months. Used as a bridge to TAVR or surgical AVR in hemodynamically unstable patients, or as palliation in patients not eligible for definitive valve replacement. Complications include aortic regurgitation, stroke, and vascular access complications.

Beck Triad

- Classic diagnostic clinical triad of Cardiac Tamponade: (1) Hypotension, (2) Distended neck veins (elevated JVP), and (3) Muffled / distant heart sounds. *See Cardiac Tamponade.*

Bicuspid Aortic Valve

- The most common congenital cardiac anomaly, present in 1-2% of the population. The aortic valve has two leaflets instead of three, predisposing to aortic stenosis (usually by age 50-60), aortic regurgitation, and infective endocarditis. Associated with aortopathy (aortic root dilation and dissection risk) and coarctation of the aorta. Regular echocardiographic surveillance is recommended. Aortic valve replacement and/or aortic root replacement may be required.

Bradycardia

- A heart rate <60 beats per minute. May be physiologic (athletes) or pathologic due to sinus node dysfunction, AV block, or medication effects. Symptomatic bradycardia causes fatigue, dizziness, syncope, or heart failure. Evaluation includes ECG, Holter monitoring, and assessment of reversible causes. Treatment: pacing (temporary or permanent) for symptomatic or high-grade AV block.

Brugada Syndrome

- A genetic channelopathy causing abnormal sodium channel function (SCN5A mutation). ECG pattern: coved ST elevation >2mm in V1-V3 (type 1) followed by negative T wave. Patients are at risk for ventricular fibrillation and sudden cardiac death, often at rest or during sleep. More common in young Southeast Asian men. Diagnosis: type 1 pattern on ECG (spontaneous or drug-induced with ajmaline/flecainide). Treatment: ICD is the only proven preventive therapy; avoid fever and sodium channel blockers.

Bundle Branch Block

- Delay or block in the electrical conduction through the bundle branches. Left Bundle Branch Block (LBBB): QRS >120 ms, broad notched R waves in lateral leads (I, V5-V6), deep S waves in V1-V2. Right Bundle Branch Block (RBBB): QRS >120 ms, rSR' pattern in V1-V2, wide S waves in I, V5-V6. RBBB can occur in healthy individuals or with RV strain. LBBB often indicates structural heart disease, cardiomyopathy, or anterior MI. Management:

evaluate underlying cause; consider cardiac resynchronization therapy for LBBB with heart failure.

Bundle of His

- A narrow band of specialized cardiac tissue that conducts electrical impulses from the AV node through the fibrous cardiac skeleton to the inter-ventricular septum. It divides into the right and left bundle branches. The bundle of His is the only electrical connection between atria and ventricles through the fibrous skeleton. Damage here causes complete (third-degree) heart block.

Caput Medusae

- Dilated periumbilical veins radiating outward from the umbilicus, seen in portal hypertension with recanalization of the umbilical vein. Not strictly a cardiac finding but relevant in right heart failure causing hepatic congestion and portal hypertension. It must be distinguished from caval collateral circulation. The sign is named after the Gorgon Medusa of Greek mythology.

Cardiac Amyloidosis

- Deposition of amyloid fibrils in the myocardium, causing restrictive cardiomyopathy with thickened, stiff ventricular walls. The most common cardiac amyloidosis is due to transthyretin (ATTR) amyloidosis, which can be wild-type (age-related) or hereditary. Diagnosis may require endomyocardial biopsy, though noninvasive diagnosis with bone scintigraphy is increasingly used. Treatment includes TTR stabilizers (tafamidis) and diuretics for symptom management.

Cardiac Amyloidosis Diagnosis

- Diagnosis involves a combination of clinical suspicion, imaging, and tissue biopsy. Non-invasive diagnosis using Tc-99m pyrophosphate (PYP) or DPD scintigraphy for ATTR cardiac amyloidosis (with negative serum/urine free light chains to exclude AL amyloidosis). Cardiac MRI shows characteristic late gadolinium enhancement pattern (subendocardial, circumferential). Endomyocardial biopsy remains the gold standard for confirming amyloid deposition.

Cardiac Amyloidosis Staging

- Mayo Clinic staging system for ATTR cardiac amyloidosis: Stage I (NT-proBNP <3000 pg/mL), Stage II (NT-proBNP 3000-8499), Stage III (NT-proBNP ≥8500). Median survival: Stage I: 69 months, Stage II: 47 months, Stage III: 14 months.

Treatment with tafamidis (TTR stabilizer) improves survival and functional capacity. ATTR-CM is increasingly recognized and may be underdiagnosed in elderly patients with unexplained LV hypertrophy.

Cardiac Arrest

- Sudden cessation of effective cardiac function, resulting in loss of pulse and consciousness. Most common rhythm in adults is ventricular fibrillation or pulseless ventricular tachycardia. Treatment follows ACLS protocol: high-quality CPR, defibrillation for shockable rhythms, and ACLS medications (epinephrine, amiodarone). Targeted temperature management improves neurological outcomes. Survival rates vary by rhythm and location: VF/VT has better prognosis than asystole/PEA.

Cardiac Conduction System

- The specialized tissue responsible for generating and conducting electrical impulses through the heart. Components include the sinoatrial (SA) node, internodal pathways, atrioventricular (AV) node, bundle of His, right and left bundle branches, and Purkinje fibers. The system ensures coordinated contraction: atria contract first, followed by ventricles, with appropriate delay at the AV node.

Cardiac Cycle

- The sequence of events occurring during one complete heartbeat, consisting of systole (contraction) and diastole (relaxation). During diastole, the ventricles fill with blood; during systole, they contract and eject blood. The cardiac cycle includes isovolumetric relaxation, ventricular filling, isovolumetric contraction, and ventricular ejection phases. The cycle takes approximately 0.8 seconds at a heart rate of 75 bpm.

Cardiac Index

- Cardiac output normalized to body surface area (BSA), calculated as CO / BSA . Normal cardiac index is 2.5-4.2 L/min/m². It provides a more accurate assessment of cardiac function than cardiac output alone, accounting for body size. A cardiac index below 2.2 L/min/m² indicates cardiogenic shock. Cardiac index is used to guide therapy in critically ill patients.

Cardiac Output Measurement

- Methods include: thermodilution via pulmonary artery catheter (bolus of cold saline and temperature change measurement), Fick principle (O₂ con-

sumption / arteriovenous O₂ difference), echocardiographic Doppler (flow velocity time integral x valve area x heart rate), and non-invasive cardiac output monitors (bioimpedance, bioreactance). CO measurement guides management of heart failure, shock, and perioperative hemodynamic optimization.

Cardiac Pacemaker Types

- Single-chamber: pacing one chamber (atrium or ventricle). Dual-chamber (DDD): paces and senses both atrium and ventricle, maintaining AV synchrony. Biventricular (CRT): paces both ventricles for resynchronization in heart failure. Rate-responsive (RR): automatically adjusts heart rate based on activity level using accelerometers or minute ventilation sensing. MRI-conditional pacemakers are now standard, allowing safe MRI scanning under specific conditions.

Cardiac Rehab Outcomes

- Cardiac rehabilitation reduces all-cause mortality by 13% and cardiovascular mortality by 26% post-MI. It improves exercise capacity, lipid profiles, blood pressure control, and glycemic control. Psychosocial benefits include reduced depression and anxiety. Despite Class I recommendation, only 20-30% of eligible patients participate. Barriers include access, cost, referral processes, and patient motivation. Home-based programs may improve participation rates.

Cardiac Resynchronization Therapy

- Biventricular pacing that synchronizes contraction of the left and right ventricles in patients with heart failure, reduced EF, and prolonged QRS duration (especially LBBB). CRT improves symptoms, exercise capacity, and quality of life, and reduces heart failure hospitalizations and mortality. Response may be incomplete in 30% of patients. Selection criteria include EF 35% or less, NYHA II-IV despite optimal medical therapy, and QRS 150 ms or greater.

Cardiac Skeleton

- A dense connective tissue framework composed of four fibrous rings that surround the heart valves and provide structural support. The cardiac skeleton includes the annuli fibrosi (valve rings), the membranous septum, and the left and right fibrous trigones. It serves as electrical insulation between atria and

ventricles, forcing impulses through the AV node, and provides attachment points for valve leaflets and cardiac muscle.

Cardiac Tamponade Physiology

- Accumulation of pericardial fluid causing compression of cardiac chambers, impairing diastolic filling and reducing cardiac output. Hemodynamic consequences include equalization of diastolic pressures (RA = RV diastolic = PCWP), pulsus paradoxus, and decreased cardiac output. Beck's triad (hypotension, muffled heart sounds, JVD) is classic but not always present. Emergent pericardiocentesis is life-saving. Echocardiography shows RA/RV diastolic collapse.

Cardiac Tumors

- Primary cardiac tumors are rare; most common benign is myxoma (75%), typically in the left atrium presenting with embolism, obstruction, or constitutional symptoms. Malignant primary cardiac tumors are rare (angiosarcoma most common). Metastatic tumors to the heart are more common than primary tumors, with lung, breast, melanoma, and lymphoma being common sources. Diagnosis is by echocardiography, cardiac MRI, or CT. Treatment depends on tumor type.

Cardiac Tumors Management

- Myxoma: surgical excision is curative, with low recurrence rate. Benign tumors (rhabdomyoma, fibroma) may be observed if asymptomatic but require surgery if causing obstruction or arrhythmia. Malignant tumors: prognosis is poor; treatment may include surgery, chemotherapy, and radiation depending on tumor type. Metastatic disease: treatment of the primary malignancy; cardiac involvement indicates advanced disease. Pericardial effusion may require drainage.

Cardiogenic Shock Management

- Low cardiac output state with end-organ hypoperfusion, typically from acute MI. Inotropes: dobutamine (increases cardiac output, decreases SVR), milrinone (PDE3 inhibitor, vasodilator). Vasopressors: norepinephrine (first-line for hypotension), dopamine. Mechanical support: IABP (modest support, SHOCK II trial no mortality benefit), Impella (percutaneous LVAD, higher support), VA-ECMO (biventricular support). Emergent revascularization is the definitive treatment.

Cardio-Oncology

- The subspecialty focusing on cardiovascular care of cancer patients, addressing cancer therapy-related cardiac dysfunction, prevention, and management. Key concerns include anthracycline cardiotoxicity, trastuzumab-related cardiomyopathy, immune checkpoint inhibitor myocarditis, and radiation-induced heart disease. Monitoring includes baseline and serial echocardiography during and after cancer treatment. Early detection and intervention can prevent irreversible cardiac damage and allow continuation of cancer therapy.

Cardiopulmonary Exercise Testing

- Comprehensive assessment of cardiovascular and pulmonary function during graded exercise on a treadmill or cycle ergometer. Measures: VO₂ max, anaerobic threshold, ventilatory efficiency (VE/VCO₂ slope), and hemodynamic responses. Used to evaluate dyspnea on exertion, determine heart failure prognosis (VO₂ max <14 mL/kg/min indicates need for transplant evaluation), assess exercise capacity for disability evaluation, and guide cardiac rehabilitation programs.

Cardiotoxicity from Chemotherapy

- Chemotherapy agents that damage the myocardium, most commonly anthracyclines (doxorubicin, daunorubicin). Cardiotoxicity presents as dilated cardiomyopathy with reduced ejection fraction. Risk is dose-dependent (doxorubicin cumulative dose >550 mg/m²). Other cardiotoxic agents include trastuzumab (reversible cardiomyopathy), cyclophosphamide, and 5-fluorouracil. Monitoring with serial echocardiography during treatment is essential. Treatment includes ACE inhibitors and beta-blockers.

Cardiovascular Health

- Cardio is shorthand for cardiovascular health or exercise that elevates heart rate and respiratory effort to strengthen the heart, lungs, and circulatory system. Aerobic activities such as walking, running, cycling, and swimming improve cardiac output, lower blood pressure, and enhance metabolic efficiency. Regular cardiovascular exercise reduces the risk of heart disease, stroke, and diabetes while improving overall longevity.

Central Venous Pressure

- Pressure in the superior vena cava or right atrium,

measured via central venous catheter. Normal: 2-8 mmHg. Elevated CVP indicates right heart failure, fluid overload, cardiac tamponade, or constrictive pericarditis. Low CVP indicates hypovolemia. CVP monitoring guides fluid resuscitation and diuretic therapy in heart failure management. Less invasive alternatives include bedside ultrasound assessment of IVC diameter and collapsibility.

Chagas Disease

– A parasitic infection caused by *Trypanosoma cruzi*, transmitted by reduviid bugs (kissing bugs), endemic in Latin America. Acute phase: fever, swelling at bite site (chagoma), Romana sign (peri-orbital edema). Chronic phase (years later): Chagas cardiomyopathy (most common and serious), megaesophagus, and megacolon. Cardiomyopathy: progressive heart failure, apical aneurysm, thrombus formation, heart block, and sudden cardiac death. Diagnosis: serology (ELISA, IFA), PCR in acute phase. Treatment: benznidazole or nifurtimox for acute and early chronic phase. Late chronic cardiomyopathy: symptomatic heart failure management, anticoagulation, and pacemaker/ICD as indicated.

Class IA Antiarrhythmics

– Sodium channel blockers that slow phase 0 depolarization and prolong the action potential duration and refractory period. Examples include quinidine, procainamide, and disopyramide. Used for atrial and ventricular arrhythmias. Quinidine can cause QT prolongation and torsades de pointes. Procainamide may cause lupus-like syndrome with long-term use. These drugs are generally reserved for cases not controlled by first-line agents due to proarrhythmic potential.

Class IC Antiarrhythmics

– Sodium channel blockers that significantly slow phase 0 depolarization without affecting action potential duration. Examples include flecainide and propafenone. Used for supraventricular arrhythmias in patients without structural heart disease. The CAST trial showed increased mortality in post-MI patients, so they are contraindicated in that setting. Flecainide is effective for atrial fibrillation and atrial flutter in structurally normal hearts.

Class III Antiarrhythmics

– Potassium channel blockers that prolong the action

potential duration and refractory period. Examples include amiodarone, sotalol, dofetilide, and ibutilide. Amiodarone is the most commonly used but has significant toxicity. Sotalol has additional beta-blocking properties and can cause torsades de pointes. Dofetilide requires inpatient initiation with QT monitoring. These drugs are used for atrial fibrillation and ventricular arrhythmias.

Continuous Murmurs

– Murmurs that persist throughout systole and diastole without interruption, produced by blood flowing continuously through an abnormal connection. The most common cause is patent ductus arteriosus (PDA), where blood flows from the aorta to pulmonary artery throughout the cardiac cycle. Other causes include arteriovenous fistulas and rupture of sinus of Valsalva. The murmur is characteristically machine-like in quality.

Corticosteroids

– Synthetic glucocorticoids with potent anti-inflammatory and immunosuppressive effects. Examples include prednisone, prednisolone, methylprednisolone, dexamethasone, and hydrocortisone. They suppress inflammatory gene expression and inhibit immune cell function. Used in autoimmune diseases, organ transplant rejection, severe allergies, and adrenal insufficiency. Side effects include osteoporosis, hyperglycemia, weight gain, avascular necrosis, cataracts, adrenal suppression, and increased infection risk.

Cor Triatriatum

– A rare congenital heart defect where the left atrium is divided into two chambers by a fibromuscular membrane, separating the pulmonary venous chamber (posterior) from the true left atrium (anterior) containing the left atrial appendage and mitral valve. The membrane obstructs pulmonary venous return, mimicking mitral stenosis. Presents in infancy with dyspnea, failure to thrive, recurrent respiratory infections, and pulmonary edema (if severe obstruction). Milder cases may present in adulthood with exertional dyspnea and pulmonary hypertension. Diagnosis: echocardiography shows the characteristic membrane in the left atrium with color Doppler demonstrating flow obstruction. Treatment: surgical excision of the membrane. Prognosis is excellent after repair.

CYP450 System

– A superfamily of heme-containing enzymes primarily in the liver that metabolize drugs and xenobiotics. Major isoforms include CYP3A4 (metabolizes 50% of drugs), CYP2D6, CYP2C9, CYP2C19, CYP1A2, and CYP2E1. CYP inducers (rifampin, carbamazepine, phenytoin) decrease drug levels; CYP inhibitors (ketoconazole, erythromycin, grapefruit juice) increase drug levels. Genetic polymorphisms in CYP enzymes affect drug metabolism, forming the basis of pharmacogenomics.

Deep Vein Thrombosis

– Formation of a blood clot in a deep vein, most commonly in the lower extremities. Risk factors include immobility, surgery, cancer, pregnancy, and thrombophilia. Presents with unilateral leg swelling, pain, and erythema. Diagnosis by venous ultrasound and D-dimer testing. Treatment: anticoagulation (heparin, DOACs, warfarin). Complications: pulmonary embolism and post-thrombotic syndrome.

Dextrocardia

– A congenital cardiac positional anomaly where the heart is located in the right hemithorax with the apex pointing to the right. Most cases are due to situs inversus totalis (complete mirror-image reversal of all thoracic and abdominal organs, affecting 1 in 10,000 births), which carries a normal life expectancy if cardiac anatomy is otherwise normal. Dextrocardia with situs solitus (heart on right but abdominal organs normally positioned) is strongly associated with congenital heart disease, particularly corrected transposition of the great arteries.

Diastolic Murmurs

– Murmurs occurring between S2 and the next S1. Early diastolic decrescendo murmurs indicate semilunar valve regurgitation (aortic regurgitation, pulmonary regurgitation). Mid-diastolic low-pitched rumbles indicate AV valve stenosis (mitral stenosis, tricuspid stenosis). Late diastolic murmurs may indicate mitral stenosis with sinus rhythm. Diastolic murmurs are almost always pathological and require echocardiographic evaluation.

Digitalis toxicity

– A potentially life-threatening adverse effect of cardiac glycoside therapy (digoxin, digitoxin) characterized by a narrow therapeutic index (0.5-2.0 ng/mL for digoxin). Toxicity occurs through Na⁺/K⁺-

ATPase inhibition, increasing intracellular sodium, which slows calcium efflux via the Na⁺/Ca²⁺ exchanger, causing increased intracellular calcium and enhanced cardiac contractility, while also increasing vagal tone and slowing AV conduction. Risk factors include advanced age, renal impairment (digoxin is renally cleared),.

Dilated Cardiomyopathy

– A cardiomyopathy characterized by ventricular dilation and impaired systolic function, resulting in reduced ejection fraction. It is the most common cause of heart failure and the leading indication for heart transplantation. Causes include idiopathic (30-50%), familial/genetic (20-35%), alcohol, viral myocarditis, peripartum, chemotherapy (doxorubicin), and tachycardia-mediated. Treatment follows standard heart failure guidelines with ACE inhibitors, beta-blockers, diuretics, and device therapy (ICD, CRT).

Dilated Cardiomyopathy Prognosis

– 5-year survival approximately 50%. Risk factors for poor prognosis: low EF, advanced NYHA class, elevated BNP, ventricular arrhythmias, family history of sudden death, and failure to respond to medical therapy. Sudden cardiac death accounts for 30-50% of mortality. ICD placement for primary prevention in patients with EF <35% despite optimal medical therapy. Heart transplant is definitive therapy for end-stage disease.

Direct Oral Anticoagulants

– DOACs directly inhibit specific coagulation factors. Direct thrombin inhibitors: dabigatran. Factor Xa inhibitors: rivaroxaban, apixaban, edoxaban, betrixaban. They have predictable pharmacokinetics, fixed dosing, and routine monitoring is not required. They have fewer drug interactions than warfarin. Dabigatran and rivaroxaban are reversed by specific agents (idarucizumab, andexanet alfa). DOACs are preferred over warfarin for non-valvular atrial fibrillation and VTE.

Double Outlet Right Ventricle

– A congenital heart defect where more than 50% of both great arteries arise from the right ventricle, with a VSD as the only outlet from the left ventricle. Classified by the position of the VSD relative to the great arteries: subaortic VSD (TOF-type physiology), subpulmonic VSD (Taussig-Bing

malformation, TGA-type physiology), doubly committed VSD, and non-committed VSD (remote from both arteries). Presents with variable physiology: cyanosis or heart failure depending on the degree of pulmonary blood flow. The Taussig-Bing malformation presents with cyanosis and early heart failure. Diagnosis: echocardiography showing both great arteries arising from the RV. Treatment: surgical repair tailored to VSD position — arterial switch operation for Taussig-Bing, intracardiac tunnel repair for subaortic VSD.

Drug Clearance

- The volume of plasma completely cleared of drug per unit time. Hepatic clearance depends on hepatic blood flow and enzyme activity; renal clearance depends on glomerular filtration, tubular secretion, and reabsorption. Total clearance determines maintenance dose. Clearance decreases in hepatic or renal impairment, requiring dose adjustment. Drug clearance is independent of concentration for first-order kinetics but constant for zero-order (saturable) kinetics.

Drug Hypersensitivity Reactions

- Immune-mediated adverse drug reactions classified by Gell and Coombs. Type I (immediate, IgE-mediated: anaphylaxis, urticaria); Type II (cytotoxic, IgG/IgM-mediated: hemolytic anemia, thrombocytopenia); Type III (immune complex-mediated: serum sickness, vasculitis); Type IV (delayed, T-cell mediated: contact dermatitis, Stevens-Johnson syndrome). Management includes drug discontinuation, supportive care, and in severe cases, immunosuppression. Cross-reactivity between related drugs must be considered.

Drug Overdose Management

- Treatment of drug overdose involves supportive care (airway, breathing, circulation), decontamination (gastric lavage, activated charcoal within 1 hour), enhanced elimination (urinary alkalization, hemodialysis), and specific antidotes when available. Key antidotes include naloxone (opioids), flumazenil (benzodiazepines), N-acetylcysteine (acetaminophen), digoxin immune Fab (digoxin), and physostigmine (anticholinergic toxicity). Treatment should be tailored to the specific drug involved.

Ductus Arteriosus

- A fetal blood vessel connecting the pulmonary

artery to the descending aorta, allowing blood to bypass the non-functioning fetal lungs. In utero, the ductus arteriosus is kept patent by prostaglandin E₂ and low oxygen tension. After birth, the ductus normally closes within 24–48 hours (functional closure) and becomes the ligamentum arteriosum by 2–3 weeks (anatomic closure). Failure of closure results in patent ductus arteriosus (PDA), a left-to-right shunt causing continuous machinery murmur, bounding pulses, and volume overload of the left heart. Prostaglandin E₁ (alprostadil) is used to maintain ductal patency in ductal-dependent congenital heart disease (e.g., pulmonary atresia, coarctation of the aorta).

DVT

- See Deep Vein Thrombosis.

Ebstein Anomaly

- A rare congenital heart defect accounting for less than 1 percent of all congenital heart disease, characterized by apical displacement of the septal and posterior leaflets of the tricuspid valve into the right ventricle, resulting in atrialization of the proximal right ventricle and a small functional right ventricular chamber. The anterior leaflet is usually large and sail-like. The tricuspid valve is often regurgitant, causing right atrial enlargement and right-to-left shunting across an associated atrial septal defect or patent foramen ovale.

Echocardiography

- Ultrasound imaging of the heart, the primary modality for assessing cardiac structure and function. Transthoracic echocardiography (TTE) is the most common approach; transesophageal echocardiography (TEE) provides better views of posterior structures (left atrium, mitral valve, aorta). Doppler echocardiography assesses blood flow velocities, valve function, and pressure gradients. Echocardiography is used to evaluate ejection fraction, valve disease, pericardial effusion, and structural abnormalities.

Edema (historically Dropsy)

- An historic term for edema, referring to the abnormal accumulation of serous fluid in the tissues or body cavities. Types: peripheral edema (dependent: feet, ankles, legs, sacrum), pulmonary edema (fluid in lung interstitium and alveoli—causes include left heart failure, ARDS, high altitude), ascites (fluid

in peritoneal cavity–cirrhosis, heart failure, malignancy), anasarca (generalized severe edema). Pathophysiology: increased hydrostatic pressure (heart failure, venous obstruction), decreased plasma oncotic pressure (nephrotic syndrome, cirrhosis, malnutrition), increased capillary permeability (inflammation, burns, sepsis), and lymphatic obstruction (lymphedema). Treatment: address underlying cause, sodium restriction, diuretics, and mechanical compression.

Eisenmenger Syndrome

- Reversal of a left-to-right cardiac shunt due to irreversible pulmonary hypertension, resulting in right-to-left shunting and cyanosis. It occurs in untreated congenital heart defects with large left-to-right shunts (VSD, ASD, PDA) that cause progressive pulmonary vascular disease. Features include cyanosis, clubbing, polycythemia, and paradoxical embolism. Management is supportive; pregnancy is contraindicated. Lung transplantation may be considered in severe cases.

Ejection Click

- A high-pitched sound occurring at the beginning of systole, caused by opening of a stenotic semilunar valve. Aortic ejection click is heard in bicuspid aortic valve and aortic stenosis with pliable leaflets. Pulmonary ejection click is heard in pulmonary stenosis and disappears as the valve becomes more calcified and immobile. An ejection click helps distinguish valvular stenosis from subvalvular or supravascular obstruction.

Ejection Fraction

- The percentage of blood ejected from the left ventricle during systole, calculated as $(\text{stroke volume} / \text{end-diastolic volume}) \times 100$. Normal EF is 55–70%. Heart failure with reduced ejection fraction (HFrEF): EF 40% or less; heart failure with preserved ejection fraction (HFpEF): EF 50% or greater. EF is measured by echocardiography, cardiac MRI, or ventriculography.

Endocardium

- The innermost layer of the heart wall, a thin membrane of endothelial cells and underlying connective tissue that lines the cardiac chambers and covers the heart valves. The endocardium is continuous with the endothelium of blood vessels and provides a smooth, non-thrombogenic surface. Endocardial

damage can predispose to infective endocarditis, and endocardial fibrosis may occur in certain conditions.

Epicardium

- The outermost layer of the heart wall, which is the visceral layer of the serous pericardium. It consists of a single layer of mesothelial cells and underlying connective tissue containing blood vessels, nerves, and adipose tissue. The epicardium produces pericardial fluid that lubricates the heart surface. It can be involved in inflammatory processes such as pericarditis and may contain epicardial fat pads.

Ewart Sign

- Dullness to percussion, decreased breath sounds, and bronchial breathing at the left infrascapular region caused by compressive atelectasis from a large pericardial effusion. It is a physical examination finding of pericardial effusion. The effusion compresses the adjacent left lower lobe, creating a zone of consolidation. Ewart sign is best detected with the patient in the left lateral decubitus position.

Exercise-Induced Arrhythmias

- Catecholamine-sensitive ventricular tachycardia and right ventricular outflow tract VT can be triggered by exercise. HCM-related sudden death risk increases during vigorous exercise. Exercise-induced myocardial ischemia may trigger ventricular arrhythmias in CAD. Arrhythmogenic right ventricular cardiomyopathy frequently presents with exercise-related VT. Athletes with structural heart disease or inherited arrhythmia syndromes may require activity restriction and ICD placement.

Extracorporeal Membrane Oxygenation

- A temporary mechanical circulatory support system that provides cardiac and/or respiratory support. VA-ECMO (veno-arterial) provides both cardiac and respiratory support; VV-ECMO (veno-venous) provides respiratory support only. Used as bridge to recovery or decision in severe cardiogenic shock, refractory cardiac arrest, or acute respiratory failure. Complications include bleeding, thromboembolism, limb ischemia, and neurological injury.

Fainting

- See Syncope (Fainting).

Frank-Starling Mechanism

- The physiological principle stating that stroke vol-

ume increases as end-diastolic volume (preload) increases, up to an optimal point. Within physiological limits, greater ventricular stretch leads to stronger contraction due to increased calcium sensitivity of myofilaments and optimal overlap of actin and myosin. This mechanism allows the heart to automatically match output to venous return. In heart failure, the curve shifts downward and rightward.

Gallavardin Phenomenon

– The dissociation of the murmur of aortic stenosis into two components: a musical quality heard at the apex and a harsh, rough quality heard at the right upper sternal border. This occurs because high-frequency components are transmitted to the apex while low-frequency components are heard at the base. It helps distinguish aortic stenosis from mitral regurgitation, which also presents with an apical murmur.

Half-Life ($t_{1/2}$)

– The time required for plasma drug concentration to decrease by 50%. It determines dosing frequency and time to steady state (4-5 half-lives). Drugs with long half-lives (e.g., amiodarone: 40-55 days, warfarin: 40 hours) can be given once daily but take longer to reach steady state and to be eliminated. Short half-lives (e.g., nitroglycerin: 3 minutes) require continuous infusion or frequent dosing. Half-life is affected by hepatic and renal function.

Heart Failure

– A clinical syndrome resulting from the heart's inability to pump sufficient blood to meet metabolic demands. It is classified by ejection fraction (HFrEF: EF 40% or less; HFpEF: EF 50% or greater) and by symptoms (NYHA class I-IV). Heart failure may be right-sided (causing peripheral edema, JVD, hepatomegaly) or left-sided (causing pulmonary congestion, dyspnea, orthopnea). Diagnosis is supported by elevated BNP or NT-proBNP levels.

Heart Failure Stages

– ACC/AHA staging: Stage A (at risk for HF but no structural disease or symptoms); Stage B (structural heart disease but no symptoms); Stage C (structural disease with prior or current symptoms); Stage D (advanced HF requiring specialized interventions). This staging system emphasizes prevention and progression. Treatment intensifies with each stage: risk factor modification (A), ACE inhibitors/beta-

blockers (B), diuretics added (C), and advanced therapies like transplant or LVAD (D).

Heart Failure with Preserved Ejection Fraction (HFpEF)

– A clinical syndrome of heart failure characterized by left ventricular diastolic dysfunction (impaired relaxation and increased stiffness) with a preserved ejection fraction ($\geq 50\%$). Most common in elderly, female, hypertensive, obese, and diabetic patients. Pathophysiology: concentric hypertrophy, myocardial fibrosis, elevated filling pressures. Clinical features: exertional dyspnea, orthopnea, paroxysmal nocturnal dyspnea, peripheral edema, S4 gallop. Diagnosis: echocardiogram (LVEF $\geq 50\%$, diastolic dysfunction parameters e.g., elevated E/e' ratio ≥ 14), elevated BNP/NT-proBNP. Treatment: SGLT2 inhibitors (dapagliflozin, empagliflozin — reduced HF hospitalization and cardiovascular mortality), loop diuretics for congestion, blood pressure control, and management of comorbidities.

Heart Health

– The state of cardiovascular well-being, characterized by efficient pumping function, clear arteries, normal blood pressure, and regular heart rhythm. Maintaining heart health involves a heart-healthy diet, regular aerobic and resistance exercise, weight management, stress reduction, and avoidance of tobacco. Preventive cardiology emphasizes early detection and management of risk factors to reduce the burden of cardiovascular disease.

Heart-Healthy Eating

– A dietary approach emphasizing foods that support cardiovascular function and reduce the risk of heart disease. Key principles include limiting saturated fats, trans fats, sodium, and added sugars while prioritizing fruits, vegetables, whole grains, lean proteins, and healthy fats like those from olive oil and fatty fish. This pattern aligns closely with the Mediterranean and DASH dietary guidelines.

Heart Murmur

– An audible extra sound produced by turbulent blood flow within the heart or great vessels, heard on auscultation. Murmurs are described by: timing (systolic, diastolic, continuous), intensity (Levine grading 1-6), location (apex, left sternal border, right upper sternal border), radiation (axilla, carotids, back), pitch (high or low frequency),

quality (blowing, rumbling, harsh, musical), and response to maneuvers (inspiration, Valsalva, squatting, standing). Systolic murmurs: (1) Aortic stenosis (ejection systolic, crescendo-decrescendo, right upper sternal border, radiating to carotids); (2) Mitral regurgitation (holosystolic/pansystolic, blowing, apex, radiating to axilla); (3) Mitral valve prolapse (mid-systolic click + late systolic murmur); (4) Hypertrophic obstructive cardiomyopathy (ejection systolic, left sternal border, increases with Valsalva); (5) Ventricular septal defect (holosystolic, pansystolic, left lower sternal border). Diastolic murmurs: (1) Aortic regurgitation (early diastolic, decrescendo, high-pitched blowing, left sternal border); (2) Mitral stenosis (mid-diastolic, low-pitched rumbling, apex, accentuated by left lateral decubitus, presystolic accentuation). Continuous murmurs: patent ductus arteriosus (machinery murmur, left infraclavicular area). Innocent murmurs: Still murmur (vibratory, left lower sternal border, common in children), pulmonary flow murmur, venous hum. Workup: echocardiogram (transthoracic echo, bubble study, transoesophageal echo if needed) to identify valvular abnormality, assess severity, and determine need for intervention.

Heart Rate

– The number of cardiac contractions (heartbeats) per minute. Normal resting heart rate (sinus rhythm): 60-100 bpm in adults; higher in children (70-120 at age 1-2 years, 80-130 in neonates). Heart rate is determined by the intrinsic firing rate of the sinoatrial (SA) node (60-100 bpm), modulated by the autonomic nervous system: sympathetic activation (noradrenaline increases heart rate through beta-1 adrenergic receptors, positive chronotropy) and parasympathetic activation (vagus nerve, acetylcholine acts on M2 receptors, negative chronotropy). Tachycardia: heart rate >100 bpm at rest. Causes: sinus tachycardia (physiological response to exercise, stress, fever, pain, hypovolaemia, anaemia, hyperthyroidism, PE, MI, heart failure), re-entrant tachycardias (AVNRT, AVRT, atrial flutter, atrial fibrillation), ventricular tachycardia. Bradycardia: heart rate <60 bpm. Causes: sinus bradycardia (physiological in athletes, sleep), sick sinus syndrome, heart block (first, second, third degree), drug effect (beta-blockers, calcium channel blockers, digoxin),

hypothyroidism, increased intracranial pressure, hypothermia. Assessment: pulse palpation (radial, carotid, apical), ECG (lead II rhythm strip for most accurate rate calculation: $300 / \text{number of large squares between R waves}$; or number of R waves x 6 for a 10-second strip).

Heart Sounds

– Audible sounds produced by the heart during the cardiac cycle, normally heard as two sounds (lub-dub). S1 (lub) is caused by closure of the mitral and tricuspid valves at the beginning of systole. S2 (dub) is caused by closure of the aortic and pulmonary valves at the end of systole. Additional sounds (S3, S4) may indicate pathology. Heart sounds are auscultated at specific chest wall locations.

Heart Valve Disorders

– Disorders affecting any of the four heart valves, including stenosis (narrowing) and regurgitation (leaking), which impair blood flow through the heart. Causes include congenital malformations, age-related degeneration, rheumatic fever, and endocarditis. Treatment ranges from medication monitoring to valve repair or replacement via surgery or transcatheter interventions.

Heart Ventricles

– See Ventricle.

Hemochromatosis Cardiomyopathy

– Iron overload cardiomyopathy from hereditary (HFE gene mutations, most common) or secondary causes. Iron deposition in the myocardium causes restrictive then dilated cardiomyopathy. Diagnosis: elevated transferrin saturation (>45%), ferritin, and genetic testing. Cardiac MRI T2* <20 ms indicates myocardial iron overload. Treatment: phlebotomy for primary hemochromatosis, iron chelation (deferoxamine) for secondary. Early treatment can reverse cardiac dysfunction.

Hepatic Drug Metabolism

– Phase I reactions (oxidation, reduction, hydrolysis) primarily by CYP450 enzymes introduce or expose functional groups. Phase II reactions (conjugation) with glucuronide, sulfate, or acetyl groups increase water solubility for renal excretion. Hepatic metabolism can activate prodrugs, inactivate active drugs, or produce toxic metabolites. Liver disease reduces metabolism, requiring dose adjustment. Enzyme induction increases metabolism (de-

creasing drug levels); enzyme inhibition decreases metabolism (increasing drug levels).

Hepatojugular Reflux

- Sustained pressure applied over the liver for 15-30 seconds causes a sustained rise in JVP of more than 3 cm above baseline. It indicates right heart failure or fluid overload, reflecting the inability of the right ventricle to accommodate increased venous return. Also seen in cardiac tamponade, constrictive pericarditis, and tricuspid regurgitation. It is a useful bedside test for volume status assessment.

Holosystolic Murmur Differential

- Pansystolic (holosystolic) murmurs are plateau-shaped and extend from S1 to S2. Differential includes: mitral regurgitation (apex, radiates to axilla, increases with handgrip), tricuspid regurgitation (left lower sternal border, increases with inspiration), ventricular septal defect (left lower sternal border, may have thrill), and functional murmurs from increased flow (anemia, thyrotoxicosis, pregnancy).

Hypertension (High Blood Pressure)

- See Hypertension.

Hypertensive Crisis

- Severe elevation in blood pressure (SBP >180 or DBP >120) requiring urgent medical attention. Two types: hypertensive emergency (with end-organ damage) and hypertensive urgency (no acute end-organ damage). Hypertensive urgency: can be managed with oral antihypertensives (captopril, clonidine, labetalol) and careful outpatient follow-up. Distinction is critical for appropriate management.

Hypertensive Heart Disease

- Left ventricular hypertrophy and diastolic/systolic dysfunction resulting from chronic hypertension. LVH is an independent cardiovascular risk factor and precursor to heart failure. Diagnosis by ECG (voltage criteria) or echocardiography (wall thickness >1.1 cm). Treatment of hypertension can regress LVH. Complications include heart failure (HFpEF initially, then HFrEF), atrial fibrillation, and sudden cardiac death. Beta-blockers, ACE inhibitors, and ARBs can regress LVH.

Hypertrophic Cardiomyopathy

- An autosomal dominant genetic disorder characterized by asymmetric left ventricular hypertrophy

(typically septal), myocyte disarray, and fibrosis. It is the most common cause of sudden cardiac death in young athletes. Many patients are asymptomatic; symptoms include dyspnea, chest pain, syncope, and palpitations. Dynamic left ventricular outflow tract obstruction occurs in 70% of patients. Treatment includes beta-blockers, calcium channel blockers, myectomy, and ICD for high-risk patients.

Hypertrophic Cardiomyopathy Genetics

- HCM is caused by mutations in genes encoding sarcomeric proteins, most commonly beta-myosin heavy chain (MYH7) and myosin-binding protein C (MYBPC3). Inheritance is autosomal dominant with variable penetrance. Genetic testing identifies causative mutations in 40-60% of cases. First-degree relatives should be screened with echocardiography and ECG. Genotype-negative family members have lower risk but still require periodic surveillance.

Hypertrophic Cardiomyopathy Treatment

- Symptomatic management: beta-blockers (first-line for exertional symptoms), non-dihydropyridine calcium channel blockers (alternative or additive), disopyramide (reduces LVOT gradient). Septal reduction therapies for refractory symptoms: surgical myectomy (gold standard, excellent long-term outcomes) or alcohol septal ablation (less invasive, higher pacemaker requirement). ICD for sudden death prevention. Lifestyle counseling: moderate exercise, avoid competitive sports, avoid dehydration and vasodilators.

Hypotension

- Abnormally low blood pressure, generally systolic <90 mmHg or mean arterial pressure <65 mmHg. Causes include hypovolemia, cardiac failure, sepsis, anaphylaxis, and medications. Orthostatic hypotension is a drop upon standing. Severe hypotension (shock) requires urgent fluid resuscitation and vasopressors. Chronic asymptomatic hypotension is usually benign.

ICD Shock Therapy

- Anti-tachycardia pacing (ATP) for slow VT delivers rapid pacing pulses to terminate the arrhythmia painlessly. Cardioversion shock synchronously terminates VT. Defibrillation shock treats VFib asynchronously. The MADIT-RIT trial showed that

higher-rate programming (detection >180-200 bpm) reduced inappropriate shocks and mortality. S-ICD (subcutaneous ICD) avoids transvenous leads but lacks ATP and pacing capability. ICD shocks are associated with psychological morbidity.

Implantable Cardioverter-Defibrillator

- An implanted device that monitors heart rhythm and delivers electrical therapy (antitachycardia pacing or defibrillation) for life-threatening ventricular arrhythmias. Indications include secondary prevention (survived cardiac arrest, sustained VT) and primary prevention (EF 35% or less with NYHA II-III symptoms despite optimal medical therapy, or post-MI with EF 35% or less after 40 days). ICDs reduce sudden cardiac death and overall mortality in selected patients.

Implantable Loop Recorder

- Subcutaneous device providing continuous ECG monitoring for up to 3 years. Used for evaluation of unexplained syncope, recurrent palpitations, cryptogenic stroke, and occult atrial fibrillation detection. Small size (coin-sized), inserted under local anesthesia in the chest. Automatically records and stores rhythm data during symptoms or detected arrhythmias. Increasingly important in the workup of cryptogenic stroke for detecting silent AFib.

Interatrial Septum

- The wall separating the right and left atria. It contains the fossa ovalis, a remnant of the foramen ovale from fetal circulation. The interatrial septum has a thinner area where transseptal puncture can be performed during cardiac catheterization. Atrial septal defects (ASD) are congenital openings that allow left-to-right shunting, potentially causing right heart failure.

Interventricular Septum

- The thick muscular wall separating the left and right ventricles. It has two portions: the muscular (inferior, thicker) and membranous (superior, thinner) portions. The septum contains parts of the cardiac conduction system, including the bundle of His. Ventricular septal defects (VSDs) are congenital openings in the septum that allow left-to-right shunting of blood.

Janeway Lesions

- Painless, erythematous or hemorrhagic macules on

the palms and soles, caused by septic microemboli in infective endocarditis. They are a minor criterion in the Duke criteria. Unlike Osler nodes, Janeway lesions are painless and represent microabscesses in the dermis. They are transient and may disappear quickly. Both Osler nodes and Janeway lesions indicate active endocarditis and guide diagnosis.

Kussmaul Sign

- Paradoxical increase in jugular venous pressure with inspiration, normally the JVP decreases with inspiration. It indicates impaired right ventricular filling during inspiration. Seen in constrictive pericarditis, restrictive cardiomyopathy, severe right heart failure, cardiac tamponade, and massive pulmonary embolism. It is a reflection of ventricular interdependence and loss of normal pericardial compliance.

Left Atrial Myxoma

- Most common primary cardiac tumor (75%), typically originating from the interatrial septum in the left atrium. Presents with embolic events (25%), intracardiac obstruction (mitral valve obstruction mimicking mitral stenosis), and constitutional symptoms (fever, weight loss, elevated ESR mimicking infection or malignancy). Echocardiography shows a mobile, pedunculated mass. Surgical excision is curative. Recurrence is rare but possible, especially in familial syndromes (Carney complex).

Left Atrium

- The upper left chamber that receives oxygenated blood from four pulmonary veins. It has thicker walls than the right atrium (3 mm) and contracts to fill the left ventricle through the mitral valve. The left atrial appendage is a common site for thrombus formation in atrial fibrillation. Left atrial enlargement is associated with mitral valve disease and atrial arrhythmias.

Left Ventricular Noncompaction

- A rare cardiomyopathy characterized by prominent myocardial trabeculations with deep intertrabecular recesses, thought to result from arrested myocardial compaction during embryogenesis. It may present with heart failure, arrhythmias, or thromboembolism. Diagnosis by echocardiography or cardiac MRI showing a noncompacted to compacted myocardial ratio >2.3 (echocardiography) or >2.2 (cardiac MRI). Treatment includes heart fail-

ure therapy, anticoagulation for thromboembolism prevention, and arrhythmia management.

Levetiracetam

– An antiepileptic drug with a unique mechanism involving binding to synaptic vesicle protein 2A (SV2A), modulating neurotransmitter release. It is effective for focal, generalized, and myoclonic seizures. It has few drug interactions and does not require therapeutic drug monitoring. Side effects include irritability, behavioral changes, somnolence, and rarely suicidal ideation. It is available in oral and IV formulations, making it useful for acute seizure treatment.

Long QT Syndrome

– A channelopathy characterized by prolonged QT interval (QTc >450 ms in men, >460 ms in women) with risk of torsades de pointes and sudden cardiac death. Acquired: drugs (antiarrhythmics, antipsychotics, antibiotics), electrolyte abnormalities (hypokalemia, hypomagnesemia), bradycardia. Congenital: LQT1 (exercise-triggered, KCNQ1), LQT2 (emotional/auditory, KCNH2), LQT3 (sleep, SCN5A). Diagnosis: ECG, stress test, genetic testing. Treatment: avoid QT-prolonging drugs, beta-blockers for LQT1/2, left cardiac sympathetic denervation, and ICD for high-risk patients.

Marfan Syndrome

– An autosomal dominant connective tissue disorder caused by mutations in the FBN1 gene (fibrillin-1). Cardiovascular manifestations include aortic root dilation and dissection, mitral valve prolapse, and aortic regurgitation. Skeletal features include tall stature, arachnodactyly, pectus deformity, and joint hypermobility. Aortic root >5.0 cm or rapid dilation warrants prophylactic aortic root replacement. Beta-blockers or ARBs reduce aortic dilation rate. Regular echocardiographic surveillance is recommended.

Mechanical Circulatory Support

– Devices that provide temporary or permanent cardiac support. Options include intra-aortic balloon pump (IABP), Impella (percutaneous ventricular assist device), TandemHeart, extracorporeal membrane oxygenation (ECMO), and durable left ventricular assist devices (LVADs). Indications include cardiogenic shock, bridge to transplant, and bridge to recovery. LVADs (HeartMate 3) are increasingly

used as destination therapy in advanced heart failure ineligible for transplant.

Mid-Systolic Click

– A sharp, high-pitched sound occurring in mid-to-late systole, associated with mitral valve prolapse. The click represents sudden tensing of the elongated chordae tendineae as the prolapsing leaflet billows into the left atrium. It may be followed by a late systolic murmur of mitral regurgitation. The click moves earlier with decreased preload (standing, Valsalva) and later with increased preload (squatting, leg elevation).

MitraClip

– A transcatheter device that creates a double orifice in the mitral valve by clipping the anterior and posterior leaflets together, reducing mitral regurgitation. It is indicated for patients with significant (3+ or 4+) mitral regurgitation who are at high risk for surgical mitral valve repair. The COAPT trial demonstrated benefit in selected patients with secondary mitral regurgitation. The procedure is performed under transesophageal echocardiographic guidance.

Mitral Stenosis

– Narrowing of the mitral valve opening, obstructing left atrial to left ventricular blood flow. Most commonly caused by rheumatic heart disease. Symptoms include dyspnea, fatigue, and atrial fibrillation. Murmur: low-pitched, rumbling mid-diastolic murmur at the apex with opening snap. Severe MS (valve area <1.5 cm²) may require percutaneous balloon mitral valvotomy or surgical replacement. Anticoagulation is indicated for atrial fibrillation.

Mitral Stenosis Murmur

– Low-pitched, rumbling mid-diastolic murmur at the apex, best heard with the bell of the stethoscope in the left lateral decubitus position. Accompanied by an opening snap (early diastolic high-pitched click) and loud S1 in pliable valves. Severe MS may show a diastolic murmur without a preceding S2 gap. Preserved sinus rhythm shows presystolic accentuation. Atrial fibrillation is common and eliminates presystolic component.

Mitral Valve Prolapse

– A valvular heart disease where the mitral valve leaflets prolapse into the left atrium during systole. Most patients are asymptomatic; some develop pal-

pitations, atypical chest pain, or dyspnea. Diagnosis by echocardiography. Complications include mitral regurgitation, infective endocarditis, and arrhythmias. Most cases require only monitoring; severe regurgitation may need surgical repair.

Murmur Classification

– Heart murmurs are classified by timing, grade, shape, location, radiation, and pitch. Timing: systolic (between S1 and S2), diastolic (between S2 and S1), or continuous. Grade: I (barely audible) to VI (heard without stethoscope). Shape: crescendo, decrescendo, or plateau. The grading system helps distinguish pathological from physiological murmurs and guides further diagnostic workup.

Myocarditis Treatment

– No specific antiviral therapy for most cases. Treatment is supportive: heart failure therapy (diuretics, ACE inhibitors, beta-blockers) for reduced EF, arrhythmia management, and avoidance of exercise during acute phase (risk of sudden death). Immunosuppression may be considered in autoimmune myocarditis or cardiac sarcoidosis. Mechanical circulatory support or transplantation may be required for fulminant myocarditis. Endomyocardial biopsy may guide therapy in selected cases.

NYHA Functional Classification

– A four-class system grading heart failure severity based on symptoms and exercise tolerance. Class I: no limitation of physical activity. Class II: slight limitation; comfortable at rest but ordinary activity causes symptoms. Class III: marked limitation; comfortable at rest but less than ordinary activity causes symptoms. Class IV: symptoms at rest; unable to carry out any physical activity without discomfort.

Orthostatic Hypotension

– Decrease in SBP ≥ 20 mmHg or DBP ≥ 10 mmHg within 3 minutes of standing. Causes: dehydration, medications (antihypertensives, diuretics, alpha-blockers, antidepressants), autonomic dysfunction (diabetes, Parkinson disease), and prolonged bed rest. Symptoms: dizziness, lightheadedness, syncope, falls. Evaluation: orthostatic vital signs, autonomic reflex testing. Treatment: address reversible causes, increase fluid/salt intake, compression stockings, midodrine or fludrocortisone.

Osler Nodes

– Painful, erythematous nodules on the pads of fingers and toes, caused by immune complex deposition in infective endocarditis. They are a minor criterion in the Duke criteria. Osler nodes are tender and may last hours to days. They must be differentiated from Janeway lesions (painless, erythematous/purpuric macules on palms and soles caused by septic microemboli). Both are classic peripheral stigmata of infective endocarditis.

Pacemaker

– An implanted electronic device that delivers electrical impulses to the heart to regulate heart rate and rhythm. Indications include symptomatic bradycardia, high-degree AV block, and sick sinus syndrome. Single-chamber pacemakers pace the atrium or ventricle; dual-chamber pacemakers pace both. Biventricular pacemakers (cardiac resynchronization therapy) improve symptoms and survival in heart failure with LBBB and prolonged QRS. Modern pacemakers are MRI-compatible.

Pacemaker Complications

– Early: pneumothorax, hematoma, cardiac perforation/tamponade, lead dislodgement. Late: lead fracture, battery depletion, infection, tricuspid regurgitation from lead interference, venous thrombosis, and pacemaker syndrome (AV dyssynchrony in VVI pacing). Electromagnetic interference from devices (cautery, TENS, certain industrial equipment). MRI-conditional pacemakers reduce restrictions but require specific programming. Regular interrogation and follow-up essential.

Palpitation

– The subjective sensation of a rapid, forceful, or irregular heartbeat. Palpitations are a common symptom with a broad differential. Causes: cardiac (arrhythmias—atrial fibrillation, supraventricular tachycardia, ventricular ectopy, atrial flutter; structural heart disease—valvular disease, cardiomyopathy, congenital heart disease), psychiatric (anxiety, panic disorder, stress), physiological (exercise, pregnancy, fever, anaemia, dehydration, caffeine, alcohol, nicotine, illicit drugs—cocaine, amphetamines), endocrine (hyperthyroidism, pheochromocytoma, hypoglycaemia), medications (sympathomimetics, bronchodilators, antihistamines, antidepressants, thyroid hormone), and electrolyte disturbances (hypokalaemia, hypomagnesaemia). Palpitations de-

scribed as 'flip-flopping' suggest ectopic beats; 'rapid and regular' suggests SVT; 'rapid and irregular' suggests atrial fibrillation. Evaluation: history (onset, offset, duration, triggers, associated symptoms—chest pain, syncope, dyspnea), ECG (12-lead; if symptoms are intermittent, 24-hour Holter, event monitor, or loop recorder), echocardiogram if structural disease suspected, and blood tests (FBC, TSH, electrolytes). Management: reassurance and lifestyle modification for benign causes; treat underlying arrhythmia or condition. Prognosis is usually excellent if no underlying structural heart disease or significant arrhythmia.

Patent Foramen Ovale

– A normal fetal communication between the right and left atria (the foramen ovale) that fails to close after birth. Present in 25-30% of the general population. Typically small and hemodynamically insignificant, with left-to-right shunting that is usually not clinically important. Most PFOs are incidental findings on echocardiography. However, PFO is associated with cryptogenic stroke (paradoxical embolism — thrombus traverses from the right to left atrium, bypassing the pulmonary circulation), migraine with aura, and decompression sickness in divers. Diagnosis: transthoracic or transesophageal echocardiography with bubble study (agitated saline contrast shows bubbles crossing from right to left atrium, especially with Valsalva maneuver). Treatment: antiplatelet therapy for cryptogenic stroke; percutaneous PFO closure for selected high-risk patients (large shunt, atrial septal aneurysm, recurrent stroke despite medical therapy).

Pericardial Effusion Etiology

– Causes: viral pericarditis (most common in developed countries), malignancy (most common in developing countries), uremia, hypothyroidism, autoimmune diseases (SLE, RA), tuberculosis (leading cause worldwide), post-MI (Dressler syndrome), post-cardiac surgery, radiation, and idiopathic. Large effusions (>200 mL) or rapidly accumulating small effusions risk tamponade. Echocardiography is the initial diagnostic test. Pericardiocentesis provides both diagnostic fluid analysis and therapeutic drainage.

Pericardial Knock

– A high-pitched, early diastolic sound caused by

sudden cessation of ventricular filling in constrictive pericarditis. It is heard at the left sternal border and may be confused with an S3 or opening snap. The knock is typically louder with inspiration and is a characteristic finding in constrictive pericarditis. It reflects the abrupt restriction of diastolic filling by the rigid pericardium.

Pericarditis

– Inflammation of the pericardium, the fibrous sac surrounding the heart. Acute pericarditis presents with sharp, pleuritic chest pain that improves with leaning forward, pericardial friction rub, and diffuse ST elevation on ECG. Causes include viral infection (most common), bacterial, uremia, MI (Dressler syndrome), radiation, and autoimmune diseases. Treatment includes NSAIDs and colchicine. Complications include pericardial effusion and cardiac tamponade.

Peripartum Cardiomyopathy

– A form of dilated cardiomyopathy occurring in the last month of pregnancy or within 5 months postpartum, with no other identifiable cause. Risk factors include advanced maternal age, multiple gestations, preeclampsia, and African American race. Presents with heart failure symptoms. Treatment includes standard heart failure therapy (ACE inhibitors are safe postpartum but contraindicated during pregnancy). Many patients recover, but some progress to severe heart failure requiring transplant.

Peripheral Artery Disease

– Atherosclerotic narrowing of arteries supplying the lower extremities. Presents with claudication (calf pain with walking, relieved by rest), rest pain, and tissue loss in severe cases. Risk factors: smoking, diabetes, hypertension, hyperlipidemia. Diagnosis: ankle-brachial index <0.90. Treatment: risk factor modification, exercise therapy, antiplatelet agents, and revascularization when indicated.

Phenytoin

– An antiepileptic drug that blocks voltage-gated sodium channels, stabilizing neuronal membranes and preventing seizure spread. It is effective for focal and generalized tonic-clonic seizures. Therapeutic drug monitoring is important due to non-linear (saturable) pharmacokinetics. Side effects include gingival hyperplasia, hirsutism, megaloblastic anemia, osteoporosis, and teratogenicity (fetal

hydantoin syndrome). It induces CYP450 enzymes, affecting metabolism of many drugs.

Phlebitis

– Inflammation of a vein, often affecting the lower extremities. Superficial thrombophlebitis: inflammation and thrombosis of a superficial vein (great saphenous vein most common), presenting with erythema, tenderness, warmth, and a palpable cord along the vein. Causes: intravenous cannulation (most common—chemical phlebitis from irritant drugs, mechanical irritation, bacterial infection), varicose veins, thrombophilia, pregnancy, prolonged travel, and Behçet disease. Diagnosis is clinical; doppler ultrasound should be performed to exclude concomitant deep vein thrombosis (15–20% of cases). Treatment: warm compresses, NSAIDs, compression stockings, elevation, and ambulation. Anticoagulation is not required for isolated superficial thrombophlebitis unless it extends to the saphenofemoral junction (then treat as DVT). Septic thrombophlebitis requires IV antibiotics and occasionally surgical excision. Deep vein thrombophlebitis (DVT) is a distinct entity requiring anticoagulation.

Pneumopericardium

– Air in the pericardial space, usually from trauma (penetrating chest injury), esophageal perforation, or iatrogenic causes (central line placement, cardiac surgery). Can cause cardiac tamponade if under tension. Diagnosis by chest X-ray showing air surrounding the heart (air-fluid level if combined with effusion). Treatment: observation if small and asymptomatic; pericardial drainage if causing tamponade.

Preload

– The end-diastolic volume or pressure in the ventricles, representing the degree of ventricular stretch before contraction. Preload is determined by venous return and is estimated by the pulmonary capillary wedge pressure (PCWP) or left ventricular end-diastolic pressure (LVEDP). According to the Frank-Starling mechanism, increased preload (within physiological limits) increases stroke volume. Pathologically elevated preload occurs in heart failure and fluid overload.

Premature Ventricular Contractions

– Ectopic beats originating from the ventricles, appearing as wide, bizarre QRS complexes that occur earlier than expected. PVCs are common in the general population and are usually benign. Frequent PVCs (>10% of total beats) may cause left ventricular dysfunction. Causes include electrolyte imbalances, stimulants, myocardial ischemia, and cardiomyopathy. Treatment is usually unnecessary unless symptomatic or causing cardiomyopathy.

PR Interval

– The time from the onset of the P wave to the onset of the QRS complex, representing the time for electrical conduction through the atria, AV node, and His-Purkinje system. Normal duration is 0.12–0.20 seconds (3–5 small boxes). Prolonged PR interval (>0.20 s) indicates first-degree AV block. Shortened PR interval (<0.12 s) may indicate Wolff-Parkinson-White syndrome or junctional rhythm.

Pulmonary Atresia

– A congenital heart defect where the pulmonary valve is completely absent (atretic), obstructing right ventricular outflow. Two main types: pulmonary atresia with intact ventricular septum (PA-IVS) and pulmonary atresia with ventricular septal defect (PA-VSD, also called tetralogy of Fallot with pulmonary atresia). PA-IVS: the right ventricle is small and hypertensive, and pulmonary blood flow depends on a patent ductus arteriosus. PA-VSD: the right ventricle is normal-sized, and pulmonary blood flow is ductal-dependent. Both present with severe cyanosis in the first days of life as the ductus closes. Diagnosis: echocardiography shows absent pulmonary valve tissue, ductal-dependent pulmonary circulation, and RV size. Treatment: PGE1 to maintain ductal patency, followed by staged surgical palliation (BT shunt, RVOT reconstruction, or unifocalization for PA-VSD; RV decompression or Fontan for PA-IVS).

Pulmonary Hypertension

– Elevated mean pulmonary artery pressure (>20 mmHg at rest) due to various etiologies. WHO Group 1: pulmonary arterial hypertension (idiopathic, heritable, drug-induced). Group 2: left heart disease. Group 3: lung disease. Group 4: chronic thromboembolic. Group 5: multifactorial. Diagnosis requires right heart catheterization. Treatment depends on group: vasodilators (endothelin recep-

tor antagonists, PDE5 inhibitors, prostacyclins) for Group 1; treat underlying cause for Groups 2-4.

Pulmonary Hypertension Classification

– WHO Classification: Group 1 (PAH: idiopathic, heritable, drug-induced, connective tissue disease-associated). Group 2 (left heart disease: systolic/diastolic dysfunction, valvular). Group 3 (lung disease/hypoxia: COPD, ILD, sleep apnea). Group 4 (chronic thromboembolic). Group 5 (multifactorial: sarcoidosis, hematologic disorders). Right heart catheterization is the gold standard for diagnosis (mean PAP >20 mmHg at rest).

Pulmonary Stenosis

– A right ventricular outflow tract obstruction at the valvular, subvalvular, or supra-valvular level. Valvular pulmonary stenosis (most common) is often congenital, frequently associated with Noonan syndrome. Symptoms depend on severity: mild is asymptomatic; moderate presents with dyspnea, fatigue, and syncope; severe presents with cyanosis and right heart failure. Physical exam: harsh systolic ejection murmur at the left upper sternal border, radiating to the back, with a prominent RV heave and a widely split S2 with a diminished P2. Diagnosis: echocardiography with Doppler measures the peak gradient (mild <30 mmHg, moderate 30-60 mmHg, severe >60 mmHg). Treatment: balloon pulmonary valvuloplasty is the procedure of choice for severe valvular stenosis (gradient >40-50 mmHg). Surgical valvotomy or valve replacement if balloon fails or for dysplastic valves (Noonan syndrome).

Pulmonic Stenosis

– Narrowing of the right ventricular outflow tract at the pulmonic valve. Causes: congenital (most common, often associated with Noonan syndrome or tetralogy of Fallot), rheumatic, carcinoid syndrome. Presents with dyspnea, fatigue, syncope. Signs: harsh systolic ejection murmur at left upper sternal border, RV hypertrophy. Diagnosis: echocardiography (pressure gradient). Treatment: balloon valvuloplasty for moderate-severe congenital PS; surgical valvotomy or valve replacement for failed valvuloplasty.

Pulsus Paradoxus

– A decrease in systolic blood pressure greater than 10 mmHg during inspiration, normally less than 10

mmHg. Exaggerated in cardiac tamponade (due to ventricular interdependence in the confined pericardial space), severe asthma, COPD exacerbation, and constrictive pericarditis. It is measured by noting the Korotkoff sounds that appear only during expiration on sphygmomanometry. Kussmaul sign (paradoxical JVD increase with inspiration) is a related finding.

Purkinje Fibers

– The terminal branches of the cardiac conduction system, distributed throughout the ventricular myocardium. They conduct impulses rapidly (up to 4 m/s) to ensure coordinated ventricular contraction from apex to base. Purkinje fibers have an intrinsic firing rate of 20-40 beats per minute. They are resistant to ischemia but can become triggered pacemakers in disease states.

Purulent Pericarditis

– Bacterial infection of the pericardial space, most commonly caused by *S. aureus*, *S. pneumoniae*, or gram-negative organisms. Often occurs as a complication of pneumonia, endocarditis, chest surgery, or immunosuppression. Presents with fever, pleuritic chest pain, and rapidly accumulating effusion with tamponade physiology. High mortality without treatment. Requires emergent pericardiocentesis or surgical drainage plus prolonged IV antibiotics.

P Wave

– The first deflection on the ECG, representing atrial depolarization. Normal P waves are upright in leads I and II, inverted in aVR, and less than 0.12 seconds (3 small boxes) in duration and 2.5 mm in amplitude. Abnormal P waves indicate atrial enlargement: peaked P waves (right atrial enlargement), notched P waves (left atrial enlargement). Absent P waves suggest atrial fibrillation or junctional rhythm.

QT Interval

– The time from the onset of the QRS complex to the end of the T wave, representing total ventricular depolarization and repolarization. Normal QT is 0.35-0.44 seconds. The corrected QT (QTc) adjusts for heart rate using Bazett's formula: $QTc = QT / \sqrt{RR \text{ interval}}$. QTc prolongation (>450 ms in men, >470 ms in women) increases the risk of torsades de pointes. QTc is shortened in hyperkalemia and digoxin effect.

Raynaud Phenomenon

- Exaggerated vasospastic response of digital arteries to cold or stress, causing well-demarcated color changes (white-blue-red) in fingers or toes. Primary Raynaud: idiopathic, symmetric, no tissue damage, normal capillaries. Secondary Raynaud: associated with connective tissue diseases (scleroderma, SLE), vascular disease, medications (beta-blockers), or occupational vibration. Diagnosis: clinical, nailfold capillaroscopy, ANA testing. Treatment: avoid cold triggers, calcium channel blockers (nifedipine), and prostacyclin analogs for severe cases.

Renal Drug Excretion

- The elimination of drugs by the kidney through glomerular filtration, active tubular secretion, and passive tubular reabsorption. Drugs eliminated renally (e.g., aminoglycosides, vancomycin, lithium, metformin) require dose adjustment in renal impairment. Renal clearance is affected by urine pH, tubular flow rate, and drug protein binding. Renal function is estimated by creatinine clearance or eGFR, guiding dosing decisions.

Restrictive Cardiomyopathy

- A cardiomyopathy characterized by impaired ventricular relaxation and filling due to stiff, noncompliant myocardium, with preserved systolic function and normal or reduced ventricular volumes. Causes include amyloidosis, sarcoidosis, hemochromatosis, endomyocardial fibrosis, and radiation. Patients present with signs of heart failure despite normal EF. Prognosis is often poor. Treatment is directed at underlying cause and managing volume overload with diuretics.

Rheumatic Heart Disease

- Valvular damage resulting from acute rheumatic fever, an autoimmune response to Group A streptococcal pharyngitis. Most commonly affects the mitral valve (stenosis/regurgitation), followed by aortic. Prevention through prompt treatment of streptococcal pharyngitis. Management: valve repair/replacement, anticoagulation for atrial fibrillation, and secondary prophylaxis with penicillin.

Right Bundle Branch

- A continuation of the bundle of His that travels along the right side of the interventricular septum to the right ventricle. It supplies the right ventricular myocardium and Purkinje fibers. Right bundle branch block (RBBB) occurs when this branch is

damaged, causing delayed right ventricular activation. RBBB is commonly associated with pulmonary embolism, right ventricular hypertrophy, and aging.

Right Ventricle

- The lower right chamber that receives blood from the right atrium through the tricuspid valve and pumps it through the pulmonary valve into the pulmonary artery. It has crescent-shaped walls (3-5 mm thick) and generates lower pressures than the left ventricle (systolic pressure 25-30 mmHg). The right ventricle is volume-overloaded in conditions like pulmonary hypertension and atrial septal defect.

Roth Spots

- Retinal hemorrhages with pale centers, seen on fundoscopic examination in infective endocarditis. They are a minor criterion in the Duke criteria. Roth spots are caused by immune complex-mediated vasculitis of retinal vessels. They can also be seen in other conditions: severe anemia, leukemia, collagen vascular diseases, and diabetic retinopathy. Their presence in the appropriate clinical context supports endocarditis diagnosis.

S3 Gallop Pathology

- A third heart sound in adults over 40 indicates ventricular dysfunction. It represents rapid ventricular filling against a dilated, noncompliant ventricle. S3 is a hallmark of systolic heart failure (HFrEF) and is associated with increased mortality. It is best heard at the apex with the bell of the stethoscope in the left lateral decubitus position. Common causes: dilated cardiomyopathy, acute MI with volume overload, severe mitral regurgitation.

S4 Gallop Pathology

- A fourth heart sound indicates atrial contraction against a stiff ventricle (decreased compliance). Associated with left ventricular hypertrophy from hypertension, aortic stenosis, and hypertrophic cardiomyopathy. S4 is best heard at the apex with the bell, and is accentuated by exertion, expiration, and isorhythmic AV dissociation. It is a sign of diastolic dysfunction and may precede symptomatic heart failure.

Second-Degree AV Block

- Intermittent failure of AV conduction. Mobitz Type I (Wenckebach): progressive PR prolongation then dropped QRS; usually benign (AV nodal, nar-

row QRS). Mobitz Type II: constant PR interval with sudden dropped QRS; more serious (infranodal, wide QRS), risk of progression to complete heart block and Stokes-Adams attacks. Treatment: Type I often no treatment needed; Type II requires pacemaker implantation due to risk of high-grade block.

Sick Sinus Syndrome

– Sinus node dysfunction causing a spectrum of arrhythmias: sinus bradycardia, sinus arrest, sinoatrial block, and tachycardia-bradycardia syndrome. Most common in elderly patients. Presents with syncope, fatigue, palpitations, and exercise intolerance. Diagnosis: ECG, Holter monitor (pauses >3 seconds). Treatment: permanent pacemaker implantation for symptomatic bradycardia. Anticoagulation needed for tachy-brady syndrome (atrial fibrillation component).

Sinoatrial Node

– The heart's natural pacemaker, located at the junction of the superior vena cava and right atrium. It consists of specialized cells that spontaneously depolarize at a rate of 60-100 beats per minute, setting the normal sinus rhythm. The SA node receives autonomic innervation: sympathetic stimulation increases heart rate, while parasympathetic (vagal) stimulation decreases it. SA node dysfunction causes sick sinus syndrome.

Stevens-Johnson Syndrome

– A severe, life-threatening mucocutaneous reaction characterized by widespread skin erythema, necrosis, and bullae formation with mucosal involvement (oral, ocular, genital). It is most commonly caused by drug reactions (sulfonamides, anticonvulsants, allopurinol, NSAIDs) and infections (*Mycoplasma pneumoniae*). It is a medical emergency requiring ICU care, wound management, infection prevention, and often burn center transfer. Mortality is 5-10%.

Strain Imaging

– Echocardiographic or MRI technique measuring myocardial deformation (shortening and thickening). Global longitudinal strain (GLS) by speckle tracking is more sensitive than ejection fraction for detecting subclinical myocardial dysfunction. GLS < -18% is normal. Used for early detection of chemotherapy cardiotoxicity, differentiating cardiomyopathies, and prognosis in heart failure. GLS may detect

dysfunction before EF declines.

Stroke Volume

– The volume of blood ejected by the left ventricle with each heartbeat, normally 60-100 mL. It is determined by three factors: preload, afterload, and myocardial contractility. Stroke volume equals end-diastolic volume minus end-systolic volume. Reduced stroke volume occurs in heart failure, hypovolemia, and cardiogenic shock. Stroke volume can be increased by exercise, positive inotropes, or fluid administration.

Supraventricular Tachycardia

– A rapid rhythm (150-250 bpm) originating above the ventricles, characterized by narrow QRS complexes. Most common forms are AV nodal reentrant tachycardia (AVNRT) and AV reentrant tachycardia (AVRT). Episodes are typically paroxysmal with sudden onset and offset. Vagal maneuvers and adenosine are diagnostic and therapeutic. Recurrent SVT may require catheter ablation of the reentrant circuit.

Systolic Murmurs

– Murmurs occurring between S1 and S2. Ejection systolic murmurs (crescendo-decrescendo) are caused by flow across semilunar valves (aortic stenosis, pulmonary stenosis) or increased flow across normal valves. Pansystolic (holosystolic) murmurs (plateau) are caused by regurgitation across AV valves (mitral regurgitation, tricuspid regurgitation) or left-to-right shunts (VSD). Timing with carotid pulsation helps distinguish aortic from mitral murmurs.

Tachycardia

– A heart rate exceeding 100 beats per minute in adults at rest. Tachycardia is a sign, not a diagnosis, and requires investigation to determine the underlying rhythm and cause. Sinus tachycardia: a physiological response to increased demand—exercise, fever, anxiety, pain, dehydration, anaemia, infection, hyperthyroidism, pulmonary embolism, heart failure, or drugs (β -agonists, caffeine, cocaine). The P wave is present and normal, rate 100–150 (up to 200 in children/young adults). Treatment: address the underlying cause. Narrow QRS tachycardia (QRS < 0.12 s): supraventricular tachycardia—AV nodal reentrant tachycardia, AV reentrant tachycardia, atrial fibrillation, atrial flutter,

atrial tachycardia. Wide QRS tachycardia (QRS >0.12 s): ventricular tachycardia (most common), SVT with aberrancy, pre-excited atrial fibrillation (Wolf–Parkinson–White). Stable tachycardia: 12-lead ECG, vagal maneuvers, adenosine (for SVT), amiodarone/procainamide (for VT). Unstable tachycardia (hypotension, altered consciousness, chest pain, acute heart failure, shock): synchronized cardioversion. Palpitations are the most common symptom of tachycardia; syncope suggests hemodynamic compromise.

TCAs (Tricyclic Antidepressants)

– Antidepressants that block reuptake of serotonin and norepinephrine, with additional anticholinergic, antihistaminic, and alpha-adrenergic blocking effects. Examples include amitriptyline, nortriptyline, imipramine, and desipramine. They are effective for depression, neuropathic pain, and migraine prophylaxis. Side effects include sedation, weight gain, dry mouth, urinary retention, constipation, orthostatic hypotension, and cardiac conduction abnormalities. Lethal in overdose due to cardiac sodium channel blockade and QT prolongation.

Third-Degree AV Block

– Complete heart block with no conduction between atria and ventricles. Atria and ventricles beat independently (AV dissociation). Ventricular escape rhythm: junctional (40-60, narrow QRS) or ventricular (20-40, wide QRS). Causes: idiopathic fibrosis, MI (inferior: transient AV nodal; anterior: infranodal), drugs, cardiomyopathy, Lyme disease, post-surgical. Symptoms: syncope, dyspnea, fatigue, heart failure. Treatment: immediate temporary pacing (transcutaneous or transvenous) and definitive permanent pacemaker implantation.

Torsades de Pointes

– A specific form of polymorphic ventricular tachycardia with QRS complexes that twist around the baseline, occurring in the setting of QT prolongation. It may degenerate to ventricular fibrillation. Causes include congenital long QT syndrome, drugs that prolong QT interval (antiarrhythmics, antibiotics, antipsychotics), electrolyte disturbances (hypokalemia, hypomagnesemia), and bradycardia. Treatment includes IV magnesium, temporary pacing, and isoproterenol.

Toxic Epidermal Necrolysis

– A severe, life-threatening drug reaction characterized by widespread full-thickness epidermal necrosis and detachment, affecting >30% of body surface area. It represents a more severe form of Stevens–Johnson syndrome. Common causative drugs include anticonvulsants (carbamazepine, phenytoin), sulfonamides, allopurinol, and NSAIDs. Treatment is supportive, similar to burn care, with ICU admission and multidisciplinary care. Mortality is 30-50%.

Tricuspid Regurgitation

– Incomplete closure of the tricuspid valve allowing blood to flow backward from the right ventricle to the right atrium during systole. Causes include right ventricular dilation (from pulmonary hypertension or left heart failure), endocarditis, rheumatic disease, and carcinoid syndrome. Murmur: pansystolic murmur at the left lower sternal border increasing with inspiration. Severe TR may require surgical repair or replacement.

Tricuspid Stenosis

– Narrowing of the tricuspid valve opening, most commonly caused by rheumatic heart disease. It is often associated with mitral stenosis. Symptoms include fatigue, edema, and hepatic congestion. Murmur: low-pitched mid-diastolic rumble at the left lower sternal border that increases with inspiration. Diagnosis is confirmed by echocardiography. Severe TS may require surgical commissurotomy or valve replacement.

T Wave

– The deflection representing ventricular repolarization. Normal T waves are upright in leads I, II, and V3-V6, and inverted in aVR. They should be at least 10% of the QRS amplitude in limb leads and 25% in precordial leads. Abnormal T waves may indicate ischemia (inversion), hyperkalemia (peaked), or pericarditis (diffuse elevation). T wave changes are nonspecific and require clinical correlation.

U Wave

– A small deflection following the T wave, best seen in precordial leads V2-V3. U waves are thought to represent repolarization of the Purkinje fibers or papillary muscles. Prominent U waves are associated with hypokalemia, bradycardia, and certain drugs (digitalis, quinidine). Inverted U waves may indicate ischemia or left ventricular hypertrophy. U

waves are normally small and may be absent.

Valproic Acid

– An antiepileptic drug that enhances GABA-mediated inhibition, blocks sodium channels, and has multiple mechanisms of action. It is effective for generalized seizures, absence seizures, and myoclonic seizures. Side effects include weight gain, tremor, hair loss, hepatotoxicity (rare in adults, higher risk in children under 2), teratogenicity (neural tube defects), and pancreatitis. It inhibits CYP enzymes and is highly protein-bound, with numerous drug interactions.

Valsalva's Manoeuvre

– Forced expiratory effort against a closed airway (glottis closed or mouth and nose pinched shut), typically performed by bearing down as if straining during a bowel movement. The manoeuvre has four phases: Phase I (onset of straining): increased intrathoracic pressure compresses the aorta, causing a transient rise in blood pressure. Phase II (sustained strain): decreased venous return to the heart reduces cardiac output and blood pressure, with compensatory reflex tachycardia and peripheral vasoconstriction (baroreceptor-mediated). Phase III (release): sudden drop in intrathoracic pressure causes a transient fall in blood pressure. Phase IV (overshoot): cardiac output returns but peripheral vessels remain constricted, causing blood pressure to overshoot above baseline, with reflex bradycardia. Clinical uses: assessing heart murmurs (dynamic auscultation — most murmurs decrease with Valsalva, except hypertrophic obstructive cardiomyopathy [increases] and mitral valve prolapse [moves earlier]), terminating supraventricular tachycardia (via vagal stimulation increasing vagal tone to the AV node), autonomic function testing (heart rate and blood pressure responses), detecting abdominal hernias, and diagnosing pelvic organ prolapse. Contraindications: severe aortic stenosis, recent MI, glaucoma, and retinopathy.

Varicose Veins

– Dilated, tortuous superficial veins, most commonly in the lower extremities. Caused by venous valve incompetence leading to venous reflux. Risk factors: family history, prolonged standing, obesity, pregnancy, and older age. Symptoms: leg heaviness, swelling, aching. Complications: skin changes,

ulceration, thrombophlebitis. Treatment: compression stockings, sclerotherapy, endovenous ablation, and surgical ligation.

Ventricular Assist Device

– A mechanical pump that supports heart function in patients with advanced heart failure. LVADs (left ventricular assist devices) are most common, supporting the failing left ventricle. The HeartMate 3 is the current standard with fully magnetically levitated rotors. Indications include bridge to transplant (BTT), destination therapy (DT), and bridge to decision. Complications include bleeding, infection, thromboembolism, and device malfunction.

Ventricular Septal Defect

– The most common congenital heart defect (30% of all CHD), characterized by an abnormal opening in the interventricular septum allowing left-to-right shunting. Types: perimembranous (most common, 70%, near the membranous septum), muscular (5-20%, completely surrounded by muscle), supracristal (5-7%, above the crista supraventricularis, associated with aortic regurgitation), and inlet (5-8%, near the tricuspid valve, common in Down syndrome). Small VSDs may close spontaneously (especially muscular). Large VSDs present with heart failure, failure to thrive, and frequent respiratory infections. On examination: holosystolic murmur at the left lower sternal border, hyperdynamic precordium, and widely split S2. Diagnosis: echocardiography shows shunt and estimates RV pressure. Treatment: small/asymptomatic — observation; large/symptomatic — surgical patch closure or transcatheter device closure. Pulmonary vascular disease develops if unrepaired (Eisenmenger syndrome).

Wolff-Parkinson-White Syndrome

– A pre-excitation syndrome caused by an accessory pathway (bundle of Kent) connecting atria and ventricles, bypassing the AV node. ECG shows short PR interval (<0.12 s), delta wave (slurred upstroke of QRS), and widened QRS. Patients are at risk for supraventricular tachycardia and, if atrial fibrillation occurs, rapid ventricular response potentially degenerating to ventricular fibrillation. Treatment includes catheter ablation of the accessory pathway.

Chapter 5

Clinical Nutrition & Metabolic Medicine

Basal Metabolic Rate (BMR)

- Minimum amount of energy expended by a fasting, resting individual in a thermoneutral environment to maintain basic vital physiological functions (respiration, cardiac function, ion pumping, metabolic homeostasis); accounts for 60–75% of total daily energy expenditure.

Beriberi

- Nutritional deficiency disorder resulting from severe lack of thiamine (vitamin B₁), essential for pyruvate dehydrogenase and α -ketoglutarate dehydrogenase in carbohydrate metabolism. Types: Wet Beriberi (cardiovascular manifestation with high-output heart failure, peripheral vasodilation, cardiomegaly, and dependent edema) and Dry Beriberi (neurological manifestation with symmetrical peripheral neuropathy, sensory loss, muscle wasting, and diminished deep tendon reflexes). Wernicke-Korsakoff syndrome represents the central nervous system manifestation (ocular abnormalities, ataxia, confusion, and anterograde amnesia), commonly associated with chronic alcoholism. Treated with immediate intravenous thiamine supplementation prior to glucose administration.

Body Mass Index (BMI)

- Anthropometric measure defined as body mass divided by the square of body height (kg/m^2). WHO classification for adults: Underweight (< 18.5), Normal weight (18.5–24.9), Overweight (25.0–29.9), Class I Obesity (30.0–34.9), Class II Obesity (35.0–39.9), and Class III / Severe Obesity (≥ 40). Serves as a population-level indicator of metabolic disease risk, though limited by inability to distinguish visceral fat from muscle mass or bone density.

Calcium-Vitamin D Synergy

- Critical physiological interplay where active Vitamin D (1,25(OH)₂D₃) upregulates intestinal ep-

ithelial expression of calcium transport proteins (Calbindin), enhancing dietary calcium absorption necessary for maintaining bone mineral density and preventing rickets and osteomalacia.

Carnitine Deficiency

- Deficit in trimethylated amino acid derivative essential for long-chain fatty acid transport into mitochondria; leads to muscle weakness, hypoketotic hypoglycemia, and dilated cardiomyopathy.

Chromium Deficiency

- Essential trace mineral deficiency impairing insulin sensitivity and peripheral glucose tolerance, resulting in hyperglycemia, glycosuria, and peripheral neuropathy.

Copper Deficiency

- Rare nutritional deficiency causing microcytic or normocytic anemia, neutropenia, sensory ataxia, and posterior column myelopathy mimicking Vitamin B12 deficiency; caused by malabsorption, gastric bypass, or excessive Zinc supplementation (which induces intestinal metallothionein trapping copper).

Dietary Fiber

- Nondigestible carbohydrates and lignin intrinsic to plant foods. Divided into Soluble Fiber (pectins, gums—form gels, lower LDL cholesterol, slow glucose absorption) and Insoluble Fiber (cellulose, hemicellulose—increase fecal bulk, accelerate intestinal transit time, prevent constipation and diverticulosis).

Enteral Nutrition

- Delivery of nutritionally complete liquid formulas directly into the stomach or small intestine via a tube, indicated for patients with a functional gastrointestinal tract who cannot meet their nutritional requirements orally (e.g., severe dysphagia, mechan-

ical ventilation, head/neck cancer, altered consciousness). Routes: Nasogastric (NG) tube, Nasojejunal (NJ) tube, Percutaneous Endoscopic Gastrostomy (PEG), or Percutaneous Endoscopic Jejunostomy (PEJ). Preferred over parenteral nutrition due to preservation of gut mucosal integrity, prevention of bacterial translocation, lower infection rates, and reduced cost.

Enteral Nutrition (EN)

– Delivery of nutritionally complete liquid formulas directly into the gastrointestinal tract via a tube (nasogastric, nasojejunal, PEG) in patients who have a functional gut but are unable to ingest adequate oral nutrition. Preferred over parenteral nutrition due to preservation of gut mucosal barrier integrity and lower risk of infection.

Essential Fatty Acid Deficiency (EFAD)

– Rare clinical deficiency resulting from inadequate dietary intake of essential polyunsaturated fatty acids: linoleic acid (omega-6) and alpha-linolenic acid (omega-3). Occurs primarily in patients receiving long-term fat-free parenteral nutrition or severe fat malabsorption syndromes. Clinical features: dry scaly dermatitis, alopecia, impaired wound healing, thrombocytopenia, growth retardation, and fatty liver. Diagnosed by an elevated plasma triene-to-tetraene ratio (> 0.2). Prevented and treated by administering intravenous lipid emulsions.

Harris-Benedict Equation

– Classic predictive empirical formula utilized in clinical nutrition to estimate an individual's Basal Energy Expenditure (BEE) based on body weight, height, age, and sex; subsequently multiplied by activity and stress factors to calculate total caloric requirements.

Indirect Calorimetry

– Gold standard clinical method for measuring resting energy expenditure (REE) and respiratory quotient (RQ) by measuring oxygen consumption (VO_2) and carbon dioxide production (VCO_2) via a metabolic cart. RQ values indicate primary energy substrate oxidized: 1.0 (carbohydrate), 0.7 (fat), 0.8 (protein).

Iodine Deficiency

– Global nutritional deficit leading to impaired thyroid hormone synthesis (T_3/T_4). Causes endemic

goiter (thyroid enlargement) and, during pregnancy, fetal Cretinism (severe intellectual disability, short stature, deaf-mutism, dysmorphic features). Prevented by universal salt iodization.

Iron Deficiency Anemia

– The most common nutritional deficiency worldwide, characterized by microcytic hypochromic red blood cells, low serum ferritin, low iron, elevated total iron-binding capacity (TIBC), and low transferrin saturation. Symptoms: fatigue, pallor, pica (ice/dirt craving), koilonychia (spoon nails), and angular cheilitis.

Kwashiorkor

– Form of severe acute malnutrition (SAM) characterized by severe protein deficiency despite adequate or borderline caloric intake (classic "edematous malnutrition"). Typically affects young children after weaning onto a low-protein, starchy carbohydrate diet. Key clinical features: generalized pitting edema (starting in feet and legs), moon face, abdominal distension ("pot belly" due to hepatomegaly from fatty liver infiltration), sparse reddish-orange hair, dry flaky-paint skin lesions, lethargy, loss of appetite, and hypoalbuminemia. High mortality if unmanaged; treated with cautious, phased nutritional rehabilitation (F-75/F-100 therapeutic milk).

Malnutrition (Undernutrition)

– Cellular imbalance between the supply of nutrients and energy and the body's demand for them to ensure growth, maintenance, and specific functions. Encompasses protein-energy malnutrition (Kwashiorkor, Marasmus) and micronutrient deficiencies (hidden hunger). Causes: inadequate food intake, poverty, severe acute/chronic illness (cancer cachexia, sepsis, inflammatory bowel disease), and malabsorption. Consequences: impaired immune function, delayed wound healing, muscle wasting, increased hospital length of stay, and elevated mortality.

Marasmus

– Form of severe acute malnutrition (SAM) resulting from a chronic, severe deficiency of both total calories and protein ("non-edematous malnutrition" or severe wasting). Affects infants under 1 year of age. Key clinical features: severe muscle wasting and loss of subcutaneous fat, giving the child an "old man" or wizened facial appearance, prominent

ribs, thin loose skin folds ("baggy pants" gluteal appearance), severe stunting, and ravenous hunger. Unlike kwashiorkor, there is no edema, hair color changes, or fatty liver infiltration.

Metabolic Syndrome

– Cluster of interconnected physiological, biochemical, and metabolic abnormalities that significantly increase the risk of developing type 2 diabetes mellitus and cardiovascular disease. Diagnostic criteria (ATP III / NCEP— ≥ 3 required): (1) Abdominal obesity (waist circumference > 102 cm in men, > 88 cm in women), (2) Elevated triglycerides (≥ 150 mg/dL), (3) Reduced HDL cholesterol (< 40 mg/dL in men, < 50 mg/dL in women), (4) Elevated blood pressure ($\geq 130/85$ mmHg or on antihypertensive therapy), and (5) Elevated fasting glucose (≥ 100 mg/dL or on antidiabetic therapy). Insulin resistance is the underlying pathophysiological mechanism.

Micronutrient Deficiencies

– Inadequate physiological availability of essential vitamins and trace minerals required in small quantities for enzymatic catalysis, hormone synthesis, cellular metabolism, and immune function. Major global deficiencies: Vitamin A (leading cause of preventable childhood blindness), Iron (microcytic anemia), Iodine (goiter, cretinism), Zinc (impaired growth, immune dysfunction, dermatitis), and Vitamin D (rickets, osteomalacia). Affects over 2 billion people worldwide ("hidden hunger"), addressed through dietary diversification, biofortification, industrial food fortification, and target supplementation.

Nasogastric Tube (NGT) Feeding

– Short-term enteral nutrition method delivering liquid nutrition formula directly into the stomach through a flexible tube passed through the nares, nasopharynx, and esophagus. Correct tube placement must be verified radiographically prior to initiating feeding.

Nitrogen Balance

– Clinical measure of net body protein breakdown versus synthesis, calculated as Nitrogen Input (dietary protein intake in grams / 6.25) minus Nitrogen Output (urinary urea nitrogen + 4g unmeasured losses). Positive balance indicates anabolic state; negative balance indicates catabolic breakdown.

Nutritional Assessment

– Comprehensive clinical evaluation of nutritional status utilizing medical history, dietary intake records, physical examination (anthropometrics, muscle wasting, edema), and laboratory markers (albumin, prealbumin, transferrin, micronutrient levels).

Parenteral Nutrition-Associated Liver Disease (PNALD)

– Hepatic complication of long-term TPN characterized by steatosis, cholestasis, and biliary sludging; mitigated by cyclic TPN administration and balancing lipid emulsion formulations.

Parenteral Nutrition (Total Parenteral Nutrition / TPN)

– Intravenous administration of complete nutritional solutions (hypertonic dextrose, amino acids, lipid emulsions, electrolytes, trace elements, and vitamins) directly into the systemic circulation, bypassing the gastrointestinal tract. Indicated when the GI tract is non-functional, inaccessible, or requires complete rest (e.g., short bowel syndrome, severe acute pancreatitis, high-output enterocutaneous fistulas, bowel obstruction). Central venous access (PICC or central line) is required for TPN to avoid thrombophlebitis. Complications: line sepsis, refeeding syndrome, fatty liver/cholestasis, metabolic bone disease, and hyper/hypoglycemia.

Pellagra

– Systemic nutritional deficiency disease resulting from a lack of niacin (vitamin B₃) or its precursor amino acid, tryptophan. Historically prevalent in populations relying heavily on untreated corn/maize diets. Classic triad (the "3 Ds"): (1) Dermatitis (photosensitive, symmetrical, hyperpigmented scaly rash with Casal collar around neck), (2) Diarrhea (stomatitis, glossitis, nausea, enteritis), and (3) Dementia (insomnia, fatigue, confusion, depression, psychosis, progressing to death—the 4th "D"). Treated with oral nicotinamide supplementation.

Percutaneous Endoscopic Gastrostomy (PEG)

– Endoscopic procedure establishing a durable enteral feeding access route by placing a tube through the anterior abdominal wall directly into the stomach; indicated for long-term enteral nutrition ($>$

4–6 weeks) in dysphagic or neurologically impaired patients.

Peripheral Parenteral Nutrition (PPN)

- Administration of low-osmolality (< 900 mOsm/L) IV nutrient formulations via a peripheral vein for short durations (< 10 – 14 days); limited by large fluid volume requirements and risk of peripheral vein thrombophlebitis.

Protein-Energy Malnutrition (PEM)

- Spectrum of clinical conditions resulting from inadequate dietary intake of protein and calories to meet metabolic demands, encompassing Kwashiorkor, Marasmus, and marasmic kwashiorkor; highly prevalent in hospitalized patients and developing countries.

Refeeding Syndrome

- Potentially fatal metabolic complication occurring when aggressive nutritional reintroduction (oral, enteral, or parenteral) is initiated in severely malnourished, starved, or anorexic patients. Pathophysiology: carbohydrate loading causes insulin release, driving cellular uptake of glucose along with phosphate, potassium, and magnesium. Rapid intracellular shift leads to severe hypophosphatemia, hypokalemia, and hypomagnesemia, resulting in cardiac arrhythmias, heart failure, respiratory failure, seizures, delirium, and sudden death. Prevention: "start low and go slow" feeding protocols with immediate thiamine supplementation and close monitoring/repletion of serum electrolytes.

Rickets

- Metabolic bone disease in infants and children caused by Vitamin D deficiency or inadequate calcium intake, leading to defective mineralization of growing growth plates. Clinical features: craniotables, rachitic rosary (enlarged costochondral junctions), bow legs (genu varum), and delayed closure of fontanelles.

Rickets & Osteomalacia

- Defective bone mineralization resulting from inadequate active vitamin D, calcium, or phosphate. Rickets occurs in growing children before epiphyseal plate closure, presenting with delayed fontanelle closure, frontal bossing, rachitic rosary (beading of costochondral junctions), Harrison groove, bowing

of legs (genu varum), and widened epiphyses. Osteomalacia occurs in adults after epiphyseal closure, presenting with diffuse bone pain, muscle weakness, waddling gait, and pseudofractures (Looser zones) on X-rays. Treated with ergocalciferol / cholecalciferol and calcium supplementation.

Scurvy

- Nutritional deficiency disease caused by severe lack of vitamin C (ascorbic acid), an essential cofactor for prolyl and lysyl hydroxylase enzymes required for stable collagen triple-helix cross-linking. Defective collagen synthesis causes capillary fragility, impaired wound healing, and bone abnormalities. Clinical features: perifollicular hemorrhages, corkscrew hairs, swollen bleeding gums, loose teeth, petechiae, ecchymoses, hemarthrosis, anemia, fatigue, and poor wound healing. Prevented and rapidly cured with oral vitamin C (ascorbic acid) supplementation.

Secondary Malnutrition

- Malnutrition resulting not from inadequate food supply, but from underlying medical conditions that impair nutrient absorption, digestion, or metabolic utilization (e.g., celiac disease, Crohn's disease, cystic fibrosis).

Selenium Deficiency

- Nutritional deficit predisposing to Keshan Disease (endemic congestive cardiomyopathy in children/young women in selenium-poor soil regions) and Kashin-Beck Disease (osteoarthropathy), as selenium is a required cofactor for antioxidant enzyme Glutathione Peroxidase.

Subjective Global Assessment (SGA)

- Validated clinical tool for assessing nutritional status at bedside based on features of history (weight change, dietary intake, GI symptoms, functional capacity) and physical exam (loss of subcutaneous fat, muscle wasting, ankle edema); classifies patients as Well Nourished (SGA A), Moderately Malnourished (SGA B), or Severely Malnourished (SGA C).

Thermic Effect of Food (TEF)

- Energy expended above resting metabolic rate for the digestion, absorption, transport, and assimilation of ingested nutrients; accounts for approximately 10% of total daily energy expenditure.

Total Daily Energy Expenditure

(TDEE)

- Total calories burned by an individual in 24 hours, calculated as the sum of Basal Metabolic Rate (BMR), Thermic Effect of Food (TEF, ~ 10%), and Non-Exercise Activity Thermogenesis (NEAT) plus Exercise Activity Thermogenesis (EAT).

Total Parenteral Nutrition (TPN)

- Complete intravenous administration of all essential nutrients (hypertonic dextrose, amino acids, lipid emulsions, electrolytes, vitamins, trace elements) via a central venous catheter (PICC, subclavian line) in patients with a non-functional or inaccessible gastrointestinal tract.

Trace Elements (Zinc, Copper, Selenium, Chromium)

- Essential inorganic minerals required in microgram to milligram quantities for catalytic enzyme activity and cellular regulation. Zinc: cofactor for > 300 enzymes (alkaline phosphatase, RNA polymerase); deficiency causes acrodermatitis enteropathica, delayed wound healing, hypogeusia, and growth failure. Copper: cofactor for cytochrome c oxidase, ceruloplasmin, superoxide dismutase; deficiency causes microcytic anemia, neutropenia, and neurodegeneration. Selenium: component of glutathione peroxidase; deficiency causes Keshan disease (cardiomyopathy). Chromium: enhances insulin action; deficiency causes glucose intolerance.

Vitamin A Deficiency

- Leading cause of preventable childhood blindness worldwide. Causes Xerophthalmia (dry eyes), Bitot spots (foamy keratin plaques on conjunctiva), Night Blindness (nyctalopia due to rod dysfunction), Keratomalacia (corneal ulceration/melting), and follicular hyperkeratosis.

Vitamin A Deficiency (Xerophthalmia)

- Major nutritional cause of preventable blindness in developing countries. Vitamin A (retinol) is essential for rhodopsin synthesis in retinal rod cells and epithelial tissue integrity. Early manifestation: nyctalopia (night blindness). Progressive manifestations (Xerophthalmia spectrum): conjunctival xerosis, Bitot spots (foamy triangular plaques on bulbar conjunctiva), corneal xerosis, and corneal ulceration/keratomalacia leading to irreversible blindness. Systemic effects: squamous metaplasia of respira-

tory/urinary epithelia, impaired immunity, and increased child mortality from measles and diarrhea.

Vitamin B12 Deficiency

- Deficiency of cobalamin caused by pernicious anemia (anti-intrinsic factor antibodies), gastric bypass, or strict vegan diet. Causes Megaloblastic Anemia (with hypersegmented neutrophils) and Subacute Combined Degeneration (SCD) of the spinal cord (posterior and lateral column demyelination causing loss of vibration/proprioception and spastic paraparesis).

Vitamin B12 Deficiency (Pernicious Anemia)

- Nutritional or malabsorptive deficiency of cobalamin (vitamin B₁₂), essential for DNA synthesis (methionine synthase) and fatty acid metabolism (methylmalonyl-CoA mutase). Causes: pernicious anemia (autoimmune destruction of parietal cells / intrinsic factor deficiency), strict vegan diet, gastrectomy, terminal ileal resection, or Crohn disease. Clinical manifestations: megaloblastic anemia (hypersegmented neutrophils, elevated MCV), glossitis ("beefy red tongue"), and neurological impairment—Subacute Combined Degeneration (SCD) of the spinal cord (demyelination of posterior and lateral columns causing loss of vibration/proprioception, spastic paraparesis, ataxia).

Vitamin D Deficiency

- Deficiency resulting from inadequate sunlight exposure or dietary intake, measured by serum 25(OH)D < 20 ng/mL. Leads to impaired intestinal calcium absorption, secondary hyperparathyroidism, Rickets in children, and Osteomalacia / Osteoporosis in adults.

Vitamin E Deficiency

- Rare deficiency causing hemolytic anemia in premature infants, spinocerebellar ataxia, loss of proprioception/vibration, and muscle weakness, resembling Friedreich ataxia.

Vitamin K Deficiency

- Coagulopathy caused by inadequate Vitamin K, leading to impaired *gamma*-carboxylation of clotting factors II, VII, IX, X, and proteins C/S; presents with prolonged Prothrombin Time (PT/INR) and hemorrhagic disease of the newborn.

Vitamin K Deficiency (Coagulopa-

thy)

– Lack of vitamin K (phylloquinone/menaquinone), an essential cofactor for gamma-glutamyl carboxylase, which converts precursor proteins into active clotting factors II, VII, IX, X, and proteins C and S. Causes: broad-spectrum antibiotic therapy (disrupts gut flora synthesis), severe fat malabsorption (biliary obstruction, celiac disease), or malnutrition. Clinical presentation: bleeding diathesis (ecchymoses, epistaxis, mucosal bleeding, hematuria, prolonged PT/INR). Newborns are uniquely vulnerable (Hemorrhagic Disease of the Newborn / Vitamin K Deficiency Bleeding) due to poor placental transfer and sterile gut; prevented by routine IM vitamin K administration at birth.

Water-Soluble Vitamins

– Group of vitamins (Vitamin C and B-complex vitamins) that dissolve in water, are not stored in significant quantities in the body (except Vitamin B12), and require regular dietary intake to prevent deficiency.

Xerophthalmia

– Spectrum of ocular manifestations of severe Vitamin A deficiency, progressing from night blindness and conjunctival xerosis to Bitot spots, corneal xerosis, and irreversible corneal ulceration (keratomalacia).

Zinc Deficiency

– Nutritional or inherited deficit (Acrodermatitis Enteropathica) causing acral and periorificial dermatitis, alopecia, chronic diarrhea, impaired wound healing, hypogeusia (decreased taste acuity), impaired cell-mediated immunity, and hypogonadism in males.

Chapter 6

Dentistry

Apical Periodontitis

– Inflammation and destruction of the periradicular tissues (periodontal ligament and alveolar bone at the apex) caused by bacterial infection of the root canal system (necrotic pulp). Presents with pain on biting/percussion (symptomatic) or asymptomatic with radiographic periapical radiolucency (asymptomatic). Acute apical abscess: severe pain, swelling (facial cellulitis, space infection), fever, and malaise. Chronic apical periodontitis: asymptomatic, well-defined periapical radiolucency. Phoenix abscess: acute exacerbation of chronic lesion. Treatment: root canal therapy (remove infected pulp, clean, shape, disinfect, and obturate the root canal system). Incision and drainage for fluctuant swelling (through the gingiva or mucosa). Antibiotics: for systemic signs, facial swelling, or immunocompromised patients (amoxicillin, clindamycin if penicillin-allergic).

Apicoectomy (Root-End Resection)

– A surgical endodontic procedure performed when conventional root canal therapy or retreatment is unsuccessful due to persistent apical disease. Indications: persistent apical periodontitis after RCT, obstructed canal (calcification, separated instrument, broken file), apical perforation, root-end cyst, and biopsy of periapical lesion. Procedure: local anesthesia, full-thickness mucoperiosteal flap elevation, osteotomy (bone window) to access the root apex, apical root-end resection (3 mm of apex removed), ultrasonic root-end preparation (3 mm deep), root-end filling (MTA mineral trioxide aggregate or Super-EBA), and flap repositioning/suturing. Success rate: 75-90% with MTA apical seal. Post-operative: mild to moderate pain, swelling, avoid heavy chewing for

1 week.

Bridge (Fixed Partial Denture)

– A fixed dental prosthesis that replaces one or more missing teeth by attaching to adjacent natural teeth (abutments) or implants. Typical: a three-unit bridge (two abutments, one pontic — artificial tooth replacing the missing tooth). Types: traditional (full-coverage crowns on abutments, pontic in between), cantilever (pontic supported on only one side — more conservative but higher failure rate), resin-bonded/Maryland bridge (wings bonded to the lingual surfaces of adjacent teeth — minimal tooth reduction, for single anterior tooth replacement), and implant-supported bridge (most conservative of adjacent teeth — no preparation of healthy adjacent teeth). Pontic design: modified ridge-lap or ovate pontic (hygienic, esthetic). Materials: PFM, full ceramic (lithium disilicate, zirconia), and metal. Relative contraindications: long span, heavy occlusal forces (bruxism), short clinical crowns (insufficient retention). Longevity: 10-15 years. Failure: abutment tooth fracture/decay (most common, 10-20% at 10 years), debonding, and pontic fracture.

Bruxism

– A repetitive jaw-muscle activity characterized by clenching or grinding of the teeth, occurring during sleep (sleep bruxism) or wakefulness (awake bruxism). Prevalence: 8-15% of adults, up to 30% of children. Etiology: multifactorial — psychosocial stress, anxiety, sleep disorders (OSA, snoring), occlusal interference, genetics, caffeine, alcohol, smoking, and certain medications (SSRIs have been implicated — may cause or worsen). Clinical consequences: tooth wear/attrition (incisal and occlusal surfaces — flattened cusps, exposed dentin), tooth sensitivity, fractures of restorations/cusps,

masticatory muscle hypertrophy (masseter hypertrophy visible), TMJ pain, morning headache, and tongue/cheek scalloping. Diagnosis: clinical exam (wear facets), history (reports of grinding from bed partner), and polysomnography (for sleep bruxism, definitive, shows rhythmic masticatory muscle activity RMMA). Treatment: occlusal splint/night guard (hard acrylic or soft, reduces wear and muscle activity), stress management, biofeedback, sleep hygiene, and in severe cases, botulinum toxin injection into masseter and temporalis muscles. Pharmacotherapy: clonidine, clonazepam (low-dose, short-term). No cure; management is symptomatic.

Composite Resin (Tooth-Colored Filling)

– An esthetic dental restorative material composed of a resin matrix (Bis-GMA, UDMA, TEGDMA) filled with inorganic particles (silica, barium glass, zirconia). Categories by filler size: microfilled (0.04 μm , polishable but weak, for anterior), hybrid (0.5-1 μm + microfillers, universal), nanofilled/nanohybrid (5-100 nm nanoparticles, best properties). Advantages: esthetic (color matched to the tooth), minimal tooth preparation (bonded restoration, preservation of sound tooth structure), and repairable. Application: acid-etch (37% phosphoric acid for 15-30 seconds — removes smear layer, creates microporosity for micro-mechanical bond), apply bonding agent (primer + adhesive), place composite in increments (<2 mm each to reduce polymerization shrinkage), light-cure (LED light 400-500 nm for 10-40 seconds), finish and polish. Polymerization shrinkage: 1.5-3%, can cause marginal gaps, post-operative sensitivity, microleakage, and secondary caries. Bulk-fill composites (can be placed in 4-5 mm increments) reduce technique sensitivity. C-factor: ratio of bonded to unbonded surfaces; higher C-factor = more shrinkage stress. Longevity: 5-8 years in posterior teeth, longer in anterior.

Crown (Dental Crown)

– A full-coverage dental restoration that encases the entire visible portion of a tooth above the gum line, restoring its shape, size, strength, and appearance. Indications: large caries/cracks (insufficient tooth structure for a filling), crown fracture, after root canal therapy (posterior teeth — endodontically treated teeth are brittle), cosmetic enhancement,

and as a bridge abutment. Crown materials: full metal (gold alloy — most durable, wear-resistant, minimal tooth reduction — 1-1.5 mm), PFM (porcelain fused to metal — good esthetics and strength, metal margin may show with gingival recession), all-ceramic (lithium disilicate — e.max, most esthetic, high strength, 1-1.5 mm reduction), and zirconia (yttria-stabilized zirconia — highest strength, used for posterior crowns and bridges, CAD/CAM fabricated, opaque). Preparation: 1-2 mm tooth reduction circumferentially with a shoulder or chamfer margin. Impression: digital (intraoral scanner — iTero, Trios, PrimeScan) or conventional (polyvinyl siloxane or alginate). Temporary crown: acrylic or bis-acryl composite temporary for 1-2 weeks while the permanent crown is fabricated. Cementation: resin cement (for ceramic and zirconia), glass ionomer, or zinc phosphate. Longevity: 10-15+ years, with proper hygiene and regular recall.

Deep Sedation and General Anesthesia in Dentistry

– Pharmacologically induced states of consciousness suppression for dental treatment, used for patients with severe dental phobia, special needs (developmental delay, autism, cerebral palsy), young children requiring extensive treatment, and lengthy/complex surgical procedures (impacted third molars, dental implants, orthognathic surgery). Practitioner: DDS/DMD with a dental anesthesia residency permit or certified registered nurse anesthetist (CRNA). Levels: moderate conscious sedation (IV: midazolam, fentanyl; oral: triazolam, hydroxyzine — patient can maintain airway and respond to verbal commands), deep sedation (propofol, ketamine — purposeful response to painful stimulation, may require airway support), and general anesthesia (endotracheal intubation, controlled ventilation). Monitoring: pulse oximetry, capnography, ECG, NIBP. Patient selection: ASA I-II generally safe, ASA III-IV require medical consultation. Risks: respiratory depression (opioids, propofol), laryngospasm, aspiration, hypotension, cardiac arrhythmia. Recovery: monitored PACU with Aldrete scoring.

Dental Abscess

– A localized collection of pus in the oral cavity, classified by origin: periapical (from necrotic pulp — most common), periodontal (from periodontal

pocket), and pericoronal (pericoronitis around partially erupted tooth, most commonly lower third molar). Signs: severe, throbbing pain, tooth tender to percussion (periapical), swelling (intraoral, extraoral, facial), cellulitis (diffuse swelling, systemic involvement — Ludwig angina for submandibular space infection, life-threatening airway compromise), lymphadenopathy, fever, and malaise. Radiographic: periapical radiolucency (periapical abscess may not be visible early — bone demineralization >30% needed for radiographic visibility). Treatment: establish drainage (root canal therapy — access the pulp chamber and allow drainage through the canal, or incision and drainage for fluctuant swelling), removal of the cause (RCT, extraction), and antibiotics for systemic involvement (amoxicillin 500 mg TID x 5-7 days, clindamycin 300 mg QID if penicillin-allergic). Severe infections: IV antibiotics, hospital admission, and surgical drainage.

Dental Calculus

- See Tartar (Dental Calculus).

Dental Caries (Tooth Decay)

- A chronic, progressive, multifactorial disease characterized by demineralization of tooth enamel and dentin by organic acids produced by bacterial fermentation of dietary carbohydrates. Etiology: cariogenic bacteria (*Streptococcus mutans*, *Lactobacillus*, *Actinomyces*), fermentable carbohydrates (sucrose most cariogenic), susceptible tooth surface, and time. Caries classification: pit and fissure (occlusal surfaces), smooth surface (interproximal, buccal/lingual), root caries (exposed root surfaces in recession), and recurrent caries (around existing restorations). Depth: incipient/reversible (enamel only, white spot lesion), moderate (dentin involvement, may be reversible if <1/3 into dentin), deep (approaching pulp, risk of pulpitis), and pulpal involvement (pulpitis, necrosis). Diagnosis: visual-tactile exam (ICDAS criteria), bitewing radiographs (detect interproximal caries not visible clinically), transillumination (DiFOTI), and laser fluorescence (DIAGNOdent). Prevention: fluoride (toothpaste, varnish, water fluoridation), dietary counseling (limit sugar frequency), pit and fissure sealants, and regular recall visits. Treatment: minimally invasive (resin infiltration for incipient lesions, GI/temporary), direct restoration (composite resin,

amalgam, glass ionomer), indirect restoration (inlay/onlay/crown), and root canal therapy for pulpal involvement. ICDAS (International Caries Detection and Assessment System): codes 0-6 based on visual appearance from sound to extensive cavitation.

Dental Emergencies

- severe toothache, knocked-out teeth, cracked or fractured teeth, abscesses, and uncontrolled bleeding from the mouth. A knocked-out permanent tooth should be placed back in the socket or in milk and seen by a dentist within 30 minutes for the best chance of reimplantation. Dental abscesses require prompt treatment to prevent spread of infection to adjacent tissues or the bloodstream.

Dental Health

- Dental health involves the care of teeth, gums, and supporting structures to prevent common problems like cavities, gum disease, and tooth loss. Regular brushing with fluoride toothpaste, flossing, and professional cleanings control plaque buildup and detect issues early. Poor dental health is linked to systemic conditions including cardiovascular disease, diabetes complications, and adverse pregnancy outcomes.

Dental Public Health

- The non-clinical dental specialty focused on preventing oral disease and promoting oral health at the population level through community-based programs, policy development, and research. Activities: community water fluoridation (optimal 0.7 mg/L, reduces caries by 25-40%), school-based sealant programs, fluoride varnish programs, oral health education, epidemiology of oral disease (NHANES data), and access-to-care initiatives. Key metrics: DMFT index (Decayed, Missing, Filled permanent Teeth), DMFS (surfaces), dmft for primary dentition. Public health challenges: disparities in oral health access (low-income, rural, racial/ethnic minorities), dental caries prevalence (most common chronic disease of childhood — 5x more common than asthma), and oral cancer screening.

Dentin

- The calcified tissue of the tooth that lies beneath the enamel (crown) and cementum (root), forming the bulk of the tooth. Dentin is composed of approximately 70% hydroxyapatite (mineral), 20% organic

matrix (primarily type I collagen), and 10% water. It contains microscopic tubules (dentinal tubules) that radiate from the pulp chamber to the enamel-dentin junction, housing odontoblast processes and allowing transmission of sensory stimuli (heat, cold, pressure) to the pulp as pain. Dentin is produced by odontoblasts throughout life (secondary and tertiary dentin). When exposed by caries or attrition, dentin hypersensitivity may occur. Dentinogenesis imperfecta is a genetic disorder causing opalescent, weakened dentin.

Dentition

– The arrangement, number, and type of teeth in the dental arch at a given stage of life. Primary dentition (deciduous teeth, baby teeth): 20 teeth, erupting from 6 months to 2.5 years. Mixed dentition: phase when both primary and permanent teeth are present (6–12 years). Permanent dentition (adult): 32 teeth including 8 incisors, 4 canines, 8 premolars, and 12 molars (including 4 third molars/wisdom teeth). Eruption timing varies but follows a predictable sequence. Dental formula records the number and type of teeth in each quadrant. Abnormalities: anodontia (congenital absence), supernumerary teeth (extra teeth), malocclusion, and impacted teeth.

Denture

– A removable dental prosthesis that replaces missing teeth and adjacent tissues. Complete denture: replaces all teeth in an arch (maxillary or mandibular). Immediate denture: placed immediately after extraction of remaining teeth (allows patient to never be without teeth; requires relining after bone resorption). Partial denture (RPD — removable partial denture): replaces some but not all teeth in an arch; held in place by clasps (cast metal — cobalt-chromium, or flexible nylon Valplast) and rests on abutment teeth. Implant-retained overdenture: denture that snaps onto 2-4 dental implants (greatly improved retention and stability, especially for the mandibular complete denture — 95% of lower denture problems solved by 2 implants). Implant-supported fixed complete denture: fixed prosthesis on 4-6 implants (All-on-4 concept). Adaptation period: 2-4 weeks for speech, eating, and saliva control. Denture stomatitis (denture sore mouth): *Candida albicans* infection under the denture — improved

by removing the denture at night, proper cleaning, and antifungal (nystatin, clotrimazole). Complications: poor fit due to bone resorption (requires reline — hard or soft tissue conditioner), fracture (may require repair), and sore spots (adjustment with acrylic bur).

Dry Socket (Alveolar Osteitis)

– A common post-extraction complication characterized by severe, throbbing pain starting 2-3 days after tooth extraction, caused by premature loss of the blood clot from the extraction socket, exposing underlying bone. Risk factors: tobacco use (nicotine reduces blood supply, clot dissolution from sucking), traumatic extraction, oral contraceptives (estrogen increases fibrinolysis), poor oral hygiene, and mandibular teeth (especially third molars — higher density bone, less blood supply). Treatment: gentle socket irrigation with warm saline to clear debris, placement of a medicated dressing (Alvogyl — butamben, eugenol, iodoform; or eugenol-soaked ribbon gauze — zinc oxide-eugenol) for immediate pain relief, and NSAIDs. The dressing may need to be changed every 1-3 days for 5-10 days until granulation tissue covers the bone. Prevention: post-operative instructions (no smoking, no spitting, no drinking through straws for 48-72 hours).

Endodontics

– The dental specialty concerned with the morphology, physiology, and pathology of the dental pulp and periradicular tissues. Endodontists perform root canal therapy (pulpectomy, pulpotomy), root canal retreatment (for failed prior RCT), endodontic surgery (apicoectomy — root-end resection with retrograde filling), and management of traumatic dental injuries (crown fractures, root fractures, luxation, avulsion). Common diagnoses: irreversible pulpitis (severe, lingering pain to thermal stimuli), pulp necrosis (no response to cold, periapical radiolucency), and acute apical abscess (pain, swelling, drainage). Treatment involves cleaning and shaping the root canal system (hand files and rotary NiTi files), disinfection (sodium hypochlorite irrigation 1-6%, chlorhexidine, calcium hydroxide), and obturation (gutta-percha with sealer). Cone-beam CT (CBCT) is used for complex anatomy (extra canals, root resorption, fractures). Success rate: >90% for initial root canal treatment.

General Dentistry

– The primary dental care provider responsible for the diagnosis, prevention, and treatment of common oral diseases including dental caries (cavities), periodontal disease, and oral pathology. General dentists perform restorative procedures (fillings, crowns, bridges), simple extractions, root canal therapy, and preventive care (cleanings, fluoride, sealants). They also coordinate comprehensive treatment plans and refer to specialists when needed. Patients are typically seen every 6 months for routine recall examinations and prophylaxis.

Gingival Hyperplasia (Overgrowth)

– Abnormal enlargement of the gingiva. Drug-induced: phenytoin (antiepileptic — most severe, 50% of patients), cyclosporine (immunosuppressant, 30%), and calcium channel blockers (nifedipine, amlodipine — 20%). Other causes: hereditary gingival fibromatosis (rare, autosomal dominant), hormonal (pregnancy, puberty), inflammatory (chronic plaque-induced gingivitis), and leukemic infiltration (acute monocytic/myelomonocytic leukemia). Presents: firm, pink, lobulated enlargement of the interdental papillae and marginal gingiva, may cover the clinical crowns. Bleeding and secondary inflammation common when plaque control is poor. Treatment: improved oral hygiene (reduces inflammatory component, drug-induced overgrowth persists), chlorhexidine mouthwash, surgical excision (gingivectomy with scalpel, electrosurgery, or laser — CO₂, diode). Discontinuation or substitution of the causative drug if possible (consult with prescribing physician). Phenytoin substitute: levetiracetam, lamotrigine. Recurrence is common if the drug continues.

Gingivitis

– Reversible inflammation of the gingiva (gums) caused by bacterial plaque biofilm accumulation at the gingival margin. Clinical signs: erythema, edema (blunted papilla), bleeding on probing (BOP — first sign, before visible redness), and loss of gingival stippling. No bone loss or clinical attachment loss (true gingivitis). Pregnancy gingivitis: hormone-mediated exaggerated response to plaque in the second/third trimester. Gingival hyperplasia/enlargement: phenytoin, cyclosporine, calcium

channel blockers, and hormonal changes. Treatment: professional prophylaxis (scaling and polishing), improved oral hygiene (brushing twice daily, flossing, antigingivitis toothpaste — stannous fluoride, triclosan), and chlorhexidine mouthwash for short-term use. Resolution: 10-14 days with plaque control.

Impacted Tooth

– A tooth that fails to fully erupt into the normal functional position within the expected time frame, most commonly the third molars (wisdom teeth — 90% of impactions), followed by maxillary canines (2-3%), mandibular premolars, and maxillary central incisors (mesiodens, supernumerary). Third molar impaction classification: relationship to the ramus and second molar (Classes I, II, III), depth (Level A, B, C), and angulation (mesioangular most common, vertical, horizontal, distoangular). Indications for extraction: pericoronitis (recurrent infection of the operculum over partially erupted tooth), caries on the distal of the second molar, non-restorable caries, periodontal disease, root resorption, orthodontic reasons, cyst formation (dentigerous cyst), and prophylactic removal (controversial, NICE guidelines recommend against routine). Complications of extraction: dry socket (alveolar osteitis — most common, 1-5%, severe pain 2-3 days post-op, treat with irrigation and medicated dressing — Alvogyl, eugenol paste), inferior alveolar nerve injury (temporary 5-10%, permanent <1%), lingual nerve injury, maxillary sinus communication, mandible fracture (rare), and infection.

Ludwig Angina

– A severe, rapidly spreading cellulitis of the sublingual, submandibular, and submental spaces, most commonly from an odontogenic source (lower second/third molar infection). Life-threatening due to airway compromise from massive bilateral swelling elevating and posteriorly displacing the tongue (airway obstruction). Signs: bilateral submandibular swelling (bull neck appearance), elevation of the tongue, trismus, dysphagia, drooling, fever, and impending airway obstruction. Pathogens: *Streptococcus viridans*, anaerobes (*Peptostreptococcus*, *Bacteroides*, *Fusobacterium*), and mixed oral flora. Airway management is the priority: awake fiberoptic intubation or cricothyrotomy/tracheostomy (may

be extremely difficult — early intervention before deterioration). Empiric IV antibiotics: high-dose penicillin + metronidazole (or ampicillin-sulbactam, clindamycin). Surgical drainage: bilateral submandibular and submental incisions with placement of Penrose drains. Extraction of the causative tooth. ICU monitoring.

Malocclusion

– Misalignment or incorrect positioning of the teeth when the jaws are closed, affecting function (chewing, speech) and/or aesthetics. Angle classification: Class I (neutroclusion — normal molar relationship, but teeth may be crowded, rotated, spaced), Class II (retrognathism — mandible posterior to maxilla, overjet — typically >3-4 mm, Division 1: protruding maxillary incisors, Division 2: retroclined central incisors), Class III (prognathism — mandible anterior to maxilla, anterior crossbite, underbite). Other descriptors: overjet (horizontal overlap of maxillary incisors over mandibular, normal 2-3 mm), overbite (vertical overlap, normal 2-3 mm, deep bite >5 mm or covering >50% of lower incisors), open bite (anterior or posterior, no vertical overlap), crossbite (anterior or posterior, buccal or lingual), crowding, spacing, midline deviation, and impacted teeth. Etiology: genetic (skeletal discrepancies), environmental (thumb sucking, tongue thrust, mouth breathing, early loss of primary teeth), and acquired (periodontal disease, trauma). Treatment: orthodontic (braces, aligners, expanders, headgear), orthognathic surgery (for severe skeletal discrepancy), and restorative (crowns, veneers to correct minor malocclusion).

Mesiodens

– The most common supernumerary tooth (extra tooth), located in the midline of the maxilla between the central incisors, shaped like a peg or cone. Prevalence: 0.15-1.9%, more common in males (2:1). May be single or multiple, erupted or impacted. Complications: delayed eruption or impaction of permanent central incisors, midline diastema, root resorption of adjacent teeth, and cyst formation (dentigerous cyst). Most are asymptomatic and found incidentally on radiographs (occlusal or panoramic). Management: early removal (when roots of central incisors are 2/3 formed, around age 8-9) prevents orthodontic complications. Orthodontic closure of

space after extraction. Associated with cleidocranial dysplasia and Gardner syndrome.

Mucogingival Deformity

– Condition involving the relationship between the gingiva and oral mucosa. Gingival recession (most common): apical migration of the gingival margin exposing the root surface, classified by Miller classification (Class I: not extending to mucogingival junction; Class II: extending to/beyond MGJ but no interproximal loss; Class III: interproximal loss; Class IV: severe interproximal loss). Causes: traumatic brushing, periodontal disease, tooth position (prominent root), thin biotype/fenestration, orthodontic movement, and frenum pull. Clinical: root exposure, dentin hypersensitivity (cold, air, touch), esthetic concern, and root caries risk. Treatment: non-surgical (desensitizing toothpaste, bonding/glass ionomer for root coverage), surgical root coverage (coronally advanced flap, subepithelial connective tissue graft — SCTG from the palate — gold standard for Class I and II, acellular dermal matrix allograft ADM, tunneling technique, and pinhole surgical technique). Free gingival graft (FGG): increases the zone of attached gingiva, not primarily for root coverage.

Odontology

– The scientific study of the structure, development, and diseases of the teeth and associated oral structures. Odontology encompasses dental anatomy, oral pathology, forensic odontology (identification of human remains through dental records, bite mark analysis), and clinical dentistry. Forensic odontology is particularly valuable when other identification methods fail, as teeth are the most durable structures in the human body and survive fire, decomposition, and trauma. Dental age estimation (through eruption patterns and cemental annulation) aids in both forensic identification and legal age determination.

Oral and Maxillofacial Surgery (OMFS)

– The dental specialty that diagnoses and surgically treats diseases, injuries, and defects of the mouth, jaws, face, and neck. Scope: dentoalveolar surgery (impacted third molar extraction — wisdom teeth, surgical extractions, pre-prosthetic surgery), dental implant placement, orthognathic surgery (cor-

rective jaw surgery for malocclusion, skeletal discrepancies — Le Fort I maxillary osteotomy, bilateral sagittal split osteotomy BSSO for mandible), temporomandibular joint surgery (arthrocentesis, arthroscopy, discectomy, total joint replacement), facial trauma (mandible fractures, Le Fort II/III mid-face fractures, zygomaticomaxillary complex ZMC fractures, orbital floor blowout fractures, nasal fractures), oral pathology (biopsy, excision of lesions, management of oral cancer — composite resection, neck dissection, microvascular reconstruction), cleft lip and palate repair, and cosmetic facial surgery (rhinoplasty, facelift, blepharoplasty). Training: 4-6 year residency after dental school, often with an MD degree.

Oral Medicine

– The dental specialty focused on the oral health care of medically complex patients and the diagnosis and non-surgical management of oral mucosal and orofacial diseases. Areas: oral mucosal diseases (lichen planus, pemphigus vulgaris, mucous membrane pemphigoid, erythema multiforme, Sjogren syndrome — autoimmune exocrinopathy causing xerostomia and dry eyes), orofacial pain (temporomandibular disorders TMD, trigeminal neuralgia, burning mouth syndrome BMS, atypical odontalgia), salivary gland disorders (xerostomia, sialolithiasis, sialadenitis, Sjogren syndrome), oral complications of cancer therapy (mucositis, osteoradionecrosis, xerostomia, infection), and management of patients with systemic disease (diabetes, cardiovascular disease, bleeding disorders, bisphosphonate-related osteonecrosis of the jaw MRONJ).

Oral Pathology

– The dental specialty concerned with the diagnosis and management of diseases of the oral and maxillofacial region. Oral pathologists examine biopsies and provide histopathologic diagnosis. Common oral lesions: aphthous ulcers (canker sores — minor, major, herpetiform, recurrent aphthous stomatitis), herpes labialis (cold sores, HSV-1 reactivation), oral candidiasis (pseudomembranous thrush, erythematous, angular cheilitis), leukoplakia (white patch, cannot be scraped off, premalignant — 10-15% dysplastic), erythroplakia (red patch, higher malignant potential 50-70%), lichen planus (reticular white striae Wickham striae, erosive), oral lichenoid reac-

tion, mucocele (mucus extravasation phenomenon), pyogenic granuloma (pregnancy tumor), fibroma, papilloma, and squamous cell carcinoma (most common oral malignancy, risk: tobacco, alcohol, HPV-16, betel nut).

Oral Squamous Cell Carcinoma (OSCC)

– The most common malignancy of the oral cavity, accounting for >90% of oral cancers. Risk factors: tobacco (smoking and smokeless — 75% of cases), alcohol (synergistic with tobacco), HPV-16 (oropharynx, base of tongue, tonsil — better prognosis), betel nut (Southeast Asia), immunosuppression (HIV, transplant), and sun exposure (lip). Premalignant lesions: leukoplakia (10-15% dysplastic or malignant), erythroplakia (50-70% high-risk), oral submucous fibrosis. Common sites: lateral tongue (most common), floor of mouth, buccal mucosa, gingiva, palate, and lip. Clinical: non-healing ulcer (>2 weeks), red/white patch, exophytic mass, pain, dysphagia, otalgia, loose teeth, cervical lymphadenopathy. Diagnosis: biopsy with histopathology, CT/MRI/PET-CT for staging. Treatment: surgical resection with negative margins (1 cm), neck dissection (therapeutic or elective for N0 with >15-20% occult metastasis risk), primary radiation (for early stage), adjuvant chemoradiation for high-risk features (positive margins, extracapsular nodal extension, perineural invasion). Prognosis: 60-70% 5-year survival for early stage, 30-50% for advanced.

Orthodontics and Dentofacial Orthopedics

– The dental specialty concerned with the diagnosis, prevention, and correction of malocclusion and dentofacial abnormalities. Orthodontists use fixed appliances (braces — metal, ceramic, lingual), clear aligners (Invisalign, Spark, ClearCorrect), and removable appliances to move teeth through bone by applying controlled forces. Key concepts: Angle classification of malocclusion — Class I (neutroclusion, normal molar relationship, may have crowding/spacing), Class II (distocclusion, mandibular retrusion, overjet — Division 1 protruding maxillary incisors, Division 2 retroclined central incisors), Class III (mesiocclusion, mandibular prognathism, anterior crossbite). Cephalometric analysis: assesses skeletal and dental relationships on lateral

cephalogram (SNA, SNB, ANB angles). Treatment phases: Phase I (interceptive, mixed dentition ages 7-10 — expander, partial braces, habit appliances), Phase II (comprehensive, full permanent dentition — braces/aligners, retention). Retention: fixed lingual retainers and/or clear vacuum-formed retainers to prevent relapse. Duration: 12-30 months. Complications: root resorption, white spot lesions (decalcification), gingival inflammation.

Pediatric Dentistry (Pedodontics)

– The dental specialty focusing on oral health care from infancy through adolescence, including children with special health care needs. Services: infant oral health exams (first visit by age 1), caries risk assessment, preventive care (fluoride varnish, sealants), restorative treatment for primary and young permanent teeth (composite fillings, stainless steel crowns for primary molars, pulp therapy), behavior management (tell-show-do, positive reinforcement, nitrous oxide sedation, protective stabilization, general anesthesia for extensive treatment), management of dental trauma (crown fractures, luxation, avulsion — reimplantation within 30 minutes best outcomes), space maintenance after early loss of primary teeth (band-and-loop, lingual arch, Nance appliance), and interceptive orthodontics (habit appliances — thumb/finger habit, tongue thrust). Early childhood caries (ECC): caries in primary teeth before age 6, severe if smooth-surface caries in children <3 years. Nursing/bottle caries: upper incisors affected by night-time bottle feeding.

Periodontal Abscess

– A localized purulent infection in the periodontal pocket wall, usually an acute exacerbation of chronic periodontitis. Presents with ovoid, erythematous, fluctuant swelling on the gingiva along the lateral root surface, severe throbbing pain, tenderness to palpation/probing, tooth mobility, and purulent exudate on probing. The tooth is vital (unlike apical abscess where pulp is necrotic). Radiographic: advanced bone loss, often vertical or crater-shaped defects. Treatment: incision and drainage through the pocket, scaling and root planing (SRP), irrigation with chlorhexidine, occlusal adjustment if traumatic occlusion, and bite-block/tooth-stabilizing splint. Antibiotics if systemic involvement (amoxicillin with or without metronidazole, or clindamycin). Peri-

odontal abscess must be distinguished from periapical abscess (pulp vitality testing, radiographic periapical vs. lateral lesion).

Periodontal Disease

– See Periodontics.

Periodontal (Gum) Disease

– Also known as periodontal disease, an inflammatory condition affecting the gums and supporting structures of the teeth. It begins as gingivitis with redness, swelling, and bleeding of the gums and can progress to periodontitis, causing gum recession, bone loss, and tooth loss. Prevention and treatment involve good oral hygiene, professional dental cleanings, and in advanced cases, scaling, root planing, or surgery.

Periodontics

– The dental specialty concerned with the supporting structures of the teeth (periodontium: gingiva, periodontal ligament, cementum, alveolar bone), including diagnosis and treatment of periodontal disease. Gingivitis: reversible inflammation of the gingiva without bone loss, caused by bacterial plaque biofilm. Periodontitis: destructive inflammatory disease with progressive loss of alveolar bone and connective tissue attachment, classified by stage (I-IV, based on severity and complexity) and grade (A-C, based on rate of progression). Chronic periodontitis (most common): slow progression, adults >30. Aggressive periodontitis: rapid bone loss, younger patients, familial pattern. Necrotizing periodontal diseases: NUG (necrotizing ulcerative gingivitis — pain, fetor oris, pseudomembranes, fever) and NUP (necrotizing ulcerative periodontitis — associated with HIV, severe immunosuppression). Periodontal probing: 6-point pocket depth measurement (normal <3 mm), bleeding on probing (active inflammation), clinical attachment level (CAL). Non-surgical treatment: scaling and root planing (SRP, deep cleaning under local anesthesia). Surgical: flap surgery (open flap debridement), osseous surgery (recontour bone), guided tissue regeneration (GTR with barrier membrane), bone grafting, and platelet-rich plasma (PRP). Maintenance: periodontal maintenance q3-4 months in treated patients.

Prosthodontics

– The dental specialty concerned with the restoration and replacement of teeth using fixed and remov-

able prostheses. Fixed prosthodontics: crowns (full coverage restoration for damaged teeth — metal, PFM, all-ceramic/e.max, zirconia), bridges (fixed partial denture replacing 1-2 missing teeth — traditional cantilever, resin-bonded Maryland bridge, implant-supported bridge), inlays and onlays (partial coverage restorations). Removable prosthodontics: complete dentures (full set for edentulous patients — conventional immediate, implant-retained overdenture), partial dentures (removable partial denture RPD with clasps, precision attachments). Implant prosthodontics: single crowns, implant-retained overdentures, implant-supported fixed complete dentures (All-on-4, All-on-6 concept using 4-6 implants with a full-arch fixed prosthesis). Maxillofacial prosthetics: obturator (for palatal defects after cancer surgery), speech aid prosthesis, nasal/auricular/ocular prosthesis, and radiation stent. Materials: polymethyl methacrylate (PMMA) denture base, cobalt-chromium alloy for RPD frameworks, ceramic (feldspathic, lithium disilicate, zirconia), and composite resin.

Space Maintainer

– A passive appliance used in pediatric dentistry to maintain the space created by the premature loss of a primary tooth, preventing adjacent teeth from drifting into the space and preserving sufficient space for the permanent successor to erupt. Types: band-and-loop (most common, for single tooth loss, unilateral — a band is cemented on the tooth adjacent to the space, with a loop extending across the edentulous space to contact the tooth on the other side), lingual arch (mandibular, maintains space when multiple primary molars are lost), Nance holding appliance (maxillary, similar to lingual arch with an acrylic button on the palate), and distal shoe (extends mesially into the extraction site to guide eruption of the first permanent molar). Crown and loop: for a missing primary molar when the adjacent tooth requires a full crown. Failure of space maintenance: space closure, crowding, impaction of the permanent tooth, and asymmetric eruption.

Submandibular Space Infection

– An infection of the submandibular space, usually from an odontogenic source (mandibular molar periapical infection spreading below the mylohyoid muscle). Presents with unilateral submandibular

swelling, tenderness, and trismus. May progress to Ludwig angina (bilateral involvement with airway compromise). Imaging: CT with contrast (identifies involved spaces and abscess formation). Treatment: surgical drainage through the submandibular approach (incision parallel to the inferior border of the mandible, through platysma into the submandibular space, blunt dissection, Penrose drain), extraction of the causative tooth, and antibiotics (amoxicillin-clavulanate, clindamycin, or penicillin + metronidazole).

Tartar (Dental Calculus)

– Hardened, calcified dental plaque that forms on the teeth, both above the gumline (supragingival calculus) and below the gumline (subgingival calculus). Calculus is primarily composed of calcium phosphate (hydroxyapatite, brushite, whitlockite) and dead bacteria, mineralised from saliva (supragingival) or gingival crevicular fluid (subgingival). It is rough and porous, providing a surface for further plaque accumulation, and is a major risk factor for periodontal disease (gingivitis → periodontitis). Calculus cannot be removed by brushing; it requires professional scaling and root planing (dental cleaning) using ultrasonic scalers and hand instruments (curettes, scalers). Subgingival calculus appears brownish-black (stained by blood products). Tartar control toothpastes (pyrophosphates, zinc citrate) can reduce new calculus formation. Systemic risk factors: smoking (more calculus), xerostomia (less protective saliva), and diet (soft, processed foods).

Teeth

– See Tooth / Teeth and Dentition.

Temporomandibular Joint Disorders (TMJ)

– Temporomandibular joint disorders encompass a group of conditions affecting the jaw joint and the surrounding muscles that control jaw movement. Symptoms include jaw pain, clicking or popping sounds with movement, difficulty chewing, and locking of the jaw, often resulting from bruxism, arthritis, trauma, or malocclusion. Diagnosis is based on clinical examination and imaging when indicated; treatment ranges from conservative measures such as soft foods, stress reduction, and oral splints to physical therapy, medications, and in severe cases, arthrocentesis or surgery.

Temporomandibular Joint Disorder (TMD)

– A group of conditions causing pain and dysfunction in the temporomandibular joint, masticatory muscles, and associated structures. Etiology: multifactorial — malocclusion, bruxism (teeth grinding/clenching), trauma (whiplash, microtrauma), arthritis (osteoarthritis, rheumatoid, psoriatic joint disease), connective tissue disease, stress/anxiety (muscle hyperactivity), and parafunctional habits. Clinical: TMJ pain (preauricular, worse with jaw function), limited mouth opening (<35-40 mm), clicking/popping/crepitus (disc displacement with reduction = click on opening, without reduction = closed lock), locking (open or closed), muscle tenderness (masseter, temporalis, pterygoid), headaches, ear pain. Imaging: panoramic X-ray, CBCT for bone assessment, MRI for disc position and morphology. Treatment: conservative first-line (80% respond) — soft diet, NSAIDs, muscle relaxants, night guard/splint (flat-plane occlusal splint), physical therapy (jaw exercises, ultrasound, TENS), moist heat/ice. Second-line: arthrocentesis (joint lavage), arthroscopy (lysis and lavage, disc repositioning), and corticosteroid injection. Surgical: discectomy, total joint replacement (for severe degenerative disease). Botulinum toxin (Botox) for bruxism and masseter hypertrophy.

TMJ Dislocation

– Anterior displacement of the mandibular condyle from the glenoid fossa, usually occurring during wide mouth opening (yawning, dental treatment, vomiting, intubation). Presents with the mouth open, inability to close, preauricular depression (empty glenoid fossa), deviation of the mandible to the contralateral side, and pain. Diagnosis: clinical, confirmed by panoramic radiograph or CT. Reduction: the operator stands in front of the patient, places thumbs on the posterior mandibular molars (intraoral technique) or on the external oblique ridge, and applies downward and backward pressure to guide the condyle back into the fossa. Gauze between the thumbs to prevent being bitten. Muscle relaxants, sedation, or benzodiazepines may facilitate reduction. Post-reduction: soft diet, avoid yawning widely, NSAIDs. Recurrent dislocation: treated with autologous blood injection, capsular tightening,

eminectomy, or zygomatic arch augmentation.

Toothache (Odontalgia)

– Pain originating from the tooth or its supporting structures. This is the most common reason for emergency dental visits. Common causes: dental caries (most common — deep caries extending to dentin/pulp), pulpitis (reversible: sharp, brief pain to cold/sweet, resolves quickly; irreversible: spontaneous, lingering, throbbing pain to cold, may last minutes), abscess (periapical or periodontal — severe pain, tenderness to biting/percussion), cracked tooth syndrome (sharp, fleeting pain on biting/release — may be intermittent, difficult to diagnose), dry socket (alveolar osteitis — severe post-extraction pain with referral to ear, 2-3 days post-op), pericoronitis (pain/swelling around erupting third molar), sinusitis (maxillary — referred pain to upper teeth, pain on bending forward), and trigeminal neuralgia (electric-shock unilateral pain triggered by light touch). Diagnosis: history (character of pain, duration, triggers), clinical exam (caries probing, percussion, palpation, mobility, periodontal probing), vitality testing (cold test — refrigerant spray, electric pulp tester — or heat test for diagnosis of irreversible pulpitis), and radiographs (bitewing, periapical, panoramic, CBCT). Treatment: depends on diagnosis — restoration (filling/crown), pulp capping, root canal therapy, extraction, periodontal treatment, or anti-inflammatory/muscle relaxant for TMD.

Tooth Decay and Cavities

– Tooth decay, also known as dental caries, is the progressive destruction of tooth enamel and dentin caused by acid produced by bacteria metabolizing sugars in the mouth. The process begins with demineralization of enamel and can progress through the dentin to the pulp, potentially causing pain, infection, and tooth loss. Prevention relies on regular brushing with fluoride toothpaste, flossing, limiting sugary foods and drinks, and professional applications of fluoride or dental sealants, while established cavities are treated with fillings, root canals, or extraction.

Tooth Eruption

– The process by which a tooth moves from its developmental position within the alveolar bone through the oral mucosa into functional occlusion. Primary

(baby/deciduous) teeth: 20 teeth, eruption begins at 6 months (lower central incisors first), complete by 30 months. Order: central incisors (6-10 months), lateral incisors (8-12 months), first molars (12-16 months), canines (16-20 months), second molars (20-30 months). Permanent teeth: 32 teeth, begins at 6 years (first molar, lower central incisor), third molars (wisdom teeth ages 17-25). Timing variability is normal. Delayed eruption: caused by systemic conditions (hypothyroidism, hypoparathyroidism, rickets, cleidocranial dysplasia, Down syndrome) or local factors (over-retained primary tooth, supernumerary tooth, cyst, scar tissue from trauma). Eruption cyst: bluish soft tissue swelling over an erupting tooth in children; resolves spontaneously without treatment. Natal teeth: teeth present at birth (most common lower central incisors, may be mobile — extraction if risk of aspiration or injury during breastfeeding).

Tooth Loss and Dental Implants

– The absence of one or more teeth, most commonly resulting from advanced periodontal disease, severe tooth decay, or trauma, and can impair chewing, speech, and facial aesthetics. Dental implants are titanium posts surgically placed into the jawbone that serve as artificial tooth roots, providing a stable foundation for crowns, bridges, or dentures. Implant-supported restorations offer superior function and longevity compared to traditional removable prosthetics, though they require adequate bone density, good oral hygiene, and a healing period of several months.

Wisdom Tooth (Third Molar)

– The third molar, the last tooth in the dental arch, typically erupting between ages 17 and 25 (hence wisdom tooth). Humans have four third molars (maxillary right and left, mandibular right and left). Wisdom teeth are the most commonly impacted (unerupted or partially erupted) teeth due to insufficient space in the jaw, with an impaction rate of 25-75%. Impaction types: mesioangular (most common, angled forward), distoangular (angled backward), vertical (upright but blocked), horizontal (lying on side, highest risk of mandibular nerve injury during extraction), and buccal/lingual. Complications: pericoronitis (inflammation and infection of the soft tissue around a partially erupted wisdom

tooth, presenting with pain, trismus, swelling, halitosis, and purulent discharge), caries (distal surface of second molar), periodontal disease, cyst formation (dentigerous cyst around the impacted crown), root resorption of adjacent teeth, and rarely tumor (ameloblastoma, odontogenic keratocyst). Management: prophylactic extraction of asymptomatic, disease-free third molars is controversial; NICE guidelines recommend against prophylactic extraction of healthy, non-pathological wisdom teeth. Indications for extraction: recurrent pericoronitis (2+ episodes), caries or periodontal disease not amenable to restoration, pathology (cyst, tumor), external root resorption of the second molar, and for orthodontic reasons (lack of space, relapse prevention). Surgical extraction: performed under local anesthesia, intravenous sedation, or general anesthesia. Assessment: panoramic radiograph (orthopantomogram, OPG) to evaluate root morphology, number of roots (1-4), root curvature, proximity to the inferior alveolar nerve canal (mandibular canal). Complications of extraction: dry socket (alveolar osteitis, 5-10% of mandibular extractions), pain, swelling, trismus, bleeding, infection, and nerve injury (inferior alveolar nerve — lip paraesthesia/anesthesia, incidence 0.5-5%; lingual nerve — tongue paraesthesia, incidence 0.1-2%). Risk of nerve injury is increased with horizontal and distoangular impactions, deep impaction, and when the nerve canal is superimposed on the root tips on OPG.

Chapter 7

Dermatology

Acne Rosacea Subtypes

– Rosacea subtypes include erythematotelangiectatic (persistent facial erythema and flushing), papulopustular (red bumps and pus-filled pimples), phymatous (skin thickening, rhinophyma), and ocular (eye irritation, blepharitis). Demodex mite overgrowth contributes to pathogenesis. Triggers include sun, heat, spicy foods, alcohol, and stress. Treatment includes metronidazole cream, ivermectin cream, oral doxycycline, and laser therapy for telangiectasias.

Acne Vulgaris

– A chronic inflammatory disease of the pilosebaceous unit (hair follicle and associated sebaceous gland), affecting approximately 85 percent of adolescents and young adults between ages 12 and 24, with a prevalence of 12 to 22 percent in young adult women and 3 percent in men, making it the most common skin condition worldwide. Pathogenesis is multifactorial: excess sebum production (driven by androgens, particularly dihydrotestosterone [DHT] converted by 5-alpha-reductase from testosterone by 5-alpha-reductase type 1 in the sebaceous gland), follicular hyperkeratinisation (abnormal desquamation of follicular epithelial cells leading to microcomedone formation), Cutibacterium acnes colonisation and proliferation within the follicle, and inflammation mediated by both innate and adaptive immune responses targeting C. acnes antigens. Comedones (open blackheads and closed whiteheads) are the primary non-inflammatory lesions, while papules, pustules, and nodules represent inflammatory lesions.

Actinic Keratosis

– A premalignant lesion caused by chronic UV exposure, appearing as rough, scaly, erythematous papules on sun-exposed skin. AK is the precursor

to squamous cell carcinoma, with approximately 10 percent progressing to invasive cancer. Risk factors include fair skin, outdoor occupation, immunosuppression, and human papillomavirus co-infection. Field cancerization describes widespread actinic damage. Treatment includes cryotherapy, topical 5-fluorouracil, imiquimod, diclofenac gel, and photodynamic therapy. Regular surveillance for progression to squamous cell carcinoma is necessary.

Actinic Keratosis Management

– Actinic keratosis management requires field-directed and lesion-directed therapy. Lesion-directed: cryotherapy (liquid nitrogen, 5 to 10 second freeze-thaw cycle), curettage, electrodesiccation. Field-directed: 5-fluorouracil cream (1 or 5 percent daily for 2 to 4 weeks), imiquimod cream (3 or 5 percent), diclofenac gel (twice daily for 60 to 90 days), photodynamic therapy (ALA or MAL followed by blue or red light), and topical tirbanibulin. Regular skin cancer screening is essential for patients with regular follow-up and lesion mapping.

Alopecia

– Hair loss from any cause. Androgenetic alopecia (male/female pattern hair loss): most common, related to DHT sensitivity. Alopecia areata: autoimmune, patchy hair loss with potential progression to totalis (scalp) or universalis (entire body). Telogen effluvium: diffuse shedding 2-3 months after a stressor (illness, childbirth, weight loss, medication). Traction alopecia: from tight hairstyles. Scarring alopecias: lichen planopilaris, discoid lupus, frontal fibrosing alopecia. Treatment: minoxidil, finasteride, corticosteroids, JAK inhibitors (for alopecia areata), and hair transplantation.

Alopecia Areata

– A common, autoimmune, non-scarring hair loss disorder affecting approximately 1 to 2 percent of the population worldwide, with a lifetime risk of 2 percent, occurring equally across sexes and ethnicities, with peak onset between 15 and 29 years. Pathogenesis involves loss of immune privilege of the hair follicle: in normal physiology, the hair follicle bulb maintains an immune-privileged microenvironment (low MHC class I expression, production of TGF- β , α -MSH, and IL-15), leading to collapse of the immune-privileged state, with CD8+ cytotoxic T cells attacking the hair follicle bulb (the anagen-stage hair follicle), causing premature catagen entry and cessation of hair growth. The condition presents as well-circumscribed, round to oval, smooth patches of non-scarring hair loss on the scalp or any body hair, and severity ranges from a single patch (patchy AA) to complete scalp hair loss (alopecia totalis) or total body hair loss (alopecia universalis).

Androgenetic Alopecia

– The most common cause of hair loss, affecting 50 percent of men and 25 percent of women by age 50. It is caused by miniaturization of hair follicles driven by dihydrotestosterone (DHT). Male pattern: receding hairline and vertex thinning. Female pattern: diffuse crown thinning with preserved frontal hairline. Treatment: minoxidil 5 percent topical (both sexes), finasteride 1 mg daily (men only), dutasteride, spironolactone (women), low-level laser therapy, and hair transplant. Finasteride and dutasteride are not recommended in women of childbearing potential due to teratogenicity.

Angioedema

– Rapid swelling of the deep dermis/subcutaneous and submucosal tissues (lips, eyelids, tongue, throat, hands, GI tract) due to mast cell mediator release (histamine—allergic/idiopathic, urticaria associated) or bradykinin-mediated (hereditary angioedema—C1 esterase inhibitor deficiency; ACE-inhibitor-induced). Features: non-pitting, non-pruritic swelling; airway involvement (laryngeal edema) is life-threatening. Diagnosis: clinical; C4, C1-INH level/function for hereditary; drug history (ACE inhibitors). Management: acute—airway management, antihis-

tamines/corticosteroids/epinephrine for histaminergic; for bradykinin: C1-INH concentrate, icatibant, ecallantide; stop ACE inhibitors; prophylaxis for hereditary (danazol, C1-INH, lanadelumab).

Atopic Dermatitis

– A chronic, relapsing inflammatory skin disease characterized by intense pruritus and xerosis, with a prevalence of 10 to 20 percent in children and 3 to 7 percent in adults worldwide, with peak onset in infancy (60 percent develop in the first year of life, 85 percent by age 5) and an increasing prevalence in industrialized nations, suggesting an environmental contribution to disease expression. Pathogenesis involves a complex interplay of epidermal barrier dysfunction (filaggrin loss-of-function mutations, the strongest known genetic risk factor, present in 20 to 40 percent of patients), immune dysregulation (TH2/TH22 polarisation with IL-4, IL-13, IL-31, and thymic stromal lymphopoietin overexpression, leading to IgE production, eosinophilia, and pruritus), and altered skin microbiome (Staphylococcus aureus colonisation, reduced microbial diversity). The disease follows a relapsing-remitting course with flares triggered by irritants, allergens, stress, infection, and climatic factors, and follows the atopic march with subsequent development of food allergy, asthma, and allergic rhinitis.

Balanitis

– Inflammation of the glans penis, often involving the prepuce (balanoposthitis). Causes include poor hygiene, irritants (soaps, detergents), infections (Candida albicans most common; also Streptococcus, Gardnerella, Trichomonas), and dermatologic conditions (lichen planus, psoriasis, cicatricial lichen sclerosus/lichen sclerosus et atrophicus). Presents with erythema, swelling, discharge, pruritus, and discomfort. Treatment depends on etiology: antifungals for Candida, antibiotics for bacterial infection, topical corticosteroids for inflammatory causes.

Baldness

– The common term for hair loss or alopecia, most frequently referring to androgenetic alopecia (male or female pattern hair loss). Affects up to 50% of men by age 50 and 25% of women by age 60. Driven by dihydrotestosterone (DHT)-mediated miniaturization of hair follicles in susceptible individuals. Other causes include alopecia areata, telogen effluvium,

traction alopecia, and scarring alopecias. Treatments: topical minoxidil, oral finasteride (men), low-level laser therapy, platelet-rich plasma injections, and hair transplantation.

Barrier Creams

– Topical preparations applied to the skin to create a physical protective layer against irritants, moisture, and pathogens. Common formulations include zinc oxide, petrolatum, dimethicone, and titanium dioxide. Indicated for preventing irritant contact dermatitis (occupational exposure to water, detergents, chemicals), managing incontinence-associated dermatitis, protecting periwound skin from maceration, and preventing moisture-associated skin damage. Barrier creams complement but do not replace regular cleansing and moisturizing.

Basal Cell Carcinoma

– The most common malignant skin tumor worldwide, accounting for approximately 80 percent of non-melanoma skin cancers, with an incidence of over 4 million cases per year in the United States and a lifetime risk of approximately 30 percent in fair-skinned populations. BCC arises from the pluripotent cells of the basal layer of the epidermis and hair follicle epithelium, driven by ultraviolet radiation-induced mutations (pyrimidine dimers, particularly in tumor suppressor genes TP53 and PTCH1), with additional involvement of the Hedgehog signalling pathway (loss of PTCH1 function or, less commonly, activating SMO mutations, leading to uncontrolled proliferation of basal cells). BCC presents as pearly, translucent papules or nodules with telangiectatic vessels, with several clinical subtypes: nodular (most common, pearly nodule with rolled border and central ulceration, so-called rodent ulcer, on the face), superficial (scaly, erythematous patch or thin plaque with thread-like border, most common on the trunk), morphoeic (sclerosing, scar-like plaque with ill-defined borders, high-risk for subclinical extension and recurrence), and pigmented (dark brown or black nodule, more common in darker skin types).

Bedbug Bites

– Cutaneous reactions to bites of *Cimex lectularius* (bedbugs), nocturnal blood-feeding insects. Bites are painless but cause erythematous, pruritic papules, often in a linear arrangement (breakfast,

lunch, dinner sign) or clusters on exposed skin (face, neck, arms, hands). Delayed hypersensitivity develops over days. Some have bullous or urticarial reactions. Diagnosis: clinical; finding bedbugs or blood spots on sheets. Treatment: symptomatic (topical corticosteroids, oral antihistamines). Secondary infection may require antibiotics. Management: professional pest control, wash bedding in hot water, encase mattresses.

Bedsore

– Pressure ulcer (decubitus): localized skin/soft tissue injury from prolonged pressure over bony prominences (sacrum, heels, occiput, trochanters), usually in immobile patients. Stages: 1 (non-blanching erythema), 2 (partial-thickness skin loss/abrasion/blister), 3 (full-thickness to subcutaneous fat), 4 (deep to muscle/bone); unstageable with eschar. Risk: immobility, incontinence, malnutrition, sensory loss, diabetes, poor perfusion. Complications: infection (cellulitis, osteomyelitis, sepsis). Prevention: repositioning (2-hourly), pressure-relieving surfaces, nutrition, skin care. Management: offloading, wound care (debridement, dressings), infection control, and surgical repair for advanced ulcers.

Boil

– Furuncle: an acute, deep infection of a hair follicle (folliculitis that extends to the dermis) by *Staphylococcus aureus*, forming a painful, red, swollen nodule with central purulent core that may spontaneously drain. Multiple or recurrent boils = furunculosis; coalescing boils form a carbuncle (larger, deep, multiple follicles, usually on the neck/back, with fever/systemic symptoms). Risk factors: diabetes, immunosuppression, obesity, poor hygiene, skin trauma, nasal MRSA carriage. Diagnosis: clinical; culture of pus. Management: warm compresses, incision and drainage of fluctuant lesions, antibiotics for surrounding cellulitis/systemic infection or recurrent disease (cover MRSA), and hygiene measures; treat predisposing factors.

Boil (Furuncle)

– A painful, deep-seated infection of a hair follicle caused most commonly by *Staphylococcus aureus*, extending into the surrounding subcutaneous tissue. Presents as a tender, erythematous, fluctuant nodule that eventually discharges pus. When multiple

adjacent follicles coalesce, it forms a carbuncle, often with systemic symptoms. Common sites: neck, face, armpits, and buttocks. Treatment: warm compresses, incision and drainage for fluctuant lesions, and antibiotics for surrounding cellulitis, large lesions, or immunocompromised patients. Recurrent furunculosis may require decolonization (mupirocin nasal ointment, chlorhexidine washes).

Bruising

– Ecchymosis/contusion: a purplish-blue discoloration from blood extravasation into skin/subcutaneous tissue following trauma; color changes with age (red-blue → purple → green/yellow—bilirubin breakdown). Spontaneous or easy bruising suggests: bleeding disorders (thrombocytopenia, hemophilia, von Willebrand), anticoagulant/antiplatelet use, corticosteroid/aging (skin fragility), liver disease, vitamin C/K deficiency, or physical abuse (pattern—hand/finger, belt marks, in children). Small punctate bruises = petechiae (thrombocytopenia, vasculitis). Diagnosis: history (including medications and injury mechanism), exam, and targeted labs (CBC, coagulation, von Willebrand panel) for unexplained bruising. Management: treat cause, protect skin.

Bullae

– Large (>1 cm) fluid-filled blisters; see also vesicle (<1 cm). Classification by level of skin cleavage (important for diagnosis): subcorneal (impetigo, pustular psoriasis), intraepidermal (pemphigus—flaccid bullae, Nikolsky positive; staphylococcal scalded skin), subepidermal (bullous pemphigoid—tense bullae, dermatitis herpetiformis, porphyria cutanea tarda, erythema multiforme, drug reactions). Causes: autoimmune, infection (bullous impetigo, SJS/TEN), drugs, trauma (friction blisters), and inherited (epidermolysis bullosa). Diagnosis: clinical, Nikolsky sign, biopsy with immunofluorescence. Management: treat cause—immunosuppression for autoimmune; wound care; avoid rupture/ infection.

Bullous Pemphigoid

– An autoimmune subepidermal blistering disease affecting elderly patients. It presents with tense blisters on erythematous or normal-appearing skin, often preceded by pruritic urticarial plaques. Autoantibodies target BP180 and BP230 (hemidesmo-

some proteins). Diagnosis is by direct immunofluorescence showing linear IgG and C3 at the basement membrane. Treatment includes high-potency topical or systemic corticosteroids and steroid-sparing agents (doxycycline, azathioprine, mycophenolate mofetil). Rituximab is used for refractory disease. Prognosis is generally good but disease can be chronic with relapses.

Candidal Intertrigo

– A Candida infection of skin folds (axillae, inframammary, inguinal, intergluteal, pannus) characterized by erythematous, macerated plaques with satellite pustules at the periphery. Most common in obese, diabetic, and immunocompromised patients, and with prolonged antibiotic use. Presents with itching, burning, and soreness. Diagnosis: clinical; KOH prep shows pseudohyphae and budding yeasts. Treatment: topical antifungals (clotrimazole, miconazole, nystatin); drying powders; keep skin folds dry. Severe or refractory cases: oral fluconazole. Prevention: weight loss, moisture management, glycemic control.

Carbuncle

– A deep, coalescent infection of multiple adjacent hair follicles by *Staphylococcus aureus* (usually MRSA), forming a larger, swollen, erythematous, painful mass with multiple draining sinuses, most often on the neck, back, or thighs; more serious than a furuncle, commonly with fever, malaise, and systemic infection. Risk factors: diabetes, immunosuppression, obesity. Complications: cellulitis, abscess, bacteremia, sepsis. Diagnosis: clinical; cultures (blood, pus). Management: incision and drainage, systemic antibiotics (cover MRSA), glycemic control, and treatment of risk factors.

Chemical Peels

– Chemical peels use acids to exfoliate skin layers. Superficial peels (glycolic acid 20 to 70 percent, salicylic acid 20 to 30 percent) affect the epidermis. Medium peels (trichloroacetic acid 35 to 50 percent) reach the papillary dermis. Deep peels (phenol 88 percent) reach the reticular dermis. Indications include acne, photoaging, hyperpigmentation, and fine wrinkles. Recovery time increases with peel depth. Post-peel care includes sun protection and emollients. Complications include infection, post-inflammatory hyperpigmentation, and scarring.

Proper patient selection and pre-treatment preparation minimise adverse effects.

Contact Allergen Testing

– Patch testing identifies allergens causing allergic contact dermatitis. Standard panel includes 35 common allergens (nickel, fragrance mix, balsam of Peru, formaldehyde, rubber accelerators, topical antibiotics, preservatives). Patches are applied to the back for 48 hours and read at 48, 72, and 96 hours. Positive reactions indicate allergens to avoid. Contact allergen databases and patient education are essential for management. False positives and negatives can occur.

Contact Dermatitis

– An inflammatory skin reaction caused by direct contact with an external agent, divided into two main types: allergic contact dermatitis (ACD, type IV delayed hypersensitivity reaction, mediated by sensitized T lymphocytes) and irritant contact dermatitis (ICD, non-immunologic, dose-dependent direct chemical or physical damage to the epidermis, accounting for 80 percent of cases). Allergic contact dermatitis requires prior sensitization to the allergen (which can occur over hours to days, while irritant contact dermatitis occurs immediately after exposure to the inciting agent). Clinical presentation varies by duration and severity, with acute ACD presenting with erythema, vesiculation, oozing, and crusting, and chronic ACD presenting with lichenification, fissuring, scaling, and hyperpigmentation. The distribution of the rash provides important clues to the causative agent. Diagnosis is primarily clinical, supported by the history of exposure and confirmed by patch testing, which is the gold standard for identifying the specific allergen.

Corns and Calluses

– Corns (heloma) are focal areas of hyperkeratosis caused by pressure and friction, typically on toes. Hard corns (heloma durum) occur on dorsal toes; soft corns (heloma molle) occur between toes. Calluses (tyloma) are diffuse hyperkeratosis on weight-bearing surfaces. Treatment includes padding, shoe modification, keratolytic agents (salicylic acid), and debridement. Diabetics should avoid self-treatment due to ulcer risk.

Cosmetic Dermatology

– Cosmetic dermatology encompasses aesthetic pro-

cedures. Botulinum toxin injections (Botox, Dysport, Xeomin) relax facial muscles reducing wrinkles. Dermal fillers (hyaluronic acid, calcium hydroxylapatite, poly-L-lactic acid, polymethylmethacrylate) restore volume. Chemical peels (glycolic, salicylic, TCA) improve skin texture and pigmentation. Laser therapy (ablative CO₂, Er:YAG, non-ablative fractional) for wrinkles, scars, and pigmentation. Intense pulsed light (IPL) for photorejuvenation.

Cutaneous Drug Eruptions

– a spectrum of reactions. Exanthematous (maculopapular) is the most common, appearing 4 to 14 days after drug initiation. Urticarial appears within hours. Photoallergic occurs at sun-exposed sites. Lichenoid resembles lichen planus. Pigmented purpuric dermatosis presents as cayenne pepper spots. Erythema nodosum presents as tender nodules on shins. Each pattern suggests different drug classes and mechanisms.

Cutaneous Lymphoma

– Cutaneous lymphomas are heterogeneous group of T-cell and B-cell malignancies primarily involving the skin. Primary cutaneous B-cell lymphomas include marginal zone lymphoma, follicle center lymphoma, and diffuse large B-cell lymphoma leg type. Primary cutaneous T-cell lymphomas include mycosis fungoides and Sézary syndrome. Diagnosis requires multiple biopsies and immunohistochemical staining. Treatment is stage-dependent, ranging from topical therapy to systemic chemotherapy and radiation.

Cutaneous T-Cell Lymphoma

– A malignancy of skin-homing T lymphocytes. Mycosis fungoides is the most common subtype, presenting as patches, plaques, and tumors in a clothing distribution. Sézary syndrome is the leukemic variant with erythroderma, lymphadenopathy, and circulating malignant cells. Diagnosis requires serial skin biopsies and T-cell receptor gene rearrangement studies. Treatment ranges from topical steroids and phototherapy to systemic therapies and extracorporeal photopheresis. Prognosis is variable; early-stage mycosis fungoides has a favourable prognosis, while tumour-stage and Sezary syndrome have poorer outcomes.

Dandruff and Scalp Conditions

– Dandruff is a common scalp condition presenting

as flaking, itching, and mild inflammation caused by overgrowth of the yeast *Malassezia*, dry skin, or seborrheic dermatitis. Other scalp conditions include psoriasis, contact dermatitis, ringworm tinea capitis, and head lice. Treatment typically involves medicated anti-dandruff shampoos containing zinc pyrithione, coal tar, salicylic acid, ketoconazole, or selenium sulfide.

Dermal Structure

– The dermis has two layers: papillary dermis (superficial, thin, containing capillaries, lymphatics, and Meissner corpuscles) and reticular dermis (deep, thick, containing dense irregular connective tissue, collagen, elastin, hair follicles, sweat glands, and sebaceous glands). The dermo-epidermal junction contains type IV collagen and laminin, anchoring the epidermis to the dermis. Dermis provides tensile strength, elasticity, and nourishment to the avascular epidermis.

Dermatitis

– Inflammation of the skin, often used interchangeably with eczema. Atopic dermatitis: chronic pruritic inflammation in flexural areas, associated with asthma and allergies, driven by skin barrier dysfunction and type 2 inflammation. Contact dermatitis: allergic (type IV hypersensitivity) or irritant (direct toxicity). Seborrheic dermatitis: erythematous patches with greasy yellow scale on scalp, face, and chest, associated with *Malassezia* yeast. Stasis dermatitis: due to chronic venous insufficiency, lower legs. Treatment: emollients, topical corticosteroids, calcineurin inhibitors, and avoidance of triggers.

Dermatofibroma

– A common benign dermal nodule, typically on the lower extremities of young adults. It presents as a firm, hyperpigmented papule that dimples when pinched (Fitzpatrick sign). It is thought to result from reactive fibrosis following minor trauma or insect bites. Dermatofibromas are asymptomatic and require no treatment. Excision is performed for diagnostic uncertainty or cosmetic reasons. They may recur after excision.

Dermatofibrosarcoma

– Dermatofibrosarcoma protuberans is a locally aggressive fibrohistiocytic tumor of the skin. It typically presents as a slowly enlarging, indurated plaque on the trunk, which may develop nodules

over time. It has a high local recurrence rate (up to 50 percent with simple excision) but low metastatic potential. Wide local excision with 2 to 3 cm margins or Mohs surgery is treatment. Imatinib is effective for unresectable or metastatic disease.

Dermatofibrosarcoma Protuberans

– A rare locally aggressive cutaneous sarcoma arising from dermal fibroblasts. It presents as a slow-growing, firm, reddish-purple plaque or nodule, typically on the trunk. It has a high local recurrence rate but low metastatic potential. Treatment is wide local excision with Mohs micrographic surgery or imatinib for unresectable disease. It is characterized by the COL1A1-PDGFB fusion gene.

Dermatographism

– Urticaria factitia: the development of linear wheals (hives) within minutes of stroking or scratching the skin, the most common form of physical urticaria. Mast cell hyper-reactivity releases histamine after minor mechanical pressure. Associated with chronic spontaneous urticaria and atopy. Features: red, itchy, raised lines following skin friction, resolving in 30-60 minutes. Diagnosis: clinical (stroking skin with a blunt object reproduces wheals). Management: avoid triggering friction/tight clothing, oral H1-antihistamines (cetirizine, fexofenadine), and reassurance; severe cases may need higher doses or add-on therapy.

Dermatopathology

– The microscopic examination of skin specimens. Histopathologic features include acanthosis (epidermal thickening), spongiosis (intercellular edema), parakeratosis (retained nuclei in stratum corneum), hyperkeratosis (thickened stratum corneum), dyskeratosis (individual cell keratinization), and Civatte bodies (apoptotic keratinocytes). Special stains include PAS (fungi), Fontana-Masson (melanin), trichrome (collagen), and Congo red (amyloid). Direct immunofluorescence diagnoses autoimmune blistering diseases (pemphigus, bullous pemphigoid, lupus erythematosus) by detecting in vivo bound immunoglobulins and complement at specific skin locations.

Digital Mucous Cyst

– A benign ganglion cyst arising from the distal interphalangeal joint, presenting as a translucent, dome-shaped nodule on the dorsal aspect of the

finger near the nail fold. It is associated with osteoarthritis of the DIP joint. Treatment includes observation, intralesional corticosteroid injection, cryotherapy, and surgical excision with joint capsule removal to prevent recurrence.

DRESS Syndrome

– Drug Reaction with Eosinophilia and Systemic Symptoms, a severe, potentially life-threatening adverse drug reaction. Typically occurs 2-8 weeks after drug initiation (latency longer than SJS/TEN). Causative drugs: anticonvulsants (phenytoin, carbamazepine, lamotrigine), allopurinol, sulfonamides, dapsone, minocycline. Presents with fever, facial edema, generalized rash (morbilliform, exfoliative dermatitis), lymphadenopathy, eosinophilia, and atypical lymphocytosis. Internal organ involvement: hepatitis (most common), nephritis, pneumonitis, myocarditis, thyroiditis. Diagnosis: RegiSCAR criteria. Treatment: immediate drug withdrawal, systemic corticosteroids, supportive care. Mortality 5-10%.

Drug Hypersensitivity Syndrome

– A severe delayed drug reaction occurring 2 to 8 weeks after drug initiation. It presents with fever, rash (morbilliform, facial edema, exfoliative dermatitis), lymphadenopathy, eosinophilia, and internal organ involvement (hepatitis most common, also nephritis, pneumonitis, myocarditis). Culprit drugs include anticonvulsants (carbamazepine, phenytoin, lamotrigine), allopurinol, sulfonamides, and minocycline, typically associated with a latency period of 2 to 8 weeks. Diagnosis is based on the RegiSCAR criteria. Treatment consists of immediate withdrawal of the culprit drug, systemic corticosteroids (prednisolone 0.5 to 2 mg/kg/day) with slow tapering over weeks to months, and supportive care including wound care, hydration, and treatment of organ-specific complications. The mortality rate is approximately 10 percent.

Dysplastic Nevus

– Atypical nevus: a melanocytic lesion with clinical and histologic atypia, larger (>5-6 mm), with irregular borders, variable color (pink-tan-brown), and a macular/papular component; often multiple in the dysplastic nevus syndrome (familial atypical mole-melanoma, FAMMM). Individuals with dysplastic nevi have increased melanoma risk (especially with

family history). Diagnosis: dermoscopy and histology (architectural disorder, cytologic atypia, lentiginous proliferation). Management: close surveillance with total body photography/dermoscopy, excision of suspicious lesions, and sun protection; risk stratification by number and family history.

Eczema

– A group of inflammatory skin conditions characterized by pruritic, erythematous, scaly patches. Atopic dermatitis is the most common form. Nummular eczema presents as coin-shaped lesions. Dyshidrotic eczema affects palms and soles with vesicles. Eczema herpeticum is a disseminated HSV infection in eczema patients, a medical emergency. Stasis dermatitis occurs in lower extremities with venous insufficiency. Treatment includes emollients, topical corticosteroids, calcineurin inhibitors (tacrolimus, pimecrolimus), and systemic immunosuppressants for severe cases.

Eczema (Atopic Dermatitis)

– A chronic inflammatory skin condition characterized by dry, itchy, and inflamed patches of skin. It is driven by a combination of genetic predisposition, immune system dysfunction, and environmental triggers. Management involves moisturizers, topical corticosteroids, avoidance of irritants, and sometimes systemic medications for moderate to severe cases.

Epidermal Inclusion Cyst

– A common benign cyst lined by stratified squamous epithelium with keratin debris. It presents as a firm, mobile, subcutaneous nodule, typically on the face, neck, and back. A central punctum is characteristic. It may become inflamed or infected. Treatment includes complete excision (including the cyst wall) to prevent recurrence. Incision and drainage alone leads to recurrence.

Epidermal Layers

– The epidermis has five layers from deep to superficial: stratum basale (germinative layer with keratinocyte stem cells and melanocytes), stratum spinosum (prickle cell layer with desmosomes), stratum granulosum (keratohyalin granules), stratum lucidum (transparent layer, only in thick skin), and stratum corneum (dead, flattened keratinocytes providing barrier function). The epidermis renews every 28 to 40 days. Keratinocytes, melanocytes,

Langerhans cells, and Merkel cells are the four main epideidermal cell types in the epidermis. The basement membrane zone anchors the epidermis to the dermis and contains type IV collagen, laminin, and integrins.

Epidermolysis Bullosa

– A group of genetic disorders causing skin fragility and blistering with minimal trauma. Simplex (intraepidermal blistering), junctional (blistering at lamina lucida), dystrophic (sublamina densa blistering), and Kindler syndrome (mixed). Dystrophic EB can cause scarring, contractures, and squamous cell carcinoma. Management includes wound care, pain control, nutritional support, and genetic counseling. New treatments include gene therapy and protein replacement.

Erysipelas

– A superficial form of cellulitis involving the upper dermis and superficial lymphatics, most commonly caused by *Streptococcus pyogenes*. It presents as a bright red, well-demarcated, raised plaque with sharp borders, typically on the face or lower extremities. Fever and chills precede the rash. Complications include abscess, bacteremia, and recurrent episodes. Treatment is penicillin or amoxicillin. Recurrent erysipelas can cause lymphedema (elephantiasis nostras).

Erythema

– Redness of the skin or mucous membranes caused by increased blood flow to dilated superficial capillaries, often a sign of inflammation, infection, or other underlying conditions. Erythema blanch on pressure (distinguishes it from purpura, which does not blanch). Causes: localized inflammation (cellulitis, dermatitis, insect bite, sunburn), systemic conditions (fever, polycythemia, carcinoid syndrome, rosacea), drug reactions, and autoimmune disease (lupus, dermatomyositis). Specific patterns include erythema multiforme (target lesions, HSV-related), erythema nodosum (painful red nodules on shins, panniculitis), erythema migrans (Lyme disease—expanding annular rash with central clearing), and erythema ab igne (reticulated hyperpigmentation from chronic heat exposure).

Erythema Multiforme

– An acute, self-limited immune-mediated reaction, most commonly triggered by herpes simplex virus

(90 percent of cases) and *Mycoplasma pneumoniae*. It presents as target lesions (iris lesions with three zones: central duskiness, middle pale edematous ring, outer erythematous halo) on extremities. Minor EM has few mucosal lesions; major EM has extensive mucosal involvement. Treatment is supportive, with acyclovir prophylaxis for HSV-triggered recurrent EM.

Erythema Nodosum

– The most common form of panniculitis, characterized by painful, erythematous, tender nodules and plaques on the bilateral shins, representing an inflammatory reaction of the subcutaneous fat. The condition is a hypersensitivity reaction to a variety of inciting antigens, most commonly infections (*Streptococcal* pharyngitis, the most frequent cause in children; tuberculosis; coccidioidomycosis; histoplasmosis; blastomycosis; *Yersinia*; *Salmonella*; *Mycoplasma*; and viral infections including Epstein-Barr virus and hepatitis B and C), medications (oral contraceptives, sulfonamides, penicillins, and NSAIDs), inflammatory bowel disease (Crohn disease and ulcerative colitis), sarcoidosis, Behcet disease, pregnancy, and malignancies (lymphoma and leukaemia). The onset is acute, with the appearance of exquisitely tender, warm, erythematous nodules, approximately 1 to 10 cm in diameter, typically on the pretibial surfaces. Individual lesions undergo an evolution of color changes resembling a bruise, resolving over 2 to 6 weeks without ulceration or scarring. Recurrence is common, particularly with streptococcal infections.

Erythrasma

– A superficial bacterial infection of the skin caused by *Corynebacterium minutissimum*, a gram-positive, aerobic bacillus that proliferates in moist, occluded environments. The infection is most common in warm, humid climates and affects the intertriginous areas, particularly the groin (most common site), axillae, inframammary folds, perineum, and interdigital web spaces of the feet (toe web spaces). Risk factors include obesity, diabetes mellitus, hyperhidrosis, advanced age, poor hygiene, and immunosuppression (HIV, organ transplant, corticosteroid use). The infection presents as well-demarcated, reddish-brown to coral-red patches or plaques with a fine scale in the intertriginous areas, often asymptomatic

with mild pruritus. Diagnosis is clinical, confirmed by Wood lamp examination demonstrating characteristic coral-red fluorescence. Treatment includes topical antibacterial agents (erythromycin gel, clindamycin lotion) or topical antifungals (clotrimazole, miconazole) for mild disease, and oral erythromycin, clarithromycin, or tetracycline for extensive or refractory cases.

First-Degree Burn

– A superficial burn affecting only the epidermis: erythema, pain, and dryness without blistering (e.g., mild sunburn); heals in 3-7 days without scarring. Assessment: size (percent BSA—rule of nines), depth, and cause (thermal, chemical, electrical). Management: cool running water, analgesia, emollients/moisturizers, and sun protection; systemic care for large areas (fluid, analgesia). Distinguish from second-degree (blistering) and third-degree (full-thickness, insensate) burns. Prognosis excellent.

Fixed Drug Eruption

– A recurrent drug reaction appearing at the same site with each exposure to the offending drug. It presents as well-demarcated, round to oval, erythematous to violaceous plaques that may blister. Common culprits include sulfonamides, tetracyclines, NSAIDs, and barbiturates. After resolution, lesions leave post-inflammatory hyperpigmentation. Genitalia, lips, and hands are common sites. Treatment is identification and avoidance of the causative drug.

Folliculitis

– Inflammation of hair follicles, presenting as pustules centered on follicles. Bacterial folliculitis (*Staphylococcus aureus*) is most common. Hot tub folliculitis (*Pseudomonas*) occurs after hot tub exposure. Gram-negative folliculitis complicates long-term antibiotic use. Pseudofolliculitis barbae (razor bumps) results from ingrown hairs. Treatment includes topical antibiotics (mupirocin), benzoyl peroxide, and avoiding shaving. Recurrent staphylococcal folliculitis may require decolonisation with mupirocin nasal ointment and chlorhexidine washes.

Fungal Infection (Tinea/Dermatophytosis)

– Superficial fungal infections of skin, hair, or nails caused by dermatophytes (*Trichophyton*, *Microsporum*, *Epidermophyton*). Tinea corporis (ringworm):

annular scaling plaque with central clearing. Tinea pedis (athlete's foot): interdigital scaling, maceration. Tinea cruris (jock itch): groin rash sparing scrotum. Tinea capitis: scaly patches with broken hairs. Onychomycosis: thickened, discolored, dystrophic nails. Diagnosis: KOH prep, culture. Treatment: topical antifungals (terbinafine, azoles); systemic (terbinafine, itraconazole, griseofulvin) for tinea capitis and onychomycosis.

Fungal Skin Infections

– Skin infections caused by dermatophytes or yeasts, including ringworm (tinea), athlete's foot, and candidiasis. These infections thrive in warm, moist environments and present with red, itchy, scaly, or ring-shaped lesions. Treatment typically involves topical or oral antifungal medications and measures to keep the skin clean and dry.

Furuncle

– See Boil. A deep follicular infection by *Staphylococcus aureus* forming a painful, erythematous nodule with a central necrotic core, often requiring incision and drainage. Recurrent furunculosis warrants screening for nasal carriage and immunosuppression (diabetes). Complications: cellulitis, bacteremia, scarring. Management: warm compresses, drainage, antibiotics if extensive (flucloxacillin or cover MRSA), and good hygiene.

Furuncle and Carbuncle

– Furuncle (boil) is a deep infection of the hair follicle caused by *Staphylococcus aureus*, presenting as a painful, erythematous nodule that may drain pus. Carbuncle is a cluster of interconnected furuncles causing a larger, more deeply invasive infection. Treatment includes warm compresses, incision and drainage, and antibiotics (dicloxacillin, cephalexin, or TMP-SMX for MRSA). Recurrent furunculosis suggests carrier state or immunodeficiency.

Genodermatoses

– Genetic skin disorders. Inherited ichthyoses (lamellar, X-linked, congenital ichthyosiform erythroderma). Epidermolysis bullosa (simplex, junctional, dystrophic). Neurocutaneous syndromes (neurofibromatosis, tuberous sclerosis, Sturge-Weber). Ectodermal dysplasias (hypohidrotic, hypotrichosis, nail dystrophy). Incontinentia pigmenti (X-linked dominant, lethal in males). Bloom syndrome, Rothmund-Thomson syndrome, and Werner syn-

drome are DNA repair disorders with photosensitivity and increased risk of skin cancer. The RASopathies (Costello, Noonan, cardiofaciocutaneous, LEOPARD syndromes) present with characteristic facies, cardiac defects, and papilomas. Multidisciplinary management and genetic counselling are essential.

Glomus Tumor

- A rare benign neoplasm arising from glomus bodies (thermoregulatory shunts), presenting as a small, blue-red, exquisitely tender subungual or digital nodule. The classic triad is severe pain, point tenderness, and cold sensitivity. Diagnosis is clinical with positive Love pin test and Hildreth sign (tumor disappears with ischemia). Treatment is surgical excision. Recurrence is uncommon if completely removed.

Gotttron Papules

- Pathognomonic dermatological sign of dermatomyositis, consisting of erythematous to violaceous lichenoid papules located over the dorsal aspects of the interphalangeal (PIP/DIP) and metacarpophalangeal (MCP) joints. May undergo necrosis or ulceration. Contrast with Systemic Lupus Erythematosus (SLE) skin lesions, which spare the joints and involve the interphalangeal spaces. Associated with proximal muscle weakness, elevated creatine kinase (CK), anti-Jo-1, and anti-Mi-2 autoantibodies.

Granuloma Annulare

- A benign inflammatory condition characterized by annular, erythematous to skin-colored plaques with raised borders and central clearing. It most commonly affects the hands, feet, and elbows. Localized form is most common; generalized form is associated with diabetes mellitus. Diagnosis is clinical with biopsy showing palisading granulomas around necrobiotic collagen. Self-resolving within 2 years. Treatment of persistent cases includes topical or intralesional corticosteroids, phototherapy, and oral corticosteroids for severe disseminated disease.

Hair Loss

- Alopecia: reduction of scalp or body hair. Types: nonscarring (androgenetic—pattern hair loss, telogen effluvium—stress/illness/drugs, anagen effluvium—chemotherapy, alopecia areata—autoimmune patches, tinea capitis,

trichotillomania) and scarring (lupus, lichen planopilaris, folliculitis decalvans). Female pattern hair loss is common. Evaluation: history (onset, medications, stress, family), exam (pattern, scarring, hair pull test), labs (TSH, ferritin, DHEA/testosterone if indicated), biopsy for scarring. Management: treat cause; minoxidil (topical), finasteride/spironolactone (androgenetic), immunotherapy/corticosteroids (alopecia areata), antifungals (tinea), and supportive measures.

Hair Loss (Alopecia)

- The partial or complete loss of hair from areas where it normally grows, most commonly the scalp. Causes include genetic predisposition (androgenetic alopecia), autoimmune conditions (alopecia areata), hormonal changes, medications, stress, and nutritional deficiencies. Treatment depends on the underlying cause and may include topical minoxidil, oral finasteride, corticosteroid injections, or hair transplantation.

Hair Loss Classification

- Hair loss (alopecia) is classified as scarring (cicatricial) or non-scarring. Non-scarring alopecias are potentially reversible: androgenetic alopecia (male and female pattern), alopecia areata, telogen effluvium, anagen effluvium, and tinea capitis. Scarring alopecias cause permanent hair loss: lichen planopilaris, discoid lupus, frontal fibrosing alopecia, and folliculitis decalvans. Diagnosis requires clinical examination, trichoscopy, and sometimes biopsy.

Herpes Zoster

- A painful, vesicular eruption resulting from reactivation of latent varicella-zoster virus (VZV, human herpesvirus 3) in the dorsal root ganglia or cranial nerve ganglia, where the virus has remained dormant since the primary varicella (chickenpox) infection, with an incidence of approximately 1 to 3 per 1,000 person-years overall and up to 10 per 1,000 person-years in adults over 60. Risk factors include advancing age (over 50 years, 50 percent of cases), immunosuppression (HIV, organ transplantation, haematological malignancies, chemotherapy, and long-term corticosteroid or anti-TNF therapy). The prodromal phase (2 to 3 days) consists of headache, photophobia, and malaise, followed by the eruption phase, where painful, grouped, vesicular lesions on an erythematous base appear in

a unilateral, single dermatomal distribution, most commonly the thoracic dermatomes (50 to 60 percent), followed by the trigeminal nerve distribution, particularly the ophthalmic division (V1, 12 to 15 percent, which requires urgent ophthalmology referral due to the risk of herpes zoster ophthalmicus). The acute neuritis and the zoster rash typically resolve over 2 to 4 weeks.

Hidradenitis

– Hidradenitis suppurativa is a chronic inflammatory follicular occlusion disease affecting apocrine gland-bearing areas (axillae, groin, inframammary). It presents with recurrent painful nodules, abscesses, sinus tracts, and scarring. Hurley staging: Stage I (single or multiple abscesses without sinus tracts), Stage II (recurrent abscesses with sinus tracts and bridging scars), Stage III (diffuse or multi-tract involvement). Smoking and obesity are risk factors. Treatment includes lifestyle modification (weight loss, smoking cessation), topical clindamycin, oral antibiotics (tetracyclines, rifampicin-clindamycin combination), biologic therapy (adalimumab, the only FDA-approved biologic for HS), and surgical deroofting or excision for advanced disease.

Hidradenitis Suppurativa

– A chronic, inflammatory, follicular occlusion disease characterized by recurrent, painful nodules, abscesses, sinus tracts, and scarring in apocrine gland-bearing areas (axillae [most common, 70 to 80 percent], groin and inguinal folds [30 to 40 percent], perineum and perianal region [20 to 35 percent], buttocks [20 to 30 percent], and inframammary folds [10 to 20 percent]), with a prevalence of 1 to 4 percent worldwide (likely underdiagnosed, with average diagnosis delay of 7-10 years). The pathogenesis begins with follicular occlusion (hyperkeratinisation of the terminal hair follicle infundibulum leading to dilation and rupture of the follicle), which triggers an intense inflammatory response with release of keratin and cell debris into the dermis, activating neutrophils, macrophages, and TH1/TH17 lymphocytes with elevated levels of TNF-alpha, IL-17, and IL-1 beta. Risk factors include smoking (the strongest environmental risk factor, present in 70 to 90 percent of patients), obesity, hormonal influences, and genetic factors (mu-

tations in NCSTN, PSENEN, and PSEN1 encoding components of the gamma-secretase complex).

Hives (Urticaria)

– A common skin condition characterized by transient, well-circumscribed, intensely pruritic, erythematous wheals (hives) of variable size and shape that blanch with pressure and resolve within 24 hours without scarring, resulting from mast cell degranulation and histamine release in the dermis. Urticaria is classified by duration: acute urticaria (less than 6 weeks, most common, accounting for 70 percent of cases, typically caused by IgE-mediated hypersensitivity reactions to foods [nuts, shellfish, eggs, milk] and medications (NSAIDs, ACE inhibitors, antibiotics, opiates) in acute urticaria, with physical triggers (dermatographism, cholinergic, cold, solar, aquagenic, delayed pressure, vibratory) accounting for 20 to 30 percent of cases; and chronic urticaria (lasting 6 weeks or longer, affecting 1 to 2 percent of the population, more common in middle-aged women, with a mean duration of 1 to 5 years, and spontaneous onset in 70 to 80 percent of cases, of which approximately 40 percent have an autoimmune basis with IgG autoantibodies targeting the high-affinity IgE receptor Fc-epsilon-RI or IgE itself). Treatment follows a stepwise approach: first-line, second-generation H1-antihistamines (cetirizine, levocetirizine, fexofenadine, loratadine, desloratadine, bilastine) up to fourfold the standard dose; second-line, add H2-antagonist or leukotriene receptor antagonist (montelukast); third-line, add omalizumab (monoclonal anti-IgE antibody, FDA-approved for chronic spontaneous urticaria) or cyclosporine for severe refractory cases.

Hyperhidrosis

– Excessive sweating beyond thermoregulatory needs. Primary focal hyperhidrosis affects palms, soles, axillae, and face without underlying cause. Secondary generalized hyperhidrosis is caused by medications, endocrine disorders, infections, or malignancies. Treatment includes topical aluminum chloride (first-line), oral anticholinergics (glycopyrrolate, oxybutynin), iontophoresis for palms and soles, botulinum toxin injection, and endoscopic thoracic sympathectomy for severe refractory cases. Secondary hyperhidrosis requires treatment of the underlying cause.

Hypertrichosis

– Excessive hair growth in androgen-independent areas, affecting both sexes, either congenital or acquired. Generalized: genetic syndromes, medications (minoxidil, cyclosporine, phenytoin, glucocorticoids), malnutrition, porphyria, hypothyroidism, and malignancy (paraneoplastic). Localized: congenital nevi, hypertrichosis lanuginosa (paraneoplastic—abrupt onset of fine lanugo hair suggests GI/lung malignancy). Distinguish from hirsutism (androgen-dependent, patterned hair in women—PCOS, adrenal, ovarian causes). Evaluation: medication and family history, exam, hormone workup if hirsutism features. Management: treat cause; cosmetic hair removal (laser, electrolysis), and address psychosocial impact.

Hypertrophic Scar

– Raised scar tissue confined to the original wound margins, caused by excessive collagen production during healing. Unlike keloids, hypertrophic scars regress over time and do not extend beyond wound boundaries. They are common after burns, surgery, and trauma. Treatment includes pressure garments, silicone sheeting, intralesional corticosteroids, and laser therapy. Early intervention prevents progression.

Hypohidrosis

– Reduced or absent sweating, leading to heat intolerance and risk of hyperthermia. Causes include autonomic neuropathy (diabetes, Parkinson disease), skin diseases (scleroderma, burns), medications (anticholinergics), and genetic disorders (hypohidrotic ectodermal dysplasia). Diagnosis is confirmed by sweat test (starch-iodine test, thermoregulatory sweat test). Treatment includes cooling measures, hydration, and avoiding heat exposure.

Ichthyosis

– A group of disorders characterized by dry, scaly skin resembling fish scales. Ichthyosis vulgaris is the most common, autosomal dominant, associated with filaggrin mutation and atopy. X-linked ichthyosis is caused by steroid sulfatase deficiency. Lamellar ichthyosis is a severe congenital form. Treatment includes keratolytics (urea, lactic acid, ammonium lactate), emollients, and retinoids for severe cases.

Immunomodulators in Dermatology

– Topical immunomodulators treat inflammatory skin diseases without corticosteroid side effects. Pimecrolimus 1 percent cream and tacrolimus 0.03 and 0.1 percent ointments are calcineurin inhibitors used for atopic dermatitis, facial eczema, and intertriginous areas. They are steroid-sparing agents. Off-label uses include vitiligo, lichen planus, and psoriasis. JAK inhibitors (ruxolitinib cream for vitiligo and atopic dermatitis) represent a new class of topical immunomodulators.

Immunotherapy in Dermatology

– Cancer immunotherapy has revolutionized skin cancer treatment. Checkpoint inhibitors (pembrolizumab, nivolumab, ipilimumab) block PD-1 or CTLA-4, enhancing T-cell mediated tumor killing. They are first-line for advanced melanoma and metastatic SCC. Cemiplimab is approved for advanced BCC and SCC. Adverse events include dermatitis, colitis, hepatitis, pneumonitis, and endocrinopathies. Skin immune-related adverse events occur in 30 to 40 percent of patients and may be the first manifestation of systemic immunotherapy toxicity, particularly when the skin is involved as a target organ of the immune response.

Ingrown Toenail

– Ingrown toenail (onychocryptosis) occurs when the nail edge grows into the surrounding skin, causing pain, redness, and swelling. It is common in adolescents and adults, exacerbated by improper nail trimming, tight shoes, and trauma. Treatment includes partial nail avulsion with matrixectomy (phenol application) for recurrent cases. Conservative management includes cotton wedge under the nail edge and proper nail trimming.

Intertrigo

– An inflammatory rash of opposing skin surfaces (skin folds) caused by friction, moisture, heat, and lack of air circulation. Affects intertriginous areas: axillae, inframammary, inguinal, abdominal folds, and intergluteal cleft. Presents with erythema, maceration, fissuring, and erosions. Often secondarily infected with *Candida albicans* (satellite pustules), bacteria (erythrasma, *Corynebacterium*), or dermatophytes. Risk factors: obesity, diabetes, hyperhidrosis, incontinence, and poor hygiene. Diagnosis: clinical; KOH prep and Wood lamp exam for secondary infections. Treatment: keep area dry (dry-

ing powders, barrier creams), topical antifungals for *Candida*, low-potency corticosteroids for inflammation. Prevention: weight loss, moisture-wicking clothing.

Isotretinoin

– A systemic retinoid used for severe, recalcitrant nodular acne. It reduces sebum production, normalizes follicular keratinization, decreases *Propionibacterium acnes*, and has anti-inflammatory effects. Dose is 0.5 to 1 mg/kg/day for 15 to 20 weeks, targeting cumulative dose of 120 to 150 mg/kg. Side effects include cheilitis (almost universal), dry skin, photosensitivity, elevated triglycerides and liver enzymes, and teratogenicity (absolute contraindication in pregnancy). Two forms of contraception are required for women of childbearing potential one month before, during, and one month after therapy due to teratogenicity (iPLEDGE risk management programme in the US). Monitoring includes monthly pregnancy tests, lipid profile, and liver function tests. Other side effects include arthralgias, myalgias, headache, pseudotumor cerebri (rare), and decreased night vision. A second course may be considered after a washout period of at least 8 to 16 weeks.

Itching

– Pruritus; see Pruritus. The sensation that provokes the desire to scratch. Acute vs. chronic (>6 weeks). Dermatologic causes (eczema, urticaria, scabies, fungal, contact dermatitis) and systemic causes (cholestasis, uremia, lymphoma, polycythemia vera, hyperthyroidism, iron deficiency). Histamine-mediated (allergy/urticaria—respond to antihistamines) vs. non-histaminergic (systemic). Management: treat underlying cause, emollients, cool compresses, antihistamines, topical steroids; investigate systemic causes when no primary skin disease. Chronic scratching causes lichenification and excoriations.

Kaposi Sarcoma

– A vascular tumor caused by human herpesvirus 8 (HHV-8), presenting as violaceous plaques and nodules on skin and mucous membranes. Four types: classic (elderly Mediterranean men), endemic (African), iatrogenic (immunosuppression post-transplant), and AIDS-associated. Cutaneous lesions are the most common presentation in AIDS.

Treatment includes antiretroviral therapy, local therapy (radiation, cryotherapy), and chemotherapy for widespread disease.

Keloid

– An overgrowth of scar tissue extending beyond the original wound margins, caused by excessive collagen deposition during wound healing. Keloids are more common in darker skin types (Fitzpatrick IV to VI) and occur at sites of trauma, surgery, piercings, and burns. They are pruritic and painful. Treatment includes intralesional corticosteroid injections, silicone sheeting, cryotherapy, laser therapy, and surgical excision with adjuvant radiation. Recurrence is common.

Keratoacanthoma

– A low-grade or well-differentiated variant of squamous cell carcinoma (SCC) originating from hair follicles. Characterized by rapid growth over 4-6 weeks into a dome-shaped, flesh-colored or erythematous nodular lesion with a central keratin-filled crater. Often resolves spontaneously over months via involution, leaving a depressed scar. Biopsy required to distinguish from invasive SCC (often treated with complete excisional surgery).

Keratosis Pilaris

– A common, benign genetic follicular condition characterized by keratotic follicular papules. Small, rough, flesh-colored or red bumps on the extensor surfaces of proximal arms, thighs, and sometimes buttocks and face. Caused by abnormal keratinization and plugging of hair follicles with retained keratin. Associated with ichthyosis vulgaris and atopic dermatitis. Onset in childhood, may improve with age. Diagnosis: clinical. Treatment: emollients with keratolytics (lactic acid, urea, salicylic acid, ammonium lactate), topical retinoids (tretinoin, adapalene), and gentle exfoliation. Laser therapy for cosmetically bothersome erythema.

Koilonychia

– Spoon nails: nails with a concave (spoon-shaped) contour, most commonly associated with iron deficiency anemia; also seen in hemochromatosis, Plummer-Vinson syndrome, malnutrition, and trauma (nail dystrophy). The nail becomes thin, brittle, and turns up at the edges so a drop of water rests in the concavity. Diagnosis: clinical; confirm iron status (ferritin, iron studies, CBC). Manage

ment: treat the underlying cause (iron supplementation), and nails typically recover with correction of deficiency. Consider other causes when iron studies are normal.

Leukonychia

– White discoloration of the nails. True leukonychia: involves the nail matrix and moves distally with nail growth (punctate, striate/Mees lines from arsenic poisoning, or total). Apparent leukonychia: pathology in the vascular nail bed that does not move with nail growth and fades upon digital pressure (e.g., Muehrcke lines from hypoalbuminemia, Terry nails from hepatic cirrhosis/liver failure).

Leukoplakia

– A clinical term for a white patch or plaque on the oral mucosa that cannot be rubbed off and cannot be characterized clinically as any other definable lesion (WHO). Leukoplakia is a potentially malignant disorder of the oral cavity, with a risk of malignant transformation to squamous cell carcinoma of approximately 1-5% per year. Risk factors: tobacco smoking, alcohol consumption, areca nut/betel quid chewing, and chronic friction (e.g., from sharp teeth or dentures). Clinical subtypes: homogeneous (flat, thin, uniform white, low risk) and non-homogeneous (speckled-red and white, nodular, verrucous, higher risk). Sites: buccal mucosa, alveolar ridge, floor of mouth (highest risk), tongue, palate. The term may also rarely be used for vulvar, penile, or laryngeal white patches. Diagnosis: biopsy (optional for homogeneous lesions, always indicated for non-homogeneous or suspicious lesions) to confirm histology (hyperkeratosis, acanthosis, dysplasia). The presence of epithelial dysplasia (mild, moderate, severe) predicts malignant potential. Management: elimination of risk factors (smoking cessation, alcohol reduction), observation for homogeneous lesions, surgical excision for dysplastic or non-homogeneous lesions, CO2 laser ablation, cryotherapy. Photodynamic therapy and topical retinoids have limited evidence. Long-term follow-up is essential.

Lice Infestations

– Pediculosis is infestation by head lice (*Pediculus humanus capitis*), body lice (*Pediculus humanus corporis*), or pubic lice (*Phthirus pubis*). Head lice cause pruritus of the scalp and posterior neck; nits (eggs) are attached to hair shafts. Body lice live in

clothing and cause dermatitis. Pubic lice (crabs) affect the pubic region and cause pruritic maculae ceruleae. Treatment includes permethrin 1 percent shampoo, oral ivermectin, malathion 0.5 percent lotion, and mechanical removal of nits. Clothing and bedding should be washed in hot water (60 degrees C) and dried on high heat to prevent reinfestation. Household contacts should be examined and treated if infested.

Lichen

– A descriptive dermatological term referring to a flat-topped, firm, papular skin lesion resembling the lichen plant (a symbiotic organism of algae and fungi growing on rocks and trees). Lichenoid describes lesions that resemble lichen planus or lichenoid drug eruptions. Specific lichenoid conditions include: lichen planus, lichen sclerosus, lichen simplex chronicus (localised neurodermatitis from chronic scratching), lichen striatus, lichen nitidus, lichen myxoedematosus (papular mucinosis), and lichenoid drug eruptions (e.g., ACE inhibitors, antimalarials, gold, quinidine, NSAIDs, thiazides). See individual entries.

Lichen Planus

– A T-cell mediated inflammatory condition affecting skin, mucous membranes, nails, and hair. Classic presentation: the 6 Ps (pruritic, purple, polygonal, planar, papules, plaques), often with Wickham striae (white lacy network on surface). Oral lichen planus affects buccal mucosa and may be erosive. Hypertrophic lichen planus affects shins. Nail lichen planus causes longitudinal ridging and pterygium. Treatment includes topical corticosteroids, systemic corticosteroids for severe disease, and acitretin. Oral and genital lichen planus may require topical calcineurin inhibitors (tacrolimus, pimecrolimus) as first-line therapy due to the risk of corticosteroid-induced atrophy of mucosal surfaces.

Lichen Sclerosus

– A chronic inflammatory skin disease most commonly affecting anogenital skin. It presents as ivory-white, atrophic plaques with wrinkled paper-like appearance. In women, it predominantly affects the vulva and perianal region (figure-eight distribution). In men, it affects the glans penis and foreskin (balanitis xerotica obliterans). Lichen sclerosus is associated with increased risk of squamous

cell carcinoma. Treatment includes ultra-potent topical corticosteroids (clobetasol/clobetasol propionate 0.05 percent ointment) as first-line therapy, applied once or twice daily for 12 to 24 weeks, with gradual tapering to maintenance. Topical calcineurin inhibitors (tacrolimus, pimecrolimus) are used for corticosteroid-sparing effect. Systemic therapy with methotrexate, mycophenolate mofetil, or phototherapy is reserved for refractory, extensive, or extragenital disease. Long-term monitoring is required due to the risk of malignant transformation (squamous cell carcinoma develops in 3 to 5 percent of patients with vulval lichen sclerosus).

Lichen Simplex Chronicus

- A thickened, leathery plaque caused by chronic scratching and rubbing (itch-scratch cycle). It commonly affects the neck, ankles, lower legs, and genital area. It is a form of neurodermatitis associated with stress and anxiety. Treatment includes breaking the itch-scratch cycle with topical corticosteroids, antihistamines, and behavioral modification. Underlying atopic dermatitis or contact dermatitis should be treated.

Lipoma

- The most common benign soft tissue tumor, composed of mature adipocytes. It presents as a soft, mobile, painless subcutaneous nodule, commonly on the trunk, neck, and proximal extremities. Lipomas grow slowly and may be multiple (familial multiple lipomatosis). Diagnosis is clinical; ultrasound or MRI for deep or atypical lesions. Treatment is observation or surgical excision for symptomatic or cosmetically concerning lipomas. Angiolipoma is a painful variant with vascular proliferative proliferation that is more symptomatic than typical lipomas.

Livedo Reticularis

- A net-like (reticulate) violaceous discoloration of the skin due to reduced blood flow in the dermal vasculature. Physiologic (cold-induced, benign) vs. pathologic: primary livedo reticularis (idiopathic, benign), and secondary—vasculitis (polyarteritis nodosa—livedo racemosa with nodules), SLE, antiphospholipid syndrome (livedo reticularis + thromboses + fetal loss), Sneddon syndrome, cryoglobulinemia, cholesterol emboli, and infections. Diagnosis: history (cold exposure, systemic

symptoms, thromboses, pregnancy loss), exam, ANA/antiphospholipid antibodies, ESR/CRP, and biopsy if vasculitis suspected. Management: treat the underlying cause; avoid cold; anticoagulation for antiphospholipid syndrome; treat vasculitis.

Macular

- A macule: a flat, circumscribed change in skin color <1 cm with no change in texture or elevation (non-palpable). Color varies: brown (melanin—freckles, lentigines, cafe-au-lait, nevus), red (erythema— inflammatory, vascular—telangiectasia, petechiae), white (vitiligo), blue/gray. Macules are distinguished from papules (elevated). Examples of macular lesions: maculopapular rash (measles, drug eruption), pityriasis rosea, tinea versicolor, and early melanoma can present as a pigmented macule (ABCDE). Larger flat lesions >1 cm are patches. Diagnosis by morphology and distribution; biopsy for suspicion of malignancy.

Medical Tattooing

- Medical tattooing (permanent makeup, micropigmentation) covers depigmented skin (vitiligo, vitiligo camouflage), restores areolas after mastectomy, and masks scars. Trichopigmentation simulates hair on bald scalp. Medical tattooing uses specialized pigments and techniques. Contraindications include keloid propensity, active skin disease, and pregnancy. Complications include infection, allergic reaction, pigment migration, and dissatisfaction. Removal requires laser therapy.

Melanoma

- A malignant neoplasm arising from melanocytes (pigment-producing cells derived from the neural crest, located in the basal layer of the epidermis, hair follicles, and mucous membranes), representing the most lethal form of skin cancer, with an incidence of approximately 20 to 30 per 100,000 persons per year in fair-skinned populations and a lifetime risk of approximately 2 to 3 percent. Risk factors include ultraviolet radiation exposure (intermittent intense sun exposure with blistering sunburns during childhood or adolescence (the single most important modifiable risk factor), high density of melanocytic nevi (greater than 50 nevi or the presence of atypical or dysplastic nevi, which confer a 5- to 20-fold increased risk), red or blonde hair,

fair skin (Fitzpatrick I and II), positive family history of melanoma, personal history of melanoma (5 to 10 percent risk of developing a second primary melanoma), and immunosuppression. The four main histopathological subtypes are superficial spreading melanoma (the most common, accounting for 70 percent of all melanomas), nodular melanoma (15 percent, presenting as a rapidly growing, elevated nodule without a clinically appreciable radial growth phase, often diagnosed late with a worse prognosis), lentigo maligna melanoma (10 percent, arising on sun-damaged facial skin of elderly patients), and acral lentiginous melanoma (5 percent, the most common melanoma in darker skin types, Fitzpatrick IV to VI, arising on the palms, soles, and subungual sites). The diagnosis is confirmed by excisional biopsy with a 1 to 2 mm clinical margin for histopathological evaluation.

Melanoma Surveillance

– regular skin examination, patient education on self-examination, and dermoscopic monitoring of atypical nevi. High-risk patients (personal or family history, numerous atypical nevi, immunosuppression) require 6-month follow-up. Standard patients require annual examination. Total body photography establishes baseline for change detection. Sentinel lymph node biopsy is recommended for melanoma 1 mm or greater or with ulceration.

Melanoma Treatment

– Stage-dependent. Stage 0 to IA: wide local excision. Stage IB to IIA: wide excision with sentinel lymph node biopsy. Stage IIB to IIC: wide excision, SLNB, and adjuvant therapy. Stage III: wide excision, SLNB or lymph node dissection, and adjuvant immunotherapy (pembrolizumab, nivolumab) or targeted therapy (dabrafenib plus trametinib for BRAF-mutant). Stage IV: systemic therapy (immunotherapy, targeted therapy, chemotherapy). BRAF and c-KIT mutations guide targeted therapy-targeted therapy). Palliative radiation for brain or bone metastases. Regular surveillance with imaging and skin examinations is required.

Merkel Cell Carcinoma

– An aggressive neuroendocrine skin cancer arising from Merkel cells. It presents as a rapidly growing, painless, red-violet nodule on sun-exposed skin of elderly patients. Approximately 80 percent are

associated with Merkel cell polyomavirus. Risk factors include immunosuppression, UV exposure, and fair skin. Treatment includes wide local excision, sentinel lymph node biopsy, and radiation therapy. Prognosis is poor with high rates of local recurrence and metastasis.

Milia

– Small, white, keratin-filled cysts appearing on the face, particularly around the eyes. They are common in newborns (neonatal milia) and adults (primary milia). Secondary milia occur after blistering injuries, dermabrasion, or laser therapy. Milia are asymptomatic and may resolve spontaneously. Treatment includes extraction with a sterile needle, topical retinoids, and chemical peels.

Mole

– Nevus: a benign proliferation of melanocytes, the most common skin lesion; also used for other nevi (moles are melanocytic nevi). Types: junctional (flat, brown—childhood), compound (slightly raised), intradermal (dome-shaped, flesh/pigmented). Congenital nevi (large ones—risk of melanoma), dysplastic (atypical) nevi (risk factor for melanoma). Features of melanoma concern: asymmetry, border irregularity, color variation, diameter >6 mm, evolution (ABCDE). Management: routine examination; any changing, atypical, or suspicious lesion warrants dermatoscopy and biopsy/excision. Sun protection reduces melanoma risk.

Molluscum Contagiosum

– A viral skin infection caused by a poxvirus, presenting as firm, dome-shaped, umbilicated papules with central dimpling, 2 to 5 mm in diameter. It is transmitted by direct skin contact, autoinoculation, and sexual contact in adults. Immunocompetent hosts clear lesions spontaneously within 6 to 12 months. Immunocompromised patients may have hundreds of lesions. Treatment includes cryotherapy, curettage, topical cantharidin, potassium hydroxide, and imiquimod. Lesions resolve within weeks to months after treatment. Spontaneous immunity is not lifelong.

Morton Neuroma

– A perineural fibrosis of the plantar digital nerve, most commonly between the third and fourth metatarsal heads. It presents as burning pain, numb-

ness, and a feeling of walking on a pebble. It is not a true neuroma but a mechanical entrapment neuropathy. Treatment includes wide shoes, metatarsal pads, corticosteroid injection, and surgical excision for refractory cases. Alcohol injection sclerotherapy is an alternative.

Mpox (monkeypox)

– A zoonotic viral disease caused by the monkeypox virus, an orthopoxvirus in the same genus as smallpox (variola) and vaccinia. The virus has two clades: clade I (formerly Congo Basin, Central African) with higher virulence and mortality (up to 10 percent), and clade II (formerly West African) with lower mortality (less than 1 percent). The 2022 global outbreak involved clade IIb, which spread predominantly through intimate contact, including sexual contact, among men who have sex with men, with cases concentrated in men who have sex with men and their close contacts. The incubation period is typically 5 to 21 days. The prodrome consists of fever, headache, myalgia, and lymphadenopathy (the most distinguishing feature from smallpox), followed by the eruption of a deep-seated, well-circumscribed, umbilicated vesiculopustular rash that evolves synchronously through macular, papular, vesicular, pustular, and crusting stages over 2 to 4 weeks, with centrifugal distribution. Oral antiviral therapy with tecovirimat (TPOXX) is used for severe disease, immunocompromised patients, and those at high risk of complications.

Nail Changes

– Abnormalities of the nails indicating local or systemic disease: koilonychia (spooning—iron deficiency), clubbing (chronic hypoxia—lung cancer, bronchiectasis, cyanotic heart disease, IBD), onycholysis (separation—psoriasis, thyroid, trauma), Beau lines (transverse grooves—acute illness, chemotherapy), Terry nails (white with distal pink band—liver disease), Muehrcke lines (hypoalbuminemia), splinter hemorrhages (endocarditis), pitting (psoriasis), yellow nail syndrome, paronychia (infection), and onychomycosis (fungal). Diagnosis: history, exam, nail culture/biopsy, and systemic evaluation. Management: treat the underlying disease; nail care and antifungals for fungal infection.

Nail Psoriasis

– Nail psoriasis affects 50 percent of patients with

psoriasis and 80 percent with nail involvement having joint disease. Features include pitting (most common), onycholysis (nail separation), oil drop sign (salmon patch), subungual hyperkeratosis, and nail plate crumbling. Nail psoriasis is associated with psoriatic arthritis. Treatment is challenging: topical corticosteroids, intralesional corticosteroids, systemic therapy for psoriasis, and apremilast. Nail avulsion is rarely needed.

Necrobiosis Lipoidica

– A chronic granulomatous skin disorder strongly associated with Diabetes Mellitus (present in 0.3–1.2% of diabetic patients, though 20% of affected patients do not have diabetes). Characterized by well-demarcated, shiny, yellow-brown shiny plaques with a central atrophic telangiectatic center and prominent violaceous border, most commonly on the pretibial area of lower extremities. Ulceration occurs in 35% of cases. Histology: palisading granulomas surrounding degenerated collagen (necrobiosis) and blood vessel wall thickening. Management: topical or intralesional corticosteroids (first-line), calcineurin inhibitors, pentoxifylline, and glucose control.

Neonatal Skin Conditions

– Common and usually benign. Erythema toxicum neonatorum (red papules and pustules on erythematous base, appears day 2 to 3, resolves by 2 weeks). Milia (tiny white cysts on nose and cheeks). Miliaria crystallina (clear vesicles from sweat duct obstruction). Sebaceous hyperplasia (yellow papules on nose and cheeks). Transient neonatal pustular melanosis (vesiculopustular rash with collarette of scale, resolves spontaneously). Acne neonatorum (comedones and papules, matmatres with sebaceous gland development and resolves without scarring). Treatment is reassurance and education for parents. Topical treatments are rarely needed.

Nettle Rash

– See Urticaria (Hives / Nettle Rash).

Neurofibroma

– A benign peripheral nerve sheath tumor. Solitary neurofibromas are common and present as soft, flesh-colored papules or nodules. Multiple neurofibromas are characteristic of neurofibromatosis type 1 (NF1). Cutaneous neurofibromas are diagnostically significant in NF1 (greater than or equal to

2 neurofibromas is one of the diagnostic criteria). Plexiform neurofibromas are pathognomonic for NF1 and carry risk of malignant transformation to malignant peripheral nerve sheath tumor (MPNST), occurring in 5 to 10 percent of patients with NF1, presenting as rapid growth, new or increasing pain, or a change in consistency of a previously stable plexiform neurofibroma.

Nevus

– A benign hamartoma of the skin; most commonly melanocytic nevus (mole). Other nevi: congenital, dysplastic/atypical, Spitz, blue nevus, halo nevus; non-melanocytic: epidermal, sebaceous, vascular (strawberry hemangioma, port-wine stain). Melanocytic nevi arise from melanocyte proliferation; atypical (dysplastic) nevi are irregular and are markers of increased melanoma risk, especially with family history. Congenital melanocytic nevi have small malignant potential (larger = higher). Diagnosis: clinical/dermoscopy; biopsy for atypical or changing lesions. Management: monitor; excise suspicious lesions (ABCDE criteria).

Nikolsky Sign

– A clinical dermatological sign in which light lateral pressure applied to normal-appearing skin causes epidermal detachment or sloughing. Positive sign indicates intraepidermal loss of cell-cell cohesion (acantholysis). Pathognomonic for Pemphigus Vulgaris (IgG anti-desmoglein 1/3 autoantibodies) and Staphylococcal Scalded Skin Syndrome (SSSS, exfoliative toxins A/B). Also positive in Toxic Epidermal Necrolysis (TEN) and Stevens-Johnson Syndrome (SJS). Negative in Bullous Pemphigoid (subepidermal split, hemidesmosomes intact).

Nutritional Dermatoses

– Nutritional deficiencies cause distinctive skin findings. Vitamin C deficiency (scurvy): perifollicular hemorrhage, corkscrew hairs, gingival bleeding. Niacin deficiency (pellagra): photosensitive dermatitis in sun-exposed areas, diarrhea, dementia. Riboflavin deficiency (ariboflavinosis): cheilosis, angular stomatitis, glossitis, seborrheic dermatitis-like eruption. Zinc deficiency (acrodermatitis enteropathica): periorificial and acral dermatitis, alopecia, diarrhea. Vitamin A deficiency: follicular hyperkeratosis, night blindness, and xerophthalmia (dryness of the conjunctiva and cornea, Bitot spots,

keratomalacia). Vitamin E deficiency: acanthocytosis, peripheral neuropathy. Vitamin K deficiency: ecchymoses, hemorrhage. Iron deficiency: koilonychia (spoon nails), angular stomatitis, glossitis, pallor. Zinc deficiency causes acral dermatitis, periorificial dermatitis, alopecia, diarrhea, and growth retardation in children (acrodermatitis enteropathica). Early recognition and appropriate replacement therapy are essential.

Occupational Dermatoses

– Work-related skin diseases. Occupational contact dermatitis accounts for 90 percent of occupational skin diseases. Irritant contact dermatitis is more common (hands, wet work) than allergic contact dermatitis. Occupations at risk include healthcare workers, hairdressers, construction workers, food handlers, and metalworkers. Common occupational allergens include rubber accelerators, fragrances, preservatives, and metals. Prevention includes hazard identification, protective equipment, barrier creams, and education. Management includes identification and avoidance of causative agents, topical corticosteroids, and emollients. Workers with occupational dermatitis may require job modification or retraining.

Onychomycosis

– Fungal nail infection, most commonly caused by dermatophytes (*Trichophyton rubrum*), affecting toenails more than fingernails. It presents as nail thickening, discoloration (yellow-brown), subungual debris, and nail separation. Diagnosis is confirmed by KOH preparation or fungal culture. Treatment includes oral terbinafine (first-line for dermatophyte), itraconazole, or topical ciclopirox for mild disease. Cure rates are 50 to 80 percent with oral therapy.

Pallor

– Paleness of the skin and mucous membranes, caused by reduced cutaneous blood flow (vasoconstriction—cold, shock, anemia, fear) or reduced hemoglobin/pigmentation. Causes: anemia (all types—iron deficiency, B12/folate, hemolysis, acute blood loss), vascular (vasovagal, cardiogenic shock, hypovolemia), metabolic (hypothyroidism), and pigment (vitiligo, albinism). Distribution: generalized (anemia) vs. localized. Clinical assessment: mucosal pallor (conjunctivae, palms—pallor in skin creases),

with anemia confirmed by CBC/hemoglobin. Management: treat the underlying cause—iron/blood transfusion for significant anemia, volume resuscitation in shock.

Papular

– A papule: a small, solid, elevated skin lesion <1 cm in diameter (palpable), of various colors and etiologies. Types: inflammatory (papular urticaria, lichen planus—purple polygonal, psoriasis—scaly), infectious (verruca/wart, molluscum, folliculitis), neoplastic (basal cell carcinoma, nevus, keratoacanthoma), and deposition (xanthoma, amyloid). Papulopustular: acne. Description includes color, shape (dome, flat-topped), surface, and distribution. Biopsy for uncertain diagnosis. Contrast with macule (flat) and nodule (>1 cm).

Paronychia

– Inflammation of the nail fold. Acute paronychia is bacterial (*Staphylococcus aureus*, *Streptococcus*), presenting as painful, erythematous, swollen nail fold with possible abscess. Treatment includes warm compresses, antibiotics, and incision and drainage if abscessed. Chronic paronychia is fungal (*Candida*) or irritant-induced, lasting greater than 6 weeks, common in wet workers. Treatment includes topical antifungals, corticosteroids, and avoiding moisture.

Patch Testing

– Patch testing identifies allergens causing allergic contact dermatitis. The standard series includes 35 allergens. Additional custom trays include occupational and personal allergens. Patches are applied to the upper back for 48 hours and removed. Reading at 48 hours (initial) and 72 to 96 hours (delayed) identifies positive reactions. Positive reactions are graded (1+ to 4+) based on erythema, edema, and vesiculation. Results guide allergen avoidance and patient education.

Pediatric Dermatology

– Pediatric dermatology encompasses conditions unique to children. Congenital lesions (birthmarks, hemangiomas, port-wine stains, café-au-lait macules). Infantile hemangiomas (strawberry marks) proliferate in first months of life and involute over years. Propranolol is first-line treatment for problematic hemangiomas. Mongolian spots (congenital dermal melanocytosis) are benign and resolve spontaneously. Neonatal acne, erythema toxicum, and

milia are self-limited.

Pediatric Dermatology Conditions

– Distinct from adult dermatology. Birthmarks include vascular (hemangiomas, port-wine stains) and pigmented (café-au-lait, congenital nevi, Mongolian spots). Infantile hemangiomas proliferate in first months then involute. Congenital melanocytic nevi carry melanoma risk proportional to size. Juvenile xanthogranuloma is a benign histiocytosis. Neonatal acne resolves spontaneously. Diaper dermatitis is common and treated with barrier creams.

Pediatric Eczema

– Pediatric eczema (atopic dermatitis in children) typically begins in infancy (2 to 6 months) with facial and extensor surface involvement. In older children, flexural involvement (antecubital and popliteal fossae) predominates. Pruritus is the hallmark, causing sleep disturbance and scratching. Associated conditions include asthma, allergic rhinitis, and food allergies (atopic march). Management includes emollients, topical corticosteroids, topical calcineurin inhibitors, and systemic therapy for severe cases. Barrier repair and proper bathing technique (lukewarm water, gentle cleanser, immediate emollient application) are essential maintenance strategies.

Pediatric Skin Tumors

– Pediatric skin tumors differ from adult tumors. Infantile hemangioma is the most common benign tumor of infancy. Congenital melanocytic nevus carries risk of melanoma (larger nevi have higher risk). Juvenile xanthogranuloma is a benign histiocytic lesion. Pyogenic granuloma is a common vascular lesion. Dermoid cysts are congenital. Malignant melanoma is rare but increasing in children. Regular monitoring of congenital nevi is recommended.

Pediculosis

– Infestation with lice. *Pediculus humanus capitis* (head lice): most common in school-age children, spread by direct head-to-head contact; presents with scalp pruritus, nits (eggs) attached to hair shafts. *Pediculus humanus corporis* (body lice): associated with poor hygiene, found in clothing seams; vector for trench fever, relapsing fever, and typhus. *Phthirus pubis* (pubic lice/crabs): sexually transmitted, infests pubic area. Treatment: permethrin, pyrethrin, malathion, ivermectin, and wet combing

for head lice; hygiene, washing clothing for body lice.

Pemphigoid

- Bullous pemphigoid (BP): an autoimmune subepidermal blistering disease of the elderly, caused by antibodies against hemidesmosome proteins (BP180, BP230) at the dermal-epidermal junction. Features: tense blisters on erythematous/urticarial skin, severe pruritus; mucosal involvement is mild. Diagnosis: skin biopsy (subepidermal blister), direct immunofluorescence (linear IgG/C3 at the basement membrane), serum BP180 antibodies. Management: high-potency topical/systemic corticosteroids, doxycycline $\pm$ niacinamide, immunosuppressants (methotrexate, azathioprine), rituximab, and IVIG for refractory; complications: infection, and increased mortality in the elderly with immunosuppression.

Pemphigus

- A group of autoimmune blistering diseases with intraepidermal blisters due to antibodies against desmogleins (cell adhesion molecules): pemphigus vulgaris (PV—flaccid blisters, mucosal involvement, positive Nikolsky sign), pemphigus foliaceus (superficial, no mucosal), paraneoplastic pemphigus. Causes: autoantibodies (IgG) against desmoglein 1/3, drug-induced (penicillamine, ACE inhibitors). Features: flaccid blisters/erosions, painful oral ulcers; severe: fluid/electrolyte loss, secondary infection. Diagnosis: skin biopsy (intraepidermal acantholysis), direct immunofluorescence (intercellular IgG/C3). Management: high-dose corticosteroids, rituximab (first-line adjunct), immunosuppressants (azathioprine, mycophenolate), IVIG; monitor for infection. Untreated: high mortality.

Pemphigus Vulgaris

- An autoimmune intraepidermal blistering disease caused by IgG antibodies against desmoglein 1 and 3. It presents with flaccid blisters that rupture easily, leaving painful erosions of skin and mucous membranes. Nikolsky sign is positive (lateral pressure causes epidermal sloughing). Diagnosis is by biopsy showing acantholysis and direct immunofluorescence showing intercellular IgG deposition. Treatment includes systemic corticosteroids and rituximab (first-line steroid-sparing agent). Prognosis is poor without treatment; immunosuppression has

dramatically improved outcomes, with mortality reduced to less than 10 percent.

Perioral Dermatitis

- A papulopustular eruption around the mouth, sparing the vermilion border. It is more common in young women and associated with topical corticosteroid use. Other triggers include fluoridated toothpaste, cosmetics, and inhaler steroids. Treatment includes discontinuation of topical steroids, topical metronidazole, erythromycin, or oral tetracyclines. It may take weeks to months to resolve.

Photosensitivity

- An abnormal skin reaction to sunlight (UVA/UVB), manifesting as rash, erythema, or burning on sun-exposed areas. Causes: drug-induced (tetracyclines, NSAIDs, thiazides, sulfonamides, fluoroquinolones, amiodarone, psoralens, retinoids), photodermatoses (polymorphous light eruption, solar urticaria, photoallergic/photoirritant contact dermatitis), porphyria (PCT—fragile blistering skin), lupus (photosensitivity in >50 percent), and xeroderma pigmentosum. Features: exposed-area erythema, papulovesicular rash, burning/tingling. Diagnosis: history (drugs, timing, distribution), phototesting, ANA, porphyrins. Management: strict sun avoidance/photoprotection, stop culprit drugs, treat underlying condition.

Pilar Cyst

- A benign cyst arising from the outer root sheath of hair follicles, most commonly on the scalp. It presents as a firm, mobile, subcutaneous nodule without a central punctum. Unlike epidermoid cysts, pilar cysts have smooth walls and contain dense keratin. They may be multiple in familial cases. Treatment is simple excision. Malignant transformation is extremely rare.

Pityriasis Rosea

- An acute, self-limited exanthematous skin condition of unknown cause (possibly viral, HHV-6/7 reactivation). Begins with a herald patch (solitary, 2-10 cm, annular, salmon-colored, scaly plaque on trunk), followed 1-2 weeks later by diffuse eruption of smaller, oval, erythematous papules and plaques with fine central scale following skin cleavage lines (Christmas tree pattern on back). Trunk and proximal extremities involved; face spared. Pruritus mild to moderate. Typically resolves in 6-8 weeks

without treatment. Diagnosis: clinical. Treatment: symptomatic (emollients, antihistamines, topical steroids). UVB phototherapy for severe pruritus.

Plantar Wart (Verruca Plantaris)

– A wart (verruca) located on the sole of the foot, caused by human papillomavirus (HPV, typically types 1, 2, 4, 63). Plantar warts are endophytic (grow inward due to pressure) rather than exophytic like common warts, and are often painful with direct pressure (walking, standing). They appear as well-circumscribed, hyperkeratotic papules or plaques on the sole, with a rough surface and loss of normal skin lines over the lesion. Paring reveals punctate black dots (thrombosed capillaries, distinguishing them from corns). Multiple warts may coalesce into a mosaic wart (mosaic verruca). Diagnosis: clinical, confirmed by paring. Plantar warts are frequently confused with corns (heloma) but are distinguished by the presence of thrombosed capillaries (black dots) and disruption of dermatoglyphics. Treatment: spontaneous resolution occurs in 30-50% within 1-2 years. First-line: salicylic acid (40% topical, daily with paring) and cryotherapy (liquid nitrogen, 10-15 second freeze, repeated every 2-4 weeks). Second-line: laser therapy (pulsed dye, CO₂), intralesional immunotherapy (Candida or mumps antigen injection), and topical immunotherapy (imiquimod, 5-fluorouracil). Refractory or mosaic warts may require surgical excision or photodynamic therapy. Immunocompromised patients (transplant, HIV) may have more extensive and resistant disease.

Porphyria Cutanea Tarda

– The most common porphyria, caused by a deficiency of hepatic uroporphyrinogen decarboxylase (UROD), leading to accumulation of uroporphyrinogens. Triggered by hepatitis C virus (HCV), alcohol abuse, iron overload (hemochromatosis), and estrogen therapy. Clinical features: severe cutaneous photosensitivity, fragile skin, tense bullae, erosions, hyperpigmentation, and hypertrichosis on sun-exposed areas (dorsum of hands, face). Diagnosis: elevated urinary and plasma porphyrins (urine fluoresces coral-red under Wood lamp). Treatment: phlebotomy (to reduce iron stores), low-dose hydroxychloroquine, and treatment of underlying HCV.

Porphyrias

– Metabolic disorders of heme synthesis causing cutaneous and neurological symptoms. Cutaneous porphyrias include porphyria cutanea tarda (blisters on sun-exposed skin, hypertrichosis, sclerodermoid changes), erythropoietic protoporphyria (immediate pain and burning on sun exposure without visible changes), and variegate porphyria. PCT is associated with hepatitis C, HIV, iron overload, and estrogen use. Treatment of PCT includes phlebotomy and hydroxychloroquine. Acute porphyrias (porphyrias (acute intermittent porphyria, variegate porphyria, hereditary coproporphyria) present with acute attacks of abdominal pain, neuropsychiatric symptoms, and autonomic instability. Diagnosis is made by porphyrin analysis in urine, plasma, and faeces. Treatment of acute attacks includes intravenous haem arginate, glucose loading, and avoidance of precipitating factors (drugs, alcohol, fasting, hormones). Long-term management includes sun avoidance, protective clothing, and regular monitoring for complications such as liver disease and hepatocellular carcinoma in PCT.

Pressure Injury

– Localized damage to the skin and/or underlying soft tissue caused by prolonged pressure, shear, or friction, most commonly over bony prominences. Stages: Stage 1 (non-blanchable erythema, intact skin), Stage 2 (partial-thickness skin loss with exposed dermis, shallow open ulcer), Stage 3 (full-thickness skin loss, subcutaneous fat visible), Stage 4 (full-thickness tissue loss with exposed bone, muscle, or tendon), Unstageable (full-thickness tissue loss with eschar or slough obscuring the wound base), and Deep Tissue Injury (persistent non-blanchable deep red/maroon discoloration). Common sites: sacrum, heels, ischial tuberosities, trochanters, and occiput. Risk factors: immobility, malnutrition, incontinence, sensory loss, and decreased perfusion. Prevention: repositioning q2h, pressure-relieving surfaces (air mattress), moisture management, and nutritional support. Treatment: wound debridement, infection control, moist wound healing, NPWT, and surgical closure (flap) for advanced stages.

Pressure Ulcer

– Localized damage to skin and underlying tissue caused by unrelieved pressure, typically over bony

prominences. Staging: Stage I (non-blanchable erythema), Stage II (partial-thickness loss), Stage III (full-thickness loss exposing fat), Stage IV (exposing bone, tendon, or muscle). Unstageable (covered by slough or eschar). Sacrum, heels, and trochanters are most common sites. Prevention includes pressure relief, turning schedules, specialty mattresses, specialty mattresses, and nutritional support. Treatment includes pressure offloading, wound debridement, infection control, moisture management, and advanced wound dressings. Surgical closure may be required for stage III and IV ulcers.

Pruritus

– Itching: an unpleasant sensation provoking scratching, a common symptom of skin and systemic disease. Causes: dermatologic (eczema, psoriasis, urticaria, scabies, xerosis, dermatitis), systemic (cholestasis—biliary obstruction, renal failure/uremia, hematologic—polycythemia vera, lymphoma/Hodgkin, hyperthyroidism, diabetes, iron deficiency, pregnancy), drug-induced, and psychogenic. Diagnosis: history (onset, duration, triggers, rash), skin exam, and targeted labs (LFTs, renal, CBC, TSH, iron, HIV). Management: treat cause, emollients, antihistamines (histaminergic itch), topical steroids/capsaicin, phototherapy (uremia/cholestasis), and avoidance of triggers; severe/refractory warrants malignancy/endocrine workup.

Psoriasis

– A chronic, immune-mediated inflammatory skin disease characterized by well-demarcated, erythematous plaques with silvery-white scale, affecting approximately 2 to 3 percent of the global population, with a bimodal age of onset (peak at 15 to 25 years and 50 to 60 years), a roughly equal male-to-female ratio, and strong genetic predisposition (concordance rate of 70 percent in monozygotic twins; HLA-Cw6 associated with early-onset psoriasis, present in 60 percent of psoriasis patients), and environmental triggers (trauma, infection, stress, medications including lithium, beta-blockers, chloroquine, interferon, and ACE inhibitors, and smoking) acting on a background of genetic susceptibility. The pathophysiology is driven by the IL-23/TH17 axis (dendritic cell-derived IL-23 activates CD4+ and CD8+ T cells to produce IL-17 and IL-22, which

stimulate keratinocyte proliferation and the production of antimicrobial peptides, chemokines, and proinflammatory cytokines, with tumour necrosis factor alpha playing a key amplifying role), leading to the characteristic histological triad of acanthosis (epidermal thickening), hyperkeratosis (thickened stratum corneum with retained nuclei, parakeratosis), and a dense dermal inflammatory infiltrate of T cells, dendritic cells, and neutrophils. The clinical presentation is typically of well-demarcated, erythematous, indurated plaques with a silvery-white micaceous scale, located symmetrically on the extensor surfaces (elbows, knees), scalp, lumbosacral area, and nails.

Psychodermatology

– Psychodermatology addresses the mind-skin connection. Stress exacerbates psoriasis, eczema, acne, and urticaria. Psychiatric disorders (depression, anxiety, body dysmorphic disorder) are associated with skin conditions. Dermatologic conditions cause psychiatric morbidity: psoriasis and depression, acne and anxiety, vitiligo and social phobia. Integrated care addressing both skin and psychological aspects improves outcomes. Cognitive behavioral therapy, mindfulness, and antidepressants may benefit patients with psychodermatological conditions.

Pustule

– A small, circumscribed elevation of skin containing pus (neutrophils) within the epidermis. Causes: bacterial (folliculitis, impetigo, furuncle), acne vulgaris (inflammatory comedones), pustular psoriasis (generalized pustular psoriasis—systemic symptoms), hidradenitis suppurativa, and drug reactions. Sterile pustules occur in psoriasis and palmoplantar pustulosis. Diagnosis: clinical, Gram stain/culture of pus (bacterial), biopsy for atypical. Management: treat cause—antibiotics (topical/systemic) for bacterial and acne, retinoids, steroids/immunosuppressants for pustular psoriasis, and drainage of furuncles/abscesses.

Pyogenic Granuloma

– A benign vascular proliferation presenting as a rapidly growing, friable, red papule or nodule that bleeds easily. It commonly occurs on fingers, face, and lips, and may be triggered by trauma or pregnancy (epulis gravidarum). Diagnosis is clinical.

Treatment includes shave excision with electrocautery, laser ablation, or topical timolol for small lesions. Recurrence rate is 15 percent.

Rash

– A general term for any visible skin eruption, change in skin color, texture, or appearance. Rashes can be localised or generalised, acute or chronic, and caused by a wide variety of aetiologies: infectious (viral—measles, rubella, varicella, roseola, erythema infectiosum, hand-foot-and-mouth disease, infectious mononucleosis, HIV seroconversion; bacterial—scarlet fever, impetigo, meningococcaemia, Lyme disease, syphilis; fungal—dermatophytosis, candidiasis), allergic/drug-induced (urticaria, maculopapular drug eruption, Stevens–Johnson syndrome/toxic epidermal necrolysis, fixed drug eruption, contact dermatitis), inflammatory (eczema/dermatitis, psoriasis, lichen planus, seborrheic dermatitis, pityriasis rosea), autoimmune (lupus erythematosus, dermatomyositis, scleroderma, vasculitis), and neoplastic (cutaneous T-cell lymphoma, Kaposi sarcoma, basal cell carcinoma). Morphological classification is essential for diagnosis: macule (flat, <1 cm), papule (raised, <1 cm), plaque (raised, >1 cm), patch (>1 cm flat), nodule (>1 cm deep), vesicle (<1 cm fluid-filled), bulla (>1 cm fluid-filled), pustule (pus-filled), wheal (transient, oedematous), and petechiae/purpura (non-blanching hemorrhagic). Distribution (central vs peripheral, flexural vs extensor, sun-exposed vs intertriginous) and configuration (annular, linear, reticulate, dermatomal) further narrow the differential. Diagnostic tools: history (onset, duration, fever, sick contacts, medications, travel), dermatoscopy, Wood lamp, skin scraping (KOH prep for fungus, scabies), Tzanck smear (herpes), patch testing, and skin biopsy. Treatment: directed at the underlying cause.

Rashes

– See Rash.

Rhinophyma

– A severe, end-stage subtype of phymatous rosacea occurring predominantly in elderly men. Characterized by progressive nodular thickening, hypertrophy, and lobular enlargement of the nasal skin with prominent, dilated pilosebaceous pores. Pathophysiology: sebaceous gland hyperplasia, fibrosis, and

chronic inflammation. Not caused by alcohol abuse (a common historical myth), though alcohol may exacerbate flushing. Treatment: surgical debulking via electrosurgery, carbon dioxide (CO_2) laser ablation, or dermabrasion.

Ringworm

– See Tinea.

Rosacea

– A chronic inflammatory skin disease characterized by facial erythema, telangiectasia, papules, pustules, and in severe cases, rhinophyma, affecting approximately 5 to 10 percent of fair-skinned adults worldwide, with a female-to-male ratio of 3 to 1 (though severe phenotypes are more common in males), with peak onset between 30 and 50 years of age. The 2002 National Rosacea Society (NRS) expert committee classification and the 2017 updated standard classification system divide rosacea into four subtypes based on the predominant clinical features: erythematotelangiectatic rosacea (ETR, characterized by persistent centrofacial erythema with telangiectasias, frequent flushing, and a tendency towards burning, stinging, and dryness), papulopustular rosacea (PPR, presenting with persistent erythema with transient, dome-shaped papules and pustules without comedones, distinguishing it from acne vulgaris, which requires treatment with metronidazole, ivermectin, azelaic acid, or oral doxycycline), phymatous rosacea (most commonly rhinophyma, with thickened, irregular, bulbous enlargement of the nose due to sebaceous gland hyperplasia and fibrosis, with a male predominance), and ocular rosacea (manifesting as blepharitis, conjunctivitis, keratitis, iritis, and chalazia, requiring ophthalmology referral and treatment with topical cyclosporine, oral doxycycline, and lid hygiene).

Sarcoidosis Skin Manifestations

– Cutaneous sarcoidosis affects 25 percent of patients with systemic sarcoidosis. Lesions include erythema nodosum (tender shin nodules, Löfgren syndrome with bilateral hilar lymphadenitis and fever), lupus pernio (violaceous plaques on nose, cheeks, ears), maculopapular eruptions, and scar sarcoidosis (granulomatous infiltration of old scars). Diagnosis requires biopsy showing non-caseating granulomas. Systemic evaluation is essential.

Scar Management

– Scar management aims to minimize hypertrophic and keloid formation. Early intervention includes silicone gel or sheeting (first-line evidence-based treatment), pressure therapy (especially for burn scars), and massage. Intralesional corticosteroids (triamcinolone) for hypertrophic scars and keloids. 5-fluorouracil injection for resistant keloids. Laser therapy (pulsed dye laser for erythema, fractional CO2 for texture). Surgical revision for mature, problematic scars. Sun protection prevents hyperpigmentation of scars and improves overall appearance.

Schwannoma

– A benign peripheral nerve sheath tumor arising from Schwann cells. It presents as a solitary, slow-growing, painless nodule along a peripheral nerve course. It can be moved laterally but not longitudinally along the nerve. Vestibular schwannoma (acoustic neuroma) arises from CN VIII. Diagnosis is by MRI. Treatment is surgical enucleation preserving nerve function. Schwannomas are encapsulated and separable from the nerve.

Seborrheic Dermatitis

– A chronic inflammatory skin condition affecting sebum-rich areas: scalp, face (nasolabial folds, eyebrows), chest, and intertriginous areas. Presents with erythematous patches with greasy, yellowish scales. Dandruff is a mild form. More common and severe in Parkinson disease, HIV/AIDS, and Down syndrome. Related to *Malassezia* yeast colonization and immune response. Treatment: ketoconazole shampoo/cream, selenium sulfide, zinc pyrithione, topical corticosteroids, and calcineurin inhibitors for facial involvement.

Seborrheic Keratosis

– A benign epidermal tumor appearing as stuck-on, waxy, hyperpigmented plaques with a verrucous surface. They are extremely common in older adults and increase in number with age. Seborrheic keratoses are not premalignant. The sign of Leser-Trélat indicates sudden eruption of multiple seborrheic keratoses, which may signal internal malignancy (gastric adenocarcinoma). Treatment is cosmetic removal by cryotherapy, curettage, or shave excision.

Seborrhoea

– See Seborrheic Dermatitis.

Second-Degree Burn

– Partial-thickness burn involving the epidermis and dermis: superficial partial-thickness (blisters, moist, painful, pink) vs. deep partial-thickness (blanching, painful, may have thrombosed capillaries). Causes: thermal (scalds, flames), chemical, electrical. Management: cool water, analgesia, blisters (debride/leave depending), sterile dressings, infection prevention (topical—silver sulfadiazine, mupirocin), tetanus prophylaxis, and fluids for significant surface area; deep partial-thickness may require excision and grafting. Complications: infection, scarring, contractures, and fluid loss. Full-thickness areas need surgical management.

Skin Aging

– intrinsic (chronological) and extrinsic (photoaging) components. Photoaging causes wrinkle formation, telangiectasias, lentigines, leather-like texture, and actinic keratoses. Intrinsic aging causes thinning, wrinkling, and delayed wound healing. Prevention includes sun protection (broad-spectrum SPF 30 or greater daily). Treatment includes topical retinoids (tretinoin), vitamin C, alpha hydroxy acids, chemical peels, laser therapy, and fillers. Tretinoin is the most evidence-based topical treatment for photoaging, with demonstrated improvement in fine wrinkles, roughness, and mottled hyperpigmentation after 3 to 6 months of regular use.

Skin Aging and Appearance

– Skin aging is a complex biological process influenced by both intrinsic factors, such as genetics and natural aging, and extrinsic factors, particularly ultraviolet radiation exposure. Chronological aging leads to thinning, dryness, and loss of elasticity, while photoaging from sun exposure causes wrinkles, pigmentation changes, and textural irregularities. Preventive measures include consistent sun protection, moisturizing, and avoiding smoking, while treatments such as topical retinoids, antioxidants, laser therapy, and injectable fillers can help improve the appearance of aging skin.

Skin Allergies and Contact Dermatitis

– Inflammatory skin reactions triggered by exposure to allergens or irritants that come into direct contact with the skin. Allergic contact dermatitis results from a delayed immune response to substances such

as nickel, poison ivy, or fragrances, while irritant contact dermatitis occurs when chemicals or physical agents damage the skin barrier directly. Symptoms include redness, itching, swelling, and blistering; management involves identifying and avoiding triggers, using topical corticosteroids, and maintaining skin barrier function with moisturizers.

Skin Allergy Testing

- prick testing (immediate hypersensitivity, IgE-mediated) and intradermal testing (more sensitive, used for drug and venom allergy). Prick testing introduces allergen extract into the epidermis; wheal and flare reaction at 15 minutes indicates sensitization. Intradermal testing injects dilute allergen into the dermis. Both tests require stopping antihistamines 3 to 7 days before testing. Negative predictive value is high; positive results require clinical correlation to confirm relevance.

Skin and Aging

- Skin aging involves intrinsic and extrinsic changes. Intrinsic aging causes thinning, wrinkling, and fragility. Extrinsic (photo)aging causes wrinkles, telangiectasias, lentigines, and actinic keratoses. Collagen loss, elastin degradation, and decreased cell turnover contribute to aging skin. Prevention includes sun protection, smoking cessation, and antioxidants. Treatment includes retinoids, vitamin C, alpha hydroxy acids, chemical peels, laser therapy, and fillers. Skin cancer screening is essential as part of the regular check-up for elderly patients.

Skin and Environment

- Environmental factors significantly affect skin health. Pollution causes oxidative stress, inflammation, and accelerated aging. Particulate matter penetrates skin, generating free radicals. Blue light from screens causes hyperpigmentation, particularly in darker skin tones. Indoor heating and air conditioning cause dryness. Water quality (hard water) affects eczema. Environmental protection includes antioxidant skincare, cleansing, and sun protection.

Skin Appendages

- hair follicles, sebaceous glands, eccrine sweat glands, and apocrine sweat glands. Hair follicles cycle through anagen (growth), catagen (transition), and telogen (resting) phases. Sebaceous glands produce sebum, an oily substance lubricating skin and hair. Eccrine glands (distributed over entire body)

produce watery sweat for thermoregulation. Apocrine glands (axillae, groin) produce viscous secretion active at puberty, responsible for body odor when metabolized by bacteria that break down fatty acids and proteins in the secretion.

Skin Barrier Function

- The skin barrier prevents water loss and protects against environmental insults. The stratum corneum acts as a physical barrier, while the acid mantle (pH 4 to 6) provides chemical defense. Lipids (ceramides, cholesterol, free fatty acids) in the intercellular space form a waterproof barrier. Tight junctions in the stratum granulosum prevent paracellular transport. Barrier dysfunction is central to atopic dermatitis, psoriasis, and ichthyosis. Emollients restore barrier function by filling intercellular lipids, while moisturisers reduce water loss and improve barrier function.

Skin Biopsy Methods

- Skin biopsy methods vary by lesion characteristics. Punch biopsy (2 to 6 mm circular blade) provides full-thickness specimen for most diagnoses. Shave biopsy (razor or scalpel) removes superficial lesions; deep shave (saucerization) includes subcutaneous fat for suspected melanoma. Excisional biopsy removes entire lesion with narrow margins, preferred for suspected melanoma. Incisional biopsy removes representative portion of large lesions. Site and technique should be chosen to optimize diagnostic yield. Proper anesthesia and haemostasis are important for optimal specimen quality.

Skin Biopsy Techniques

- Skin biopsy is essential for diagnosing skin conditions. Punch biopsy (2 to 6 mm) is most common, providing full-thickness skin sample for histopathology and direct immunofluorescence. Shave biopsy (razor or scalpel) is used for superficial lesions but may not include deep dermis. Excisional biopsy removes entire lesion with margins, used for suspected melanoma. Incisional biopsy removes representative portion of large lesions. Site selection depends on suspected diagnosis: perilesional for immunofluorescence (perilesional normal skin) or center of lesion for routine histology.

Skin Cancer Epidemiology

- Skin cancer epidemiology reveals increasing incidence worldwide. Basal cell carcinoma is the most

common cancer (1 million cases annually in the US). Squamous cell carcinoma is second (approximately 200,000 cases annually). Melanoma is less common but most deadly (about 100,000 new cases annually in the US). Incidence of melanoma has increased 200 percent over the past 30 years. UV radiation is the primary risk factor. Skin cancer screening and sun protection are public health priorities.

Skin Cancer Prevention

- Skin cancer prevention focuses on UV radiation protection. Broad-spectrum sunscreen (SPF 30 or greater) applied daily and reapplied every 2 hours during sun exposure. Protective clothing, hats, and sunglasses. Seeking shade during peak UV hours (10 AM to 4 PM). Avoiding tanning beds. Vitamin D supplementation for those with strict sun avoidance. Sunscreen reduces melanoma risk by 50 percent with intermittent use. Sunscreen use in children is particularly important.

Skin Cancer Screening

- Skin cancer screening uses the ABCDE criteria for melanoma, the ugly duckling sign, and total body skin examination. Dermoscopy (dermatoscopy) magnifies skin lesions revealing structures invisible to the naked eye, improving diagnostic accuracy. Skin self-examination teaches patients to monitor moles for changes. Annual screening is recommended for high-risk patients (personal or family history of melanoma, numerous atypical nevi, immunosuppression).

Skin Cancer Staging

- Skin cancer staging guides treatment and prognosis. Melanoma: Breslow thickness (most important prognostic factor), ulceration, mitotic rate, sentinel lymph node status (AJCC 8th edition). Basal cell carcinoma: rarely metastasizes; high-risk features include size greater than 2 cm, location on face, perineural invasion, and recurrent tumors. Squamous cell carcinoma: AJCC staging based on size, depth, perineural invasion, and nodal metastasis. High-risk features include thickness greater than 2 mm greater than 2 mm for SCC and greater than 2 cm for BCC. Sentinel lymph node biopsy is indicated for high-risk SCC and melanoma.

Skin Cancer Surgery

- Skin cancer surgical techniques maximize cure while minimizing morbidity. Wide local excision with ap-

propriate margins (BCC: 4 mm, SCC: 4 to 6 mm, melanoma: based on Breslow thickness). Mohs micrographic surgery provides 99 percent cure rate for BCC and 97 percent for SCC with tissue preservation. Sentinel lymph node biopsy for melanoma greater than 1 mm or with ulceration. Reconstruction ranges from primary closure to flaps and grafts.

Skin Flaps

- Skin flaps transfer tissue with its blood supply. Rotation flaps rotate adjacent tissue into defect. Advancement flaps slide tissue forward. Transposition flaps move tissue across intervening skin. Random pattern flaps rely on dermal plexus; axial pattern flaps have named vascular pedicle. Flaps provide better color and texture match than grafts for facial reconstruction. Design follows relaxed skin tension lines and aesthetic subunits.

Skin Grafts

- Skin grafts replace lost skin. Split-thickness grafts (epidermis and part of dermis) heal by re-epithelialization of donor site, allowing reuse. Full-thickness grafts (entire dermis) provide better cosmetic results but require primary closure of donor site. Sheet grafts provide smooth surface; mesh grafts cover larger areas but have quilted appearance. Graft take requires vascular ingrowth from wound bed (plasmatic imbibition day 1 to 2, inosculation day 2 to 3, revascularization day 3 to 5).

Skin Immune System

- The skin immune system (SALT: skin-associated lymphoid tissue) provides immunological surveillance. Langerhans cells (dendritic cells in epidermis) capture antigens and present them to T cells. Dermal dendritic cells, mast cells, and resident T cells form an innate and adaptive immune network. Cytokines (IL-1, IL-6, TNF-alpha, IL-17, IL-23) mediate inflammatory responses. The skin immune system is involved in contact dermatitis, psoriasis, atopic dermatitis, and skin cancer immunosurveillance.

Skin Microbiome

- The skin microbiome is the community of microorganisms (bacteria, fungi, viruses) residing on the skin. *Staphylococcus aureus* colonization is increased in atopic dermatitis and psoriasis. *Cutibacterium acnes* plays a role in acne. Diversity is de-

creased in diseased skin. Probiotics and prebiotics are being studied for dermatologic conditions. Topical antimicrobials and emollients modulate the microbiome. Disruption of the microbiome contributes to skin disease pathogenesis.

Skin of Color

– Skin of color (Fitzpatrick IV to VI) has unique dermatologic considerations. It is more prone to hyperpigmentation disorders (post-inflammatory hyperpigmentation, melasma, acanthosis nigricans) and keloid formation. It is less prone to skin cancer but presents with more advanced disease when it occurs. Dermoscopic features differ in pigmented skin. Misdiagnosis is common: vitiligo appears as ash-gray macules, lupus may present with hyperpigmentation rather than erythema. Culturally competent dermatological care acknowledges these differences and ensures accurate diagnosis and appropriate management for patients with skin of color.

Skin Pigmentation

– Determined by melanin produced by melanocytes in the stratum basale. Eumelanin (brown-black) and pheomelanin (red-yellow) are the two types. Melanin production is stimulated by UV radiation through melanocyte-stimulating hormone (MSH). Fitzpatrick skin type classification (I to VI) describes pigmentation and sun response. Hyperpigmentation disorders include melasma, post-inflammatory hyperpigmentation, and lentigines. Hypopigmentation disorders include vitiligo, pityriasis alba (post-inflammatory hypopigmentation) and albinism (congenital hypopigmentation, oculocutaneous or ocular). Treatment of hyperpigmentation includes sun protection, topical hydroquinone, azelaic acid, kojic acid, vitamin C, retinoids, chemical peels, and laser therapy.

Skin Tags

– Benign fibroepithelial polyps occurring in intertriginous areas (neck, axillae, groin, under breasts). They are associated with obesity, insulin resistance, and pregnancy. Skin tags are asymptomatic but may become irritated or bleed. Treatment includes snipping, cryotherapy, electrocautery, and shave excision. They are harmless and require no biopsy unless atypical.

Squamous Cell Carcinoma

– Cutaneous squamous cell carcinoma (cSCC) is the second most common non-melanoma skin cancer, accounting for approximately 20 percent of non-melanoma skin cancers, with an incidence of over 1 million cases per year in the United States and a lifetime risk of approximately 7 to 11 percent in fair-skinned populations, with increasing incidence. cSCC arises from keratinocytes of the epidermis (squamous cells), driven by ultraviolet radiation-induced mutations (TP53 tumor suppressor mutations in great part due to TP53 hotspot mutations in sun-exposed skin), ultraviolet B (UVB) signature mutations (C to T and CC to TT transitions at dipyrimidine sites), and chronic immunosuppression (organ transplant recipients have a 65 to 250-fold increased risk of cSCC). cSCC typically presents as an erythematous, hyperkeratotic, indurated papule or plaque on sun-exposed areas (face, ears, scalp, dorsal hands, forearms, lower legs) and may arise de novo, from actinic keratosis (the precursor lesion), from Bowen disease (squamous cell carcinoma in situ), or from erythroplasia of Queyrat (penile carcinoma in situ). High-risk features for local recurrence and metastasis include tumour thickness greater than 2 mm, Clark level IV or V, perineural invasion, lymphovascular invasion, poor differentiation, location on the ear or lip, diameter greater than 2 cm, and recurrence after prior treatment.

Stevens-Johnson Syndrome

– SJS: a severe, potentially fatal mucocutaneous reaction with widespread epidermal detachment (<10 percent BSA; overlap SJS/TEN 10-30 percent; toxic epidermal necrolysis >30 percent), most commonly drug-induced (sulfonamides, anticonvulsants—carbamazepine, lamotrigine, allopurinol, NSAIDs, nevirapine) or infectious (Mycoplasma). Features: prodromal fever, then painful erythema, targetoid lesions, blistering and skin sloughing, and mucosal involvement (oral, ocular, genital). Diagnosis: clinical; skin biopsy (full-thickness epidermal necrosis). Management: withdraw culprit drug, supportive burn-unit care (fluids, wound care, infection prevention), and controversial immunomodulation (corticosteroids, IVIG, cyclosporine); ocular sequelae common; high mortality (10-30 percent).

Subcutaneous Tissue

– Subcutaneous tissue (hypodermis, superficial fascia) lies beneath the dermis and connects skin to underlying structures. It contains adipose tissue (fat), blood vessels, nerves, and the superficial muscular aponeurotic system (SMAS). Subcutaneous fat provides insulation, cushioning, and energy storage. The thickness varies by body site, age, sex, and nutritional status. Liposuction removes subcutaneous fat. Subcutaneous injections (insulin, heparin, vaccines) deposit medication in this layer.

Sunburn

– Acute erythema (and later edema, pain, blistering, peeling) of skin from excessive ultraviolet (UV) radiation (UVB predominantly), causing DNA damage and inflammatory response. Risk: repeated sunburn increases skin cancer risk (melanoma, basal/squamous cell carcinoma) and photoaging. Features: erythema 3-5 hours post-exposure, maximal at 12-24 h, pain, tenderness; severe: blistering, systemic symptoms (fever, chills, dehydration). Management: cool compresses, emollients (aloe), NSAIDs/analgesics, hydration; severe with blistering: wound care, fluids; complications: infection, pigmentary change. Prevention: sunscreen (broad-spectrum SPF 30+), protective clothing, avoid peak sun, and photoprotection in photosensitive individuals.

Sun Protection (Photoprotection)

– Sun protection involves measures taken to reduce exposure to ultraviolet radiation from the sun, which is the primary environmental risk factor for skin cancer and photoaging. Recommended strategies include applying broad-spectrum sunscreen with a sun protection factor of at least 30, wearing protective clothing and wide-brimmed hats, seeking shade during peak ultraviolet hours between 10 a.m. and 4 p.m., and avoiding tanning beds. Consistent sun protection throughout life significantly reduces the risk of melanoma, squamous cell carcinoma, and basal cell carcinoma, as well as preventing premature skin aging.

Systemic Antifungals

– Systemic antifungals treat extensive or refractory fungal infections. Terbinafine is first-line for onychomycosis (6 weeks for fingernails, 12 weeks for toenails) and tinea capitis. Itraconazole pulse therapy (200 mg twice daily for 1 week per month)

treats onychomycosis. Fluconazole treats tinea corporis, cruris, and versicolor. Griseofulvin treats tinea capitis (requires 12 to 16 weeks). Voriconazole and posaconazole treat invasive fungal infections. Hepatic function monitoring is required.

Telogen Effluvium

– Diffuse hair shedding caused by premature entry of hair follicles into the telogen (resting) phase. Triggers include severe illness, surgery, childbirth, rapid weight loss, emotional stress, medications (beta-blockers, retinoids, anticoagulants), and nutritional deficiencies (iron, zinc, vitamin D). Acute TE resolves within 6 months; chronic TE lasts longer than 6 months. Diagnosis is clinical with positive hair pull test and normal scalp examination. Treatment addresses the underlying trigger; recovery of normal hair growth occurs over 3 to 6 months, though the condition may become chronic if the triggering factor persists.

Third-Degree Burn

– Full-thickness burn destroying the epidermis and dermis (into subcutaneous tissue): wound is white, leathery, charred, painless (nerve destruction), and non-blanching; no spontaneous healing—requires skin grafting. Assessment: percent BSA (rule of nines), inhalation injury (facial burns, soot, hoarseness—intubation), and depth. Management: advanced burn care—fluid resuscitation (Parkland formula: $4 \text{ mL/kg} \times \% \text{BSA crystalloid}$), analgesia, escharotomy (circumferential—compartment), wound debridement and grafting, infection control (topical antimicrobials), nutritional support, and ICU care. Complications: infection/sepsis, hypovolemic shock, contractures, hypertrophic scarring, and multiorgan failure.

Tinea Capitis

– A dermatophyte infection of the scalp and hair shafts, most common in children. It presents as scaly patches, alopecia, black dots (broken hairs), kerion (inflamed boggy plaque), and impetigo of Hilgart (pyogenic reaction). Trichophyton tonsurans and Microsporum canis are the most common organisms. Diagnosis is by KOH preparation and fungal culture. Treatment requires oral antifungals (griseofulvin, terbinafine, itraconazole) for 4 to 8 weeks. Topical agents alone are ineffective. Selenium sulfide shampoo can reduce spore shedding.

Treatment of close contacts and fomite disinfection prevent spread.

Tinea Corporis

- A dermatophyte infection of glabrous skin, presenting as annular, erythematous, scaly plaques with raised, active borders and central clearing. It is contagious through direct contact with infected persons, animals, or contaminated objects. Diagnosis is by KOH preparation showing branching septate hyphae. Treatment includes topical antifungals (terbinafine, clotrimazole, miconazole) for 2 to 4 weeks. Oral terbinafine or itraconazole for extensive or refractory disease.

Tinea (Dermatophytosis)

- Superficial fungal infection by dermatophytes. Tinea corporis (ringworm): annular, scaly, erythematous plaque with central clearing. Tinea pedis (athlete's foot): interdigital scaling, maceration, and fissuring. Tinea cruris (jock itch): erythematous, pruritic rash in groin with raised border. Tinea capitis: scaly scalp patches with broken hairs, more common in children; may cause kerion (inflammatory mass). Diagnosis: KOH preparation and culture. Treatment: topical terbinafine or azoles for mild to moderate; systemic terbinafine, itraconazole for extensive, scalp, or nail involvement.

Tinea Pedis

- A dermatophyte infection of the feet. Moccasin type (diffuse scaling of sole and sides), interdigital type (most common, between toes), vesiculobullous type (acute inflammation), and ulcerative type. Associated with tinea unguium (nail infection). Treatment includes topical antifungals (terbinafine, butenafine, clotrimazole). Oral terbinafine for refractory cases. Preventive measures include keeping feet dry, wearing sandals in public showers, and treating nail infection (onychomycosis) concurrently.

Tinea Versicolor

- A superficial fungal infection caused by *Malassezia* species, presenting as hypo- or hyperpigmented macules with fine scale on the trunk and proximal extremities. It is more noticeable after sun exposure due to unaffected tanning of surrounding skin. Diagnosis is clinical with KOH showing spaghetti and meatballs appearance (hyphae and spores). Treatment includes selenium sulfide shampoo, topical antifungals (ketoconazole, ciclopirox), and oral flu-

conazole fluconazole (200 to 400 mg single dose or 300 mg weekly for 2 weeks) for extensive or recurrent disease, with a 50 to 80 percent response rate but high relapse rates (more than 50 percent within 2 years, requiring maintenance therapy).

Topical Antibiotics

- Topical antibiotics treat superficial bacterial skin infections. Mupirocin 2 percent ointment is first-line for impetigo and folliculitis (inhibits bacterial protein synthesis). Retapamulin 1 percent ointment is an alternative. Fusidic acid is used outside the US. Topical gentamicin and bacitracin are less effective and may cause contact dermatitis. Neomycin has high allergy rates and is no longer recommended. Topical antibiotics should be used for limited areas and short durations to prevent resistance. Widespread or deep infections require systemic antibiotics.

Topical Antifungals

- Topical antifungals treat superficial fungal infections. Allylamines (terbinafine, naftifine) inhibit squalene epoxidase, fungicidal. Azoles (clotrimazole, miconazole, ketoconazole, econazole) inhibit ergosterol synthesis, fungistatic. Ciclopirox has broad-spectrum activity. Tolnaftate is effective against dermatophytes. Application frequency: allylamines once or twice daily for 1 to 2 weeks; azoles once or twice daily for 2 to 4 weeks. Treatment should continue 1 to 2 weeks after clinical resolution to prevent recurrence.

Topical Calcineurin Inhibitors

- Non-steroidal anti-inflammatory agents used for atopic dermatitis and facial eczema. They inhibit T-cell activation by blocking calcineurin, preventing cytokine production. Advantages over corticosteroids: no skin atrophy, safe for face and intertriginous areas. Side effects include transient burning and itching at application site. Black box warning for malignancy risk has not been substantiated by real-world use, though FDA requires it. Intermittent therapy is safe for long-term use.

Topical Corticosteroid Potency

- Topical corticosteroids are classified into seven potency groups. Group 1 (ultra-high): clobetasol propionate 0.05 percent. Group 2 (high): betamethasone dipropionate 0.05 percent. Group 3 to 4 (medium): triamcinolone acetonide 0.1 per-

cent. Group 5 to 6 (low): hydrocortisone 1 percent. Group 7 (lowest): hydrocortisone 0.5 percent. Face, groin, and intertriginous areas require low-potency steroids. Thick plaques on palms and soles may require ultra-high potency. Prolonged use causes skin atrophy, skin atrophy, telangiectasias, striae, and perioral dermatitis. Occlusion increases potency. Short-term use of appropriate potency minimises adverse effects while maximising efficacy.

Topical Retinoids

– Vitamin A derivatives used for acne, photoaging, and hyperpigmentation. Tretinoin (all-trans retinoic acid) is the most studied. Adapalene is more stable and less irritating. Tazarotene is the most potent. Mechanism: normalizes follicular keratinization, increases cell turnover, and stimulates collagen production. Side effects include irritation, erythema, peeling, and photosensitivity. Start with low concentration, alternate nights, and use moisturizer. Sunscreen is mandatory during retinoid therapy. Results are seen over 4 to 6 months. Maintenance therapy with lower frequency is needed.

Urticaria

– A common skin condition characterized by the transient appearance of wheals (raised, erythematous or white plaques with surrounding flare), angioedema (swelling of the deeper dermis and subcutaneous tissue, often involving the lips, eyelids, tongue, and extremities), or both, with a prevalence of 15 to 20 percent of the population experiencing at least one episode during their lifetime, and chronic urticaria (episodes occurring on most days for greater than 6 weeks) affecting 1 to 2 percent of the population, more common in middle-aged women. The diagnosis is clinical. Treatment follows a stepwise approach: second-generation antihistamines first-line, with up dosing as needed; add H₂-antagonist or montelukast second-line; add omalizumab or cyclosporine third-line.

Verruca (Wart)

– Benign epidermal hyperplasia caused by human papillomavirus (HPV). Common warts (verruca vulgaris): rough papules on hands/fingers. Plantar warts: painful lesions on soles, grow inward due to pressure. Flat warts (verruca plana): smooth, flat-topped papules on face, hands, legs. Filiform warts: finger-like projections, often on face. Genital

warts (condyloma acuminata): sexually transmitted. Diagnosis: clinical. Treatment: cryotherapy, salicylic acid, cantharidin, imiquimod, podophyllin, and laser therapy. Most warts resolve spontaneously over months to years.

Vesicle

– A small (<1 cm) fluid-filled blister within the epidermis, containing clear fluid (serum) or, if infected, pus. Causes: viral (herpes simplex, herpes zoster, varicella, hand-foot-mouth disease), dermatitis (contact, dyshidrotic eczema), autoimmune (pemphigus, bullous pemphigoid early), and friction burns. Grouped vesicles on an erythematous base suggest herpesvirus; dermatomal distribution suggests zoster. Diagnosis: clinical, Tzanck smear, viral PCR, biopsy (pemphigus—*intraepidermal acantholysis*; pemphigoid—*subepidermal*). Management: treat cause—antivirals for herpes, topical steroids for eczema, immunosuppression for autoimmune blisters; keep clean to prevent superinfection. Larger than 1 cm: bulla.

Vitiligo

– An acquired, autoimmune pigmentary disorder characterized by well-demarcated, white macules and patches resulting from the destruction of epidermal melanocytes, affecting approximately 0.5 to 2 percent of the global population, with equal distribution across sexes and races, and an age of onset typically before 30 years (50 percent before age 20). Pathogenesis involves autoimmune destruction of melanocytes: CD8⁺ cytotoxic T cells infiltrate the lesional and perilesional epidermis, targeting melanocyte-specific antigens such as tyrosinase, Melan-A/MART-1, and gp100, with the destruction mediated by the release of cytotoxic granules containing perforin and granzyme B. The exact trigger for the loss of self-tolerance is unknown but is thought to involve a combination of genetic susceptibility (more than 30 susceptibility loci identified, most importantly the MHC class II region on chromosome 6p21.3, including HLA-DRB1*04 and HLA-DQB1*03), environmental triggers (oxidative stress, mechanical trauma, Koebner phenomenon, and chemical exposure to monobenzene and other phenolic compounds), and autoimmune diathesis (association with other autoimmune diseases, particularly thyroid disease, found in 15 to 25 percent

of patients, most commonly Hashimoto thyroiditis).

Vitiligo and Pigmentation Disorders

– Vitiligo is a chronic skin condition characterized by the loss of melanocytes, resulting in well-defined white patches on the skin and sometimes mucous membranes. The exact cause is not fully understood but involves an autoimmune process in which the body attacks its own pigment-producing cells, and it may be associated with other autoimmune diseases. Pigmentation disorders also include melasma, characterized by brown patches on the face often triggered by hormonal changes, and post-inflammatory hyperpigmentation, which follows skin injury or inflammation; treatments range from topical corticosteroids and phototherapy to depigmentation and cosmetic camouflage.

Vitiligo Treatment

– Vitiligo treatment options include topical corticosteroids (first-line for limited disease), topical calcineurin inhibitors (tacrolimus, pimecrolimus for face and intertriginous areas), narrowband UVB phototherapy (first-line for widespread disease), excimer laser for localized lesions, and systemic immunosuppressants for rapidly progressive disease. JAK inhibitors (ruxolitinib cream) are FDA-approved for vitiligo. Surgical options include autologous melanocyte transplantation for stable disease (lesions stable for at least 6 to 12 months), including suction blister grafting, punch grafting, and cultured melanocyte transplantation, with repigmentation rates of 50 to 90 percent in properly selected patients.

Warts

– See Verruca (Wart).

Wen (Epidermoid Cyst)

– See Epidermal Inclusion Cyst.

Wound Healing Phases

– Wound healing occurs in overlapping phases: hemostasis (immediate, platelet aggregation and clot formation), inflammation (days 1 to 4, neutrophils and macrophages clear debris and bacteria), proliferation (days 4 to 21, granulation tissue, angiogenesis, epithelialization, collagen deposition), and remodeling (day 21 to 2 years, collagen maturation, scar strengthening to 80 percent of original strength). Factors impairing healing include diabetes, infection,

ischemia, malnutrition, and steroids.

Xanthelasma

– Xanthelasma palpebrarum are soft, yellow, lipid-filled papules or plaques on the medial canthus of the eyelids (upper more commonly than lower), the most common form of cutaneous xanthoma. They are composed of foam cells (lipid-laden macrophages) in the superficial dermis. Xanthelasma is associated with hyperlipidemia (elevated LDL, low HDL) in approximately 50% of patients; the other 50% are normolipidaemic. It may also be associated with diabetes, obesity, and cardiovascular disease (xanthelasma is an independent risk factor for atherosclerotic cardiovascular disease). Diagnosis: clinical. Treatment: options for cosmetic removal include surgical excision (elliptical excision with primary closure, risks of ectropion or scar), laser therapy (CO₂, argon, or pulsed dye laser), chemical cautery (trichloroacetic acid, which should be used sparingly to avoid eyelid scarring), and radiofrequency ablation. Underlying hyperlipidemia should be screened and managed.

Xanthoma

– Cutaneous deposits of lipids (cholesterol, triglycerides) in the dermis or tendons, presenting as yellow-orange papules, nodules, or plaques. Xanthomas are classified by clinical morphology and location: eruptive xanthomas (sudden eruption of multiple small, red-yellow papules on buttocks, extensor surfaces — pathognomonic for hypertriglyceridaemia, chylomicronaemia syndrome, lipoprotein lipase deficiency), tuberous xanthomas (firm, painless, yellow-red nodules on elbows, knees, buttocks — seen in familial hypercholesterolaemia, Sitosterolaemia), tendinous xanthomas (subcutaneous nodules within tendons, most commonly the Achilles tendon and extensor tendons of the hands — pathognomonic for familial hypercholesterolaemia, cerebrotendinous xanthomatosis), and planar xanthomas (flat or slightly raised yellow plaques on palms, flexural creases, or intertriginous areas — associated with type III hyperlipoproteinaemia/dysbetalipoproteinaemia). Diagnosis: clinical, serum lipid panel, and biopsy (foam cells, Touton giant cells). Xanthomas are not harmful themselves but are markers of underlying lipid disorders that require treatment to reduce cardio-

vascular risk.

Xeroderma

– See Xerosis.

Xerosis

– Abnormally dry skin, common in elderly patients and winter months. It results from decreased sebaceous and sweat gland activity, impaired skin barrier function, and environmental factors. Treatment includes regular emollient application (cream or ointment rather than lotion), gentle cleansing, and humidification. Severe xerosis may progress to asteatotic eczema (eczema craquelé) with cracked, porcelain-like appearance.

Zinc Ointment (Zinc Oxide)

– Zinc oxide is a topical agent with mild antiseptic, astringent, and barrier-protective properties, used in a wide range of dermatological preparations. Mechanism: zinc is an essential trace element and cofactor for numerous metalloenzymes involved in wound healing (matrix metalloproteinases, DNA polymerases, superoxide dismutase). Zinc oxide has anti-inflammatory effects (inhibits neutrophil degranulation and mast cell degranulation), provides UV protection (physical sunscreen, blocks UVA and UVB), and forms a protective barrier over irritated or denuded skin that reduces moisture loss and protects from friction and irritants. Indications: nappy/diaper rash (the most common use — as a barrier cream that protects the perineal skin from moisture and faecal enzymes), minor wounds, abrasions, and burns, sun protection (physical sunscreen, often combined with titanium dioxide), and as a topical treatment for acne vulgaris and seborrhoeic dermatitis. Zinc sulphate is used in oral zinc supplementation for zinc deficiency and for treatment of Wilson disease (blocks intestinal copper absorption). Adverse effects: topical — skin irritation, contact dermatitis (rare). Oral zinc: nausea, gastric irritation, copper deficiency with long-term high doses (zinc inhibits copper absorption via metallothionein induction).

Chapter 8

Emergency Medicine

High-Yield Clinical Reference: APGAR Newborn Assessment

Sign	0 Points	1 Point	2 Points
Appearance (Color)	Blue or pale overall	Body pink, extremities blue	Completely pink
Pulse (Heart Rate)	Absent	< 100 bpm	> 100 bpm
Grimace (Reflex)	No response	Grimace / feeble cry	Active cry
Activity (Tone)	Limp / flaccid	Some flexion of extremities	Active movement
Respiration (Effort)	Absent	Slow, irregular	Good, strong cry

Assessed at 1 minute and 5 minutes after birth.

Score: 7–10 = Normal; 4–6 = Moderate depression;

0–3 = Severe depression.

Abscess

– A localized collection of pus within a tissue, organ, or cavity, typically caused by bacterial infection. Abscesses form when bacteria (most commonly *Staphylococcus aureus* including MRSA) invade tissue, triggering an intense inflammatory response with neutrophil accumulation and tissue necrosis. The body attempts to wall off the infection, creating a walled-off cavity filled with purulent material (dead neutrophils, bacteria, necrotic tissue). Clinical presentation includes a painful, swollen, erythematous, warm mass that may fluctuate (indicating fluid collection). Systemic symptoms (fever, leukocytosis) may be present. Diagnosis is primarily clinical; ultrasound confirms the presence and size of a fluid collection. Treatment requires incision and drainage (I and D) for Source control, as antibiotics alone cannot penetrate the abscess wall effectively. Small abscesses (< 2 cm) may respond to warm compresses and antibiotics. Culture should be obtained to guide antibiotic therapy, particularly for recurrent abscesses or MRSA risk factors. Complications include cellulitis, bacteremia, and

sepsis if untreated. Common locations include skin and soft tissue (furuncles, carbuncles), perianal (perianal abscess), intra-abdominal (from perforated viscus), dental (dental abscess), and brain (cerebral abscess).

Acute Aortic Syndromes

– A spectrum of life-threatening conditions involving the thoracic aorta, including aortic dissection, intramural hematoma (IMH), and penetrating aortic ulcer (PAU). Aortic dissection involves an intimal tear

creating a false lumen. Classification (Stanford): Type A involves the ascending aorta (surgical emergency); Type B involves only the descending aorta (medical management unless complicated). Clinical presentation: sudden onset of severe, tearing or ripping chest or back pain radiating to the interscapular region, hypertension or hypotension, pulse deficits, aortic regurgitation murmur, or neurological deficits. Diagnosis: CT angiography (gold standard), transesophageal echocardiography (TEE), or MRI. Management: anti-impulse therapy (IV beta-blockers like esmolol/labetalol targeting HR < 60 bpm and SBP 100–120 mmHg), followed by emergency surgery for Type A or TEVAR/medical management for Type B.

Acute Coronary Syndrome (ACS)

– A spectrum of conditions caused by reduced coronary blood flow and myocardial ischemia: unstable angina, non-ST-elevation MI (NSTEMI), and ST-elevation MI (STEMI). Usual cause: rupture/erosion of an atherosclerotic plaque with superimposed thrombosis. Features: chest pain (pressure/crushing, radiating to arm/jaw), dyspnea, diaphoresis, nausea; atypical in women, diabetics, elderly. Diagnosis: ECG (ST elevation for STEMI), serial troponin. Management: aspirin, antiplatelet

(P2Y12), anticoagulant, nitroglycerin, morphine (as needed), statin, beta-blocker; reperfusion—primary PCI within 90 minutes (STEMI) or fibrinolysis.

Acute Coronary Syndromes

– A spectrum of conditions comprising unstable angina (UA), non-ST-elevation myocardial infarction (NSTEMI), and ST-elevation myocardial infarction (STEMI). Pathophysiology: atherosclerotic plaque rupture or erosion leading to thrombus formation and acute coronary artery occlusion. STEMI: complete occlusion presenting with ST-segment elevation in contiguous leads (≥ 1 mm in limb leads, ≥ 2 mm in precordial leads) or new LBBB. NSTEMI: partial occlusion causing cardiac troponin elevation without ST elevation. Unstable angina: ischemic symptoms at rest or increasing frequency without troponin elevation. Management: STEMI requires immediate reperfusion via primary percutaneous coronary intervention (PCI) within 90 minutes (door-to-balloon) or fibrinolysis within 30 minutes if PCI is unavailable within 120 minutes. Medical therapy: dual antiplatelet therapy (aspirin + P2Y12 inhibitor), anticoagulation (heparin), high-intensity statin, beta-blocker, and ACE inhibitor.

Adrenal Crisis

– An acute, life-threatening manifestation of severe adrenal insufficiency. Causes: primary (Addison disease), secondary (pituitary failure), or tertiary (exogenous corticosteroid withdrawal). Precipitants: systemic infection, trauma, surgery, or abrupt steroid cessation. Clinical presentation: severe hypotension refractory to vasopressors and fluid resuscitation, fever, abdominal pain, vomiting, hyponatremia, hyperkalemia, hypoglycemia, and altered mental status. Emergency management: immediate administration of IV hydrocortisone 100 mg bolus, followed by 200 mg/24 hours continuous infusion; aggressive isotonic saline fluid resuscitation; dextrose for hypoglycemia; and identification and treatment of the underlying precipitating cause.

Advanced Cardiovascular Life Support (ACLS)

– A set of clinical interventions for the urgent treatment of cardiac arrest, stroke, myocardial infarction, and life-threatening arrhythmias. Includes airway management, ECG rhythm interpretation, electrical defibrillation/cardioversion, transcutaneous pac-

ing, and administration of emergency medications (epinephrine, amiodarone, atropine, adenosine, lidocaine).

Airway Management

– The assessment and control of the patient's airway to ensure patency, oxygenation, and ventilation, a critical emergency skill. Techniques: positioning (head-tilt/chin-lift, jaw thrust), suction, oral/nasal airways, bag-valve-mask ventilation, supraglottic devices (LMA, i-gel), and definitive airway (endotracheal intubation—direct laryngoscopy, video laryngoscopy; surgical cricothyroidotomy as rescue). Rapid-sequence intubation (RSI) uses induction agents and paralytics. Confirm placement (ETCO₂, capnography, auscultation, CXR). Failure requires back-up strategies (difficult airway algorithm).

Altitude Illness

– Acute mountain sickness (AMS): headache + 1 symptom (nausea, fatigue, dizziness, insomnia) at >2500 m. HACE: AMS + ataxia/altered mental status (cerebral edema). HAPE: dyspnea at rest, cough, frothy sputum, crackles, hypoxemia (noncardiogenic pulmonary edema). Prevention: gradual ascent (300-500m/day above 3000m), acetazolamide 125 mg q12h prophylaxis. Treatment: descent (immediate for HACE/HAPE), oxygen, acetazolamide, dexamethasone 8 mg load then 4 mg q6h (HACE), nifedipine 30 mg ER q12h (HAPE), portable hyperbaric chamber (Gamow bag).

Anaphylaxis

– A severe, potentially life-threatening systemic hypersensitivity reaction characterized by rapid onset of multisystem involvement, primarily affecting the skin, respiratory tract, cardiovascular system, and gastrointestinal tract. It is mediated by IgE-dependent mast cell and basophil degranulation (Type I hypersensitivity) or by direct mast cell activation (non-IgE mediated, e.g., radiocontrast, opioids, vancomycin). Common triggers: foods (peanuts, tree nuts, shellfish, fish, eggs, milk, soy, wheat), medications (penicillins, NSAIDs, neuromuscular blocking agents, radiocontrast), insect stings (Hymenoptera: bees, wasps, fire ants), and exercise (exercise-induced anaphylaxis, often food-dependent). Clinical criteria: acute onset (minutes to hours) with involvement of skin/mucosa PLUS respiratory compromise (wheeze, stridor, dyspnea,

hypoxia) OR reduced blood pressure (systolic less than 90 mmHg in adults, or greater than 30 percent decrease from baseline) OR gastrointestinal symptoms (vomiting, crampy abdominal pain) with skin involvement. Management: immediate intramuscular epinephrine (0.3-0.5 mg of 1:1,000 solution in the mid-outer thigh, repeat every 5-15 minutes as needed) is the first-line and most critical intervention. Adjunctive treatments: high-flow oxygen, IV fluids (normal saline or lactated Ringer's for hypotension), H1 antihistamine (diphenhydramine 25-50 mg IV), H2 antihistamine (famotidine 20 mg IV), corticosteroids (methylprednisolone 125 mg IV or prednisone 40-60 mg PO), and albuterol nebulizer for bronchospasm. Patients should be observed for at least 4-6 hours (biphasic reaction occurs in 1-20 percent of cases). All patients discharged after anaphylaxis should receive an epinephrine auto-injector and referral to an allergist.

Asphyxia

- A life-threatening lack of oxygen due to drowning, choking, or an obstruction of the airways.

Aspiration

- The inhalation of foreign material (oropharyngeal secretions, gastric contents, food, liquid, or blood) into the larynx and lower respiratory tract. Aspiration pneumonitis (Mendelson syndrome) is a chemical lung injury caused by acidic gastric fluid. Aspiration pneumonia is an infectious lung process developing after inhalation of colonized oral secretions. Risk factors: impaired consciousness (alcohol intoxication, stroke, seizure, general anesthesia), dysphagia, enteral tube feeding, and vomiting. Clinical features: sudden cough, dyspnea, wheezing, hypoxemia, fever, and infiltrate on chest radiograph (commonly right lower lobe due to steeper right mainstem bronchus angle). Management: airway suctioning, supplemental oxygen, bronchodilators, and empiric antibiotics for aspiration pneumonia.

Avulsion

- An injury in which tissue is forcibly torn from the body by shearing or pulling. Common forms include dental, fingertip, nail, and degloving avulsions. Management focuses on hemorrhage control, debridement, tissue preservation, and urgent consultation. Avulsed teeth should be reimplanted within 60 minutes, handled by the crown, and stored in

milk, saline, or saliva.

Bag-Mask Ventilation

- Manual ventilation of a non-breathing or inadequately breathing patient using a self-inflating bag (AMBU) attached to a mask sealed over the face. Effective technique: correct mask size, jaw thrust/head extension, two-person technique (two-hand seal), adequate tidal volumes with ETCO₂ monitoring. Indicated in respiratory failure, arrest, or pre-intubation; complications: gastric insufflation, aspiration, barotrauma. Used for brief support and as a bridge to a definitive airway.

Basic Life Support (BLS)

- Level of medical care used for victims of life-threatening illnesses or injuries until full medical care can be provided. Focuses on the High-Quality CPR compression-to-ventilation ratio (30:2 in adults), chest compression depth (2-2.4 inches, 100-120/min), early use of an Automated External Defibrillator (AED), and relief of foreign body airway obstruction.

Battle Sign (Mastoid Ecchymosis)

- Ecchymosis (bruising) over the mastoid process behind the ear. Pathognomonic sign of a basilar skull fracture, specifically involving the petrous temporal bone. Arises from extravasation of blood along the path of the posterior auricular artery. Typically appears 1-3 days after traumatic head injury. Often accompanied by periorbital ecchymosis ("raccoon eyes"), hemotympanum, CSF rhinorrhea, or CSF otorrhea. Requires non-contrast CT of the head and immediate neurosurgical consultation. Lumbar puncture and nasogastric tube insertion are contraindicated.

Bends (Decompression Sickness)

- A condition resulting from rapid ascent from deep water or pressurized environment, causing dissolved inert gases (primarily nitrogen) to form bubbles in tissues and blood. Symptoms range from joint pain (the bends), skin rash (cutis marmorata), and neurologic deficits (paresthesias, weakness, confusion) to respiratory distress (the chokes) and cardiovascular collapse. Treatment: 100% oxygen and recompression in a hyperbaric chamber. Prevention: staged ascent with decompression stops and adherence to dive tables or computers.

Bite Wound

– A tissue injury inflicted by animal or human teeth that introduces oral and skin flora into the wound. Cat bites involve *Pasteurella multocida*, dog bites *Capnocytophaga canimorsus*, and human bites *Eikenella corrodens*. Hand, face, and genital wounds are high-risk. Management includes irrigation, debridement, tetanus and rabies prophylaxis, amoxicillin-clavulanate for high-risk bites, and delayed suturing on the hand.

Bites and Stings

– Injuries caused by the biting or stinging apparatus of arthropods (insects, spiders, ticks), marine animals, snakes, and mammals. Insect stings (bees, wasps, hornets, ants): local reaction (pain, erythema, edema, pruritus at sting site, self-limited over hours to days); large local reaction (extensive swelling spreading beyond the sting site, diameter >10 cm, peaking at 24-48 hours, resolves in 5-10 days); systemic allergic reaction/anaphylaxis (urticaria, angioedema, bronchospasm, hypotension, cardiovascular collapse — medical emergency requiring intramuscular epinephrine). Management: remove stinger (scrape, do not squeeze), cold compress, antihistamines (cetirizine, loratadine), and NSAIDs for pain. Anaphylaxis: IM epinephrine (0.3-0.5 mg, anterolateral thigh, repeat q5-15min as needed), IV fluids, supplemental oxygen, and hospital observation. Venom immunotherapy for patients with prior systemic reactions. Tick bites: Lyme disease (*Borrelia burgdorferi*, erythema migrans rash), Rocky Mountain spotted fever, and tick-borne encephalitis. Remove tick with fine-tipped tweezers, grasp as close to skin as possible, pull straight upward. No folklore remedies (matches, petroleum jelly, nail polish). Snake bites: pit vipers (rattlesnakes, copperheads, cottonmouths) cause local tissue destruction, coagulopathy, and systemic effects; treatment is antivenom (Fab fragments). Coral snakes cause neurotoxicity (descending paralysis, respiratory failure). Management: immobilisation, splinting, pressure immobilisation bandage for elapid bites (not for pit viper bites, which increases local necrosis). Mammal bites (dogs, cats, humans): high risk of infection (*Pasteurella multocida* in cat bites, *Capnocytophaga canimorsus* in dog bites, *Eikenella corrodens* in human bites). Management: wound irrigation, debridement, ra-

bies prophylaxis if indicated, tetanus vaccination update, and prophylactic antibiotics (amoxicillin-clavulanate) for high-risk bites (cat, hand, deep, delayed presentation, immunosuppressed). Marine stings (jellyfish, Portuguese man-of-war): nematocyst discharge causes painful, linear, urticarial eruptions. Management: rinse with vinegar (acetic acid) to inactivate nematocysts, remove tentacles with gloved hands, hot water immersion (45°C for 20 minutes) for pain, and antivenom for box jellyfish (*Chironex fleckeri*) stings.

Blunt Trauma

– Injury caused by a blunt impact without skin penetration, most often from traffic collisions, falls, assaults, or blast waves. Mechanisms include direct impact, deceleration shear, and crush, producing solid-organ laceration, hollow viscus rupture, and fractures. Management follows ATLS: primary survey with hemorrhage control, contrast CT imaging, serial reassessment, and laparotomy for the unstable patient.

Burns and Scalds

– Tissue damage caused by thermal, chemical, electrical, or radiation exposure. Burns from dry heat (flame, hot surfaces) and scalds from moist heat (hot liquids, steam) are classified by depth: superficial (first-degree: epidermal involvement, painful erythema without blisters), partial-thickness (second-degree: epidermal and dermal involvement, painful blisters), and full-thickness (third-degree: destruction of all skin layers and subcutaneous tissue, painless leathery or charred appearance). Total Body Surface Area (TBSA) is estimated using the Rule of Nines or Lund-Browder chart. Initial management: airway assessment for inhalation injury, fluid resuscitation using the Parkland formula (4 mL x kg x %TBSA over 24 hours, half given in the first 8 hours), pain management, sterile dressings, and referral to a burn center.

Cardiac Arrest

– The abrupt cessation of effective cardiac pumping with loss of effective circulation, leading to unconsciousness, apnea, and absent pulses. Causes (H's and T's): hypovolemia, hypoxia, hydrogen ion (acidosis), hypo/hyperkalemia, hypothermia, tension pneumothorax, tamponade, toxins, thrombosis (coronary/pulmonary). Rhythms: VF/VT (shock-

able), asystole/PEA (non-shockable). Management: high-quality CPR (100-120/min, 5-6 cm depth), early defibrillation, epinephrine (1 mg q3-5 min), airway/ventilation, treat reversible causes; post-ROSC targeted temperature management and PCI. Prognosis depends on rapidity of CPR/defibrillation.

Cardiac Tamponade

– A life-threatening condition caused by fluid accumulation within the pericardial space under increased pressure, compromising cardiac diastolic filling and severely reducing cardiac output. Causes: trauma, pericarditis, post-cardiac surgery, aortic dissection, or malignancy. Clinical features: Beck triad (hypotension, muffled heart sounds, jugular venous distension), pulsus paradoxus (systolic BP drop > 10 mmHg during inspiration), tachycardia, and tachypnea. Diagnosis: bedside echocardiography demonstrating pericardial effusion with right ventricular diastolic collapse and IVC plethora. Treatment: emergency pericardiocentesis (ultrasound-guided) or surgical pericardial window, alongside IV fluid boluses to maintain preload while preparing for drainage.

Cardiopulmonary Resuscitation (CPR)

– An emergency life-saving procedure performed to restore circulation and breathing in a person in cardiac arrest. Basic life support (BLS) sequence: check responsiveness, activate emergency medical services, and begin chest compressions (rate 100–120/min, depth 5–6 cm in adults, allowing full chest recoil). Give rescue breaths at a 30:2 ratio (compressions to breaths). Compression-only CPR is recommended for untrained bystanders. Advanced cardiovascular life support (ACLS) includes defibrillation for shockable rhythms (VF/pulseless VT), advanced airway management, IV/IO vascular access, and pharmacotherapy (epinephrine 1 mg every 3–5 min, amiodarone 300 mg bolus). High-quality CPR with minimal interruptions is the single most important determinant of cardiac arrest survival.

Choking

– Acute upper airway obstruction by a foreign body, producing sudden respiratory distress and risk of asphyxia. Cues include the universal choking sign, inability to speak or cough, stridor, and cyanosis.

Treatment alternates five back blows and five abdominal thrusts in responsive adults, using chest thrusts in obese or pregnant patients. Complete obstruction with unconsciousness requires CPR and laryngoscopy.

Coma

– A state of profound unconsciousness characterized by the inability to wake up, lack of awareness, and absence of voluntary responses to external stimuli. Causes are categorized as structural CNS lesions (stroke, hemorrhage, trauma, brain tumor, herniation) or metabolic/toxic encephalopathies (hypoxia, hypoglycemia, diabetic ketoacidosis, hepatic encephalopathy, drug overdose, severe hyponatremia, sepsis). Assessment: Glasgow Coma Scale (GCS < 8 indicates severe impairment requiring endotracheal intubation for airway protection), pupillary light reflex, corneal reflex, and doll's eye (oculocephalic) reflex. Emergency management: immediate ABCs, administration of the 'coma cocktail' if indicated (dextrose for hypoglycemia, thiamine, naloxone for opioid toxicity), non-contrast head CT, and treatment of the underlying cause.

Cricothyrotomy

– An emergency surgical airway created by incising the cricothyroid membrane to place a cuffed tube, used when orotracheal intubation is impossible. Indications include severe facial trauma, upper airway obstruction, hemorrhage, and the failed airway. It is the final rescue airway in adults. Needle cricothyrotomy with jet ventilation is generally preferred in young children.

Crush Injury

– Tissue damage from prolonged compression of a body part by a heavy object, producing ischemia, reperfusion, and rhabdomyolysis. Compartment syndrome is a frequent threat. Crush syndrome adds hyperkalemia, acidosis, myoglobinuric acute kidney injury, arrhythmia, and coagulopathy. Priorities include fluid resuscitation begun before releasing the compressing object, fasciotomy, urine alkalinization, and treatment of hyperkalemia.

Defibrillation

– The delivery of a controlled electrical shock to the heart to terminate life-threatening arrhythmias, specifically ventricular fibrillation (VF) and pulseless ventricular tachycardia (pVT), allowing the

sinoatrial node to resume normal rhythm. Defibrillation is time-critical: survival decreases by 7–10% per minute without it. Automated external defibrillators (AEDs) analyze rhythm and deliver shocks with voice prompts for bystander use. Biphasic waveforms (150–200 J) are more effective than monophasic (360 J) with less myocardial damage. For shockable rhythms: defibrillate immediately, then resume CPR for 2 minutes before rhythm check. Energy selection: adult 120–200 J biphasic; pediatric 2–4 J/kg.

Dehydration

– A state of total body water depletion resulting from excessive fluid loss, inadequate fluid intake, or both. Causes: gastrointestinal losses (vomiting, diarrhea), renal losses (diabetic ketoacidosis, diabetes insipidus, diuretic overuse), skin losses (burns, excessive sweating), or inadequate intake. Classified by severity: mild (3–5% body weight loss), moderate (6–9%), and severe ($\geq 10\%$, leading to hypovolemic shock). Clinical signs: dry mucous membranes, decreased skin turgor, sunken eyes, tachycardia, hypotension, oliguria, and altered mental status. Management: oral rehydration therapy with glucose-electrolyte solutions for mild-to-moderate dehydration; rapid IV fluid resuscitation (isotonic 0.9% normal saline or lactated Ringer's) for severe dehydration or shock.

Disaster Medicine

– The branch of emergency medicine addressing prevention, preparedness, response, and recovery for mass-casualty events. Triage systems include START and SALT, with red, yellow, green, and black tagging by acuity. The guiding ethic is the greatest good for the greatest number, reversing routine single-patient priorities. Effective response depends on incident command, mutual aid, and drills.

Emergency Department

– The hospital unit providing continuous acute care to unscheduled patients with illness or injury. Staffed by emergency physicians and nurses, it uses triage systems such as the Emergency Severity Index to prioritize by acuity. Core functions are resuscitation, diagnosis, stabilization, treatment, and disposition. Common challenges include overcrowding, boarding, and ambulance diversion.

Emergency Ultrasound

– Bedside ultrasound performed and interpreted by the emergency physician to answer focused clinical questions. Applications include FAST for trauma, cardiac assessment in arrest or shock, suspected aneurysm, ectopic pregnancy, hydronephrosis, biliary disease, and procedural guidance. Advantages are speed, portability, and absence of radiation; limitations include operator dependence and restricted acoustic windows.

External Bleeding

– Visible blood loss from the body surface from arteries, veins, or capillaries, usually due to laceration or penetrating injury. Control follows the Stop the Bleed approach: firm direct pressure, wound packing, and tourniquet use for exsanguinating extremity hemorrhage. Loss exceeding roughly 1500 mL or uncontrolled hemorrhage prompts blood products and massive transfusion protocol, with operative or angiographic intervention if persistent.

Focused Assessment with Sonography in Trauma (FAST)

– A bedside ultrasound examination in trauma to detect free intraperitoneal/pericardial fluid (hemorrhage). Views: right upper quadrant (Morison pouch), left upper quadrant (splenorenal), pelvic (Pouch of Douglas/rectovesical), and subxiphoid pericardial. Positive findings prompt laparotomy in unstable patients. Sensitivity for hemoperitoneum is good; the extended FAST (eFAST) adds pneumothorax assessment. Rapid, repeatable, and portable; a core component of ATLS shock evaluation.

Foreign Body Aspiration

– Inhalation of a foreign object into the airway, most common in young children (coins, nuts, small toys) and elderly. Features: sudden choking, cough, wheeze (often unilateral), decreased breath sounds, respiratory distress; chronic aspiration may present with recurrent pneumonia. Diagnosis: history, chest X-ray (air trapping, atelectasis, radiopaque object), CT, bronchoscopy. Management: immediate Heimlich maneuver (choking adult/infant) for complete obstruction; rigid bronchoscopy for retrieval; surgery rarely. Complications: pneumonitis, lung abscess, asphyxia.

Glasgow Coma Scale (GCS)

– A standardized scale assessing level of consciousness

after brain injury, scoring eye opening (1-4), verbal response (1-5), and motor response (1-6) for a total of 3-15. Severity: 13-15 mild, 9-12 moderate, 8 or less severe (coma). Used to triage, monitor trends, and predict outcome; the motor component is the most predictive. Limitations: intubation (verbal untestable), alcohol, and drugs. Serial GCS assessment guides management (e.g., need for intubation, neurosurgery).

Head Injury

– Trauma to the scalp, skull, or brain; a spectrum from mild concussion to severe traumatic brain injury (TBI). Classification: scalp lacerations, skull fractures (linear, depressed, basilar), and intracranial hemorrhage (epidural, subdural, subarachnoid, intraparenchymal), diffuse axonal injury, cerebral contusion. Presentation: headache, vomiting, amnesia, loss of consciousness, focal deficits, altered mental status. Red flags: worsening GCS, unequal pupils, seizure, coagulopathy. Management: ABCs, immobilization, CT scan (per criteria), neurosurgical consultation for mass lesions; observation and CT for mild TBI. Basilar skull signs: raccoon eyes, Battle sign, CSF rhinorrhea/otorrhea.

Heat-Related Illnesses (Heat Stroke and Heat Exhaustion)

– Heat-related illnesses range from mild (heat cramps, heat edema, heat syncope) to severe (heat exhaustion, heat stroke). Heat exhaustion: hypovolemia and electrolyte depletion from excessive sweating (headache, dizziness, nausea, fatigue, core temp 37–40°C). Heat stroke: life-threatening emergency defined by core temperature > 40°C (104°F) accompanied by central nervous system dysfunction (altered mental status, delirium, seizures, coma). Classified as classic (passive, occurring in elderly during heat waves) or exertional (strenuous physical activity in hot humid weather). Pathophysiology: thermoregulatory failure leading to direct cellular toxicity, SIRS, rhabdomyolysis, AKI, ARDS, DIC, and multi-organ failure. Treatment: immediate aggressive cooling (cold water immersion, evaporative misting and fan, ice packs to groin/axillae/neck, cold IV fluids) targeting core temperature < 39°C within 30 minutes.

Hyperkalemia

– Serum potassium above 5.5 mEq/L (severe >6.5),

a life-threatening electrolyte emergency. Causes: renal failure, potassium-sparing diuretics, ACE-I/ARB, tumor lysis, rhabdomyolysis, Addison disease, metabolic acidosis, excess intake. ECG changes: peaked T waves, prolonged PR, widened QRS, loss of P waves, sine wave, VF/asystole. Treatment: stabilize myocardium (IV calcium gluconate/chloride), shift into cells (insulin + glucose, beta-agonists, sodium bicarbonate if acidotic), and remove potassium (diuretics, cation exchange resins, dialysis). Continuous ECG monitoring; treat empirically if ECG changes are present.

Hyperkalemic Emergency

– Severe hyperkalemia (serum potassium > 6.5 mEq/L) or any hyperkalemia accompanied by ECG changes represents a life-threatening cardiac emergency. ECG progression: peaked T waves, prolonged PR interval, flattened P waves, QRS widening, sine-wave pattern, and ventricular fibrillation/asystole. Staged emergency treatment: (1) Cardiac membrane stabilization: IV calcium gluconate 1–2 g or calcium chloride 1 g over 2–5 minutes; (2) Intracellular potassium shift: IV regular insulin 10 units with 50% dextrose (D50W), inhaled albuterol 10–20 mg, and IV sodium bicarbonate (if metabolic acidosis present); (3) Potassium elimination: loop diuretics (furosemide), gastrointestinal cation exchangers (sodium zirconium cyclosilicate, patiomer), or emergency hemodialysis.

Hyperpyrexia

– Extremely elevated body temperature >41.5°C (106.7°F), a medical emergency. Causes: heat stroke (environmental, classic or exertional, with CNS dysfunction), malignant hyperthermia (anesthesia trigger: succinylcholine, volatile anesthetics, treat with dantrolene), neuroleptic malignant syndrome (antipsychotics, rigidity, autonomic instability, elevated CK, treat with dantrolene and bromocriptine), serotonin syndrome (SSRIs/MAOIs, clonus, hyperreflexia, agitation, treat with cyproheptadine and supportive care), CNS infection/injury, and thyrotoxicosis. Management: ABCs, immediate cooling (evaporative, ice packs, cold IV fluids, cooling blanket), dantrolene, and treatment of underlying cause. Remove from heat source.

Hypothermia

– A medical emergency defined by a core body tem-

perature below 35°C (95°F). Classified as mild (32–35°C: shivering, dysarthria, apathy), moderate (28–32°C: cessation of shivering, delirium, Osborn J waves on ECG), and severe (< 28°C: coma, fixed pupils, severe bradycardia, ventricular fibrillation, or asystole). Evaluation includes rectal or esophageal core temperature monitoring and ECG. Management principles: gentle handling to avoid triggering ventricular fibrillation; passive external rewarming for mild cases; active external and internal rewarming (warmed IV fluids 40–42°C, heated humidified oxygen, cavity lavage, ECMO/cardiopulmonary bypass) for moderate-to-severe hypothermia. Patients should not be pronounced dead until rewarmed to > 32°C ('not dead until warm and dead').

Hypovolemic Shock

– A state of inadequate organ tissue perfusion resulting from severe intravascular volume loss (>15–30% of circulating volume). Causes: acute hemorrhage (trauma, GI bleeding) or non-hemorrhagic fluid loss (severe vomiting, diarrhea, burns, dehydration). Clinical signs: tachycardia, hypotension, cold clammy extremities, oliguria, altered mental status. Treatment: rapid IV isotonic crystalloids (Normal Saline/Lactated Ringer's), blood product transfusion (packed red blood cells, FFP, platelets in 1:1:1 ratio for massive hemorrhage), and source control.

ICU (Intensive Care Unit)

– A specialized hospital unit providing continuous monitoring and advanced organ support for critically ill patients. ICU admission criteria include: airway compromise, respiratory failure ($\text{PaO}_2/\text{FiO}_2 < 300$), hemodynamic instability ($\text{MAP} < 65$ despite fluids), severe metabolic disturbance, and multi-organ dysfunction. Staffing comprises a multidisciplinary team: intensivists, ICU nurses, physiotherapists, pharmacists, and dietitians. Core interventions: mechanical ventilation, vasopressors/inotropes, renal replacement therapy, central venous and arterial line monitoring, and nutritional support. Prognostic scoring systems (APACHE II, SOFA, SAPS II) quantify mortality risk and guide clinical decision-making. Common ICU complications: ventilator-associated pneumonia, catheter-related bloodstream infection, pressure injuries, and

ICU-acquired weakness.

Insect Sting

– Tissue injury and envenomation by Hymenoptera (bees, wasps, hornets, fire ants). Local reactions produce pain, erythema, edema, and pruritus. Systemic anaphylaxis with bronchospasm, hypotension, and urticaria requires immediate intramuscular epinephrine 0.3 to 0.5 mg and observation for biphasic reactions. Local care includes stinger removal by scraping, cold compresses, antihistamines, and referral for venom immunotherapy in systemic reactors.

Internal Bleeding

– Hemorrhage within body cavities, not visible externally, most commonly in the chest, abdomen, retroperitoneum, or skull. Clues include hypotension, tachycardia, falling hematocrit, abdominal distension, dullness to chest percussion, and altered mental status. Diagnosis relies on FAST ultrasound, contrast CT, and peritoneal aspiration in unstable patients. Management combines blood-product resuscitation with source control via embolization or surgery.

Intubation

– Placement of an endotracheal tube (ETT) into the trachea to secure the airway, providing a definitive airway for ventilation, oxygenation, and airway protection. Indications: airway obstruction, respiratory failure, inadequate oxygenation/ventilation, GCS 8 or less, cardiac arrest. Procedure: preoxygenation, rapid-sequence intubation (RSI—induction + paralysis), laryngoscopy (direct or video), tube placement with cuff inflation, confirmation (ETCO₂, capnography, bilateral breath sounds, CXR), securement. Complications: esophageal intubation, aspiration, dental trauma, hypotension, hypoxia. Failed airway requires backup (LMA, cricothyroidotomy).

Intubation (Endotracheal)

– The placement of a flexible plastic tube into the trachea via the mouth (orotracheal) or nose (nasotracheal) to secure an airway, maintain patency, permit mechanical ventilation, and prevent aspiration. Rapid Sequence Intubation (RSI) utilizes an induction agent (etomidate, propofol, ketamine) followed immediately by a neuromuscular blocker (succinylcholine, rocuronium).

Major Trauma

– Injury of significant severity (often multiple injuries) causing physiologic derangement and risk of death or disability; managed per ATLS: primary survey (A-E: airway, breathing, circulation with hemorrhage control, disability, exposure/environment), then secondary survey (head-to-toe examination), with adjuncts (FAST, X-ray, CT). Major trauma mechanisms: road traffic collisions, falls, penetrating injury, blast. Priorities: identify and treat life-threatening injuries (tension pneumothorax, massive hemorrhage, cardiac tamponade), early transfusion (massive hemorrhage protocol), and transfer to a trauma center.

Mass Casualty

– An incident in which casualties exceed immediately available resources, requiring disaster protocols and altered standards of care. Field management integrates START triage, patient distribution across facilities, and an incident command structure. Repeated re-triage and reassessment of resources are mandatory. The goal is the greatest good for the greatest number, with attention to provider safety and support.

Multi-Organ Failure

– Progressive dysfunction of two or more organ systems after an overwhelming insult such as sepsis, trauma, hemorrhagic shock, burns, or pancreatitis. Severity is quantified by the SOFA score across respiratory, coagulation, hepatic, cardiovascular, neurologic, and renal domains. Management is supportive intensive care with ventilation, renal replacement, and vasoactive support. Mortality rises steeply with the number of failing organs.

Multiple Trauma

– Trauma involving injury to more than one body region or system (polytrauma); common in high-energy mechanisms (RTC, falls, blast). Associated with high mortality from hemorrhage, head injury, and multi-organ failure. Managed with systematic assessment (ATLS primary and secondary surveys), injury severity scoring (ISS), early hemorrhage control (tourniquets, pelvic binder, REBOA/surgery), damage-control resuscitation (permissive hypotension, balanced transfusion), and definitive surgical management. Outcomes depend on prehospital time, injury severity, and coordinated multidisciplinary care.

Near Drowning

– A submersion event with survival for at least 24 hours. The principal injury is hypoxia from laryngospasm, aspiration, and respiratory distress syndrome, often compounded by hypothermia. Treatment begins with rescue breathing and CPR, oxygen, and intubation for respiratory failure. Cervical precautions apply only with suspected trauma. Rewarming and serial observation follow for 6 to 24 hours.

Needle Decompression

– An emergency procedure for immediate relief of a tension pneumothorax. Involves inserting a large-bore catheter-over-needle (14-16 gauge, ≥ 8 cm length) into the second intercostal space in the midclavicular line or fifth intercostal space in the anterior axillary line on the affected side. Converts tension pneumothorax into a simple pneumothorax prior to definitive chest tube (tube thoracostomy) placement.

Neonatal Emergency

– A life-threatening condition in the first 28 days of life requiring rapid resuscitation. The neonatal algorithm warms and dries the infant, clears the airway, and assesses heart rate, escalating to positive-pressure ventilation, compressions at a 3:1 ratio, and epinephrine if heart rate stays below 60. Common emergencies include respiratory distress, ductal-dependent cyanotic heart disease, sepsis, hypoglycemia, and bilious vomiting.

Nucleus pulposus

– The gel-like shock-absorbing central portion of each spinal disc.

Obstetric Emergencies

– Life-threatening conditions occurring during pregnancy, labor, or the postpartum period. Includes ectopic pregnancy (ruptured: surgical emergency; stable: methotrexate), preeclampsia/eclampsia (hypertension, proteinuria, seizures; treated with IV magnesium sulfate for seizure prophylaxis and IV labetalol/hydralazine for BP control), placental abruption (painful vaginal bleeding, uterine tenderness), placenta previa (painless vaginal bleeding), and postpartum hemorrhage (PPH: blood loss > 1000 mL, managed with uterine massage, oxytocin, methylergonovine, misoprostol, and tranexamic acid).

Oxygen Therapy

– The administration of supplemental oxygen to treat or prevent hypoxia, a core emergency intervention. Delivery: nasal cannula (low flow, 1-6 L/min), simple face mask (5-10 L/min), non-rebreather mask (10-15 L/min, high concentration), venturi mask (controlled FiO₂), high-flow nasal cannula (heated, humidified), and NIV/ventilator. Target SpO₂ 94-98 percent generally; 88-92 percent in COPD with CO₂ retention. Risks: oxygen toxicity (long-term high FiO₂), CO₂ retention, absorption atelectasis, fire hazard. Titrate to oxygenation while avoiding hyperoxia.

Parkland Formula

– A burn resuscitation formula used to calculate the 24-hour IV fluid requirement (Lactated Ringer's solution) for burn patients: Fluid Volume (mL) = 4 × Body Weight (kg) × % Total Body Surface Area (TBSA) burned (second-half rule). Half of the calculated volume is administered over the first 8 hours post-burn; the remaining half is infused over the subsequent 16 hours. Targeted to urine output 0.5-1.0 mL/kg/h.

Pediatric Emergencies

– Urgent medical conditions in pediatric patients evaluated using the Pediatric Assessment Triangle (PAT: Appearance, Work of Breathing, Circulation to Skin). Common conditions include severe croup (stridor at rest, treated with nebulized racemic epinephrine and dexamethasone 0.6 mg/kg), bronchiolitis (wheezing/crackles in infants, supportive care), pediatric anaphylaxis (epinephrine 0.01 mg/kg IM), febrile seizures, pediatric dehydration, and septic shock (treated with 20 mL/kg isotonic fluid boluses and early broad-spectrum antibiotics).

Pelvic Fracture

– Disruption of the pelvic ring, usually from high-energy collisions or falls, sometimes from low-energy falls in the elderly. The Young-Burgess classification distinguishes lateral, anteroposterior, vertical-shear, and combined patterns that determine stability and hemorrhage risk. Retroperitoneal hemorrhage is a leading cause of preventable traumatic death. Initial management includes a pelvic binder, early transfusion, and angiographic embolization.

Penetrating Trauma

– Injury from a foreign object such as a bullet or knife that breaches the skin and traverses tissue. Severity

depends on kinetic energy, tissue density, yaw, and fragmentation, producing a permanent tract and a temporary cavity. Evaluation addresses entry, exit, and trajectory. Management ranges from local wound care to operative exploration, with tetanus prophylaxis and antibiotics.

Pericardiocentesis

– Emergency ultrasound-guided aspiration of fluid from the pericardial sac to relieve cardiac tamponade. Performed via subxiphoid approach (needle angled at 30–45° toward the left shoulder) or parasternal approach. Diagnostic and therapeutic, rapidly improving stroke volume and systemic blood pressure.

Periorbital Ecchymosis (Raccoon Eyes)

– Bilateral periorbital ecchymosis (dark purplish discoloration around the eyes) sparing the tarsal plate. Classic physical exam sign of a basilar skull fracture involving the anterior cranial fossa (cribriform plate or orbital roof). Arises from tracking of venous blood into periorbital soft tissues. Delayed presentation (1-3 days post-trauma). Accompanied by anosmia, CSF rhinorrhea, or Battle sign. Non-contrast head CT is essential.

Point of Care Testing

– Diagnostic testing performed at the bedside to yield rapid results that guide emergency management. Common applications include glucose, hemoglobin, blood gases with lactate, troponin, D-dimer, urinalysis, pregnancy, and rapid infectious assays. Benefits include reduced turn-around time and faster decisions in stroke, sepsis, and acute coronary syndrome; trade-offs include lower precision and the need for quality assurance and confirmatory testing.

Post-traumatic headache

– A persistent headache resulting from a head or neck injury, sometimes lasting for a year or more.

Procedural Sedation

– Levels: minimal (anxiolysis), moderate (conscious sedation), deep, general anesthesia. Pre-procedure: fasting (2h clear liquids, 6h light meal), ASA class, airway assessment (Mallampati), consent, monitoring (BP, HR, SpO₂, ETCO₂, ECG), rescue equipment. Agents: propofol (0.5-1 mg/kg bolus, 2575 mcg/kg/min infusion; hypotension, apnea), ketamine (1-2 mg/kg IV, 4-5 mg/kg IM; pre-

serves airway/respiration, emergence reaction, hypertension), midazolam (0.02-0.04 mg/kg; amnesia, respiratory depression with opioids), fentanyl (1-2 mcg/kg; respiratory depression), etomidate (0.2-0.3 mg/kg; hemodynamic stability, myoclonus, adrenal suppression). Reversal: flumazenil (BZD), naloxone (opioids). Discharge: Aldrete score ≥ 9 , responsible adult, no driving.

Psychiatric Emergencies

– Acute behavioral disturbances, severe agitation, suicidal ideation, or psychosis posing immediate danger to the patient or others. Management of the acutely agitated patient: verbal de-escalation techniques first-line; pharmacologic restraint if de-escalation fails (IM olanzapine 10 mg, ziprasidone 20 mg, or haloperidol 5 mg plus lorazepam 2 mg). Suicide risk assessment: evaluation of ideation, plan, intent, and means, requiring safety precautions and involuntary psychiatric hold if imminent risk is identified.

Pulmonary Embolism

– Obstruction of pulmonary arteries by thrombus (usually from DVT). Risk factors: Virchow triad (stasis, hypercoagulability, endothelial injury). Wells score (clinical probability), PERC rule (low risk exclusion). D-dimer (age-adjusted: age $\times 10$ ug/L if >50) for low/intermediate probability. CTPA (gold standard); VQ scan (pregnant, contrast allergy); echocardiography (RV strain: McConnell sign, 60/60 sign, TAPSE). Risk stratification: massive (hemodynamic instability, SBP <90 or vasopressors), submassive (normotensive + RV dysfunction + biomarker elevation), low-risk (normotensive, no RV dysfunction). Management: anticoagulation (LMWH, DOAC, UFH, warfarin). Massive PE: systemic thrombolysis (alteplase 100 mg over 2h, tenecteplase 0.5 mg/kg single bolus) if no contraindication; catheter-directed thrombolysis/mechanical thrombectomy if contraindication; surgical embolectomy if failed. Submassive: consider catheter-directed therapy if clinical deterioration. IVC filter if anticoagulation contraindicated.

Puncture Wound

– A deep, narrow wound from a sharp object such as a nail, needle, or tooth that carries bacteria deeply into tissue. Foot and hand punctures risk osteomyelitis and septic arthritis. Pseudomonas is the classic pathogen in plantar punctures through

rubber soles. Management includes irrigation, debridement, tetanus prophylaxis, and antibiotics for deep or contaminated wounds.

Replantation

– Surgical reattachment of a completely amputated part, usually a digit or hand, to restore function. Favorable indications include the thumb, multiple digits, the hand at wrist level, and any part in a child. Contraindications include severe crush, contamination, comorbidity, and ischemia beyond roughly 6 hours. The part is wrapped in saline gauze, sealed, and iced for transfer.

Resuscitation

– The emergency restoration of physiologic function after cardiac or respiratory arrest, severe hemorrhage, or shock. Components: recognition and call for help, high-quality CPR, defibrillation for shockable rhythms, airway/ventilation, IV/IO access, medications (epinephrine, amiodarone), and treatment of reversible causes. Includes fluid/blood resuscitation in hemorrhagic shock (massive transfusion, balanced products), and post-resuscitation care (targeted temperature management, oxygenation, perfusion). Follows AHA/BLS/ACLS/PALS and ATLS algorithms; goal is return of spontaneous circulation (ROSC) and neurologically intact survival.

Sepsis

– Life-threatening organ dysfunction caused by a dysregulated host response to infection. Defined clinically by a change in Sequential Organ Failure Assessment (SOFA) score ≥ 2 points. Septic shock: subset of sepsis with persistent hypotension requiring vasopressors to maintain mean arterial pressure (MAP) ≥ 65 mmHg and serum lactate >2 mmol/L despite adequate fluid resuscitation. Emergency management: 1-hour bundle (measure lactate, obtain blood cultures, administer broad-spectrum antibiotics, infuse 30 mL/kg crystalloid for hypotension/lactate ≥ 4 , apply vasopressors like norepinephrine).

Shock

– A state of inadequate tissue perfusion and oxygenation leading to cellular dysfunction and organ failure; classified by cause. Hypovolemic (hemorrhage, dehydration), cardiogenic (MI, arrhythmia, cardiomyopathy), obstructive (tension pneumothorax, cardiac tamponade, pulmonary embolism),

and distributive (septic, anaphylactic, neurogenic). Features: hypotension, tachycardia, altered mental status, cool/clammy skin (or warm in septic), oliguria, lactic acidosis. Management: ABCs, treat underlying cause, restore perfusion (IV fluids/blood for hypovolemic, vasopressors for distributive, inotropes for cardiogenic), monitor lactate. Early recognition and goal-directed therapy improve outcomes.

SIRS

– Systemic Inflammatory Response Syndrome, a clinical response to a nonspecific insult (infection, trauma, pancreatitis, burns, autoimmune). Diagnosis requires ≥ 2 of: temperature $>38^{\circ}\text{C}$ or $<36^{\circ}\text{C}$, heart rate >90 bpm, respiratory rate >20 breaths/min or $\text{PaCO}_2 <32$ mmHg, WBC $>12,000$ or $<4,000$ or $>10\%$ bands. SIRS is non-specific but was historically used as a screening tool for sepsis (qSOFA and SOFA scores are now preferred). Sepsis: SIRS + confirmed infection. Severe sepsis: sepsis + organ dysfunction. Septic shock: sepsis + hypotension despite adequate fluid resuscitation. Management: source control, IV fluids, vasopressors, and antibiotics.

Snake Bite

– Envenomation by Crotalidae (pit vipers) or Elapidae (coral snakes). Crotalid venom causes local tissue destruction and consumptive coagulopathy; elapid venom causes neurotoxicity with descending paralysis and respiratory failure. Management includes immobilizing the limb at heart level, removing constricting items, and avoiding tourniquets, ice, and incision. Treatment uses Crotalidae polyvalent immune Fab antivenom, analgesia, and fluids, with poison control consultation.

Spider Bite

– Envenomation by *Loxosceles* (brown recluse) or *Latrodectus* (black widow) species. *Loxosceles* venom causes a dermonecrotic lesion that may progress to an eschar with hemolysis. *Latrodectus* venom causes severe muscle spasm, abdominal rigidity, hypertension, and diaphoresis resembling an acute abdomen. Management is supportive with wound care, analgesia, opioids, benzodiazepines, tetanus update, and antivenom in severe cases.

Status Epilepticus

– A continuous seizure lasting more than 5 min-

utes or repeated seizures without recovery of consciousness between them; a medical emergency with high morbidity/mortality. Types: generalized convulsive (most common, dangerous) and non-convulsive. Causes: medication non-compliance, epilepsy, stroke, infection (encephalitis), metabolic, trauma, alcohol withdrawal, tumor. Management: ABCs, glucose/thiamine, first-line benzodiazepine (lorazepam 0.1 mg/kg IV, midazolam IM), second-line anticonvulsants (fosphenytoin, valproate, levetiracetam), third-line anesthetic doses (propofol, midazolam infusion) with EEG monitoring for refractory status. Treat cause and investigate (CT, LP, labs).

Sudden Cardiac Death

– Unexpected death from a cardiac cause, generally within one hour of symptom onset or, if unwitnessed, within 24 hours of last being seen well. The leading cause in adults is coronary disease producing ventricular fibrillation or pulseless tachycardia. Intervention requires emergency activation, CPR, and prompt defibrillation, followed by targeted temperature management and implantable defibrillators for secondary prevention.

Tension Pneumothorax

– A life-threatening emergency occurring when air enters the pleural space via a one-way valve mechanism, continuously increasing intrapleural pressure, causing complete collapse of the ipsilateral lung, mediastinal shift to the contralateral side, compression of the vena cava, severely compromised venous return, and obstructive shock. Clinical presentation: severe dyspnea, cyanosis, hypotension, tachycardia, absent breath sounds on the affected side, hyperresonance to percussion, tracheal deviation away from the affected side, and distended neck veins. Immediate intervention: emergency needle decompression (14-gauge needle placed in the 2nd intercostal space midclavicular line or 5th intercostal space anterior axillary line) before chest radiograph, followed by tube thoracostomy (chest tube).

Toxic Ingestion

– Exposure to a toxic substance by swallowing, accidental or intentional. Management begins with airway, breathing, and circulatory support, history, and examination for toxidromes (anticholinergic, cholinergic, opioid, sympathomimetic). Decontami-

nation uses activated charcoal within one hour and whole-bowel irrigation for selected agents. Antidotes include naloxone, N-acetylcysteine, fomepizole, and digoxin Fab; hemodialysis applies to salicylates, methanol, and lithium.

Toxicology

– The study of the adverse effects of chemicals and drugs on living organisms, applied clinically as poisoning/toxicology management and analytically in drug testing. Clinical toxicology: recognition and management of poisoning (toxidromes—anticholinergic, cholinergic, opioid, sympathomimetic, sedative-hypnotic), decontamination (activated charcoal, whole-bowel irrigation), enhanced elimination (dialysis, alkalization), and antidotes (naloxone, flumazenil, N-acetylcysteine, fomepizole). Analytical toxicology: testing blood/urine for drugs of abuse, therapeutic drugs, and poisons. Principles: supportive care first, specific antidotes when indicated, and consultation with poison control.

Trauma

– Physical injury to the body caused by external forces; a leading cause of death and disability worldwide, especially in young people. Mechanisms: blunt (road traffic collision, falls, assaults) and penetrating (stab, gunshot); blast injuries have primary, secondary, tertiary, and quaternary effects. Trauma care follows ATLS principles: systematic primary survey (A-E), identification and treatment of life threats, resuscitation, secondary survey, and definitive care. Scoring systems (ISS, RTS) assess severity and prognosis. Prevention, rapid transport, and organized trauma systems reduce mortality.

Trauma Scoring Systems

– Tools that quantify the severity of injury to predict outcome and guide triage and research. Anatomic: Injury Severity Score (ISS)—based on Abbreviated Injury Scale (AIS) of three most injured body regions, 1-75. Physiologic: Revised Trauma Score (RTS)—GCS, systolic BP, respiratory rate. Combined: TRISS—ISS + RTS + age. Used for triage decisions (trauma team activation), outcome prediction (mortality), benchmarking, and research. Limitations: individual variability, weighting differences.

Traumatic Brain Injury (TBI)

– Injury to the brain caused by external mechanical force; a spectrum from concussion to severe injury with intracranial hemorrhage or diffuse axonal injury. Mechanisms: acceleration-deceleration, direct impact, penetrating. Types: concussion (transient neurologic dysfunction), contusion, diffuse axonal injury (DAI), epidural hematoma (middle meningeal artery—lucid interval), subdural hematoma (bridging veins—elderly, anticoagulation), subarachnoid hemorrhage, and intracerebral hemorrhage. Presentation: headache, vomiting, amnesia, altered GCS, focal deficits, seizures. Management: ABCs, oxygenation, ICP control (elevate head, hyperosmolar therapy, sedation, decompressive craniectomy), seizure prophylaxis, and neurosurgery for mass lesions; avoid secondary injury (hypoxia, hypotension).

Triage

– The sorting and prioritization of patients according to the severity of their condition to ensure the most efficient use of limited resources, especially in emergencies and mass casualties. Systems: five-level triage (ESI—Emergency Severity Index, levels 1-5 based on resources and acuity), military (immediate, delayed, minimal, expectant), and disaster triage (START—Simple Triage and Rapid Treatment; walking wounded first, color tags red/yellow/green/black). Decisions balance medical need, resource availability, and potential for benefit; dynamic and reassessed.

Troponins

– Proteins found in heart muscle that leak into the circulation during a heart attack or other heart injury.

Universal Precautions

– Infection control measures applied to all patients to prevent transmission of blood-borne and other pathogens, regardless of perceived infection risk: hand hygiene, gloves, masks, eye protection, gowns, and safe handling/disposal of sharps and waste. Assumes all blood and body fluids are potentially infectious (HIV, hepatitis B/C). Standard precautions extend to all body substances, non-intact skin, and mucous membranes. Essential in emergency and surgical settings; reduces occupational exposure and nosocomial infection.

Venous Access

– The establishment of access to the venous system for fluid resuscitation, medication, blood products, and blood sampling. Routes: peripheral venous cannulation (IV—common), intraosseous (IO—emergency when IV fails, tibia/humerus), central venous catheter (CVC—subclavian, internal jugular, femoral—for vasopressors, CVP monitoring, hemodialysis), and ultrasound-guided access. Indications: shock, cardiac arrest, poor peripheral access, long-term therapies, monitoring. Complications: infection, thrombosis, hematoma, arterial puncture, pneumothorax (central), air embolism. Timely, aseptic access is critical in resuscitation.

Chapter 9

Endocrinology

Acromegaly Complications

– Systemic complications of chronic growth hormone excess include diabetes mellitus from insulin resistance, cardiovascular disease with cardiomyopathy and arrhythmias, sleep apnea from macroglossia and upper airway soft tissue hypertrophy, hypertension, colon polyps and increased colorectal cancer risk, osteoarthritis, carpal tunnel syndrome, and increased mortality. Screening colonoscopy is recommended at diagnosis and at regular intervals. Cardiac assessment with echocardiography is important. Regular dermatological surveillance for skin lesions and colonoscopic screening according to standard guidelines are recommended.

Addison Disease

– Primary adrenal insufficiency resulting from destruction or dysfunction of the adrenal cortex, leading to deficiency of cortisol, aldosterone, and adrenal androgens. Most common cause in developed countries is autoimmune adrenalitis (autoimmune polyglandular syndrome type 2), with anti-21-hydroxylase antibodies present in 85-90 percent of cases. Other causes include infections (tuberculosis, histoplasmosis, CMV in HIV/AIDS), hemorrhage, metastatic infiltration, and genetic disorders (congenital adrenal hyperplasia, adrenoleukodystrophy, and autoimmune polyglandular syndrome type 1). Presents with fatigue, hyperpigmentation of the skin and oral mucosa, weight loss, hypotension, and salt craving. Diagnosis is made by elevated ACTH with a low cortisol level and a poor response to cosyntropin stimulation testing. Treatment requires lifelong glucocorticoid and mineralocorticoid replacement therapy with stress dose adjustments during illness or surgery.

Addisonian Crisis

– Life-threatening emergency resulting from acute cortisol deficiency in patients with adrenal insufficiency. Precipitated by infection, trauma, surgery, or abrupt discontinuation of chronic glucocorticoid therapy. Presents with severe hypotension or shock unresponsive to fluids and vasopressors, profound weakness, nausea, vomiting, abdominal pain, fever, confusion, and hypoglycemia. Laboratory findings include hyponatremia, hyperkalemia, hypoglycemia, and eosinophilia. Treatment is immediate IV hydrocortisone, aggressive fluid resuscitation with normal saline and dextrose to correct hypoglycemia, vasopressor support if needed, and treatment of the underlying precipitating cause.

Adrenal Cortex Physiology

– The adrenal cortex produces three classes of steroid hormones from the three zones. The zona glomerulosa produces mineralocorticoids primarily aldosterone regulating sodium and potassium balance under the influence of angiotensin II and potassium. The zona fasciculata produces glucocorticoids primarily cortisol regulating glucose metabolism protein catabolism and the stress response under the influence of ACTH. The zona reticularis produces adrenal androgens including DHEA and DHEA-S under the influence of ACTH.

Adrenal Hemorrhage

– Bleeding into the adrenal gland most commonly occurring in critically ill patients with sepsis, coagulopathy, or anticoagulation therapy. Bilateral adrenal hemorrhage may cause acute adrenal insufficiency with circulatory collapse. Waterhouse-Friderichsen syndrome: adrenal hemorrhage associated with meningococcal sepsis. Diagnosis is by CT showing enlarged adrenal glands with hemorrhage. Treatment includes stress-dose corticosteroids for

bilateral involvement.

Adrenal Insufficiency

– Deficient production of cortisol by the adrenal cortex classified as primary adrenal insufficiency or Addison disease from adrenal gland destruction, secondary from pituitary ACTH deficiency, and tertiary from chronic exogenous glucocorticoid suppression of the hypothalamic-pituitary-adrenal axis. Primary causes include autoimmune adrenalitis accounting for eighty percent in developed countries, tuberculosis, fungal infections, metastatic disease, and hemorrhage. Presents with fatigue, weakness, weight loss, hyperpigmentation, hypotension, and salt craving in primary disease, whereas secondary deficiency presents without hyperpigmentation or hyperkalaemia.

Adrenal Medulla Physiology

– The adrenal medulla produces catecholamines primarily epinephrine and norepinephrine in response to sympathetic nervous system activation. Epinephrine accounts for approximately eighty percent and norepinephrine approximately twenty percent of catecholamine output. These hormones mediate the fight-or-flight response through alpha and beta adrenergic receptors causing tachycardia hypertension bronchodilation and metabolic mobilization including glycogenolysis and lipolysis. Pheochromocytomas arise from the adrenal medulla and secrete excess catecholamines causing episodic hypertension, headache, sweating, and palpitations.

Adrenal Myelolipoma

– Benign adrenal tumor composed of mature adipose tissue and hematopoietic elements. Usually asymptomatic and discovered incidentally. No malignant potential. May cause adrenal hemorrhage if large. Diagnosis is by imaging showing fat attenuation on CT. No treatment required unless symptomatic from mass effect or hemorrhage.

Adrenal Venous Sampling

– Interventional radiology procedure for lateralizing aldosterone secretion in primary hyperaldosteronism. Catheterization of both adrenal veins allows measurement of aldosterone and cortisol levels to calculate selectivity index confirming successful cannulation and lateralization ratio. Lateralization to one gland suggests aldosterone-producing adenoma amenable to adrenalectomy. Bilateral secre-

tion suggests bilateral adrenal hyperplasia managed medically. The procedure is technically challenging and requires an experienced interventional radiologist, with success rates of approximately seventy to eighty percent for right adrenal vein cannulation and higher for the left.

Adrenocorticotrophic Hormone

– ACTH (corticotropin): a peptide hormone from the anterior pituitary (cleaved from POMC) that stimulates the adrenal cortex to produce cortisol (zona fasciculata) and adrenal androgens; regulated by hypothalamic CRH and cortisol negative feedback (circadian). Elevated ACTH: primary adrenal insufficiency (Addison), ectopic ACTH syndrome (Cushing), and ACTH-secreting pituitary adenoma (Cushing disease); suppressed ACTH: adrenal Cushing, exogenous steroids, secondary adrenal insufficiency. Measurement with cortisol and dynamic tests (dexamethasone suppression, CRH stimulation, petrosal sampling) distinguishes causes of hypercortisolism.

Aicardi-Goutieres Syndrome

– Rare autosomal recessive inflammatory disorder mimicking congenital viral infection. Characterized by cerebral calcifications, white matter disease, cerebral atrophy, and cerebrospinal fluid lymphocytosis. Presents with severe neurodevelopmental impairment, seizures, and spasticity. Some forms involve interferon pathway dysregulation with elevated interferon-alpha in cerebrospinal fluid. Diagnosis is by clinical features, brain imaging showing calcifications, and genetic testing. No specific treatment is available; management is supportive and includes anticonvulsants, physiotherapy, and management of feeding difficulties. Prognosis is poor with many children not surviving beyond early childhood.

Alpha-Glucosidase Inhibitors

– Oral glucose-lowering medications including acarbose, miglitol, and voglibose that delay carbohydrate digestion and glucose absorption in the small intestine by inhibiting brush border alpha-glucosidase enzymes. Reduce postprandial glucose excursions without affecting fasting glucose significantly. Side effects include flatulence, bloating, and diarrhea from undigested carbohydrates reaching the colon. Contraindicated in inflammatory bowel disease and

hepatorenal impairment. Effective A1c reduction of approximately 0.5 to 0.8 percent is modest compared with other oral agents.

Amiodarone-Induced Thyroid Dysfunction

– Thyroid abnormalities occurring in approximately fifteen to twenty percent of patients on amiodarone due to the high iodine content of the molecule. Type one results from iodine-induced increased thyroid hormone synthesis in patients with underlying thyroid disease. Type two results from destructive thyroiditis. Diagnosis is by thyroid function tests, thyroid uptake, and color flow Doppler. Type one is treated with thionamides. Type two is treated with corticosteroids. Amiodarone-induced hypothyroidism is managed with levothyroxine replacement without discontinuing amiodarone if it is clinically indicated. Amiodarone should be discontinued if possible when hyperthyroidism develops.

Amylin Analogues

– Pramlintide is a synthetic analogue of amylin a co-secreted hormone from pancreatic beta cells that slows gastric emptying suppresses postprandial glucagon secretion and promotes satiety. Used as adjunctive therapy with insulin in type one and type two diabetes. Reduces postprandial glucose excursions and A1c. Side effects include nausea and injection site reactions. Risk of hypoglycemia when combined with insulin requiring dose reduction.

Androgen Deficiency

– Hypogonadism in males: reduced testosterone production causing symptoms and signs. Causes: primary (testicular—Klinefelter, mumps orchitis, chemotherapy, trauma) and secondary (pituitary/hypothalamic—prolactinoma, iron overload, pituitary lesions, opioids, obesity, aging). Features: low libido, erectile dysfunction, fatigue, decreased muscle mass and bone density, anemia, depression, reduced body hair, gynecomastia (primary). Diagnosis: morning total testosterone (<8 nmol/L) plus symptoms, LH/FSH (distinguish primary vs secondary), prolactin, iron studies. Management: testosterone replacement (gel, injections, implants) after excluding prostate cancer and hematocrit monitoring; treat cause. Also female androgen deficiency considerations.

Antidiuretic Hormone Physiology

– Antidiuretic hormone also known as vasopressin is synthesized in the supraoptic and paraventricular nuclei of the hypothalamus and stored in the posterior pituitary. Released in response to increased serum osmolality detected by hypothalamic osmoreceptors and decreased blood volume detected by baroreceptors. Acts on the collecting duct through V2 receptors inserting aquaporin-2 water channels causing water reabsorption and urine concentration. Also causes vasoconstriction through V1 receptors at higher concentrations causing vasoconstriction. Deficiency leads to diabetes insipidus, while excess causes syndrome of inappropriate antidiuretic hormone secretion.

Aromatase Excess Syndrome

– Rare autosomal dominant condition caused by mutations in the CYP19A1 gene leading to overexpression of aromatase enzyme and excessive estrogen production. Presents in males with gynecomastia, advanced bone age, and accelerated linear growth with early epiphyseal closure. In females with precocious puberty, macroclitoris, and virilization. Diagnosis is by elevated estradiol and suppressed gonadotropins. Treatment is with aromatase inhibitors anastrozole or letrozole to reduce estrogen synthesis and manage symptoms.

Blood Glucose Monitoring

– Blood sugar monitoring involves measuring glucose levels in the blood to manage diabetes, typically using a glucometer with finger-stick testing or continuous glucose monitors that track interstitial glucose in real time. Regular monitoring helps patients and clinicians adjust insulin doses, diet, and physical activity to maintain target glycemic ranges. Advances include flash glucose monitoring systems and smartphone-integrated sensors that improve convenience and data trends.

Bone Densitometry

– Dual-energy X-ray absorptiometry measures bone mineral density at the lumbar spine and hip. Results are expressed as T-score comparing to young adult mean and Z-score comparing to age-matched controls. T-score of minus 1.0 to minus 2.5 indicates osteopenia. T-score of minus 2.5 or less indicates osteoporosis. T-score of minus 2.5 with fragility fracture indicates severe osteoporosis. Fracture risk assessment using FRAX incorporates clinical risk

factors and BMD to estimate ten-year probability of hip fracture over ten years.

Bone Turnover Markers

- Biochemical markers reflecting the rate of bone remodeling. Formation markers include bone-specific alkaline phosphatase, osteocalcin, and N-terminal and C-terminal propeptides of type I procollagen. Resorption markers include C-terminal and N-terminal telopeptides of type I collagen and deoxypyridinoline. Elevated markers indicate increased bone turnover as in primary hyperparathyroidism Paget disease and osteomalacia. Suppressed markers indicate low bone turnover as in adynamic bone disease. Useful for monitoring response to osteoporosis therapy and assessing metabolic bone disease.

Calcitonin

- A 32-amino-acid peptide hormone secreted by the parafollicular C-cells of the thyroid gland in response to elevated serum calcium. It lowers blood calcium by inhibiting osteoclast-mediated bone resorption and increasing renal calcium excretion. Its physiologic role in humans is minor compared to PTH and vitamin D; however, calcitonin is a sensitive tumor marker for medullary thyroid carcinoma (MTC). Synthetic calcitonin (salmon calcitonin, more potent than human) was historically used for Paget disease of bone, osteoporosis, and hypercalcemia but has been largely replaced by bisphosphonates, denosumab, and other agents due to modest efficacy and association with malignancy risk with long-term use.

Calcium Sensing Receptor

- G-protein coupled receptor expressed primarily on parathyroid glands and renal tubular cells that senses extracellular ionized calcium levels. On parathyroid glands activation suppresses PTH secretion. On renal tubular cells activation increases calcium excretion and decreases phosphate reabsorption. Inactivating mutations cause familial hypocalciuric hypercalcemia and neonatal severe hyperparathyroidism. Activating mutations cause autosomal dominant hypocalcemia. The calcium sensing receptor is the target for cinacalcet, a calcimimetic used in secondary hyperparathyroidism of chronic kidney disease and parathyroid carcinoma.

Carcinoid Heart Disease

- Cardiac complication of carcinoid syndrome occurring in approximately fifty percent of patients with hepatic metastases. Serotonin and other vasoactive substances bypass hepatic metabolism and cause endocardial fibrosis affecting the right-sided heart valves particularly the tricuspid and pulmonary valves. Tricuspid regurgitation is the most common finding followed by pulmonary stenosis. Presents with right heart failure including edema ascites and fatigue. Diagnosis is by echocardiography. Treatment includes diuretics for heart failure and valve replacement surgery for severe valvular disease. Somatostatin analogues may slow disease progression.

Catecholamine Crisis

- Acute life-threatening elevation of catecholamines causing severe hypertension, tachycardia, and multi-organ dysfunction. Occurs in pheochromocytoma and paraganglioma precipitated by anesthesia, surgery, trauma, or medications that stimulate catecholamine release. Treatment includes immediate IV phentolamine or nitroprusside for blood pressure control followed by beta-blockade once adequate alpha-blockade is established. Beta-blockers should never be given before alpha-blockade due to the risk of unopposed alpha-adrenergic stimulation causing hypertensive crisis.

Chvostek Sign

- A clinical sign of latent tetany caused by hypocalcemia (ionized $Ca^{2+} < 4.4$ mg/dL). Elicited by tapping the facial nerve over the parotid gland just anterior to the ear canal. Positive response: involuntary twitching or contraction of ipsilateral facial muscles (lip twitching or facial spasm). Indicates increased neuromuscular excitability from low extracellular calcium.

Closed-Loop Insulin Delivery

- Automated insulin delivery systems that combine continuous glucose monitoring with an insulin pump and control algorithm. The algorithm adjusts basal insulin delivery based on sensor glucose values in real time. Hybrid closed-loop systems require user-initiated meal boluses but automatically manage basal rates. Fully automated systems are in development. Current systems include Medtronic 780G, Omnipod 5, Tandem Control-IQ, and CamAPS FX. Improve time in range and reduce hypoglycemia compared to conventional insulin pump therapy.

Congenital Adrenal Hyperplasia

– Group of autosomal recessive disorders caused by enzyme deficiencies in the adrenal steroidogenesis pathway. Twenty-one hydroxylase deficiency is the most common accounting for approximately ninety-five percent of cases. Impaired cortisol synthesis leads to elevated ACTH driving adrenal androgen excess causing virilization in females and precocious puberty in males. Severe forms present with salt-wasting crisis in neonates from aldosterone deficiency. Diagnosis is by elevated 17-hydroxyprogesterone levels and genetic testing. Treatment includes glucocorticoid replacement to suppress ACTH and androgen excess, mineralocorticoid replacement for salt-wasting forms, and corrective surgery for virilised genitalia in females.

Congenital Hyperinsulinism

– Condition of inappropriate insulin secretion in neonates and infants causing severe hypoglycemia. Most commonly caused by mutations in the KATP channel genes ABCC8 and KCNJ11. Histologically classified into focal and diffuse forms. Presents with severe symptomatic hypoglycemia in the first days of life. Diagnosis requires demonstration of inappropriately elevated insulin and C-peptide during hypoglycemia. Treatment includes continuous glucose infusion, diazoxide as first-line medical therapy, and octreotide for diazoxide-unresponsive cases. Surgical resection of focal lesions or near-total pancreatectomy for diffuse disease may be necessary.

Congenital Hyperthyroidism

– Thyrotoxicosis present at birth most commonly caused by maternal Graves disease with transplacental passage of thyroid-stimulating immunoglobulins. Presents with tachycardia, irritability, poor feeding, weight loss, and goiter. Transient neonatal hyperthyroidism resolves as maternal antibodies are cleared over weeks to months. Neonatal Graves disease requires treatment with methimazole and beta-blockers. Rare causes include TSH receptor mutations causing constitutive activation and McCune-Albright syndrome.

Congenital Hypothyroidism

– Thyroid hormone deficiency present at birth occurring in approximately one in two thousand to four thousand live births. Most common cause is thyroid dysgenesis including aplasia, ectopia, and hypoplasia.

Universal newborn screening with TSH or T4 allows early detection and treatment preventing intellectual disability. Presentation in unscreened infants includes prolonged jaundice, constipation, poor feeding, lethargy, hypotonia, macroglossia, and umbilical hernia. Treatment is levothyroxine replacement starting at ten to fifteen micrograms per kilogram daily with dose adjustment based on thyroid function tests.

Continuous Glucose Monitoring

– Technology measuring interstitial glucose levels continuously providing real-time glucose data, trends, and alerts. Sensors are inserted subcutaneously typically in the abdomen or arm and measure glucose every five minutes. Devices include Dexcom, FreeStyle Libre, and Medtronic Guardian systems. Provides time in range the percentage of time glucose remains between seventy and one hundred eighty milligrams per deciliter, glucose variability metrics, and trend arrows. Alerts notify patients of impending or current hypoglycemia and hyperglycemia. Data can be shared remotely with caregivers and healthcare providers, improving diabetes management.

Cortisol

– The primary glucocorticoid produced by the adrenal cortex (zona fasciculata) under ACTH control; essential for stress response, metabolism, and homeostasis. Functions: gluconeogenesis, glycogenolysis, protein catabolism, lipolysis, anti-inflammatory/immunosuppressive effects, and maintenance of vascular tone. Regulation: HPA axis—CRH (hypothalamus) → ACTH (pituitary) → cortisol; negative feedback at hypothalamus/pituitary; diurnal rhythm (peak morning). Excess: Cushing syndrome (weight gain, striae, hypertension, hyperglycemia, immunosuppression); deficiency: adrenal insufficiency (hypotension, hyperkalemia, hyponatremia, hypoglycemia). Measured by serum, urine free cortisol, or dexamethasone suppression tests.

Cushing Disease

– Hypercortisolism caused by a pituitary ACTH-secreting adenoma, the most common cause of endogenous Cushing syndrome (70%). Presents with central obesity, moon face, buffalo hump, violaceous striae, proximal myopathy, easy bruising, osteoporosis, hypertension, hyperglycemia, depression, and

menstrual irregularities. Diagnosis: elevated 24-hour urinary free cortisol, abnormal dexamethasone suppression test, late-night salivary cortisol; ACTH level differentiates ACTH-dependent from independent causes; pituitary MRI localizes adenoma. Treatment: transsphenoidal adenomectomy is first-line; bilateral adrenalectomy for refractory cases.

Cushing Syndrome

– Clinical state resulting from chronic exposure to excess glucocorticoids regardless of cause. Most common endogenous cause is Cushing disease from pituitary ACTH-secreting adenoma accounting for approximately seventy percent. Ectopic ACTH syndrome from non-pituitary tumors including small cell lung cancer and carcinoid tumors accounts for approximately fifteen percent. Adrenal adenomas and carcinomas account for approximately fifteen percent. Exogenous glucocorticoid administration is the most common cause of exogenous Cushing syndrome from prescribed corticosteroids including prednisolone and dexamethasone for inflammatory conditions.

Cushing Syndrome Complications

– Untreated Cushing syndrome carries significant morbidity and mortality from cardiovascular disease, infections, thromboembolic events, and metabolic derangements. Cardiovascular complications include accelerated atherosclerosis, hypertension, and dyslipidemia. Infection risk is increased from immunosuppression. Venous thromboembolism occurs at high rates. Metabolic complications include diabetes, osteoporosis, and myopathy. Psychiatric manifestations include depression, cognitive impairment, and psychosis. Cardiovascular risk remains elevated even after biochemical cure, necessitating long-term surveillance.

Dawn Phenomenon

– Physiological increase in blood glucose occurring in the early morning hours between approximately three and eight AM driven by counter-regulatory hormone surges including growth hormone, cortisol, and catecholamines. More pronounced in patients with diabetes who lack the compensatory insulin response. Can be identified by comparing overnight and fasting glucose values. Differentiated from the Somogyi effect which is rebound hyperglycemia after

nocturnal hypoglycemia. Management involves adjustment of basal insulin rates and consideration of continuous glucose monitoring to detect and address early morning hyperglycemia.

Delayed Puberty

– Failure to develop secondary sexual characteristics by age thirteen in girls and age fourteen in boys. Causes include constitutional delay which is the most common, chronic illness, malnutrition, hypogonadotropic hypogonadism from Kallmann syndrome or pituitary disease, and hypergonadotropic hypogonadism from gonadal failure. Diagnosis includes bone age assessment, hormone levels including LH, FSH, testosterone or estradiol, and imaging. Treatment is sex steroid replacement to induce puberty with monitoring of growth and bone age progression. Underlying causes should be addressed where possible.

Denosumab for Osteoporosis

– Fully human monoclonal antibody targeting RANK ligand preventing osteoclast formation activation and survival. Reduces fracture risk at the spine hip and non-vertebral sites. Administered as subcutaneous injection every six months. Advantages include no renal dose adjustment and effectiveness even with oral bisphosphonate intolerance. Disadvantages include risk of vertebral fractures after discontinuation due to rebound bone loss requiring bisphosphonate transition therapy or extended denosumab therapy indefinitely.

Diabetes and Metabolic Health

– Closely linked through insulin resistance, obesity, dyslipidemia, and hypertension, collectively known as the metabolic syndrome. Poor metabolic health increases the risk of developing type 2 diabetes and worsens glycemic control in existing diabetes. Improving metabolic health through weight loss, dietary changes, and physical activity can prevent or reverse type 2 diabetes in some individuals.

Diabetes Complications

– Diabetes complications arise from chronic hyperglycemia damaging blood vessels and nerves over time. Microvascular complications include diabetic retinopathy leading to vision loss, nephropathy progressing to kidney failure, and neuropathy causing pain and loss of sensation. Macrovascular complications include accelerated atherosclerosis manifesting

as heart attack, stroke, and peripheral artery disease.

Diabetes insipidus

– A disorder characterized by polyuria (excessive urine output exceeding 40 mL/kg/24 hours) and polydipsia due to deficient secretion of antidiuretic hormone (ADH, vasopressin) from the posterior pituitary (central diabetes insipidus) or renal resistance to ADH action (nephrogenic diabetes insipidus). Central DI is caused by destruction of the hypothalamic-pituitary axis from head trauma, neurosurgery, tumors (craniopharyngioma, germinoma), infiltrative diseases (Langerhans cell histiocytosis, sarcoidosis), and idiopathic causes. Nephrogenic DI is caused by genetic mutations (AVPR2 or AQP2), drugs (lithium, demeclocycline), hypercalcaemia, hypokalaemia, and chronic kidney disease. Diagnosis involves water deprivation test measuring urine osmolality and response to desmopressin. Central DI shows marked improvement with desmopressin, whereas nephrogenic DI shows minimal response. Treatment includes desmopressin for central DI, correction of underlying cause for nephrogenic DI, and thiazide diuretics with a low-sodium diet for partial nephrogenic DI.

Diabetes Medications

– Diabetes medications lower blood glucose through various mechanisms: metformin reduces hepatic glucose production; sulfonylureas stimulate insulin secretion; SGLT2 inhibitors increase urinary glucose excretion; GLP-1 receptor agonists enhance incretin effects; and insulin replaces deficient hormone. Choice of therapy depends on diabetes type, glycemic targets, patient preferences, cardiovascular and renal status, and cost.

Diabetes Mellitus

– A metabolic disorder characterized by chronic hyperglycemia resulting from insufficient insulin production, insulin resistance, or both. Type 1 diabetes results from autoimmune destruction of pancreatic beta cells, while type 2 is driven by genetic and lifestyle factors leading to insulin resistance. Long-term complications affect the eyes, kidneys, nerves, and cardiovascular system; management focuses on glycemic control, diet, exercise, and medications.

Diabetes Mellitus Type 1

– An autoimmune disease characterized by destruc-

tion of pancreatic beta cells leading to absolute insulin deficiency. Usually presents in childhood or young adulthood with acute onset of polyuria, polydipsia, weight loss, and diabetic ketoacidosis (DKA) at diagnosis in many. Laboratory: hyperglycemia, positive autoantibodies (GAD, IA-2, ZnT8), low C-peptide. Lifelong insulin therapy required. Intensive glycemic control reduces microvascular and macrovascular complications.

Diabetes Mellitus Type 2

– A progressive metabolic disorder characterized by insulin resistance and relative insulin deficiency, strongly associated with obesity and physical inactivity. Typically presents in adults but increasingly seen in younger populations. Diagnosis: fasting glucose ≥ 126 mg/dL, HbA1c $\geq 6.5\%$, or OGTT ≥ 200 mg/dL. Management: lifestyle modification, metformin first-line, followed by additional oral agents, GLP-1 receptor agonists, SGLT2 inhibitors, and ultimately insulin as beta-cell function declines.

Diabetes Prevention

– Preventing diabetes focuses on reducing the risk of developing type 2 diabetes through lifestyle interventions and risk factor management. Maintaining a healthy body weight, engaging in regular physical activity, and following a balanced diet low in refined sugars and saturated fats are cornerstone strategies. For individuals with prediabetes, structured programs involving dietary changes, exercise, and sometimes metformin can significantly lower the likelihood of progression to overt diabetes.

Diabetic Complications

– The chronic and acute consequences of diabetes mellitus. Microvascular: retinopathy (leading cause of blindness), nephropathy (leading cause of ESRD—albuminuria, declining GFR), neuropathy (peripheral—stocking-glove, autonomic—gastroparesis, erectile dysfunction, postural hypotension, cardiac autonomic). Macrovascular: accelerated atherosclerosis—CAD, cerebrovascular disease, PAD. Acute: diabetic ketoacidosis (DKA), hyperosmolar hyperglycemic state (HHS), hypoglycemia. Foot complications: ulceration, infection, Charcot. Prevention: intensive glycemic control (reduces microvascular), blood pressure control, statins, foot care, and screening (eye, renal, neuro).

Diabetic Foot Disease

- Complex multifactorial condition resulting from the combination of peripheral neuropathy, peripheral arterial disease, and impaired immune function in diabetes. Neuropathy leads to loss of protective sensation and foot deformities. Peripheral arterial disease impairs healing. Minor trauma progresses to ulceration and infection. The Wagner classification grades ulcers from zero to five based on depth and presence of gangrene. Treatment includes offloading, wound care, infection management, revascularisation for peripheral arterial disease, and amputation for non-salvageable tissue loss. Multidisciplinary foot care teams are essential for optimal outcomes.

Diabetic Ketoacidosis

- An acute, life-threatening complication of diabetes mellitus, more common in type 1. Characterized by hyperglycemia (>250 mg/dL), metabolic acidosis ($\text{pH} < 7.3$, bicarbonate < 15 mEq/L), and ketonemia. Precipitating factors: infection, missed insulin doses, MI, pancreatitis, and stress. Presents with polyuria, polydipsia, nausea, vomiting, abdominal pain, Kussmaul respirations, and altered mental status. Treatment: fluid resuscitation, insulin infusion, potassium replacement, and correction of precipitating cause.

Diabetic Ketoacidosis Monitoring

- Monitoring during DKA management includes hourly blood glucose measurement, serum electrolytes every two to four hours, venous blood gas assessment, beta-hydroxybutyrate levels, and fluid balance. Resolution criteria include blood glucose less than two hundred milligrams per deciliter, bicarbonate greater than fifteen milliequivalents per liter, venous pH greater than seven point three, and anion gap less than twelve. Transition to subcutaneous insulin occurs when resolution criteria are met and the patient is eating and drinking normally. Frequent monitoring of potassium is essential because levels fall during insulin therapy and require aggressive replacement to prevent hypokalaemia.

Diabetic Neuropathy

- Most common complication of diabetes affecting approximately fifty percent of patients. Distal symmetric polyneuropathy presents with stocking-glove sensory loss, burning pain, and loss of proprioception. Autonomic neuropathy causes gastropare-

sis, orthostatic hypotension, erectile dysfunction, and sudomotor dysfunction. Mononeuropathies include cranial nerve palsies particularly third nerve palsy and carpal tunnel syndrome. Diagnosis is by clinical examination and nerve conduction studies. Treatment includes optimised glycaemic control, symptomatic management of neuropathic pain with agents such as gabapentin, pregabalin, amitriptyline, or duloxetine, and management of autonomic complications.

Diabetic Retinopathy

- A microvascular complication of diabetes mellitus and a leading cause of blindness in working-age adults. Non-proliferative DR (NPDR): microaneurysms, dot-blot hemorrhages, exudates (hard and cotton-wool spots), and venous beading. Proliferative DR (PDR): retinal neovascularization, vitreous hemorrhage, and tractional retinal detachment. Macular edema (DME) can occur at any stage and is the most common cause of vision loss. Risk factors: poor glycemic control, hypertension, duration of diabetes. Management: strict glucose and blood pressure control; anti-VEGF injections (ranibizumab, aflibercept, bevacizumab) and focal laser for DME; panretinal photocoagulation for PDR.

Dipeptidyl Peptidase-4 Inhibitors

- Oral glucose-lowering medications including sitagliptin, saxagliptin, linagliptin, and alogliptin that inhibit the enzyme degrading incretin hormones GLP-1 and GIP. Resulting increase in active incretin levels enhances glucose-dependent insulin secretion and suppresses glucagon. Neutral effect on weight and low hypoglycemia risk. Cardiovascular safety has been demonstrated though some agents showed increased heart failure hospitalizations. Dose adjustment required in renal impairment for all except linagliptin which is hepatobiliary excreted.

Dwarfism

- Short stature resulting from a medical condition, most commonly achondroplasia (the most common form of skeletal dysplasia, caused by gain-of-function mutation in FGFR3, presenting with rhizomelic limb shortening, macrocephaly, frontal bossing, and trident hands). Other causes: growth hormone deficiency, hypothyroidism, Turner syndrome, Noonan syndrome, skeletal dysplasias (osteogenesis imperfecta, spondyloepiphyseal dysplasia), and intrauter-

ine growth restriction. Diagnosis: history, physical exam, growth chart analysis, skeletal survey, genetic testing, and endocrine evaluation. Management: growth hormone therapy for GH deficiency; limb lengthening procedures in selected cases; management of complications (spinal stenosis, obesity, obstructive sleep apnea, otitis media).

Ectopic ACTH Syndrome

– Adrenocorticotrophic hormone secretion by non-pituitary tumors causing Cushing syndrome. Most commonly caused by small cell lung cancer and bronchial carcinoid tumors. Other sources include thymic carcinoid, pancreatic neuroendocrine tumors, and medullary thyroid carcinoma. Ectopic ACTH typically causes more severe hypercortisolism than Cushing disease with pronounced hypokalemia and metabolic alkalosis. Diagnosis requires demonstration of non-suppressible cortisol after high-dose dexamethasone suppression test, inferior petrosal sinus sampling for localisation of ACTH source, and imaging of the pituitary and adrenal glands.

Ectopic Thyroid Tissue

– Thyroid tissue located outside the normal pre-tracheal position resulting from failure of normal thyroid descent during embryological development. Most commonly found at the base of the tongue termed lingual thyroid. May be the only functioning thyroid tissue. Symptoms include dysphagia, dysphonia, and upper airway obstruction. Diagnosis is by imaging with thyroid scan confirming uptake in the ectopic location. Treatment includes levothyroxine supplementation to suppress TSH and reduce ectopic tissue size. Surgical excision is reserved for symptomatic lesions.

Empty Sella Syndrome

– Herniation of subarachnoid space into the sella turcica, compressing the pituitary gland and flattening it against the sellar floor. Primary: due to congenital weakness of the diaphragma sella. Secondary: post-surgery, post-radiation, or pituitary apoplexy (Sheehan syndrome). Most are asymptomatic. Symptoms when present: headache, visual field defects, and endocrine dysfunction (hypopituitarism, growth hormone deficiency, hyperprolactinemia). Diagnosis: MRI shows CSF filling the sella with compressed pituitary. Treatment: endocrine replacement as needed; no treatment for the empty

sella itself.

Endocrine Disrupting Chemicals

– Environmental chemicals that interfere with endocrine function including bisphenol A, phthalates, pesticides, and polychlorinated biphenyls. Potential associations with diabetes, obesity, thyroid dysfunction, reproductive disorders, and hormone-sensitive cancers. Evidence is strongest for associations with type two diabetes and obesity. Avoidance strategies include limiting plastic food containers choosing organic produce and avoiding personal care products with parabens and phthalates. Regulatory bodies continue to evaluate the health impact of these chemicals and develop guidelines for safe exposure limits.

Endocrine Glands

– Ductless glands that secrete hormones directly into the bloodstream to regulate distant target organs. Major endocrine glands: hypothalamus (releasing/inhibiting hormones regulating the pituitary), pituitary gland (anterior: GH, TSH, ACTH, FSH, LH, prolactin; posterior: ADH, oxytocin), thyroid gland (T4, T3, calcitonin), parathyroid glands (PTH), adrenal glands (cortex: cortisol, aldosterone, androgens; medulla: epinephrine, norepinephrine), pancreas (islets of Langerhans: insulin, glucagon, somatostatin), ovaries (estrogen, progesterone), testes (testosterone), pineal gland (melatonin), and kidneys (erythropoietin, renin). The endocrine system maintains homeostasis through feedback loops (primarily negative feedback), with the hypothalamic-pituitary axis serving as the master regulator.

Endocrinology

– The branch of medicine concerned with the study, diagnosis, and treatment of disorders of the endocrine system—the network of glands that secrete hormones regulating metabolism, growth and development, tissue function, sexual function, reproduction, sleep, and mood. Endocrinologists manage conditions including diabetes mellitus, thyroid disorders (hyperthyroidism, hypothyroidism, nodules, cancer), adrenal disorders (Cushing syndrome, Addison disease, pheochromocytoma), pituitary disorders (acromegaly, prolactinoma, hypopituitarism), parathyroid and calcium disorders (hyperparathyroidism, osteoporosis), and reproductive endocrinology (infertility, PCOS, menopause). Diagnostic

tools: hormone assays, stimulation/suppression tests, and imaging (ultrasound, CT, MRI, nuclear medicine).

Euthyroid Sick Syndrome

- Abnormal thyroid function tests in patients with non-thyroidal illness (critical illness, starvation, major surgery) without intrinsic thyroid disease. Pattern: low T3 (most common), low T4, reverse T3 elevated, normal or low TSH. The severity correlates with illness severity. In critical illness: low T3 and T4 are associated with worse prognosis. T4 and TSH may rise during recovery. No treatment indicated; thyroid hormone replacement does not improve outcomes. Correct the underlying illness.

Familial Hypocalciuric Hypercalcemia

- Autosomal dominant condition caused by inactivating mutations in the calcium-sensing receptor gene leading to a higher set point for calcium-mediated PTH suppression. Presents with mild hypercalcemia, inappropriately normal or mildly elevated PTH, and low urinary calcium excretion with calcium-to-creatinine clearance ratio less than 0.01. Benign condition that does not require parathyroidectomy. Distinguished from primary hyperparathyroidism by urinary calcium excretion to prevent unnecessary surgery. Genetic testing confirms the diagnosis and identifies the specific mutation in the calcium-sensing receptor gene for definitive classification.

Follicle Stimulating Hormone

- FSH: a gonadotropin secreted by the anterior pituitary, regulating gonadal function. In females: stimulates ovarian follicle growth and estradiol production; LH surge triggers ovulation. In males: stimulates Sertoli cells and spermatogenesis. Controlled by GnRH and feedback (estrogen, inhibin). Clinical use: evaluation of infertility and gonadal dysfunction—high FSH with low estradiol/testosterone indicates primary gonadal failure (menopause, ovarian failure, Klinefelter); low FSH suggests hypogonadotropic hypogonadism (pituitary/hypothalamic). Used with LH, estradiol, testosterone, and in IVF for ovarian stimulation and monitoring.

Follicular Thyroid Carcinoma

- Second most common thyroid carcinoma accounting for approximately ten percent of cases. Distinguished from follicular adenoma by capsular or vascular invasion on histological examination which cannot be determined by fine-needle aspiration. Metastasizes hematogenously to bone, lung, and liver. Treatment includes total thyroidectomy with radioactive iodine ablation. Prognosis is generally favorable though worse than papillary carcinoma particularly with distant metastases.

guished from follicular adenoma by capsular or vascular invasion on histological examination which cannot be determined by fine-needle aspiration. Metastasizes hematogenously to bone, lung, and liver. Treatment includes total thyroidectomy with radioactive iodine ablation. Prognosis is generally favorable though worse than papillary carcinoma particularly with distant metastases.

Galactina

- A hormone produced by the placenta that stimulates prolactin secretion from the anterior pituitary. Involved in mammary gland development during pregnancy and the onset of lactation postpartum. Elevated levels are associated with pathological galactorrhoea and certain pituitary tumors. Measurement is a component of the assessment of hyperprolactinaemia.

Galactorrhea

- Milky nipple discharge not associated with normal lactation, caused by hyperprolactinemia or nipple/breast stimulation. Causes: prolactinoma (pituitary adenoma), medications (antipsychotics, metoclopramide, estrogens, opiates, verapamil, SSRIs), hypothyroidism (TRH stimulates prolactin), chest wall trauma, renal failure, and stress. Features: spontaneous or expressible discharge, amenorrhea, headache/visual field defects if macroadenoma, hypogonadism. Evaluation: serum prolactin, TSH, pregnancy test, MRI pituitary if hyperprolactinemic or symptoms suggest tumor. Management: dopamine agonists (cabergoline, bromocriptine) for prolactinoma, stop offending drug, treat hypothyroidism.

Galactorrhoea

- The spontaneous flow of milk from the breast not associated with childbirth or breastfeeding. Galactorrhoea can be unilateral or bilateral and is caused by hyperprolactinaemia (elevated prolactin). Aetiologies: pituitary prolactinoma (most common), hypothalamic-pituitary stalk compression, medications (antipsychotics, metoclopramide, verapamil, oral contraceptives, opioids), hypothyroidism (TRH stimulates prolactin release), chronic renal failure, chest wall irritation (herpes zoster, surgery, trauma). Galactorrhoea may also be idiopathic. Diagnostic workup: serum prolactin, TSH, pregnancy test (beta-hCG), MRI pituitary with contrast. Manage-

ment: treat underlying cause; dopamine agonists (cabergoline, bromocriptine) for prolactinoma.

Galactosaemia

– A rare autosomal recessive disorder of galactose metabolism caused by deficiency of one of three enzymes: galactose-1-phosphate uridylyltransferase (GALT, classic galactosaemia, type I), galactokinase (GALK, type II), or UDP-galactose epimerase (GALE, type III). Classic galactosaemia (GALT deficiency, incidence 1:30,000-60,000) presents in the neonatal period within days of milk feeding: vomiting, diarrhea, failure to thrive, jaundice, hepatomegaly, cataracts (due to galactitol accumulation), hypoglycemia, and *E. coli* sepsis. Diagnosis: newborn screening (GALT enzyme activity in dried blood spot), urine reducing substances. Long-term complications despite dietary restriction: speech and learning difficulties, ataxia, ovarian failure (in females), decreased bone density. Treatment: life-long lactose/galactose-free diet.

Gastrinoma

– Gastrin-secreting neuroendocrine tumor causing Zollinger-Ellison syndrome characterized by gastric acid hypersecretion leading to severe peptic ulcer disease, diarrhea, and esophagitis. Approximately sixty percent are malignant with liver metastases. Multiple endocrine neoplasia type 1 association in approximately twenty percent. Diagnosis is by elevated fasting gastrin level and positive secretin stimulation test. Treatment includes high-dose proton pump inhibitors for acid control and surgical resection of localised disease. Somatostatin analogues control symptoms in functioning tumors. Chemotherapy and peptide receptor radionuclide therapy are options for metastatic disease.

Gestational Diabetes Mellitus

– Glucose intolerance first recognized during pregnancy affecting approximately six to nine percent of pregnancies. Results from insulin resistance induced by placental hormones including human placental lactogen, cortisol, and progesterone combined with insufficient beta cell compensation. Risk factors include advanced maternal age, obesity, family history of diabetes, previous gestational diabetes, polycystic ovary syndrome, and certain ethnicities. Universal screening is performed at twenty-four to twenty-eight weeks of gestation with a seventy-five

gram oral glucose tolerance test. Treatment includes lifestyle modification and insulin or metformin if glycaemic targets are not met. Glucose levels normalise after delivery but affected women have increased long-term risk of type two diabetes.

Gigantism

– A rare condition of excessive growth and tall stature caused by growth hormone (GH) hypersecretion that begins before epiphyseal plate closure in childhood, before the onset of puberty. The most common cause is a GH-secreting pituitary adenoma (usually a benign somatotroph adenoma, often macroadenoma greater than 1 cm), which may be sporadic or associated with genetic syndromes (McCune-Albright syndrome, multiple endocrine neoplasia type 1, Carney complex, familial isolated pituitary adenoma from germline mutations in the AIP gene). Presents with accelerated linear growth, tall stature, large hands and feet, coarse facial features, and delayed skeletal maturation. Diagnosis is confirmed by elevated IGF-1 and GH levels that fail to suppress on glucose tolerance testing. Pituitary MRI identifies the responsible adenoma. Treatment includes transsphenoidal adenomectomy, medical therapy with somatostatin analogues, and rarely radiotherapy. Early diagnosis and intervention improve final height outcomes.

Glucagonoma

– A rare pancreatic neuroendocrine tumor secreting glucagon. Classic presentation: 4 Ds — diabetes mellitus (mild, new onset), dermatitis (necrolytic migratory erythema, characteristic painful, erythematous, blistering rash on groin, perineum, extremities), diarrhea, and deep vein thrombosis. Presents with weight loss, glossitis, and hypoaminoacidemia. Most are malignant and metastatic at diagnosis. Diagnosis: elevated glucagon level (>500 pg/mL) and pancreatic tumor on imaging. Treatment: surgical resection; somatostatin analogs for symptom control; chemotherapy and PRRT for advanced disease.

Glucocorticoid Replacement Therapy

– Replacement of cortisol deficiency in adrenal insufficiency using hydrocortisone in divided doses. Typical regimen is ten to fifteen milligrams in the morning and five to ten milligrams in the early afternoon mimicking the physiological cortisol di-

urnal rhythm. Alternative preparations include prednisolone and dexamethasone though these have longer half-lives and are less physiological. Fludrocortisone is added for mineralocorticoid replacement in primary adrenal insufficiency. Stress dosing requires doubling or tripling of the daily hydrocortisone dose during intercurrent illness, fever, or minor surgery, with parenteral administration for major surgery or when oral intake is not possible. Patient education about sick-day rules and provision of an emergency injectable glucocorticoid kit are essential to prevent adrenal crisis.

Glucocorticoids

– A class of steroid hormones produced by the zona fasciculata of the adrenal cortex, regulated by the hypothalamic-pituitary-adrenal (HPA) axis. Cortisol is the primary endogenous glucocorticoid, essential for: (1) carbohydrate metabolism (gluconeogenesis, glycogenolysis, peripheral insulin resistance); (2) protein metabolism (catabolism in muscle, connective tissue, bone); (3) fat metabolism (lipolysis, fat redistribution to face and trunk); (4) anti-inflammatory and immunosuppressive effects (inhibit phospholipase A2, COX-2, pro-inflammatory cytokines); (5) stress response; (6) maintenance of blood pressure (permissive effect on catecholamines). Synthetic glucocorticoids (prednisolone, dexamethasone, betamethasone, hydrocortisone) are used therapeutically for: autoimmune and inflammatory diseases (rheumatoid arthritis, asthma, inflammatory bowel disease, SLE), allergic reactions, organ transplant rejection, adrenal insufficiency (replacement therapy), cerebral edema (dexamethasone), and fetal lung maturation (betamethasone). Side effects of chronic use: Cushing syndrome (central obesity, moon face, buffalo hump, striae), osteoporosis, diabetes, hypertension, immunodeficiency, cataract, growth suppression in children.

Glucose Management Indicator

– Derived metric from continuous glucose monitoring that estimates the hemoglobin A1c equivalent based on mean sensor glucose values. Formula converts mean glucose to an A1c-equivalent value allowing comparison between CGM data and traditional A1c. Provides a more comprehensive picture of glycemic control than A1c alone because it reflects glucose variability and the complete glucose profile rather

than a weighted average.

Glycaemia

– The concentration of glucose in the blood, normally maintained within a narrow range (fasting: 3.9-5.5 mmol/L or 70-100 mg/dL) through the coordinated action of insulin (lowers glucose) and counter-regulatory hormones (glucagon, cortisol, catecholamines, growth hormone). Disorders of glycaemia: hyperglycemia (elevated glucose, diagnostic of diabetes mellitus when fasting >7.0 mmol/L or HbA1c >48 mmol/mol), hypoglycemia (low glucose, <3.0 mmol/L clinically significant, causes: insulin overdose, sulfonylurea excess, insulinoma, liver failure, alcohol excess). Glycaemic control is assessed by: self-monitored blood glucose (SMBG), continuous glucose monitoring (CGM), HbA1c (glycated haemoglobin, reflects average glucose over 2-3 months).

Glycosuria

– The presence of glucose in the urine. Normally, the renal tubules reabsorb filtered glucose via sodium-glucose co-transporters (SGLT2 in proximal tubule). Glycosuria occurs when blood glucose exceeds the renal threshold (approximately 10 mmol/L or 180 mg/dL), overwhelming reabsorptive capacity. Causes: (1) hyperglycemia (diabetes mellitus, most common); (2) renal glycosuria (benign condition with low renal threshold, due to SGLT2 mutation); (3) pregnancy (decreased renal threshold due to increased GFR). Diagnostic significance: glycosuria is a screening finding for diabetes; its absence does not exclude diabetes. SGLT2 inhibitors (dapagliflozin, empagliflozin) are a class of antidiabetic drugs that intentionally induce glycosuria by blocking renal glucose reabsorption.

Goiter

– Enlargement of the thyroid gland, which can be diffuse or nodular. Causes: iodine deficiency (most common worldwide), Hashimoto thyroiditis, Graves disease, multinodular goiter, and thyroid cancer. May be associated with normal, hyperthyroid, or hypothyroid function. Large goiters can cause compressive symptoms: dysphagia, dysphonia, and stridor. Diagnosis: thyroid ultrasound, TSH, and thyroid scan. Treatment depends on etiology and symptoms.

Gonadotrophins

– Hormones that stimulate the gonads. The anterior pituitary secretes follicle-stimulating hormone (FSH) and luteinising hormone (LH), both glycoprotein hormones sharing a common alpha subunit (identical to TSH and hCG alpha) with a unique beta subunit. FSH: females–stimulates ovarian follicle growth and estrogen production; males–stimulates Sertoli cells for spermatogenesis. LH: females–triggers ovulation and corpus luteum formation (progesterone); males–stimulates Leydig cells to produce testosterone. Human chorionic gonadotrophin (hCG) is produced by the placenta and maintains the corpus luteum in early pregnancy. Therapeutically, gonadotrophins are used in assisted reproductive technology (IVF, ovulation induction, spermatogenesis induction).

Gonads

– The primary reproductive organs: testes in males and ovaries in females. Functions: (1) gamete production (spermatogenesis in testes, oogenesis in ovaries); (2) sex steroid hormone secretion (testosterone from testicular Leydig cells; estrogen and progesterone from ovarian follicular cells and corpus luteum). Gonadal function is regulated by the hypothalamic-pituitary-gonadal axis: GnRH from hypothalamus stimulates gonadotrophins (LH and FSH) from anterior pituitary, which act on the gonads. Disorders: hypogonadism (primary: gonadal failure; secondary: pituitary/hypothalamic deficiency), hypergonadism (precocious puberty), gonadal dysgenesis (Turner syndrome, Klinefelter syndrome).

Graves Disease

– Autoimmune disorder and most common cause of hyperthyroidism characterized by thyroid-stimulating immunoglobulins that bind and activate the thyroid-stimulating hormone receptor causing unregulated thyroid hormone synthesis and secretion. The diffuse goiter reflects TSH receptor stimulation. Ophthalmopathy occurs in approximately twenty-five percent with proptosis, periorbital edema, diplopia, and in severe cases optic nerve compression. Pretibial myxedema is a localized dermopathy. Diagnosis is confirmed by elevated free T4 and suppressed TSH, positive thyroid-stimulating immunoglobulins, and increased radioactive iodine uptake on thyroid scintigraphy.

Growth Hormone Deficiency

– Insufficient secretion of growth hormone from the anterior pituitary, causing short stature in children and metabolic effects in adults. In children: delayed growth, short stature, delayed bone age, and increased fat mass. In adults: decreased muscle mass, increased fat mass, reduced bone density, fatigue, and dyslipidemia. Diagnosis: low IGF-1, GH stimulation testing. Treatment: recombinant human GH (somatropin) replacement.

Growth Hormone Physiology

– Growth hormone is secreted in a pulsatile pattern by pituitary somatotroph cells regulated by hypothalamic GHRH which stimulates release and somatostatin which inhibits release. GH acts directly on tissues and indirectly through IGF-1 produced primarily by the liver. GH promotes linear growth in children and in adults regulates body composition with anabolic effects on muscle catabolic effects on adipose tissue effects on bone metabolism and glucose homeostasis. GH secretion decreases with aging, contributing to sarcopenia and increased adiposity in the elderly. Testing for GH deficiency requires provocative testing with insulin tolerance test or glucagon stimulation test, as random GH levels are unreliable due to pulsatile secretion.

Gynaecomastia

– The benign enlargement of breast tissue in males. Pathophysiology: an imbalance between estrogen (stimulates breast tissue growth) and androgen (suppresses) activity, resulting in increased estrogen-to-testosterone ratio. Gynaecomastia can be: (1) Physiologic: neonatal (transient, maternal estrogen), pubertal (60-70% of boys, peak age 13-14, typically resolves within 2 years), senescent (ageing-related increase in aromatase activity and decrease in testosterone). (2) Pathologic: hypogonadism (primary–Klinefelter syndrome, secondary–pituitary failure), hyperthyroidism (increased aromatisation), liver cirrhosis (impaired estrogen metabolism), testicular tumors (Leydig cell, Sertoli cell, choriocarcinoma–hCG stimulates estrogen), renal failure, refeeding after starvation. (3) Drug-induced: anti-androgens (spironolactone, cimetidine, finasteride, bicalutamide), estrogens, anabolic steroids, GnRH agonists, calcium channel blockers, digoxin, isoniazid, HIV drugs, tricyclic antidepressants, methadone,

marijuana. Diagnosis: true gynaecomastia (palpable concentric disc of firm tissue >0.5 cm) vs pseudogynaecomastia (adipomastia, fatty enlargement without breast tissue). Workup: breast examination, testicular exam, LFT, TFT, serum hCG, LH, FSH, testosterone (total and free), prolactin, estradiol. Imaging: mammography if asymmetric or suspicious. Management: reassurance for physiologic gynaecomastia (spontaneous regression); discontinuation of offending drugs; medical therapy: tamoxifen (SERM, reduces estrogen effect on breast) or raloxifene; severe/long-standing cases (fibrotic stage >12 months): subcutaneous mastectomy (liposuction or surgical excision).

Hashimoto Thyroiditis

– Autoimmune thyroiditis characterized by lymphocytic infiltration and progressive destruction of thyroid follicles leading to hypothyroidism. Most common cause of hypothyroidism in iodine-sufficient areas. Anti-thyroid peroxidase and anti-thyroglobulin antibodies are present. The thyroid may be diffusely enlarged and firm or atrophic. Patients present with fatigue, weight gain, cold intolerance, constipation, dry skin, and depression. Subclinical hypothyroidism with elevated TSH and normal free T4 levels is common and may progress to overt hypothyroidism. Treatment is levothyroxine replacement titrated to achieve normal TSH levels.

Healthy Eating for Diabetes

– A dietary approach designed to maintain stable blood glucose levels in individuals with diabetes mellitus. It emphasizes carbohydrate consistency, high fiber intake, lean proteins, and healthy fats while minimizing refined sugars and simple carbohydrates. Meal planning often involves carbohydrate counting or the plate method, and coordination with medication and physical activity is essential.

Hemoglobin A1c

– Glycated hemoglobin reflecting average blood glucose concentration over the preceding two to three months corresponding to the red blood cell lifespan. Formed by non-enzymatic glycation of hemoglobin at the N-terminal valine of the beta chain. The percent of glycated hemoglobin is directly proportional to mean glucose levels. Used for diagnosis of diabetes with greater than or equal to 6.5 percent indicating diabetes, 5.7 to 6.4 percent indicating

prediabetes, and less than 5.7 percent indicating normoglycaemia. Limitations include interference from haemoglobinopathies, anaemia, and conditions affecting red blood cell lifespan, which may give falsely low or high values independent of glycaemic control.

Hemoglobin A1c Variability

– Factors that affect hemoglobin A1c accuracy include hemoglobinopathies such as sickle cell disease and thalassemias which alter red blood cell lifespan and glycation rates, iron deficiency anemia which shortens red blood cell survival lowering A1c, vitamin B12 and folate deficiency, pregnancy, chronic kidney disease, erythropoietin therapy, and recent blood transfusion. Conditions that shorten red blood cell lifespan lower A1c while those that prolong lifespan raise A1c independent of glycemic control. When A1c and glucose data are discordant, alternative methods such as fructosamine or glycated albumin may provide useful complementary information, and a careful review for conditions affecting red blood cell turnover is warranted.

Hirsutism

– Excess terminal hair growth in women in a male-pattern distribution (face—upper lip, chin, sideburns; chest, back, lower abdomen, inner thighs). Hirsutism affects 5-10% of women of reproductive age. Pathophysiology: increased androgen production or increased end-organ sensitivity. The modified Ferriman-Gallwey (mFG) score quantifies hirsutism (score >8 indicates hirsutism). Causes: (1) Polycystic ovary syndrome (PCOS, 70-80% of cases): elevated LH:FSH ratio, hyperandrogenism, anovulation. (2) Idiopathic hirsutism (15-20%): normal serum androgens, increased 5-alpha-reductase activity (converts testosterone to DHT in the hair follicle). (3) Non-classic congenital adrenal hyperplasia (NCCAH, 5-10%): 21-hydroxylase deficiency (elevated 17-hydroxyprogesterone). (4) Androgen-secreting tumors (ovarian or adrenal, rare, rapidly progressive): testosterone >200 ng/dL, DHEAS >700 mcg/dL. (5) Cushing syndrome: central obesity, striae, hypertension, hyperglycemia. (6) Medications: danazol, testosterone, anabolic steroids, ciclosporin, valproate, phenytoin. (7) Other: HAIR-AN syndrome (hyperandrogenism, insulin resistance, acanthosis nigricans), hyperprolactinaemia. Diag-

nosis: serum total and free testosterone, SHBG, DHEAS, 17-OHP, LH, FSH, prolactin, TSH, free T4; pelvic ultrasound for PCOS. Management: (1) Mechanical: hair removal by shaving, waxing, electrolysis, laser hair removal (most effective, targets melanin in hair bulb). (2) Pharmacological: combined oral contraceptive pill (first line for PCOS, reduces ovarian androgen production, increases SHBG), anti-androgens (spironolactone 100-200 mg/day, finasteride, cyproterone acetate, flutamide—teratogenic, requires contraception), metformin (insulin sensitizer, modest benefit), eflornithine cream (topical, inhibits ornithine decarboxylase, slows hair growth). (3) Treatment of underlying cause (CAH: glucocorticoids; tumor: surgical removal).

Hormone

– A chemical messenger produced by endocrine glands, secreted into the bloodstream, and transported to distant target cells where it binds to specific receptors to exert a physiological effect. Hormones regulate: growth and development (growth hormone, thyroid hormone, sex steroids), metabolism (insulin, glucagon, cortisol, thyroid hormone, adrenaline), reproduction (LH, FSH, estrogen, progesterone, testosterone, prolactin), fluid and electrolyte balance (ADH, aldosterone), calcium homeostasis (PTH, calcitonin, vitamin D), and stress response (cortisol, adrenaline, noradrenaline). Hormone classification: (1) Peptide/protein hormones (water-soluble): hypothalamic releasing factors, pituitary hormones, insulin, glucagon, PTH, calcitonin; bind to cell surface receptors (GPCRs, receptor tyrosine kinases), act via second messengers (cAMP, IP3/DAG, Ca²⁺). (2) Steroid hormones (lipid-soluble): cortisol, aldosterone, estrogen, progesterone, testosterone, vitamin D; synthesised from cholesterol, bind to intracellular receptors (cytoplasmic/nuclear receptors), act as transcription factors (slow genomic effects, hours-days). (3) Amino acid-derived: thyroid hormones (T3/T4, iodothyronines, nuclear receptors), catecholamines (adrenaline/noradrenaline, GPCRs), melatonin. (4) Prostaglandins/leukotrienes (eicosanoids): paracrine/autocrine. Hormone secretion is regulated by feedback loops (most commonly negative feedback: e.g., T4 inhibits TRH and TSH;

insulin lowers glucose which reduces further insulin secretion) and by the hypothalamic-pituitary axis. Disorders: overproduction (hyperfunction) or underproduction (hypofunction) of hormones cause endocrine diseases.

Hormone Replacement Therapy (HRT)

– The administration of exogenous estrogen (with or without progestogen) to relieve symptoms of estrogen deficiency and prevent long-term health consequences in postmenopausal women. Indications: moderate-severe vasomotor symptoms (hot flushes, night sweats, 80% of women experience at some point), urogenital atrophy (vaginal dryness, dyspareunia, recurrent UTIs), prevention of osteoporosis (in women at high fracture risk who cannot tolerate bisphosphonates), and premature ovarian insufficiency (POI, <40 years, HRT needed at least until average age of menopause). Estrogen-only: for women post-hysterectomy; reduces risk of endometrial cancer. Combined estrogen-progestogen: for women with intact uterus (unopposed estrogen increases endometrial cancer risk; progestogen protects by inducing endometrial shedding). Administration routes: oral (conjugated equine estrogens 0.3-0.625 mg, estradiol 1-2 mg; medroxyprogesterone acetate 2.5-5 mg), transdermal (patches/gel, avoids first-pass hepatic metabolism, lower VTE risk), vaginal (cream, ring, tablets for urogenital symptoms only, minimal systemic absorption). Risks: VTE (2-4 fold increased, highest in first year), breast cancer (5-6 extra cases per 10,000 women-years with combination HRT >5 years, lower with estrogen-only), stroke, gallbladder disease, endometrial cancer (if unopposed estrogen). The Women's Health Initiative (WHI) 2002 found overall risks outweighed benefits for chronic disease prevention in older women (mean age 63), leading to reduced HRT use. Current guidelines (NICE, IMS): HRT is safe and effective for symptom management in women aged <60 or <10 years from menopause onset; lowest effective dose for shortest duration (no arbitrary upper limit for symptom management); tibolone (synthetic steroid) is an alternative. Contraindications: breast cancer (current or prior), estrogen-dependent tumors, unexplained vaginal bleeding, active VTE, history of VTE if not anticoagulated, arterial disease, pregnancy, por-

phyria.

Hungry Bone Syndrome

– Severe hypocalcemia occurring after parathyroidectomy particularly in patients with severe preoperative hyperparathyroidism and high bone turnover. Rapid bone remineralization after removal of excess PTH sequesters calcium and phosphorus from the serum causing symptomatic hypocalcemia. Risk factors include severe preoperative hyperparathyroidism, high alkaline phosphatase, and osteitis fibrosa cystica. Prevention includes preoperative calcium and vitamin D supplementation. Treatment is aggressive intravenous and oral calcium and calcitriol supplementation, often requiring high doses that are gradually tapered as bone turnover normalises over weeks to months.

Hyperaldosteronism Complications

– Beyond hypertension and hypokalemia, primary hyperaldosteronism causes target organ damage including left ventricular hypertrophy, fibrosis, stroke, coronary artery disease, atrial fibrillation, and chronic kidney disease. These complications occur at higher rates than in essential hypertension of similar severity. Cardiovascular risk persists even after treatment of the hyperaldosteronism supporting early diagnosis and intervention. Screening is recommended for all patients with resistant hypertension, spontaneous or diuretic-induced hypokalaemia, or adrenal incidentaloma, and is cost-effective given the high prevalence and cardiovascular morbidity.

Hypercalcemia

– Serum calcium greater than 10.5 milligrams per deciliter. Causes summarized by mnemonic MALIGNANT: Myeloma, Metastases, Metabolic bone disease, Hyperparathyroidism, Adrenal insufficiency, Paget disease, Immobilization, Thiazide diuretics, Addison disease, Neonatal, Tumor-derived PTHrP. Symptoms include stones bones groans and psychic moans referring to nephrolithiasis, bone pain, constipation, and depression. Treatment includes saline hydration, loop diuretics after hydration, bisphosphonates for sustained calcium lowering, and denosumab for refractory hypercalcaemia. Underlying cause should be addressed.

Hypercalcemia of Malignancy

– Elevated serum calcium caused by cancer,

a common paraneoplastic and oncologic emergency. Mechanisms: PTHrP secretion (most common—squamous cell lung, breast, renal, ovarian), osteolytic metastases (breast, myeloma), 1,25-dihydroxyvitamin D (lymphoma), and ectopic PTH (rare). Features: nausea, constipation, polyuria, dehydration, confusion, bradycardia, shortened QT; severe (>14 mg/dL) is life-threatening. Diagnosis: corrected calcium, PTH (suppressed), PTHrP, imaging; identify the tumor. Management: aggressive IV fluids, calcitonin, bisphosphonates (zoledronic acid), denosumab, steroids (lymphoma), treat underlying malignancy, hemodialysis for refractory cases.

Hyperglycemia

– Elevated blood glucose levels above normal range (>140 mg/dL postprandial or >126 mg/dL fasting). Acute hyperglycemia can cause osmotic diuresis, dehydration, and electrolyte disturbances. Chronic hyperglycemia leads to microvascular (retinopathy, nephropathy, neuropathy) and macrovascular complications. Management: treat underlying diabetes, insulin or oral hypoglycemics as indicated, and address precipitating factors.

Hypernatremia

– Serum sodium greater than 145 mEq/L. Always indicates free water deficit relative to sodium. Causes include inadequate water intake particularly in elderly and cognitively impaired patients, diabetes insipidus, osmotic diuresis from hyperglycemia, and GI or renal water losses. Treatment is free water replacement with rate of correction dependent on chronicity. Overly rapid correction risks cerebral edema particularly in chronic hypernatremia. D5W or hypotonic saline is used for correction.

Hyperosmolar Hyperglycemic State

– Hyperglycemic emergency characterized by severe hyperglycemia greater than 600 milligrams per deciliter, hyperosmolality greater than 320 milliosmoles per kilogram, and profound dehydration without significant ketosis. Primarily occurs in type two diabetes where enough endogenous insulin is present to prevent ketogenesis but insufficient to control glucose. Presents with extreme dehydration, altered mental status, seizures, and focal neurological deficits. Mortality rates range from five to twenty percent. Treatment is aggressive IV fluid

resuscitation, insulin infusion to lower glucose and shift fluids intracellularly, and careful electrolyte monitoring and replacement.

Hyperparathyroidism

– A disorder of excessive parathyroid hormone (PTH) secretion from one or more of the four parathyroid glands, classified as primary, secondary, or tertiary. Primary hyperparathyroidism is caused by a single parathyroid adenoma (80-85 percent), multigland hyperplasia (10-15 percent, associated with MEN1 and MEN2A), or parathyroid carcinoma (less than 1 percent). It is the most common cause of hypercalcemia in the outpatient setting, with a prevalence of 1-4 per 1000 adults, most common in postmenopausal women with a prevalence of approximately two percent in those over fifty-five years. Symptoms of hypercalcaemia include polyuria, polydipsia, nephrolithiasis, bone pain, constipation, fatigue, and cognitive dysfunction. Severe hypercalcaemia above fourteen milligrams per deciliter may cause altered mental status, cardiac arrhythmias, and acute kidney injury. Diagnosis requires elevated serum calcium with inappropriately normal or elevated PTH. Localisation is performed with sestamibi scan, ultrasound, or four-dimensional CT to identify the abnormal parathyroid gland. Parathyroidectomy is curative for symptomatic or complicated disease. Asymptomatic patients may be monitored if they meet specific criteria including age, calcium level, bone density, and renal function parameters.

Hyperprolactinemia

– Elevated serum prolactin levels most commonly caused by prolactin-secreting pituitary adenomas termed prolactinomas. Other causes include medications particularly antipsychotics and metoclopramide, hypothyroidism, stalk effect from non-functioning pituitary adenomas, renal failure, and chest wall lesions. Women present with galactorrhea, amenorrhea, and infertility. Men present with decreased libido, erectile dysfunction, and rarely galactorrhea. Macroprolactinomas may present with mass effects including headache, visual field defects, and hypopituitarism. Diagnosis includes serum prolactin measurement to exclude stalk effect, MRI of the pituitary, and full pituitary hormone assessment to evaluate for hypopituitarism. Treatment of prolactinomas is with dopamine agonists, while

non-functioning adenomas causing mass effects are managed with transsphenoidal surgery.

Hyperthyroidism

– A condition of excess thyroid hormone production and secretion from the thyroid gland, resulting in thyrotoxicosis (elevated serum T4 and T3 concentrations). The most common cause is Graves disease (60-80 percent of cases), an autoimmune disorder caused by thyroid-stimulating immunoglobulins (TSI) that bind to and activate the TSH receptor on thyroid follicular cells, leading to unregulated thyroid hormone production and thyroid gland enlargement. Other causes include toxic multinodular goiter (toxic nodular goiter) caused by autonomously functioning thyroid nodules in older adults with long-standing multinodular goiter, often presenting with subclinical hyperthyroidism, atrial fibrillation, and cardiovascular complications. Other causes include thyroiditis (subacute, silent, postpartum), exogenous thyroid hormone excess, and rare causes such as struma ovarii, TSH-secreting pituitary adenoma, and hCG-mediated hyperthyroidism in trophoblastic disease. Clinical features reflect increased metabolic rate: weight loss despite increased appetite, heat intolerance, diaphoresis, tremor, palpitations, tachycardia, atrial fibrillation, anxiety, irritability, insomnia, frequent bowel movements, oligomenorrhoea, and proximal myopathy. In older patients, apathetic hyperthyroidism may present with lethargy, depression, weight loss, and atrial fibrillation without classic signs of adrenergic excess. Laboratory findings include suppressed TSH with elevated free T4 and T3. T3 toxicosis, where only T3 is elevated with normal T4, may occur early in Graves disease or in toxic nodular goiter. Thyroid scintigraphy shows diffuse increased uptake in Graves disease, heterogeneous uptake in toxic multinodular goiter, and a focal hot nodule in toxic adenoma, whereas uptake is low in thyroiditis.

Hyperthyroidism (Thyrotoxicosis)

– See Hyperthyroidism.

Hypocalcemia

– Serum calcium less than 8.5 milligrams per deciliter or ionized calcium less than 4.5 milligrams per deciliter. Causes include hypoparathyroidism, vitamin D deficiency, hypomagnesemia, hyperphosphatemia, and critical illness. Symptoms include

perioral numbness, paresthesias, muscle cramps, carpedal spasm, Chvostek sign, Trousseau sign, seizures, and QTc prolongation. Acute symptomatic hypocalcemia is treated with IV calcium gluconate. Chronic management includes oral calcium and calcitriol supplementation, along with magnesium repletion if hypomagnesaemia is present to correct the impaired PTH secretion.

Hypoglycemia

– Low blood glucose (<70 mg/dL) with autonomic (sweating, palpitations, tremor, anxiety) and neuroglycopenic (confusion, seizures, coma) symptoms. In diabetic patients, common causes: excessive insulin or sulfonylurea doses, missed meals, exercise, and alcohol intake. Severe hypoglycemia requires glucagon or IV dextrose. Whipple triad: symptoms consistent with hypoglycemia, low plasma glucose, and symptom resolution with glucose administration.

Hypoglycemia in Diabetes

– Blood glucose less than 70 milligrams per deciliter in patients with diabetes. Classification by level: level one less than 70, level two less than 54 which is clinically significant hypoglycemia, and level three severe hypoglycemia requiring assistance. Causes include insulin or sulfonylurea overdose, missed meals, excessive exercise, and alcohol consumption. Counter-regulatory hormone responses including glucagon and epinephrine cause tremor, sweating, palpitations, and anxiety. Neuroglycopenic symptoms including confusion, drowsiness, visual disturbance, slurred speech, seizures, and loss of consciousness occur with progressive cerebral glucose deprivation. Treatment is immediate ingestion of fast-acting carbohydrate for conscious patients, or intramuscular glucagon or intravenous dextrose for severe hypoglycemia with altered consciousness.

Hypoglycemia Unawareness

– Loss of the warning symptoms of hypoglycemia including tremor, sweating, and palpitations occurring in patients with recurrent hypoglycemia particularly type one diabetes. Results from attenuated counter-regulatory hormone responses particularly impaired glucagon and epinephrine responses. Significantly increases the risk of severe hypoglycemia. Associated with long diabetes duration, recurrent hypoglycemic episodes, and autonomic neuropathy. Man-

agement includes liberalization of glycemic targets, structured education in hypoglycemia recognition, avoidance of hypoglycemia to restore symptomatic awareness, and use of continuous glucose monitoring with alerts.

Hypogonadism

– Decreased functional activity of the gonads (testes or ovaries) with reduced sex hormone production. Male hypogonadism: low testosterone causing decreased libido, erectile dysfunction, infertility, reduced muscle mass, and osteoporosis. Female: estrogen deficiency causing amenorrhea, hot flashes, and osteoporosis. Primary: gonadal failure (e.g., Klinefelter, Turner). Secondary: pituitary/hypothalamic dysfunction (e.g., prolactinoma, hypothalamic amenorrhea). Diagnosis: sex hormone levels, LH/FSH. Treatment: hormone replacement therapy.

Hypogonadism in Men

– Testosterone deficiency resulting from inadequate testicular function classified as primary testicular failure or secondary hypothalamic-pituitary dysfunction. Primary causes include Klinefelter syndrome, cryptorchidism, orchitis, trauma, and chemotherapy. Secondary causes include Kallmann syndrome, pituitary tumors, hyperprolactinemia, and chronic illness. Symptoms include decreased libido, erectile dysfunction, fatigue, decreased muscle mass, increased body fat, osteoporosis, and depression. Diagnosis includes morning total testosterone on at least two occasions, LH and FSH to distinguish primary from secondary hypogonadism, prolactin, and iron studies to exclude haemochromatosis. Testosterone replacement therapy is indicated for symptomatic men with confirmed deficiency after excluding contraindications including prostate cancer and untreated sleep apnoea.

Hypogonadism in Women

– Testosterone deficiency in women causing decreased libido, fatigue, depressed mood, and reduced sense of well-being. Causes include oophorectomy, premature ovarian insufficiency, adrenal insufficiency, hypopituitarism, and medications. Diagnosis is challenging due to the lack of well-established reference ranges for female testosterone levels. Treatment with transdermal testosterone at physiological doses may improve symptoms. Benefits and risks of

long-term therapy are still under investigation, and long-term safety data are limited. Individualised treatment decisions should weigh potential benefits against possible adverse effects on cardiovascular health and breast cancer risk.

Hypomagnesemia

– Serum magnesium less than 1.7 milligrams per deciliter. Causes include gastrointestinal losses from diarrhea, renal losses from diuretics and alcohol, malnutrition, and medications including proton pump inhibitors. Manifestations include muscle cramps, tremor, seizures, cardiac arrhythmias including torsades de pointes, and refractory hypokalemia and hypocalcemia. Treatment is magnesium replacement orally for mild cases and intravenously for severe or symptomatic hypomagnesemia. Always consider checking serum magnesium in any patient with unexplained hypokalaemia or hypocalcaemia, as hypomagnesaemia impairs renal potassium conservation and PTH secretion, making electrolyte repletion difficult until magnesium is normalised.

Hyponatremia

– Serum sodium less than 135 mEq/L. Most common electrolyte disorder in hospitalized patients. Causes are classified by volume status: hypovolemic from GI losses and diuretics, euvolemic from SIADH and hypothyroidism, and hypervolemic from heart failure, cirrhosis, and nephrotic syndrome. Acute hyponatremia with neurological symptoms requires rapid correction with hypertonic saline. Chronic hyponatremia should be corrected slowly at no more than eight milliequivalents per liter per twenty-four hours to prevent osmotic demyelination syndrome. Use of vasopressin receptor antagonists (vaptans) may be considered in euvolemic and hypervolemic hyponatremia when conventional therapy is insufficient.

Hypoparathyroidism

– Deficiency or absence of parathyroid hormone causing hypocalcemia and hyperphosphatemia. Most commonly occurs after thyroid or parathyroid surgery from inadvertent removal of parathyroid glands. Autoimmune hypoparathyroidism may occur alone or as part of autoimmune polyendocrine syndrome type one. Symptoms of hypocalcemia include perioral tingling, muscle cramps, carpopedal

spasm, Chvostek sign, Trousseau sign, seizures, and cardiac arrhythmias. Chronic hypocalcemia causes basal ganglia calcifications. Treatment requires oral calcium and active vitamin D (calcitriol) supplementation to maintain serum calcium in the low-normal range and avoid hypercalciuria.

Hypoparathyroidism Management

– Treatment of chronic hypocalcemia from hypoparathyroidism includes oral calcium supplementation in divided doses and active vitamin D calcitriol to enhance calcium absorption. Goal is to maintain serum calcium in the low-normal range to prevent hypercalciuria and renal complications. Thiazide diuretics reduce urinary calcium excretion. Magnesium supplementation may be needed if hypomagnesemia is present. PTH replacement therapy with recombinant human PTH is approved for refractory cases not controlled with conventional therapy, but its use is limited by cost and the need for twice-daily injections.

Hypopituitarism

– Deficiency of one or more pituitary hormones most commonly from pituitary adenomas, craniopharyngiomas, pituitary surgery or radiation, traumatic brain injury, or infiltrative diseases. Growth hormone deficiency is typically the first hormone lost followed by gonadotropins then TSH and ACTH. Diagnosis requires dynamic testing of pituitary reserve. Treatment is replacement of deficient hormones with levothyroxine, hydrocortisone, sex steroids, desmopressin for DI, and growth hormone.

Hypothalamic-Pituitary-Adrenal Axis Physiology

– The hypothalamus releases CRH in a diurnal rhythm peaking in the early morning stimulating pituitary corticotrophs to secrete ACTH which stimulates the adrenal cortex to produce cortisol. Cortisol exerts negative feedback on both the hypothalamus and pituitary suppressing CRH and ACTH release. The system is activated during physiological stress overriding normal feedback mechanisms. Assessment of axis integrity uses the overnight dexamethasone suppression test for Cushing screening and the ACTH stimulation test for adrenal insufficiency assessment.

Hypothalamic-Pituitary-Gonadal Axis Physiology

– The hypothalamus releases GnRH in a pulsatile fashion stimulating pituitary gonadotrophs to secrete LH and FSH. In males LH stimulates Leydig cells to produce testosterone while FSH stimulates Sertoli cells to support spermatogenesis. In females FSH stimulates follicular development and estrogen production while the LH surge triggers ovulation. Sex steroids exert negative feedback on the hypothalamus and pituitary. Disruption at any level causes reproductive dysfunction.

Hypothalamic-Pituitary-Thyroid Axis Physiology

– The hypothalamus secretes TRH stimulating pituitary thyrotrophs to release TSH which stimulates the thyroid gland to produce T4 and T3. T3 the more biologically active form is produced by peripheral conversion of T4 by deiodinase enzymes. T3 and T4 exert negative feedback on both the hypothalamus and pituitary suppressing TRH and TSH release. The system maintains thyroid hormone levels within a narrow range with TSH being the most sensitive indicator of axis dysfunction.

Hypothyroidism

– A common condition of inadequate thyroid hormone production, with a prevalence of 4-10 percent in the general population and up to 20 percent in women over 60 years. Primary hypothyroidism accounts for 99 percent of cases, most commonly caused by chronic autoimmune (Hashimoto) thyroiditis (lymphocytic infiltration leading to gradual follicular destruction, associated with elevated anti-thyroid peroxidase [TPO] and anti-thyroglobulin antibodies), followed by iatrogenic causes (radioactive iodine therapy for Graves disease, radiation therapy for head and neck cancers, and medications (amiodarone, lithium, tyrosine kinase inhibitors). Clinical features reflect reduced metabolic rate including fatigue, lethargy, cold intolerance, weight gain, constipation, dry skin, hair loss, hoarseness, bradycardia, and delayed tendon reflexes. Severe hypothyroidism may cause myxedema, pericardial effusion, and cognitive impairment. Myxedema coma is a life-threatening complication with hypothermia, altered mental status, and respiratory depression. Diagnosis is confirmed by elevated TSH with low free T4. Positive TPO antibodies indicate autoimmune

etiology. Treatment is levothyroxine replacement with a starting dose based on patient age, weight, and cardiovascular risk, titrated to achieve normal TSH. In elderly patients or those with ischemic heart disease, a low starting dose of twenty-five to fifty micrograms daily with gradual titration is recommended to avoid precipitating myocardial ischemia or arrhythmia.

Inhaled Insulin

– Rapid-acting insulin delivered via inhalation as a powder using the Afrezza device. Approved for mealtime insulin coverage in adults with diabetes. Onset of action within twelve minutes and duration of approximately three hours providing a more physiological postprandial insulin profile than subcutaneous rapid-acting analogs. Contraindicated in smokers and patients with chronic lung disease. Spirometry monitoring is required before initiation and periodically during therapy. Reduces postprandial glucose excursions and may reduce hypoglycemia compared with injectable mealtime insulin in selected patients. Absorption variability and limited dosing options restrict widespread use.

Insulin

– A hormone produced by pancreatic beta cells that promotes glucose uptake by cells, reduces hepatic glucose production, and inhibits lipolysis. Types include rapid-acting (lispro, aspart), short-acting (regular), intermediate-acting (NPH), long-acting (glargine, detemir), and ultra-long-acting (degludec). Used in type 1 diabetes and type 2 diabetes when oral agents fail. Side effects include hypoglycemia and weight gain. Insulin is administered by injection or insulin pump.

Insulin Injection Technique

– Proper technique for subcutaneous insulin injection includes selecting appropriate injection sites rotating between abdomen thighs buttocks and upper arms using appropriate needle length four to eight millimeters for most adults pinching skin for thin patients to avoid intramuscular injection rotating injection sites within an area to prevent lipohypertrophy and using a new pen needle or syringe for each injection. Site selection affects absorption rate with abdomen being fastest followed by arm and thigh being slower. Proper disposal of sharps using a sharps container is essential for safety.

Insulin Pen Devices

– Pre-filled or reusable insulin pen devices providing convenient and accurate insulin delivery. Benefits include portability precision dosing discrete injection and reduced needle phobia. Modern pen devices provide half-unit dosing capabilities memory features and Bluetooth connectivity for integration with continuous glucose monitoring systems and insulin dose tracking applications. Insulin pen needles are typically four to eight millimeters in length with thirty-one gauge diameter for minimal discomfort. Smart insulin pens integrate with digital health platforms for automated dose logging and decision support, enhancing diabetes self-management.

Insulin Preparations

– Hormone synthesized by pancreatic beta cells that regulates glucose homeostasis by promoting glucose uptake in skeletal muscle and adipose tissue, suppressing hepatic glucose production, and inhibiting lipolysis. Available preparations include rapid-acting insulin analogs including lispro, aspart, and glulisine with onset fifteen to thirty minutes and duration three to five hours, short-acting regular insulin with onset thirty to sixty minutes and duration six to eight hours, intermediate-acting NPH insulin with onset one to two hours and peak four to twelve hours, long-acting insulin analogs including glargine, detemir, and degludec with relatively flat pharmacokinetic profiles and duration up to twenty-four to forty-two hours respectively, and pre-mixed preparations containing fixed ratios of rapid-acting and intermediate-acting insulin.

Insulin Pump Therapy

– Continuous subcutaneous insulin infusion delivering rapid-acting insulin analog through a catheter placed subcutaneously typically in the abdomen. Provides basal insulin at programmed rates and bolus doses at mealtimes. Advantages include reduced glycemic variability, improved time in range, flexibility in meal timing, and reduced hypoglycemia compared to multiple daily injections. Advanced systems integrate with continuous glucose monitors as hybrid closed-loop or automated insulin delivery systems. Disadvantages include risk of infusion site infection, catheter occlusion, and diabetic ketoacidosis from infusion set failure. Candidates require appropriate training and commitment to pump man-

agement.

Insulin Resistance

– Diminished biological response to physiological insulin concentrations resulting in impaired glucose disposal in peripheral tissues and failure to suppress hepatic glucose production. Pathophysiological hallmark of type two diabetes and metabolic syndrome. Develops from complex interactions between genetic susceptibility, obesity particularly visceral adiposity, physical inactivity, and inflammatory mediators. Mechanisms include post-receptor signaling defects in the insulin signaling cascade including IRS-1 phosphorylation, PI3K activation, and GLUT4 translocation to the cell membrane. Management primarily involves lifestyle modification with weight loss, physical activity, and dietary changes, along with pharmacotherapy including metformin, thiazolidinediones, and other insulin sensitizers.

Insulin Resistance Syndromes

– Rare inherited severe insulin resistance syndromes include Donohue syndrome also known as leprechaunism, Rabson-Mendenhall syndrome, and type A insulin resistance syndrome caused by mutations in the insulin receptor gene. Donohue syndrome is the most severe with death in infancy. Rabson-Mendenhall syndrome presents with dental and nail abnormalities and pineal hyperplasia. Type A insulin resistance presents with acanthosis nigricans, hyperandrogenism in females, and severe insulin resistance. Treatment includes high-dose insulin therapy, metformin, and consideration of recombinant human IGF-1 in selected cases. Genetic counselling is recommended for affected families.

Kallmann Syndrome

– Congenital form of hypogonadotropic hypogonadism caused by failure of GnRH neuron migration from the olfactory placode to the hypothalamus during embryonic development. Characterized by delayed puberty with low LH and FSH and anosmia or hyposmia from olfactory bulb hypoplasia. Associated features include renal agenesis, cleft palate, and synkinesia. Treatment is pulsatile GnRH therapy for fertility or sex steroid replacement for virilization or feminization.

Klinefelter Syndrome

– Most common sex chromosome aneuploidy in males with a karyotype of 47,XXY occurring in approxi-

mately one in six hundred live male births. Characterized by small firm testes, gynecomastia, tall stature with long extremities, and infertility from azoospermia. Testosterone levels are low with elevated gonadotropins reflecting primary testicular failure. Learning disabilities and behavioral issues may occur. Testosterone replacement therapy beginning at puberty improves virilization, bone density, and quality of life. Fertility options including assisted reproductive techniques should be discussed as spermatogenesis is not restored by testosterone therapy alone.

Liddle Syndrome Treatment

– Liddle syndrome is an autosomal dominant cause of early-onset hypertension with hypokalemia and metabolic alkalosis caused by gain-of-function mutations in ENaC sodium channel subunits. Aldosterone levels are suppressed. Unlike primary hyperaldosteronism the hypertension responds to ENaC blockers amiloride or triamterene but not to spironolactone because the channel is constitutively active independent of aldosterone. Genetic testing confirms the diagnosis. Dietary sodium restriction is important for management as it distinguishes the condition from primary hyperaldosteronism and directs appropriate therapy.

Lipodystrophy Syndromes

– Rare conditions characterized by selective loss of adipose tissue leading to severe insulin resistance, diabetes, and hypertriglyceridemia. Congenital generalized lipodystrophy involves loss of all body fat from birth. Familial partial lipodystrophy involves loss of limb and truncal fat with fat accumulation in face and neck. Acquired forms occur with antiretroviral therapy particularly protease inhibitors. Diagnosis is by clinical examination and imaging showing absent or abnormal fat distribution on dual-energy X-ray absorptiometry. Management focuses on metabolic complications including metformin for diabetes, fibrates and omega-3 fatty acids for hypertriglyceridaemia, and leptin replacement therapy with metreleptin for congenital generalized lipodystrophy.

Low Testosterone (Hypogonadism)

– Low testosterone (male hypogonadism) is a clinical syndrome of deficient testosterone production by the testes (primary) or inadequate stimulation by

the pituitary/hypothalamus (secondary), defined as total testosterone <300 ng/dL on two morning measurements with consistent symptoms. Symptoms include low libido, erectile dysfunction, fatigue, depressed mood, decreased muscle mass and bone density, increased body fat, hot flashes, and reduced energy. Causes: primary (Klinefelter syndrome, testicular trauma/orchitis, chemotherapy, aging), secondary (pituitary tumors, hemochromatosis, obesity, sleep apnea, opioids, glucocorticoids). Diagnosis requires confirmatory labs: total/free testosterone, LH, FSH, prolactin, iron studies; pituitary MRI if secondary. Testosterone replacement therapy (gels, injections, pellets, buccal tablets) improves symptoms but requires monitoring of hematocrit, PSA, and fertility impact; contraindicated in untreated prostate or breast cancer.

Luteinizing Hormone

– LH: a gonadotropin secreted by the anterior pituitary, regulating gonadal steroidogenesis. In females: stimulates theca cells to produce androgens (aromatized to estradiol); mid-cycle LH surge triggers ovulation (used in ovulation prediction and timing of intercourse/IVF). In males: stimulates Leydig cells to produce testosterone. Controlled by GnRH and gonadal steroid feedback. Elevated LH: primary gonadal failure, menopause (with high FSH); low LH: hypogonadotropic hypogonadism, pituitary disease. LH/FSH ratio is elevated in polycystic ovary syndrome. Measured in infertility evaluation and pituitary workup.

Maturity Onset Diabetes of the Young

– A monogenic form of diabetes with autosomal dominant inheritance, typically presenting before age 25 with non-insulin-dependent hyperglycemia. Caused by mutations in transcription factors or enzymes of beta-cell function. MODY subtypes: GCK-MODY (MODY 2, mild fasting hyperglycemia, no treatment needed), HNF1A-MODY (MODY 3, most common, sulfonylurea-responsive), HNF4A-MODY (MODY 1, sulfonylurea-responsive). Distinguished from type 1 diabetes by negative autoantibodies and detectable C-peptide. Distinguished from type 2 diabetes by young age, lack of obesity, and strong family history. Diagnosis: genetic testing. Treatment: varies by subtype; diet, sulfonylureas, or insulin.

McCune-Albright Syndrome

– Sporadic condition caused by activating mutations in the *GNAS1* gene encoding the Gs alpha subunit leading to constitutive activation of adenylyl cyclase. Classic triad includes polyostotic fibrous dysplasia of bone, cafe-au-lait skin spots with irregular coast-of-Maine borders, and autonomous endocrine hyperfunction including precocious puberty, hyperthyroidism, growth hormone excess, and Cushing syndrome. Diagnosis is clinical and confirmed by genetic testing of affected tissue. Treatment targets the specific endocrine abnormality with surgery, medical therapy, or radiation as appropriate for the individual endocrine tumor type. Orthopaedic management of fibrous dysplasia may include bisphosphonates and surgical correction of deformities.

Medullary Thyroid Carcinoma

– Neuroendocrine tumor arising from parafollicular C cells that produce calcitonin. Accounts for approximately five percent of thyroid carcinomas. May be sporadic or hereditary as part of multiple endocrine neoplasia type two A or two B. Serum calcitonin serves as a tumor marker. Diagnosis requires FNA with calcitonin immunohistochemistry. Total thyroidectomy with central lymph node dissection is the standard treatment. RET proto-oncogene mutation testing is mandatory in all patients to identify hereditary medullary thyroid carcinoma and guide prophylactic thyroidectomy in affected family members. Tyrosine kinase inhibitors such as vandetanib and cabozantinib are used for advanced or metastatic disease.

Menopausal Hormone Therapy (MHT)

– Menopausal hormone therapy (MHT), formerly called hormone replacement therapy (HRT), is the use of estrogen with or without progestogen to alleviate moderate-to-severe menopausal vasomotor symptoms (hot flashes, night sweats), genitourinary syndrome of menopause (vaginal dryness, dyspareunia, urinary urgency), and prevent osteoporosis. Estrogen-alone therapy is used in post-hysterectomy women; combined therapy (estrogen + progestogen) is required for those with an intact uterus to prevent endometrial hyperplasia/cancer. Regimens: systemic (oral, transdermal patch/gel, spray) for vasomotor symptoms; low-dose vaginal (cream,

tablet, ring) for genitourinary symptoms with minimal systemic absorption. The Women's Health Initiative (WHI) established that MHT increases risk of breast cancer, venous thromboembolism, and stroke, though absolute risk is low in women aged <60 or within 10 years of menopause onset. Treatment should use the lowest effective dose for the shortest duration needed, individualizing based on risk profile (cardiovascular, thrombotic, breast cancer).

Menopause and Perimenopause

– Menopause is the permanent cessation of menstruation for 12 consecutive months, reflecting ovarian follicle depletion and estrogen decline, occurring at a median age of 51–52 years in North America. Perimenopause (menopausal transition) begins 4–8 years before the final menstrual period, characterized by variable cycle length, vasomotor symptoms (hot flashes, night sweats—affecting 80% of women), sleep disturbance, mood changes, vaginal dryness, and declining fertility. Diagnosis is clinical based on age and menstrual pattern changes; FSH elevation (>25 IU/L) and AMH decline confirm ovarian aging but are not required. Health implications include accelerated bone loss (osteoporosis risk), increased cardiovascular risk, weight gain (central adiposity), and genitourinary syndrome. Management: lifestyle modification (cooling layers, exercise, calcium/vitamin D), MHT for moderate–severe symptoms (most effective), non-hormonal options (SSRIs/SNRIs, gabapentin, oxybutynin) for vasomotor symptoms, and vaginal estrogen for urogenital atrophy.

Metabolic Acidosis

– A primary acid-base disorder characterized by decreased serum bicarbonate (<22 mEq/L) and pH <7.35. Causes are classified by anion gap (AG). High AG: diabetic ketoacidosis, lactic acidosis, renal failure, starvation, toxins (methanol, ethylene glycol, salicylates). Normal AG (hyperchloremic): diarrhea, renal tubular acidosis, acetazolamide. Compensation: respiratory alkalosis (Kussmaul respirations). Treatment: address the underlying cause; sodium bicarbonate reserved for severe acidosis (pH <7.0).

Metabolic Syndrome

– Cluster of interrelated metabolic risk factors increasing cardiovascular disease and type two di-

abetes risk. Defined by the presence of at least three of five criteria: waist circumference greater than 40 inches in men or greater than 35 inches in women, triglycerides greater than 150 milligrams per deciliter, HDL cholesterol less than 40 milligrams per deciliter in men or less than 50 in women, blood pressure greater than 130/85 millimeters of mercury, and fasting glucose greater than 100 milligrams per deciliter, with treatment thresholds and targets individualised based on overall cardiovascular risk profile and presence of other metabolic risk factors.

Metformin in Prediabetes

- Metformin reduces progression from prediabetes to type two diabetes by approximately thirty-one percent in high-risk individuals. Most effective in younger patients under sixty with BMI greater than 35 and women with prior gestational diabetes. The Diabetes Prevention Program demonstrated sustained benefit over ten years of follow-up. Recommended by many guidelines as an adjunct to lifestyle modification in high-risk prediabetic individuals.

Mitochondrial Diabetes

- Diabetes caused by mutations in mitochondrial DNA particularly the m.3243A>G mutation in the MT-TL1 gene. Maternally inherited. Often associated with sensorineural hearing loss termed maternally inherited diabetes and deafness. Patients are typically lean with impaired insulin secretion. Diagnosis requires genetic testing. Insulin therapy is usually necessary though some patients respond to sulfonylureas. Screening for associated conditions including cardiac disease, seizures, and gastrointestinal dysmotility, and psychiatric disturbance. Genetic counselling is important given the maternal inheritance pattern.

Morbid Obesity

- Severe obesity defined clinically as BMI ≥ 40 kg/m² or BMI ≥ 35 kg/m² with obesity-related comorbidities (type 2 diabetes, hypertension, obstructive sleep apnoea, non-alcoholic fatty liver disease, osteoarthritis, cardiovascular disease). Morbid obesity significantly increases all-cause mortality (hazard ratio 2.5–3.0 compared with normal weight). Management: intensive lifestyle intervention, pharmacotherapy (GLP-1 receptor agonists—semaglutide 2.4 mg weekly, tirzepatide; phentermine–topiramate; naltrexone–bupropion),

and bariatric/metabolic surgery (Roux-en-Y gastric bypass, sleeve gastrectomy, adjustable gastric band, biliopancreatic diversion with duodenal switch). Bariatric surgery achieves 25–35% total body weight loss and induces remission of type 2 diabetes in 60–80% of patients (the SOS study and STAMPEDE trial). Eligibility per NICE guidelines: BMI ≥ 40 , or BMI ≥ 35 with recent-onset type 2 diabetes; consideration of psychological suitability, commitment to lifelong follow-up, and nutritional supplementation.

Multiple Endocrine Neoplasia Type 1

- An autosomal dominant tumor syndrome caused by MEN1 gene mutation (menin). Characterized by tumors of the parathyroid (hyperparathyroidism in 95% of patients by age 50, most common), pancreatic islet cells (gastrinoma causing Zollinger-Ellison syndrome, insulinoma, glucagonoma, VIPoma), and anterior pituitary (prolactinoma most common, GH, ACTH). Other tumors: carcinoid, adrenal adenoma, lipomas. Diagnosis: clinical criteria, genetic testing for MEN1 mutation. Management: surgical resection of tumors; peptide receptor radionuclide therapy for advanced neuroendocrine tumors.

Multiple Endocrine Neoplasia Type 2

- An autosomal dominant tumor syndrome caused by RET proto-oncogene mutations. Type 2A (95%): medullary thyroid carcinoma (MTC, nearly 100% penetrance), pheochromocytoma (50%), and hyperparathyroidism (20–30%). Type 2B: MTC, pheochromocytoma, mucosal neuromas, marfanoid habitus; more aggressive MTC. Management: prophylactic thyroidectomy based on RET mutation risk stratification; screen for pheochromocytoma before thyroid surgery; annual lab and imaging surveillance.

Myxedema Coma

- Severe decompensated hypothyroidism characterized by altered mental status, hypothermia, bradycardia, hypoventilation, hyponatremia, and hypoglycemia. Most commonly occurs in elderly patients with long-standing untreated hypothyroidism precipitated by infection, surgery, or sedative medications. Mortality rates exceed fifty percent. Diagnosis is clinical with low free T4 and elevated TSH. Treat-

ment includes IV levothyroxine and IV hydrocortisone to prevent adrenal crisis, passive rewarming, and supportive care in the intensive care unit setting including respiratory and haemodynamic support.

Neonatal Diabetes Mellitus

– Diabetes diagnosed within the first six months of life. Can be transient or permanent. Transient neonatal diabetes mellitus is caused by abnormalities at chromosome 6q24 and usually resolves but may relapse in adolescence. Permanent neonatal diabetes mellitus is most commonly caused by mutations in the KCNJ11 or ABCC8 genes encoding the KATP channel subunits. Patients with KCNJ11 mutations can often transition from insulin to sulfonylureas with excellent glycemic control due to the specific mechanism of action targeting the KATP channel defect.

Neuroendocrine Tumors Grading

– Classification of neuroendocrine tumors by proliferative rate using Ki-67 index and mitotic count. Well-differentiated low-grade tumors have Ki-67 less than three percent and fewer than two mitoses per ten high-power fields. Intermediate-grade tumors have Ki-67 of three to twenty percent. Poorly differentiated high-grade tumors have Ki-67 greater than twenty percent. Grading guides prognosis and treatment intensity with low-grade tumors treated with somatostatin analogs and high-grade tumors require chemotherapy including everolimus and temozolomide and peptide receptor radionuclide therapy.

Neurofibromatosis Type 1

– Autosomal dominant disorder caused by mutations in the NF1 gene encoding neurofibromin on chromosome seventeen. Diagnostic criteria include two or more of the following: six or more café-au-lait spots, two or more neurofibromas or one plexiform neurofibroma, axillary or inguinal freckling, optic pathway glioma, two or more Lisch nodules, bony abnormalities, and a first-degree relative with NF1. Endocrine manifestations include pheochromocytoma and growth hormone excess.

Non-Functioning Pituitary Adenoma

– Pituitary adenomas that do not secrete clinically significant hormones. The most common pituitary adenomas to present with mass effects. Typically macroadenomas at diagnosis causing headaches, vi-

sual field defects particularly bitemporal hemianopia from optic chiasm compression, and hypopituitarism from compression of normal pituitary tissue. Diagnosis is by MRI showing a pituitary mass and hormone testing to exclude functioning adenomas. Management includes transsphenoidal surgery for symptomatic macroadenomas causing visual compromise or hypopituitarism. Post-operative surveillance is required with MRI and hormone monitoring to detect recurrence.

Normocalcemic Hyperparathyroidism

– Condition of elevated parathyroid hormone with persistently normal serum calcium and normal vitamin D levels. Exclusion of secondary causes of elevated PTH including vitamin D deficiency, renal insufficiency, and medications is required. Represents an early or mild form of primary hyperparathyroidism. May progress to overt hypercalcemia. Monitoring includes annual calcium PTH levels and bone density assessment. Parathyroidectomy is considered for patients with complications or progressive disease. Management includes monitoring calcium, PTH, and bone density annually, with parathyroidectomy considered for patients who develop complications such as worsening bone density, nephrolithiasis, or progression to hypercalcaemia.

Obesity

– Abnormal or excessive fat accumulation that presents a health risk. Defined by BMI: ≥ 30 kg/m² (class I: 30-34.9, class II: 35-39.9, class III: ≥ 40). Major risk factor for type 2 diabetes, hypertension, cardiovascular disease, sleep apnea, osteoarthritis, certain cancers, and reduced life expectancy. Management: lifestyle interventions, pharmacotherapy (GLP-1 agonists, phentermine-topiramate, naltrexone-bupropion), and bariatric surgery for severe obesity.

Oestrogen Replacement Therapy

– See Hormone Replacement Therapy (HRT).

Osteomalacia

– Impaired mineralization of newly formed osteoid in adults resulting from vitamin D deficiency, phosphate depletion, or defective mineralization. Causes include vitamin D deficiency from inadequate intake, malabsorption, and impaired synthesis, phosphate

depletion from tumor-induced osteomalacia with fibroblast growth factor twenty-three excess, and medications including bisphosphonates and aluminum. Presents with diffuse bone pain, muscle weakness particularly proximal, and increased fracture risk. Diagnosis is confirmed by low 25-hydroxyvitamin D levels, elevated alkaline phosphatase, and characteristic radiographic findings including Looser zones (pseudofractures) on X-ray. Treatment is high-dose vitamin D supplementation with calcium, and treatment of the underlying cause where possible.

Papillary Thyroid Carcinoma

- Most common histological subtype of thyroid carcinoma accounting for approximately eighty percent of cases. Characterized by nuclear features including nuclear grooves, intranuclear cytoplasmic inclusions, and Orphan Annie eye nuclei. Often multifocal and bilateral with lymph node metastases. Excellent prognosis with greater than ninety-five percent ten-year survival. Treatment includes total thyroidectomy with radioactive iodine ablation for intermediate and high-risk disease. TSH suppression with levothyroxine for high-risk patients to reduce recurrence risk.

Parathyroid Crisis

- Severe hypercalcemia with calcium greater than fourteen milligrams per deciliter causing altered mental status, cardiac arrhythmias, and acute kidney injury. Most commonly occurs in patients with primary hyperparathyroidism precipitated by dehydration, immobility, or thiazide diuretics. Treatment requires aggressive IV normal saline hydration, loop diuretics after adequate hydration, calcitonin for rapid but transient calcium reduction, bisphosphonates for sustained calcium lowering, and denosumab for refractory cases. Urgent parathyroidectomy is the definitive treatment once the patient is stabilised.

Parathyroid Hormone Physiology

- Parathyroid hormone is the primary regulator of calcium homeostasis secreted by the four parathyroid glands in response to low ionized calcium levels detected by the calcium-sensing receptor. PTH increases serum calcium through three mechanisms: stimulating osteoclastic bone resorption to release calcium and phosphorus, increasing renal calcium reabsorption in the distal tubule, and stimulating re-

nal production of active vitamin D which enhances intestinal calcium absorption. PTH also increases phosphate excretion in the proximal tubule, thereby lowering serum phosphate. PTH secretion is tightly regulated by ionised calcium through negative feedback on the calcium-sensing receptor.

PCOS

- See Polycystic Ovary Syndrome.

Pemberton Sign

- Physical exam sign of retrosternal goiter: elevating both arms above the head for 1 minute induces facial flushing, cyanosis, and stridor due to thoracic inlet obstruction. *See Goiter.*

Pheochromocytoma

- Catecholamine-secreting tumor arising from chromaffin cells of the adrenal medulla or extra-adrenal paraganglia. Approximately ten percent are bilateral, ten percent are extra-adrenal, and ten percent are malignant. Classic presentation includes episodic headache, sweating, and palpitations with sustained or paroxysmal hypertension. Associated with hereditary syndromes including von Hippel-Lindau, multiple endocrine neoplasia type two, and neurofibromatosis type one. Diagnosis is by plasma free metanephrines or 24-hour urinary fractionated metanephrines, which have high sensitivity for detection. Imaging with CT or MRI of the abdomen and pelvis localises the tumor. MIBG scintigraphy or PET-CT with FDG or gallium-DOTATATE may be used for staging and detection of metastatic disease. Definitive treatment is laparoscopic adrenalectomy following adequate pre-operative alpha-blockade with phenoxybenzamine or doxazosin for at least ten to fourteen days, combined with beta-blockade after alpha-blockade is established. Metastatic disease requires debulking surgery, radionuclide therapy, or tyrosine kinase inhibitors.

Phosphate Homeostasis

- Serum phosphate is regulated by the interplay of PTH vitamin D and fibroblast growth factor 23. PTH promotes renal phosphate excretion. Active vitamin D stimulates intestinal phosphate absorption. FGF23 produced by osteocytes inhibits renal phosphate reabsorption and suppresses 1-alpha-hydroxylase reducing active vitamin D production. Hyperphosphatemia occurs in advanced CKD and is

associated with cardiovascular calcification and increased mortality. Management includes dietary phosphate restriction and phosphate binders in chronic kidney disease.

Pituitary Apoplexy

– Acute hemorrhage or infarction within a pituitary adenoma causing sudden headache, visual field defects, ophthalmoplegia, and altered consciousness. Medical emergency requiring urgent glucocorticoid administration to prevent adrenal crisis from acute ACTH deficiency. Severe cases with visual compromise require emergent transsphenoidal surgery. Mild cases may be managed conservatively with close monitoring and hormone replacement. Risk factors include pregnancy, dopamine agonist therapy, and anticoagulation as risk factors. Immediate management focuses on haemodynamic stabilisation, glucocorticoid administration, and urgent neurosurgical consultation.

Polycystic Ovary Syndrome

– Common endocrine disorder affecting six to twelve percent of reproductive-aged women characterized by hyperandrogenism, ovulatory dysfunction, and polycystic ovarian morphology on ultrasound. Diagnostic criteria include two of three features: oligoanovulation, clinical or biochemical hyperandrogenism, and polycystic ovaries after exclusion of other causes. Associated with insulin resistance, obesity, type two diabetes, and cardiovascular risk. Treatment includes lifestyle modification for weight management, combined oral contraceptive or progestin therapy for menstrual regulation and endometrial protection, antiandrogens like spironolactone for hirsutism, metformin for insulin resistance and glucose intolerance, and ovulation induction with letrozole or clomiphene citrate for infertility. Long-term monitoring for cardiovascular risk factors and glucose intolerance is essential.

Polydipsia

– Excessive, unquenchable thirst. A classic symptom of hyperosmolar states and endocrine disorders. Primary causes: Diabetes Mellitus (osmotic diuresis from hyperglycemia), Diabetes Insipidus (central lack of ADH or nephrogenic ADH resistance leading to massive dilute urine output), and Psychogenic Polydipsia (compulsive water drinking in psychiatric patients, e.g., schizophrenia). Evaluated via water

deprivation test and serum/urine osmolality.

Polyphagia

– Excessive, uncontrollable hunger or increased appetite. Classic cardinal symptom of uncontrolled Diabetes Mellitus (cellular starvation due to lack of insulin or insulin resistance), Hyperthyroidism (elevated basal metabolic rate), Prader-Willi Syndrome, and atypical depression. Accompanied by weight loss in uncontrolled DM and hyperthyroidism.

Precocious Puberty

– Onset of secondary sexual characteristics before age eight in girls and age nine in boys. Central precocious puberty results from early activation of the hypothalamic-pituitary-gonadal axis. Causes include CNS tumors, hydrocephalus, and idiopathic. Peripheral precocious puberty results from autonomous sex steroid production from adrenal tumors, gonadal tumors, or congenital adrenal hyperplasia. Diagnosis includes bone age X-ray, GnRH stimulation test, and imaging of the brain and adrenal glands. Treatment is with GnRH agonists for central precocious puberty to suppress the axis and slow pubertal progression, while peripheral causes are managed by addressing the underlying source of sex steroid production.

Prediabetes

– Intermediate state of hyperglycemia between normal glucose homeostasis and diabetes defined by fasting glucose 100 to 125 milligrams per deciliter, two-hour glucose during oral glucose tolerance test 140 to 199 milligrams per deciliter, or A1c 5.7 to 6.4 percent. Individuals are at increased risk for progression to type two diabetes with annual progression rates of approximately five to ten percent. Cardiovascular disease risk is already elevated. Lifestyle intervention with weight loss of five to seven percent and increased physical activity is the cornerstone of prevention and is more effective than metformin. For individuals with additional risk factors, metformin may be considered.

Premature Ovarian Insufficiency

– Loss of ovarian function before age forty characterized by amenorrhea, hypergonadotropic hypogonadism, and estrogen deficiency. Causes include genetic disorders particularly Turner syndrome and fragile X premutations, autoimmune oophoritis, iatrogenic from chemotherapy or radiation, and id-

iopathic. Associated with decreased bone density, cardiovascular risk, and infertility. Diagnosis requires four months of amenorrhea with elevated FSH greater than twenty-five milli-international units per millilitre on two occasions four weeks apart. Treatment includes hormone replacement therapy with estrogen and progesterone, and fertility options including oocyte donation for those desiring pregnancy.

Pretibial Myxedema

– Localized dermatopathy occurring in approximately five percent of patients with Graves disease caused by glycosaminoglycan deposition in the dermis particularly over the pretibial area. Presents as non-pitting indurated plaques with a *peau d'orange* appearance. Pathogenesis involves orbital fibroblasts stimulated by thyroid autoantibodies producing excessive hyaluronic acid. Usually occurs in patients with severe ophthalmopathy. Treatment includes topical corticosteroids and compression bandaging through a multidisciplinary approach with dermatology and endocrinology input.

Primary Aldosteronism

– Overproduction of aldosterone by the adrenal glands (Conn syndrome: adrenal adenoma; or bilateral adrenal hyperplasia). Causes hypertension with hypokalemia (40% normokalemic). Presents with treatment-resistant hypertension with or without hypokalemia, metabolic alkalosis, low plasma renin, and high aldosterone-to-renin ratio (ARR >30). Diagnosis: elevated ARR, confirmatory testing (saline suppression test, captopril challenge, oral sodium loading), adrenal CT and adrenal vein sampling to distinguish unilateral from bilateral. Treatment: unilateral adrenalectomy for adenoma; mineralocorticoid receptor antagonists (spironolactone, eplerenone) for bilateral hyperplasia.

Primary Hyperaldosteronism

– Autonomous aldosterone secretion most commonly caused by an aldosterone-producing adrenal adenoma termed Conn syndrome. Leads to hypertension, hypokalemia, metabolic alkalosis, and suppressed renin. Accounts for approximately five to ten percent of hypertensive patients. Screening is by elevated aldosterone-to-renin ratio. Diagnosis requires confirmatory salt loading test demonstrating failure to suppress aldosterone. Localization is

by adrenal CT and adrenal vein sampling to distinguish unilateral from bilateral disease. Unilateral aldosterone-producing adenoma is treated with laparoscopic adrenalectomy. Bilateral hyperplasia is managed medically with mineralocorticoid receptor antagonists such as spironolactone or eplerenone.

Primary Hyperparathyroidism

– Autonomous overproduction of parathyroid hormone from one or more abnormal parathyroid glands causing hypercalcemia. Most commonly caused by a single parathyroid adenoma accounting for approximately eighty-five percent. Multigland hyperplasia accounts for approximately ten to fifteen percent and parathyroid carcinoma is rare. Clinical manifestations include nephrolithiasis, osteoporosis, neuropsychiatric symptoms, gastrointestinal symptoms, and cardiovascular disease. Many patients are asymptomatic at diagnosis, identified incidentally through routine biochemical testing. Surgery is recommended for all symptomatic patients and for asymptomatic patients who meet criteria including age under fifty, serum calcium greater than one milligram per decilitre above the upper limit of normal, osteoporosis, nephrolithiasis, or renal impairment.

Prolactinoma Treatment

– Dopamine agonists are first-line medical therapy for prolactinomas. Cabergoline is preferred over bromocriptine due to higher efficacy, less side effects, and twice-weekly dosing improving compliance. Normalize prolactin levels in approximately eighty to ninety percent of patients and significantly reduce tumor size in most. Surgery is reserved for dopamine agonist-resistant tumors, patient intolerance, or cerebrospinal fluid leak from macroadenomas. Radiation therapy is reserved for refractory cases. Long-term monitoring with serial prolactin measurements and MRI is required to detect recurrence.

Prolactin Physiology

– Prolactin is the only pituitary hormone primarily under tonic inhibitory control by the hypothalamus through dopamine acting on D2 receptors. Prolactin stimulates lactation suppresses GnRH and is important for reproductive function. Physiological elevations occur during pregnancy lactation breast stimulation sleep and stress. Hyperprolactinemia suppresses the hypothalamic-pituitary-gonadal axis

causing amenorrhea infertility and galactorrhea in women and erectile dysfunction and hypogonadism in men. Management of hyperprolactinemia involves treatment of the underlying cause and dopamine agonist therapy when indicated.

Radioactive Iodine Ablation

– Treatment of differentiated thyroid carcinoma using iodine-131 to destroy residual thyroid tissue after total thyroidectomy. Indications include intermediate and high-risk disease for remnant ablation and treatment of residual or recurrent disease. Patients must be hypothyroid or receive recombinant TSH to maximize iodine uptake. Preparation includes low-iodine diet for one to two weeks and discontinuation of thyroid hormone or levothyroxine withdrawal. Side effects include sialadenitis, taste changes, xerostomia, and rarely radiation thyroiditis. Long-term risks include secondary malignancies such as leukaemia and salivary gland tumors. Gonadal dysfunction may occur, and sperm or oocyte cryopreservation should be considered before treatment. Pregnancy is contraindicated for six to twelve months after ablation.

Renin-Angiotensin-Aldosterone System Physiology

– The RAAS regulates blood pressure and fluid electrolyte balance. Renin released from juxtaglomerular cells cleaves angiotensinogen to angiotensin I. Angiotensin converting enzyme converts angiotensin I to angiotensin II which causes vasoconstriction and stimulates aldosterone secretion from the adrenal cortex. Aldosterone acts on the collecting duct to promote sodium reabsorption and potassium secretion. The system is activated by decreased renal perfusion decreased sodium delivery to the macula densa, and decreased sodium chloride delivery. Dysregulation of this system contributes to hypertension, heart failure, and chronic kidney disease. Pharmacological inhibitors of the RAAS including ACE inhibitors, angiotensin receptor blockers, and mineralocorticoid receptor antagonists are cornerstones of cardiovascular and renal protective therapy.

Rickets

– A childhood disorder of impaired mineralization of growing bone due to vitamin D deficiency, calcium deficiency, or phosphate deficiency. Presents

with bone pain, deformities (bowed legs, wrist enlargement, rachitic rosary), growth retardation, and hypocalcemic seizures. Predisposing factors: dark skin, limited sun exposure, exclusive breastfeeding without supplementation. Diagnosis: low 25-hydroxyvitamin D, elevated ALP, characteristic X-ray findings. Treatment: high-dose vitamin D and calcium supplementation.

Sheehan Syndrome

– Postpartum pituitary necrosis resulting from severe hemorrhage and hypotension during delivery. The pituitary gland is enlarged during pregnancy and particularly vulnerable to ischemic injury from blood loss. Presentation varies from fatigue and failure to lactate to panhypopituitarism. Growth hormone and prolactin deficiency occur first. Diagnosis is by hormone testing. Treatment is lifelong hormone replacement of all deficient axes.

Statins in Diabetes

– HMG-CoA reductase inhibitors are first-line therapy for cardiovascular risk reduction in diabetic patients. Most adults with diabetes aged forty to seventy-five benefit from moderate-intensity statin therapy regardless of baseline LDL cholesterol. High-intensity statin therapy with atorvastatin forty to eighty milligrams or rosuvastatin twenty to forty milligrams is indicated for patients with established atherosclerotic cardiovascular disease or multiple risk factors. Benefits include reduction in major adverse cardiovascular events and all-cause mortality. Statin therapy should be continued regardless of baseline lipid levels, and adherence is critical for optimal cardiovascular prevention.

Subacute Thyroiditis

– Inflammatory condition of the thyroid most likely viral in etiology presenting with painful tender thyroid enlargement, fever, and malaise. Associated with elevated erythrocyte sedimentation rate and C-reactive protein. Disease course includes thyrotoxicosis from hormone release during gland destruction, followed by hypothyroidism, and then recovery in most patients. Diagnosis is clinical with the typical presentation and characteristic elevated inflammatory markers. Treatment includes NSAIDs for pain and inflammation, and beta-blockers for symptomatic thyrotoxicosis during the initial phase. Glucocorticoids may be used in severe cases. Thy-

roid function should be monitored as the patient may require levothyroxine replacement during the subsequent hypothyroid phase.

T3

- Triiodothyronine, the most biologically active thyroid hormone, produced by deiodination of T4 in peripheral tissues (liver, kidney) and secreted by the thyroid. Regulates metabolism (BMR), protein/carbohydrate/lipid metabolism, growth, and development. Serum T3 is a small fraction of thyroid output but more potent and faster-acting than T4. Elevated: hyperthyroidism (also low T3 syndrome/illness); decreased: hypothyroidism (and non-thyroidal illness, starvation). Measurement: total or free T3; used with TSH/T4 to assess thyroid status and monitor. T3 (liothyronine) is used in severe hypothyroid states and thyroid storm.

T4

- Thyroxine, the main hormone secreted by the thyroid gland (thyroxine, 80-90 percent of secretion), converted to the active T3 in tissues. Bound largely to thyroxine-binding globulin (TBG); free T4 is the active unbound fraction. Regulates metabolism, growth, and development. Used with TSH for thyroid diagnosis: low TSH + high free T4 = hyperthyroidism; high TSH + low free T4 = hypothyroidism; subclinical states show isolated TSH change. Measurement: total or free T4; TBG changes (pregnancy, estrogens, liver disease) affect total but not free. Replacement therapy: levothyroxine.

Teriparatide for Osteoporosis

- Recombinant human parathyroid hormone fragments one through thirty-four that stimulate osteoblast-mediated bone formation. Indicated for severe osteoporosis with fractures or very low T-scores and for patients who have failed or are intolerant to bisphosphonates. Daily subcutaneous injection for up to two years. Increases bone density more rapidly than anti-resorptive agents. Must be followed by anti-resorptive therapy with bisphosphonates or denosumab to maintain gains. Romosozumab an anti-sclerostin antibody, builds bone rapidly and is given as monthly subcutaneous injections for one year, after which antiresorptive therapy is required to maintain bone density gains.

Testosterone

- The primary male sex hormone, an androgen pro-

duced mainly in the testicles that is essential for the development of male reproductive tissues, secondary sexual characteristics, and overall health. In addition to its role in sexual function and sperm production, testosterone influences muscle mass, bone density, fat distribution, red blood cell production, and mood. Testosterone levels naturally decline with age, and abnormally low levels can cause reduced libido, erectile dysfunction, fatigue, loss of muscle mass, and osteoporosis; testosterone replacement therapy is available but requires careful consideration of potential risks.

Tetany

- A clinical syndrome of neuromuscular hyperexcitability caused by hypocalcaemia (most common—total calcium <2.1 mmol/L, ionised calcium <1.1 mmol/L), but also caused by hypomagnesaemia, hypokalaemia, and alkalosis (respiratory or metabolic). Symptoms: perioral paresthesias (tingling around the mouth), numbness and tingling in the fingers and toes, muscle cramps, carpopedal spasm (flexion of the wrist and metacarpophalangeal joints, extension of the interphalangeal joints, adduction of the thumb—'obstetrician's hand'), and laryngospasm (stridor, respiratory distress—life-threatening). Latent tetany: elicited by Trousseau sign (carpopedal spasm induced by inflation of a BP cuff above systolic pressure for 3 minutes) and Chvostek sign (tapping the facial nerve anterior to the ear causes ipsilateral facial muscle twitching). Causes of hypocalcaemia: hypoparathyroidism (post-surgical—most common, autoimmune, DiGeorge syndrome), vitamin D deficiency/insufficiency, chronic kidney disease, acute pancreatitis, pseudohypoparathyroidism, and drugs (bisphosphonates, denosumab, furosemide, phenytoin). Treatment: IV calcium gluconate 10–20 mL of 10% solution (for acute symptomatic tetany) given slowly with cardiac monitoring, followed by oral calcium and vitamin D/calcitriol. Treat underlying cause.

Thiazolidinediones

- Insulin sensitizers activating peroxisome proliferator-activated receptors primarily in adipose tissue and skeletal muscle. Agents include pioglitazone and rosiglitazone. Mechanisms include enhanced insulin-mediated glucose uptake, altered adipokine secretion, and reduced hepatic glucose

output. Effective A1c reduction of one to one point five percent. Side effects include weight gain, fluid retention leading to heart failure exacerbation, increased fracture risk particularly in postmenopausal women and in premenopausal women with polycystic ovary syndrome where they may promote ovulation. Due to safety concerns, pioglitazone is more commonly used than rosiglitazone, and both require careful monitoring for adverse effects.

Thyroglobulin Surveillance

- Thyroglobulin produced only by thyroid follicular cells serves as a tumor marker after total thyroidectomy for differentiated thyroid carcinoma. In patients who have undergone complete thyroidectomy and radioactive iodine ablation thyroglobulin should be undetectable. Rising thyroglobulin levels indicate residual or recurrent thyroid tissue. Stimulated thyroglobulin after recombinant human TSH or thyroid hormone withdrawal provides greater sensitivity for detecting recurrence. The thyroglobulin antibody assay is essential as autoantibodies can interfere with the measurement causing falsely low or undetectable levels, limiting the utility of the test in antibody-positive patients.

Thyroglossal Duct Cyst

- Congenital midline neck mass resulting from persistence of the thyroglossal duct the embryological tract of thyroid descent. Most common congenital neck mass presenting in childhood. Located at or near the hyoid bone and moves with swallowing and tongue protrusion. Diagnosis is by ultrasound demonstrating a cystic midline neck mass. Thyroid tissue may be present within the cyst. Treatment is surgical excision with Sistrunk procedure which includes removal of the central portion of the hyoid bone to prevent recurrence related to the embryological tract. Recurrence is rare after complete excision.

Thyroid Cancer Staging

- American Joint Committee on Cancer TNM staging for differentiated thyroid carcinoma incorporates tumor size, extent of invasion, lymph node metastases, and distant metastases. Age is a critical prognostic factor with patients under fifty having more favorable outcomes. Stage I is any tumor without metastases in patients under fifty. Stage II includes

distant metastases or extrathyroidal extension in patients under fifty and larger tumors in patients over fifty. Risk stratification systems include the American Thyroid Association risk stratification, which categorises patients into low, intermediate, and high-risk groups to guide post-operative management including the need for radioactive iodine ablation and the intensity of TSH suppression therapy.

Thyroid Disorders

- Conditions affecting the thyroid gland, a butterfly-shaped endocrine organ in the neck that produces hormones regulating metabolism, growth, and development. Hyperthyroidism involves excessive thyroid hormone production, causing symptoms such as weight loss, tachycardia, heat intolerance, and anxiety, while hypothyroidism results from insufficient hormone production and leads to fatigue, weight gain, cold intolerance, and depression. Autoimmune diseases including Graves disease and Hashimoto thyroiditis are common causes; management includes medications, radioactive iodine therapy, or thyroid surgery depending on the specific disorder.

Thyroid Eye Disease

- Autoimmune inflammatory disorder of the orbital tissues associated with Graves disease characterized by expansion of extraocular muscles and orbital fat. Pathogenesis involves orbital fibroblasts expressing the TSH receptor targeted by the same thyroid-stimulating immunoglobulins affecting the thyroid. Clinical features include proptosis, periorbital edema, chemosis, lid retraction, and diplopia. Severe disease can cause optic nerve compression. Treatment includes smoking cessation, selenium supplementation which has been shown to slow progression of mild to moderate thyroid eye disease, glucocorticoids for active inflammatory disease, and orbital radiotherapy or surgical decompression for sight-threatening proptosis or optic neuropathy. Teprotumumab, an IGF-1 receptor inhibitor, is a newer targeted therapy that reduces proptosis and diplopia in active disease.

Thyroid Function Tests

- Laboratory assessment of the hypothalamic-pituitary-thyroid axis. TSH is the most sensitive screening test with elevated levels indicating pri-

mary hypothyroidism and suppressed levels indicating hyperthyroidism. Free T4 measures the biologically active unbound thyroxine. Total T4 and T3 reflect bound and unbound hormone and are affected by binding protein abnormalities. T3 thyrotoxicosis occurs when T3 is preferentially elevated in early Graves disease or toxic adenoma. TSH receptor antibodies can also be measured to confirm autoimmune etiology. Interpretation of thyroid function tests must account for non-thyroidal illness, medication effects, and binding protein abnormalities that can alter total hormone levels without affecting free hormone concentrations.

Thyroid Hormone

- Iodinated thyronines triiodothyronine (T3) and thyroxine (T4) produced by thyroid follicular cells under TSH control. T4 is the principal secreted prohormone, converted peripherally to active T3 by deiodinases. Acting through nuclear thyroid hormone receptors TR- α and TR- β , they regulate basal metabolic rate, thermogenesis, growth, and development. Most circulates protein-bound to thyroxine-binding globulin.

Thyroiditis

- Inflammation of the thyroid gland with various etiologies. Hashimoto thyroiditis: autoimmune, most common cause of hypothyroidism in iodine-sufficient areas. Subacute (De Quervain) thyroiditis: post-viral, presents with painful thyroid and transient hyperthyroidism followed by hypothyroidism. Postpartum thyroiditis: autoimmune, occurs within 1 year of delivery. Silent thyroiditis: painless lymphocytic thyroiditis. Diagnosis: TSH, T4, TPO antibodies, thyroid ultrasound, and radioactive iodine uptake.

Thyroiditis Classification

- Inflammatory conditions of the thyroid classified by clinical presentation and etiology. Hashimoto thyroiditis is chronic autoimmune with hypothyroidism. Graves disease is autoimmune with hyperthyroidism. Subacute thyroiditis is painful and likely viral. Silent thyroiditis and postpartum thyroiditis are painless autoimmune causing transient thyrotoxicosis followed by hypothyroidism. Riedel thyroiditis is rare idiopathic fibrosis causing a stony-hard goiter that may compress adjacent structures. Diagnosis is by clinical presentation, thyroid func-

tion tests, ultrasound, and radioactive iodine uptake which is low in inflammatory thyroiditis and high in Graves disease. Management is directed at the underlying etiology.

Thyroid Nodule Evaluation

- Systematic approach to evaluation of thyroid nodules detected by physical examination or imaging. Thyroid ultrasound characterizes nodule features including size, composition, echogenicity, margins, calcifications, and shape. TI-RADS classification stratifies malignancy risk and guides biopsy decisions. Fine-needle aspiration biopsy is indicated for nodules meeting size and suspicious feature criteria. Bethesda cytology classification categorizes results from non-diagnostic through suspicious for malignancy to malignant. Management of benign nodules is observation with serial ultrasound, while malignant or suspicious nodules require surgical resection. Molecular testing of biopsy specimens may help refine risk stratification and guide surgical decision-making.

Thyroid Stimulating Hormone

- TSH (thyrotropin): the anterior pituitary hormone that stimulates the thyroid to produce and release T4 and T3, controlled by TRH (hypothalamus) and negative feedback from thyroid hormones. The most sensitive screening test for thyroid dysfunction: high TSH indicates primary hypothyroidism (with low T4), low TSH indicates hyperthyroidism (with high T4/T3); subclinical disease shows isolated TSH abnormality. TSH also elevated in pituitary TSH-secreting tumor (rare, with high T4) and in recovery. Monitoring: target TSH to normalize during levothyroxine therapy. Pregnancy has trimester-specific TSH targets.

Thyroid Storm

- Life-threatening exacerbation of thyrotoxicosis presenting with hyperpyrexia, tachycardia, heart failure, altered mental status, and multi-organ dysfunction. Precipitated by infection, surgery, trauma, or iodine load in patients with untreated hyperthyroidism. Mortality rates range from twenty to thirty percent. Diagnosis is clinical based on Burch-Wartofsky scoring system. Treatment includes beta-blockers to control heart rate, thionamides to block new thyroid hormone synthesis, iodine to block thyroid hormone release (the Plummer effect), corti-

costeroids to reduce peripheral conversion of T4 to T3 and support haemodynamics, and aggressive supportive care including cooling, hydration, and management of heart failure. Definitive treatment of hyperthyroidism with radioactive iodine or thyroidectomy should follow after stabilisation.

Time in Range

– Percentage of time that continuous glucose monitoring readings remain within the target glucose range of seventy to one hundred eighty milligrams per deciliter for most adults with diabetes. General target is greater than seventy percent corresponding to approximately seventeen hours per day. Time below range less than seventy is less than four percent. Time below fifty-four is less than one percent. Time above range greater than one hundred eighty is less than twenty-five percent. Time in range correlates well with A1c and is a more dynamic measure of glycaemic control. Each ten percent increase in time in range corresponds to an approximate 0.5 percent reduction in A1c. Time in range targets may be individualised for older adults, pregnant women, and those with frequent hypoglycemia.

Trousseau Sign of Latent Tetany

– A sensitive and specific clinical sign of hypocalcemia. Elicited by inflating a blood pressure cuff on the upper arm to a pressure greater than systemic systolic blood pressure for 3 minutes. Positive response: carpopedal spasm characterized by flexion of the wrist and MCP joints, extension of the interphalangeal joints, and adduction of the thumb ("obstetrician's hand"). More sensitive and specific than Chvostek sign.

Turner Syndrome

– Chromosomal abnormality in females with complete or partial absence of one X chromosome most commonly with a karyotype of 45,X occurring in one in two thousand five hundred live female births. Features include short stature, webbed neck, shield chest, lymphedema, streak gonads causing primary amenorrhea and infertility, congenital heart defects particularly bicuspid aortic valve and coarctation of the aorta, and renal anomalies. Ovarian failure leads to estrogen deficiency requiring hormone replacement therapy for breast development and maintenance of secondary sexual characteristics, and estrogen replacement for bone health and cardio-

vascular protection. Growth hormone therapy may be considered during childhood to improve adult height. Fertility options including oocyte donation should be discussed.

Type 1 Diabetes Mellitus

– Type 1 diabetes is an autoimmune disease in which the immune system attacks and destroys the insulin-producing beta cells of the pancreas, resulting in absolute insulin deficiency. It typically presents in childhood or adolescence with symptoms of polyuria, polydipsia, weight loss, and fatigue, and requires lifelong insulin therapy through multiple daily injections or an insulin pump. Management involves careful monitoring of blood glucose levels, carbohydrate counting, and balancing insulin doses with physical activity to maintain near-normal glycemia and prevent acute complications like diabetic ketoacidosis and long-term complications affecting the eyes, kidneys, nerves, and cardiovascular system.

Type 2 Diabetes Mellitus

– Type 2 diabetes is a chronic metabolic disorder characterized by insulin resistance and progressive pancreatic beta-cell dysfunction, leading to hyperglycemia. It is strongly associated with obesity, physical inactivity, and genetic predisposition, and typically develops in adulthood, though increasing rates are seen in younger populations. Management begins with lifestyle modifications including weight loss, dietary changes, and exercise, then progresses to oral medications such as metformin, and may eventually require insulin as beta-cell function declines over time.

Vasopressin (Antidiuretic Hormone, ADH)

– See Antidiuretic Hormone (ADH).

VIPoma

– A rare pancreatic neuroendocrine tumor secreting vasoactive intestinal peptide (VIP), causing WDHA syndrome: watery diarrhea (large volume, 3-5 L/day), hypokalemia, and achlorhydria/acidosis. Most are malignant and located in the pancreatic tail. Diagnosis: elevated VIP levels, pancreatic tumor on imaging. Treatment: surgical resection for localized disease; somatostatin analogs (octreotide) control symptoms; chemotherapy or peptide receptor radionuclide therapy for metastatic disease.

Virilisation

– The development of male secondary sexual characteristics in females, resulting from excessive androgen production or exposure. Causes: congenital adrenal hyperplasia (21-hydroxylase deficiency, the most common), androgen-secreting tumors (ovarian or adrenal), Cushing syndrome, exogenous androgen use (anabolic steroids, testosterone therapy), and polycystic ovary syndrome (mild hyperandrogenism). Clinical features: hirsutism (male-pattern hair growth on face, chest, back, and abdomen), temporal hair recession (male-pattern baldness), deepening of the voice, clitoromegaly, increased muscle mass, acne, and amenorrhoea/oligomenorrhoea. The severity and age of onset depend on the cause: prenatal virilisation (ambiguous genitalia at birth, classically in congenital adrenal hyperplasia) vs. postpubertal virilisation (gradual onset in PCOS, rapid onset suggests tumor). Evaluation: serum testosterone (total and free), DHEAS, 17-hydroxyprogesterone, and imaging (ovarian/adrenal ultrasound, CT/MRI). Treatment: directed at the underlying cause — glucocorticoid replacement for CAH, surgical resection of tumors, antiandrogens (spironolactone, cyproterone acetate) and cosmetic measures (electrolysis, laser hair removal) for PCOS.

Von Hippel-Lindau Disease

– Autosomal dominant syndrome caused by mutations in the VHL tumor suppressor gene on chromosome three predisposing to hemangioblastomas of the central nervous system and retina, clear cell renal cell carcinoma, pheochromocytoma, pancreatic cysts and neuroendocrine tumors, and endolymphatic sac tumors. Retinal hemangioblastomas are the most common initial manifestation. CNS hemangioblastomas occur most commonly in the cerebellum and spinal cord. Screening includes annual ophthalmological examination, imaging of the brain and spine every two to three years, and abdominal imaging for renal cell carcinoma and pancreatic lesions. Treatment is surgical resection of symptomatic tumors, with targeted therapies such as sunitinib and belzutifan for advanced renal cell carcinoma.

Weight Loss

– The intentional reduction of body weight, typically through a combination of dietary modification, increased physical activity, and behavioral changes.

Achieving sustainable weight loss requires creating a consistent calorie deficit while preserving lean muscle mass through adequate protein intake and strength training. Even modest weight loss of 5 to 10 percent of body weight can produce significant health benefits, including improved blood glucose control, reduced blood pressure, and decreased risk of cardiovascular disease.

Weight Loss and Management

– Weight loss and management encompasses the ongoing process of achieving and maintaining a healthy body weight through sustainable lifestyle modifications. Effective weight management integrates a balanced, calorie-controlled diet, regular physical activity, behavioral strategies such as self-monitoring and goal setting, and adequate sleep and stress management. Long-term success requires a shift from short-term dieting to permanent lifestyle changes, as weight regain is common without sustained behavioral support and environmental modifications.

Wolfram Syndrome

– Autosomal recessive disorder caused by mutations in the WFS1 gene encoding wolframin. Classic triad of diabetes mellitus, optic atrophy, and diabetes insipidus. Additional features include sensorineural deafness, neurodegeneration, and psychiatric illness. Onset of diabetes typically in the first decade. Progressive optic atrophy leads to blindness. Diagnosis is by clinical criteria and genetic testing. Treatment is supportive with insulin for diabetes and desmopressin for diabetes insipidus.

Chapter 10

Ear, Nose, and Throat (ENT)

Adenoidectomy

- The surgical removal of the pharyngeal tonsils (adenoids), which are lymphoid tissue structures located in the nasopharynx, and it is commonly performed in children for obstructive sleep apnea, chronic nasal obstruction, recurrent otitis media, and chronic rhinosinusitis that is refractory to medical management. The adenoids are typically most prominent between the ages of three and seven years and undergo spontaneous involution during childhood, and adenoid hypertrophy can.

Allergic Rhinitis

- Allergic rhinitis, commonly known as hay fever, is a type I IgE-mediated hypersensitivity reaction of the nasal mucosa to inhaled allergens, characterized by sneezing, nasal congestion, rhinorrhea (clear, watery nasal discharge), nasal pruritus, and conjunctival symptoms including itching, tearing, and redness.

Anosmia

- The complete loss of the sense of smell, while hyposmia: a reduced sense of smell, and these conditions can significantly impair quality of life by reducing the ability to appreciate food flavors, detect environmental hazards such as gas leaks and smoke, and enjoy activities. The causes of anosmia are numerous and include post-viral olfactory loss (the most common cause, often following upper respiratory viral infections including SARS-CoV-2), chronic rhinosinusitis with nasal polyps, head trauma (particularly frontal lobe injuries that disrupt the olfactory nerves), neurodegenerative diseases (Alzheimer disease, Parkinson disease), congenital conditions (Kallmann syndrome), endocrine disorders (hypothyroidism, diabetes), medication side effects, and toxic exposures (smoking, industrial chemicals). The diagnosis involves olfactory testing

using standardized smell identification and threshold tests, nasal endoscopy to evaluate for anatomical causes, and MRI to assess the olfactory bulbs and frontal lobes. Treatment depends on the underlying cause and may include intranasal corticosteroids for inflammatory causes, olfactory training for postviral anosmia, and management of underlying medical conditions.

Aphonia

- Complete loss of the ability to phonate, distinct from dysphonia in which voice is present but abnormal. Causes are organic (bilateral vocal cord paralysis, severe laryngitis, laryngeal trauma, structural lesions) or psychogenic (conversion disorder, muscle tension dysphonia). Whispered speech and cough are usually preserved. Laryngoscopy assesses vocal cord mobility; imaging is added when neurologic or mass lesions are suspected.

Aphthous Ulcer

- Recurrent, painful, round or oval ulcers of the oral mucosa, commonly called canker sores. Three types: minor (most common, <1 cm, heal in 7-14 days without scarring), major (>1 cm, deeper, heal over weeks with scarring), and herpetiform (multiple pinhead-sized ulcers that fuse). Etiology unclear: immune-mediated, genetic predisposition, stress, trauma, nutritional deficiencies (B12, folate, iron), and food sensitivities. Diagnosis: clinical. Treatment: symptomatic (topical corticosteroids, amlexanox, lidocaine, oral hygiene). Severe cases: systemic corticosteroids, colchicine, or dapsone.

Arytenoid Cartilage

- The arytenoid cartilages are a pair of small, pyramid-shaped cartilages located on the posterior aspect of the larynx, articulating with the superior border of the cricoid cartilage lamina, and they serve

as the attachment points for the vocal cords and the intrinsic laryngeal muscles that control vocal cord movement. Each arytenoid cartilage has a vocal process (anteriorly), to which the vocal cord ligament attaches, and a muscular process (laterally), to which the posterior cricoarytenoid and lateral cricoarytenoid muscles attach. The movement of the arytenoid cartilages on the cricoid cartilage during phonation, breathing, and swallowing causes the vocal cords to adduct (close), abduct (open), and tense, and the posterior cricoarytenoid muscle is the sole abductor of the vocal cords, making it critical for maintaining airway patency. The arytenoid cartilages may become displaced or subluxed by trauma, intubation injury, or surgery, and arytenoid dislocation can cause hoarseness and vocal cord paresis.

Audiogram

- A chart that shows a person's ability to hear at different pitches or frequencies.

Audiologist

- A health professional who assesses hearing and fits hearing aids.

Audiometry

- A complete hearing test that involves listening to sounds of different frequencies and volume.

Benign Paroxysmal Positional Vertigo (BPPV)

- A common peripheral vertigo from dislodged otoconia (canalithiasis) within the semicircular canals, most often the posterior canal. Brief episodes of rotational vertigo lasting under one minute provoked by changes in head position. The Dix-Hallpike maneuver reproduces vertigo with characteristic torsional nystagmus, and the canalith repositioning (Epley) maneuver cures most patients.

Cerumen

- A substance that helps keep dirt out of the ear and lubricates the skin in the ear. More commonly known as earwax.

Cerumen Impaction

- The accumulation of cerumen (earwax) in the external auditory canal to the point where it causes symptoms or prevents adequate visualization of the tympanic membrane, and it is a common condition affecting approximately five to ten percent of children and up to thirty percent of elderly individuals

and cognitively impaired adults. Cerumen is a normal, protective secretion of the ceruminous glands in the cartilaginous portion of the external auditory canal, composed of secretions from modified apocrine glands mixed with dead skin cells and hair, and it serves to moisturize the canal skin, trap debris, and provide antimicrobial protection. Symptoms of impaction include aural fullness, decreased hearing, tinnitus, pruritus, pain, and a feeling of obstruction, and impacted cerumen may be visible as a yellow, brown, or dark mass obscuring the tympanic membrane. Treatment includes softening agents such as mineral oil, docusate sodium, or hydrogen peroxide, followed by manual removal using curettes, irrigation, or suction, and patients should be advised against inserting cotton swabs or other objects into the ear canal.

Cholesteatoma

- A pathological accumulation of keratinizing squamous epithelium within the middle ear, mastoid, or temporal bone that behaves like a locally invasive, destructive lesion, causing progressive conductive hearing loss, chronic otorrhea, and potential complications including ossicular erosion, labyrinthine fistula, facial nerve paralysis, and intracranial infections. The condition may be congenital (arising from embryonic epithelial remnants within the temporal bone) or acquired (typically developing from retraction pockets of the pars flaccida or perforations of the tympanic membrane), and it grows by the accumulation and desquamation of keratin debris within the squamous epithelial-lined sac. The cholesteatoma matrix produces proteolytic enzymes and inflammatory mediators that erode adjacent bony structures, including the ossicles, the bony labyrinth, and the mastoid cortex. Diagnosis is confirmed by otoscopy showing a retraction pocket or pearly white mass behind the tympanic.

Chronic Rhinosinusitis

- A heterogeneous group of disorders characterized by persistent inflammation of the paranasal sinuses lasting more than twelve weeks, with symptoms including nasal obstruction, purulent rhinorrhea (anterior or posterior), facial pain or pressure, and olfactory dysfunction, and it is classified into chronic rhinosinusitis without nasal polyps and chronic rhinosinusitis with nasal polyps based on the presence

or absence of nasal polyps on endoscopic examination. The pathogenesis is multifactorial, involving bacterial biofilm formation, mucociliary dysfunction, immunological dysregulation (type 2 inflammation in polyp disease), and anatomical factors that impair sinus drainage. The diagnosis is confirmed by nasal endoscopy showing mucosal edema, polyps, or purulent drainage from the sinus ostia, and CT imaging of the sinuses showing mucosal thickening and sinus opacification. Treatment includes intranasal corticosteroids, saline irrigation, antibiotics for acute exacerbations, and surgical intervention with functional endoscopic sinus surgery for patients who fail medical therapy.

Cochlear Implant

– A cochlear implant is an electronic medical device that bypasses damaged or absent inner ear hair cells to provide direct electrical stimulation of the auditory nerve, restoring a perception of sound in individuals with severe to profound sensorineural hearing loss who derive limited benefit from hearing aids. The device consists of an external component (microphone, speech processor, and transmitter coil) and an internal component (receiver-stimulator and electrode array inserted into the cochlea), and it works by converting sound into electrical signals that are transmitted to the electrode array, which stimulates the spiral ganglion neurons of the auditory nerve. The implant does not restore normal hearing but provides a representation of environmental sounds and speech that the brain learns to interpret through auditory rehabilitation. Indications include bilateral severe to profound sensorineural hearing loss in adults who receive limited benefit from appropriately fitted hearing aids, and bilateral severe to profound sensorineural hearing loss in children (typically implanted at twelve to eighteen months of age) to support speech and language development. The surgery is performed under general anesthesia and is generally safe, with risks including facial nerve injury, meningitis, and device failure.

Conductive Hearing Loss

– A type of hearing loss caused by impairment of the transmission of sound through the outer ear, middle ear, or both, preventing sound vibrations from reaching the cochlea efficiently, and it is typically characterized by a conductive gap (an air-bone

gap on audiometry indicating a difference between air conduction and bone conduction thresholds). Common causes in-

Cricoid Cartilage

– The cricoid cartilage is a complete, ring-shaped cartilage located at the base of the larynx, directly above the trachea and below the thyroid cartilage, and it is the only complete cartilaginous ring in the airway, providing structural support and maintaining airway patency. The cricoid cartilage is shaped like a signet ring, with a narrow anterior arch and a broad posterior lamina that articulates with the arytenoid cartilages superiorly. The cricothyroid membrane, connecting the thyroid and cricoid cartilages anteriorly, is the site of emergency cricothyrotomy (cricothyroidotomy) for securing the airway when intubation is not possible. The cricothyroid muscle, which attaches to the cricoid and thyroid cartilages, is the only intrinsic laryngeal muscle that is not innervated by the recurrent laryngeal nerve, and it functions to tense the vocal cords. The cricoid cartilage is prone to fracture in blunt neck trauma, and cricoid fracture can cause airway compromise, subglottic stenosis, and recurrent laryngeal nerve injury.

CSF Rhinorrhea

– Cerebrospinal fluid rhinorrhea is the leakage of cerebrospinal fluid from the subarachnoid space through a defect in the skull base into the nasal cavity or paranasal sinuses, resulting in a clear, watery nasal discharge that may be mistaken for allergic rhinitis or sinusitis. The most common causes include trauma (skull base fractures), iatrogenic injury (following sinus or skull base surgery), spontaneous.

Deafness

– Complete or partial loss of the ability to hear, classified by type: conductive deafness (impaired sound transmission through the external or middle ear, causes include cerumen impaction, otitis media, otosclerosis, tympanic membrane perforation), sensorineural deafness (damage to the cochlea or auditory nerve, causes include presbycusis, noise exposure, ototoxic drugs, Meniere disease, acoustic neuroma), and mixed hearing loss. Diagnosis: audiometry (pure-tone, speech), tympanometry, and otoacoustic emissions. Management: hearing aids, cochlear implants (for severe-to-profound sen-

sorineural loss), bone-anchored hearing aids (for conductive or single-sided deafness), and surgical correction of underlying causes.

Decibel

– A logarithmic unit (dB) used to measure the intensity of sound. The decibel scale compares a given sound pressure level to a reference level (0 dB = 20 micropascals, the threshold of normal hearing at 1 kHz). The scale is logarithmic: an increase of 10 dB represents a tenfold increase in sound intensity. Normal conversation: 60 dB. Threshold of pain: 120 dB. Prolonged exposure to sounds >85 dB causes noise-induced hearing loss. Audiometry measures hearing thresholds in dB hearing level (dB HL) across frequencies 250–8000 Hz.

Deviated Septum

– Displacement of the nasal septum from the midline, congenital or acquired from trauma, and present to some degree in most adults. Significant deviation narrows one nasal cavity, impairing airflow and sinus drainage and producing obstruction, congestion, recurrent sinusitis, epistaxis, and sleep disturbance. Symptomatic persistent obstruction is treated with septoplasty, often with turbinate reduction.

Dix-Hallpike Maneuver

– The Dix-Hallpike maneuver is a diagnostic test used to identify benign paroxysmal positional vertigo by detecting the characteristic nystagmus and vertigo that occur when displaced otoconia within the posterior semicircular canal move in response to gravity during specific head positioning. The patient is seated on the examination table, and the examiner rotates the patient's head forty-five degrees toward the side being tested, then quickly lays the patient back with the head hanging below the level of the shoulders, maintaining the head rotation.

Dysphonia

– An abnormal voice quality encompassing hoarseness, breathiness, roughness, vocal fatigue, pitch breaks, and strained or whispered speech. It is organic when due to structural laryngeal pathology (nodules, polyps, laryngitis, laryngeal cancer) and functional when due to voice misuse, muscle tension dysphonia, or psychogenic causes. Laryngoscopy and videostroboscopy assess the mucosal wave.

Earache (Otalgia)

– Pain originating from the ear, a common symptom with diverse causes. Otalgia is classified as primary (originating within the ear itself) or secondary/referred (pain perceived in the ear but arising from another site). Primary causes: otitis media, otitis externa, Eustachian tube dysfunction, cholesteatoma, foreign body, cerumen impaction, barotrauma, mastoiditis. Referred causes: temporomandibular joint dysfunction, dental pathology (molar caries, abscess, impacted wisdom teeth), tonsillitis, pharyngitis, sinusitis, cervical spine disorders, trigeminal neuralgia, and malignancies of the pharynx or larynx. Evaluation: otoscopy, pneumatic otoscopy, tuning fork tests (Rinne, Weber), and assessment of surrounding structures. Management depends on etiology.

Ear canal

– A tube leading from the eardrum to the outer ear.

Ear Diseases

– Any disorder affecting the structures of the ear—external ear (pinna, ear canal), middle ear (tympanic membrane, ossicles, Eustachian tube), or inner ear (cochlea, vestibular apparatus). Broad categories: congenital (microtia, atresia, preauricular sinus), infectious (otitis externa, otitis media, mastoiditis), inflammatory (Eustachian tube dysfunction, cholesteatoma), traumatic (tympanic membrane perforation, temporal bone fracture, barotrauma), neoplastic (acoustic neuroma, glomus tumor, squamous cell carcinoma), and degenerative (presbycusis, Meniere disease, otosclerosis). Diagnosis: otoscopy, audiometry, tympanometry, and imaging (CT temporal bone, MRI internal auditory meatus). Management is etiology-specific.

Eardrum

– A thin membrane separating the ear canal and middle ear.

Ear Infections

– Infections of the ear, most commonly affecting the middle ear (otitis media) or the outer ear canal (otitis externa). They are often caused by bacteria or viruses and present with ear pain, drainage, hearing loss, and sometimes fever. Recurrent ear infections in children may require tympanostomy tubes or other interventions to prevent complications.

Ear, Nose, and Throat (ENT)

– A medical specialty (otolaryngology) focused on

the diagnosis and treatment of disorders affecting the ears, nose, throat, head, and neck. Conditions managed include hearing loss, sinusitis, tonsillitis, voice disorders, and head and neck cancers. Otolaryngologists also perform surgical procedures such as tonsillectomy, sinus surgery, and cochlear implantation.

Earwax

– Cerumen, a waxy secretion produced by the ceruminous glands in the outer third of the external auditory canal. Earwax lubricates and protects the skin of the ear canal, trapping dust, debris, and microorganisms to prevent them from reaching the tympanic membrane. Normal self-cleaning mechanism migrates wax laterally through epithelial migration. Impaction occurs when cerumen accumulates excessively, causing conductive hearing loss, itching, tinnitus, a feeling of fullness, or discomfort. Excessive use of cotton buds can cause impaction. Treatment: cerumenolytic drops (sodium bicarbonate, hydrogen peroxide, olive oil) or micro-suction/ear irrigation. Irrigation is contraindicated with known tympanic membrane perforation, previous ear surgery, or active otitis media.

Epistaxis

– Epistaxis, commonly known as a nosebleed, is hemorrhage from the nasal mucosa that can range from minor, self-limited bleeding to severe, life-threatening hemorrhage requiring emergency intervention, and it is a common presenting complaint in both primary care and emergency departments.

Epley Maneuver

– The Epley maneuver, also known as the canalith repositioning maneuver, is a therapeutic procedure used to treat posterior canal benign paroxysmal positional vertigo by repositioning displaced calcium carbonate crystals (otoconia) from the posterior semicircular canal back into the utricle through a series of sequential head and body position changes guided by the physician. The procedure begins with the patient seated, the head rotated forty-five degrees toward the affected ear, and the patient is rapidly laid back with the head hanging (the Dix-Hallpike position), maintaining the head rotation for thirty to sixty seconds until the nystagmus resolves. The head is then rotated ninety degrees to the opposite side while maintaining the neck extension,

held for thirty to sixty seconds, and the patient is then rolled onto their side with the nose pointing toward the floor, held for thirty to sixty seconds, before sitting upright. The maneuver relies on gravity to guide the otoconia through the semicircular canal and back into the utricle, with a success rate of approximately eighty percent after one to two treatments, and patients are advised to avoid lying flat on the affected side for several days afterward.

Esophageal Foreign Body

– Ingestion of a foreign object lodged in the esophagus. Most common in children (coins, batteries, toys) and adults with dentures (food bolus), psychiatric illness, or prisoners. Common sites: cricopharyngeus (C6, 60%), aortic arch (T4), and gastroesophageal junction. Symptoms: dysphagia, odynophagia, drooling, and foreign body sensation. Sharp objects: risk of perforation. Button batteries: require emergency removal due to rapid tissue necrosis and perforation. Diagnosis: X-ray neck/chest/abdomen (AP and lateral). Treatment: endoscopic removal (urgent for sharp, batteries, large objects, or complete obstruction). Glucagon IV for distal esophageal food impaction may facilitate passage. Bougienage for smooth coins in children.

Ethmoidal Sinus

– The ethmoidal sinuses, also known as ethmoidal air cells, are a collection of multiple small, thin-walled, air-containing cavities within the ethmoid bone between the orbits and above the nasal cavity, and they are divided into anterior and posterior groups based on their drainage sites. The anterior ethmoidal air cells, typically numbering six to twelve, drain through the ethmoidal infundibulum into the middle meatus, while the posterior ethmoidal air cells, typically numbering three to eight, drain into the superior meatus. The ethmoidal sinuses are separated from the orbits by the paper-thin lamina papyracea, and from the anterior cranial fossa by the fovea ethmoidalis (the roof of the ethmoid labyrinth), making complications of ethmoidal sinusitis potentially dan-

External otitis

– An infection or irritation of the outer ear, ear canal, or both. Also called swimmer's ear.

FESS

– Functional endoscopic sinus surgery is a minimally invasive surgical technique that uses nasal endoscopes and specialized instruments to restore normal sinus drainage and ventilation by removing obstructive tissue and opening blocked sinus ostia, while preserving as much normal sinus mucosa and anatomy as possible. The procedure is indicated for chronic rhinosinusitis with or without nasal polyps that has failed medical therapy, recurrent acute sinusitis, and complications of sinusitis including mucocoele and orbital complications. FESS involves the uncinectomy (removal of the uncinate process to access the maxillary sinus ostium), ethmoidectomy (removal of ethmoidal air cells), maxillary antrostomy (enlargement of the maxillary sinus ostium), frontal sinusotomy (opening of the frontal sinus drainage pathway), and sphenoidotomy (opening of the sphenoid sinus), depending on the extent of disease. The procedure is performed under general anesthesia using rigid endoscopes with angles of 0, 30, 45, and 70 degrees, and it offers the advantages of direct visualization, targeted tissue removal, preservation of normal anatomy, and faster recovery compared to traditional open sinus surgery.

Frontal Sinus

– The frontal sinuses are paired, air-filled cavities located within the frontal bone above the orbits and the root of the nose, separated by a bony septum that may be deviated to one side, and they are the last of the paranasal sinuses to develop, typically appearing around age seven and reaching full size by late adolescence. The frontal sinuses are irregular in.

Gargle

– The act of rinsing the mouth and throat with a liquid, holding it at the back of the throat while exhaling to create a bubbling action. Used for relief of sore throat or as a delivery method for antiseptics, anaesthetics, and anti-inflammatory agents. Common gargle solutions: warm saline, chlorhexidine (antibacterial), benzydamine (NSAID), lidocaine (local anesthetic), hydrogen peroxide (dilute). Not effective for treating bacterial pharyngitis. Gargling does not reach the larynx or lower airways.

Globus Sensation

– The persistent or intermittent sensation of a lump or foreign body in the throat without an anatomic

lesion or dysphagia, also termed globus pharyngeus, typically noticed between meals. There is no impedance to swallowing and no weight loss; the feeling worsens with stress, anxiety, or laryngopharyngeal reflux. Flexible laryngoscopy excludes structural lesions.

Glossitis

– Inflammation of the tongue. Causes: (1) Infection: bacterial (*Streptococcus*, *Actinomyces*), viral (HSV, Coxsackie–herpangina, HIV), fungal (*Candida*–oral thrush). (2) Nutritional deficiencies: iron (atrophic glossitis, smooth red tongue), B12 (magenta tongue), riboflavin (purple-red tongue with fissures), niacin (pellagra, beefy red tongue), folate. (3) Autoimmune: geographic tongue (benign migratory glossitis), lichen planus, pemphigus, Behçet disease. (4) Trauma: burns (hot food/drink), bite injury, ill-fitting dentures or orthodontic appliances. (5) Allergic: contact stomatitis (toothpaste, mouthwash, food). (6) Systemic: amyloidosis, sarcoidosis, Crohn disease. Symptoms: pain, burning, swelling, redness, altered taste, difficulty eating. Diagnosis: clinical examination, nutritional bloods, swab for culture, biopsy if persistent. Treatment: directed at cause (antifungals for *Candida*, B12 injections for pernicious anaemia, avoidance of irritants).

Glottis

– The opening between the vocal folds (true vocal cords) in the larynx, through which air passes during respiration and phonation. Boundaries: anterior (anterior commissure, attachment of vocal folds to thyroid cartilage), posterior (arytenoid cartilages and posterior commissure). The glottis has three functional states: (1) Open (respiration): vocal folds abducted by posterior cricoarytenoid muscles, creating a triangular opening. (2) Closed (swallowing, valsalva): vocal folds adducted, protecting the lower airway. (3) Oscillating (phonation): vocal folds vibrate as air passes through, producing sound. Glottic aperture size directly affects airway resistance and voice production. Glottic edema (angioedema, anaphylaxis) causes stridor and airway obstruction.

Hair Cells

– The sensory receptor cells of the inner ear that convert mechanical sound vibrations into electrical neural signals, and they are named for the bundle

of stereocilia projecting from their apical surface. The inner hair cells, arranged in a single row along the length of the cochlea, are the primary auditory receptors, with approximately 95 percent of the auditory nerve fibers innervating them, and they are responsible for transmitting sound information to the brain. The outer hair cells, arranged in three rows, function as cochlear amplifiers through a unique property called electromotility, in which the cells change length in response to electrical stimulation, actively amplifying the motion of the basilar membrane and enhancing the ear's sensitivity to quiet sounds and its ability to distinguish between different frequencies. Hair cells are highly susceptible to damage from loud noise exposure, ototoxic medications (including aminoglycoside antibiotics, cisplatin, and loop diuretics), aging, and genetic mutations, and once damaged in mammals, they do not regenerate, leading to permanent sensorineural hearing loss.

Hay Fever (Allergic Rhinitis)

- An IgE-mediated, type I hypersensitivity reaction to airborne allergens (pollen, dust mites, mould spores, animal dander). Hay fever: seasonal allergic rhinitis (caused by grass, tree, and weed pollens), while perennial allergic rhinitis occurs year-round (house dust mites, pet dander, mould). Pathophysiology: allergen cross-links IgE on sensitised mast cells in nasal mucosa, triggering degranulation (histamine, leukotrienes, prostaglandins) within minutes (early phase: sneezing, itching, rhinorrhea, nasal congestion). Late phase (4-6 hours): eosinophil and basophil recruitment, causing persistent congestion and hyperreactivity. Symptoms: sneezing paroxysms, anterior rhinorrhea (clear watery discharge), nasal congestion, post-nasal drip, nasal pruritus, palatal/ear itching, conjunctival symptoms (itchy, red, watery eyes, periorbital edema). Associated conditions: asthma (80% of asthmatics have rhinitis, unified airway concept), eczema, sinusitis, nasal polyps, otitis media with effusion. Diagnosis: clinical (symptom pattern, seasonal/perennial triggers), allergen-specific IgE testing (skin prick test or serum specific IgE, RAST). Management: (1) Allergen avoidance (encasing mattresses and pillows, HEPA filters, avoiding outdoor activity during high pollen counts, saline nasal irrigation). (2) Pharmacological: oral/nasal antihistamines (cetirizine, loratadine, fexofenadine), intranasal corticosteroids (beclomethasone, fluticasone, mometasone—first-line for moderate-severe intermittent or persistent disease), leukotriene receptor antagonists (montelukast—adjunctive with asthma), intranasal mast cell stabilisers (cromoglycate), oral decongestants (pseudoephedrine—short-term only). (3) Immunotherapy: allergen-specific subcutaneous (SCIT) or sublingual (SLIT) immunotherapy, modifies the immune response (induces IgG-blocking antibodies, regulatory T cells, shifts from Th2 to Th1), highly effective for pollen and dust mite allergies.

Hearing aid

- An electronic device worn in or behind the ear by people with hearing problems that makes sounds louder.

Hearing Aids and Devices

- Electronic devices worn in or behind the ear that amplify sound for individuals with hearing loss. Modern hearing aids include digital signal processing, directional microphones, and connectivity to smartphones and other audio sources. Cochlear implants are surgically implanted devices that directly stimulate the auditory nerve for those with severe-to-profound hearing loss who do not benefit from conventional hearing aids.

Hearing Loss

- Reduced ability to hear, classified as conductive (outer/middle ear pathology: cerumen impaction, otitis media, otosclerosis, tympanic membrane perforation), sensorineural (inner ear or auditory nerve: presbycusis, noise exposure, ototoxic drugs, Meniere disease, acoustic neuroma), or mixed. Presents with difficulty understanding speech, especially in background noise. Diagnosis: audiometry (pure tone average, speech discrimination), tympanometry. Treatment: hearing aids, cochlear implants for severe-to-profound SNHL, surgical correction for conductive causes. Prevention: noise protection, ototoxic medication monitoring.

Hoarseness

- A subjective change in voice quality characterized by roughness, breathiness, strain, or altered pitch; a subset of dysphonia rather than a diagnosis. Common causes include acute viral laryngitis, voice

overuse, smoking, reflux, and vocal cord lesions (nodules, polyps, papillomas, laryngeal carcinoma). Hoarseness beyond two weeks warrants laryngoscopy to exclude malignancy.

Hyposmia

- Decreased sensitivity to odors in which olfaction is reduced but not absent, distinct from anosmia and parosmia, and the most common olfactory complaint. Causes overlap with anosmia: postviral upper respiratory infection (the leading cause), chronic rhinosinusitis with nasal polyps, conductive nasal obstruction, head trauma, neurodegenerative disease, smoking, and aging. Diagnosis uses smell tests and nasal endoscopy.

Impedance hearing testing

- A test that sends sound waves to the eardrum to determine if a problem in the middle ear is causing hearing loss.

Incus

- The incus, commonly known as the anvil, is the middle ossicle of the three bones in the middle ear, articulating with the malleus at the incudomalleolar joint and with the stapes at the incudostapedial joint. It is the largest of the three ossicles and is shaped like a premolar tooth, with a body and two processes: the long process, which descends parallel to the manubrium of the malleus and articulates with the stapes via the lenticular process, and the short process, which projects posteriorly and is attached to the posterior wall of the middle ear by the posterior incudal ligament. The incus functions as a lever in the ossicular chain, amplifying sound vibrations from the tympanic membrane to the oval window with an amplification factor of approximately 1.3, and combined with the area ratio between the tympanic membrane and oval window, provides a total sound pressure amplification of approximately 22-fold. The long process of the incus is particularly vulnerable to ischemic necrosis due to its tenuous blood supply, and erosion of this structure is a common complication of chronic otitis media and cholesteatoma.

Inner ear

- The deepest part of the ear, consisting of the cochlea and the labyrinth.

Kiesselbach Plexus

- Kiesselbach plexus, also known as Little area, is a

highly vascularized region located on the anterior nasal septum where five arterial anastomoses converge, making it the most common site of epistaxis (nosebleed), accounting for approximately ninety.

Labyrinth

- The inner ear. It contains the cochlea, which is responsible for hearing, as well as structures that are needed for balance.

Labyrinthitis

- Inflammation of the labyrinth, the inner ear structure containing the cochlea and vestibular apparatus, resulting in both auditory and vestibular symptoms including sudden, severe vertigo, sensorineural hearing loss, tinnitus, nausea, and vomiting. The condition is distinguished from vestibular neuritis, which involves inflammation of the vestibular nerve without cochlear involvement, by the presence of hearing loss. Labyrinthitis may be caused by viral infections (the most common cause, often following upper respiratory infections), bacterial infections (typically spreading from middle ear infections or meningitis), autoimmune diseases, or ototoxic medications. The viral form is generally self-limited, with gradual improvement over days to weeks, though some patients experience persistent vestibular symptoms and residual hearing loss. Bacterial labyrinthitis is more severe and can result in permanent hearing loss and vestibular dysfunction, requiring aggressive antibiotic treatment and potentially surgical drainage of the middle ear. Treatment includes vestibular suppressants for acute vertigo, antiemetics, and vestibular rehabilitation therapy for persistent symptoms.

Laryngectomy

- Surgical removal of part or all of the larynx, most often for squamous cell carcinoma of the larynx or hypopharynx and less often for severe trauma or refractory aspiration. Total laryngectomy requires a permanent tracheostomy, so the patient breathes through a neck stoma; partial laryngectomy preserves voice and swallowing. Voice rehabilitation uses esophageal speech, an electrolarynx, or tracheoesophageal puncture.

Laryngitis

- Inflammation of the larynx and vocal cords that presents with hoarseness, voice loss, sore throat, dry cough, and a sensation of a lump in the throat

(globus sensation), and it may be acute or chronic. Acute laryngitis is most commonly caused by viral upper respiratory infections, and it is usually self-limited, resolving within one to two weeks, though it may be accompanied by fever, malaise, and cervical lymphadenopathy. Chronic laryngitis lasting more than three weeks may be caused by voice abuse, laryngopharyngeal reflux, chronic sinusitis with postnasal drip, smoking, environmental irritants, allergic rhinitis, and certain medications, and it can lead to chronic hoarseness and permanent vocal cord changes if not addressed. The diagnosis is typically clinical, based on history and laryngoscopy findings of vocal cord erythema, edema, and sometimes hemorrhagic spots. Treatment of acute laryngitis includes voice rest, hydration, humidification, and avoidance of irritants, while chronic laryngitis requires identification and treatment of the underlying cause.

Laryngopharyngeal Reflux (LPR)

– Retrograde movement of gastric contents above the upper esophageal sphincter into the larynx and pharynx, producing chronic hoarseness, throat clearing, globus sensation, cough, excessive throat mucus, and laryngospasm, often without heartburn. Laryngoscopic posterior laryngitis is suggestive but non-specific, and dual-probe pH or impedance monitoring confirms the diagnosis. Treatment combines proton pump inhibitors, histamine-2 antagonists, alginate antacids, and lifestyle measures.

Laryngoscopy

– A medical procedure used to visualise the larynx (voice box) and adjacent structures of the throat. Types: (1) Indirect laryngoscopy: the simplest technique, using a laryngeal mirror angled at 120 degrees to reflect the laryngeal image, with a headlight or external light source. (2) Flexible nasolaryngoscopy (or transnasal flexible laryngoscopy): a thin, flexible fiberoptic endoscope passed through the nostril to visualise the nasal cavity, pharynx, and larynx. Performed under topical anesthesia (lidocaine spray, decongestant). The patient is awake and phonates to assess vocal fold movement. Used for evaluating hoarseness, stridor, dysphagia, laryngeal masses, and vocal cord paralysis. (3) Direct laryngoscopy: performed under general anesthesia using a rigid laryngoscope (e.g., Macintosh or Miller blade for

intubation; suspension laryngoscope for surgery), providing a direct view of the larynx and subglottis. Used for biopsy, removal of laryngeal lesions (polyps, nodules, papillomas), laser surgery, and foreign body removal. (4) Video laryngoscopy: uses a camera at the tip of a rigid laryngoscope blade, providing an indirect view of the glottis on a screen. Improves glottic visualisation in difficult airways (e.g., Cormack-Lehane grade 3-4, obesity, limited neck mobility). Devices: GlideScope, McGrath, C-MAC, Airtraq.

Larynx

– The larynx, commonly known as the voice box, is a complex organ located in the anterior neck between the pharynx and the trachea that serves three primary functions: phonation (voice production), protection of the lower airway from aspiration during swallowing, and regulation of airflow during respiration. The laryngeal skeleton consists of several cartilages including the thyroid cartilage (the largest, commonly known as the Adam's apple), the cricoid cartilage (the only complete cartilaginous ring in the airway), the paired arytenoid cartilages (which articulate with the vocal cords), and the epiglottis (which covers the laryngeal inlet during swallowing). The larynx contains two pairs of folds: the true vocal cords (vocal folds), which are responsible for phonation and are covered by stratified squamous epithelium, and the false vocal cords (vestibular folds), which are located superior to the true cords and play a role in airway protection. The larynx is innervated by the superior laryngeal nerve (sensory to the supraglottic larynx) and the recurrent laryngeal nerve (motor to all intrinsic laryngeal muscles except the cricothyroid), and injury to these nerves,.

Malleus

– The malleus, commonly known as the hammer, is the largest of the three ossicles in the middle ear and is the most laterally positioned, with its handle (manubrium) embedded in the fibrous layer of the tympanic membrane and its head articulating with the incus at the incudomalleolar joint. The malleus is an irregularly shaped bone approximately 8 to 9 millimeters in length, consisting of a head, neck, anterior process, lateral process, and manubrium, and it transmits vibrations from the tympanic membrane to the incus and subsequently to the stapes and oval

window. The tensor tympani muscle attaches to the handle of the malleus and contracts reflexively in response to loud sounds, increasing the stiffness of the ossicular chain and reducing the transmission of potentially damaging low-frequency sounds to the inner ear. During middle ear infections, the malleus may become eroded by cholesteatoma or chronic inflammation, leading to conductive hearing loss, and its assessment during otoscopy is important for evaluating middle ear pathology.

Mastoidectomy

– A surgical procedure that involves the removal of diseased mastoid air cells and bone from the mastoid portion of the temporal bone, performed for chronic otitis media with cholesteatoma, mastoiditis, or as a component of surgery for acoustic neuroma and other skull base tumors. The canal wall up (closed) mastoidectomy technique preserves the bony wall between the external auditory canal and the mastoid cavity, maintaining the normal anatomy and eliminating the need for ongoing mastoid cavity care, while the canal wall down (open) mastoidectomy removes the bony wall, creating a common cavity between the external auditory canal and the mastoid, which is indicated for extensive cholesteatoma that cannot be completely removed through a canal wall up approach. The canal wall down technique results in a larger mastoid cavity that requires periodic cleaning and is prone to accumulation of debris and recurrent infection, but it provides better access and visualization for complete removal of cholesteatoma. The procedure is performed under general anesthesia using a postauricular.

Mastoiditis

– Bacterial infection of the mastoid air cells, typically a complication of acute otitis media. Presents with postauricular pain, swelling, erythema, and tenderness, fever, and otorrhea. Diagnosis: CT temporal bone shows mastoid air cell opacification with bony destruction. Complications: subperiosteal abscess, Bezold abscess (pus tracking into sternocleidomastoid), facial nerve palsy, sigmoid sinus thrombosis, meningitis, and intracranial abscess. Treatment: IV antibiotics (ceftriaxone, vancomycin), myringotomy with tube placement, and mastoidectomy for refractory cases.

Meatuses

– The nasal meatuses are the air passages located beneath each corresponding turbinate on the lateral wall of the nasal cavity, and they serve as the drainage pathways for the paranasal sinuses and the nasolacrimal duct. The inferior meatus, located beneath the inferior turbinate, receives drainage from the nasolacrimal duct, which carries tears from the eye to the nasal cavity. The middle meatus, located beneath the middle turbinate, receives drainage from the maxillary sinus through the hiatus semilunaris, the frontal sinus through the frontonasal duct, and the anterior ethmoidal air cells through the ethmoidal infundibulum. The superior meatus, located beneath the superior turbinate, receives drainage from the posterior ethmoidal air cells. The sphenoidal recess, located above and behind the superior turbinate, receives drainage from the sphenoid sinus. Understanding the drainage pathways of the paranasal sinuses through the meatuses is essential for diagnosing and treating sinusitis, as obstruction of these narrow drainage pathways can.

Meniere Disease

– An inner ear disorder characterized by recurrent episodes of vertigo lasting 20 minutes to 12 hours, with fluctuating sensorineural hearing loss, tinnitus, and aural fullness. Due to endolymphatic hydrops. Diagnosis: clinical criteria; audiometry shows low-frequency SNHL during attacks. Treatment: low-sodium diet, diuretics (hydrochlorothiazide), intratympanic steroids, intratympanic gentamicin for vertigo control, and surgical interventions (endolymphatic sac decompression, vestibular nerve section) for refractory cases.

Middle Ear

– The middle ear, also known as the tympanic cavity, is an air-filled, mucosa-lined space within the temporal bone that lies between the tympanic membrane laterally and the medial wall of the middle ear (abrynthine wall) medially, and it contains the three ossicles (malleus, incus, and stapes) that transmit sound vibrations from the tympanic membrane to the oval window of the inner ear. The middle ear is divided into three compartments: the mesotympanum (directly behind the tympanic membrane), the epitympanum or attic (above the level of the tympanic membrane), and the hypotympanum (below

the level of the tympanic membrane). The middle ear is connected to the nasopharynx by the Eustachian tube, which equalizes air pressure on both sides of the tympanic membrane, and it is lined by a mucous membrane that is continuous with the lining of the Eustachian tube and the pharynx. The.

Mixed Hearing Loss

– A combination of both conductive and sensorineural hearing loss occurring in the same ear, resulting in a hearing deficit that involves impaired sound transmission through the outer or middle ear in addition to cochlear or neural dysfunction. The audiometric pattern shows both an air-bone gap indicating the conductive component and elevated bone conduction thresholds indicating the sensorineural component, and the total hearing loss is the sum of both components. Common causes include chronic otitis media or cholesteatoma with superimposed presbycusis, otosclerosis with cochlear involvement, and noise exposure with concurrent middle ear pathology. The management of mixed hearing loss requires addressing both components: treating the conductive component medically or surgically when possible (such as repairing a tympanic membrane perforation or reconstructing the ossicular chain) and managing the sensorineural component with hearing amplification or cochlear implantation as indicated.

Nasal Cavity

– The nasal cavity is the paired, air-filled space located between the nasal septum medially and the lateral nasal wall, extending from the nares (nostrils) anteriorly to the choanae (posterior openings into the nasopharynx) posteriorly, and it serves three primary functions: warming, humidifying, and filtering inspired air; olfaction (smell); and resonance of the voice. The lateral nasal wall contains three scroll-like bony projections called turbinates (superior, middle, and inferior), which increase the surface area of the nasal mucosa and create turbulent airflow to optimize air conditioning. Beneath each turbinates lies a corresponding meatus: the superior, middle, and inferior meatuses, which receive drainage from the paranasal sinuses. The nasal septum, composed of both cartilage and bone, divides the nasal cavity into two halves and is lined by a.

Nasal Congestion

– A sensation of nasal stuffiness or obstruction from engorgement of the venous sinusoids within the nasal mucosa, especially the inferior turbinates; a symptom shared by many conditions. Causes include viral upper respiratory infections, allergic and non-allergic rhinitis, sinusitis, pregnancy, hypothyroidism, rhinitis medicamentosa, and structural obstruction (deviated septum, polyps). Chronic unilateral congestion raises suspicion of neoplasm.

Nasal Polyps

– Benign, pedunculated, edematous outgrowths of the sinus and nasal mucosa that arise most commonly from the ethmoidal sinuses and protrude into the nasal cavity through the middle meatus, causing nasal obstruction, anosmia (loss of smell), and rhinorrhea. The polyps are composed of edematous stroma with a sparse inflammatory infiltrate including eosinophils, lymphocytes, and plasma cells, and they are associated with type 2 inflammation, elevated tissue and serum IgE levels, and aspirin sensitivity in approximately thirty to forty percent of patients (Samter triad: aspirin sensitivity, asthma, and nasal polyposis). Nasal polyps are more common in adults, particularly males over the age of forty, and they are associated with chronic rhinosinusitis, asthma, aspirin sensitivity, cystic fibrosis, and primary ciliary dyskinesia.

Nasal Septum

– The nasal septum is the midline structure that divides the nasal cavity into two halves, consisting of an anterior cartilaginous portion (the septal cartilage or quadrilateral cartilage), a posterior bony portion (the perpendicular plate of the ethmoid bone and the vomer), and the membranous portion (the columella) at the anterior nasal opening. The septum provides structural support for the nose, divides the nasal airflow, and supports the nasal mucosa, which is richly vascularized by branches of the internal and external carotid arteries. Deviation of the nasal septum is extremely common, with virtually all individuals having some degree of asymmetry, and significant deviation can cause nasal obstruction, impaired sinus drainage, recurrent.

Nasopharyngeal Carcinoma

– A malignancy arising from the epithelial lining of the nasopharynx, and it has a unique geographical and ethnic distribution, with highest incidence in

southern China, Southeast Asia, and North Africa. The tumor is strongly associated with Epstein-Barr virus infection, which is present in virtually all cases of undifferentiated nasopharyngeal carcinoma, and dietary factors including salt-preserved fish and other nitrosamine-containing foods. The tumor typically arises in the lateral wall of the nasopharynx (fossa of Rosenmüller) and often presents with a painless neck mass (cervical lymphadenopathy), nasal obstruction, epistaxis, hearing loss from Eustachian tube obstruction, and cranial nerve palsies. Diagnosis is confirmed by endoscopic examination and biopsy, and staging involves MRI of the nasopharynx and neck and PET-CT. Nasopharyngeal carcinoma is highly radiosensitive, and the primary treatment is radiation therapy combined with chemotherapy for locally advanced disease, with chemotherapy regimens typically including cisplatin and 5-fluorouracil.

Neck Cancer

– Human papillomavirus, particularly HPV-16, is an increasingly important etiological factor in head and neck squamous cell carcinoma, particularly oropharyngeal cancer, and it is responsible for the rising incidence of oropharyngeal cancer in younger patients without traditional risk factors of tobacco and alcohol use. HPV-positive oropharyngeal cancer has distinct epidemiological, clinical, and molecular characteristics compared to HPV-negative disease, including a younger age of presentation, better performance status, smaller primary tumors with larger cervical lymph node metastases, and significantly improved prognosis, with five-year survival rates of approximately eighty to ninety percent compared.

Non-Allergic Rhinitis

– Non-allergic rhinitis, also known as vasomotor rhinitis, is a chronic nasal condition characterized by nasal symptoms including congestion, rhinorrhea, and sneezing that are not caused by an IgE-mediated allergic response, and it is distinguished from allergic rhinitis by the absence of allergen-specific IgE, negative allergy testing, and the absence of the systemic symptoms typically associated with allergic rhinitis. The pathogenesis involves dysfunction of the autonomic nervous system regulation of the nasal mucosal blood vessels and glands, leading to exaggerated vasodilation and increased mucus pro-

duction in response to environmental triggers.

Oral Leukoplakia

– A white patch or plaque on the oral mucosa that cannot be scraped off and cannot be characterized as any other diagnosable disease, considered a potentially malignant disorder. Risk factors: tobacco use (most common), alcohol, and betel nut chewing. Most common sites: buccal mucosa, alveolar ridge, and tongue. Dysplasia (mild, moderate, severe) found on biopsy in 10-40% of cases. Progression to invasive squamous cell carcinoma: 1% per year for non-dysplastic, higher with dysplasia. Diagnosis: biopsy for histology. Treatment: excision or laser ablation for dysplastic lesions; observation for non-dysplastic. Risk factor modification essential. Long-term surveillance required.

Ossicles

– Three bones in the middle ear that move in response to sound vibrations.

Otic capsule

– The otic capsule is the dense bony shell (otic capsule bone) that surrounds and protects the inner ear structures, including the cochlea, vestibule, and semicircular canals, forming the hardest bone in the human body. It develops from the otic placode and undergoes endochondral ossification, and unlike other temporal bone components, it undergoes very little remodeling after development, making it resistant to otosclerosis but susceptible to otic capsule dehiscence (superior semicircular canal dehiscence syndrome), in which thinning or absence of the bone over the superior semicircular canal creates a third window phenomenon, causing sound- or pressure-induced vertigo (Tullio phenomenon), conductive hearing loss, and autophony.

Otitis Externa

– Otitis externa, commonly known as swimmer's ear, is an infection or inflammation of the external.

Otitis media

– A group of inflammatory conditions of the middle ear, most commonly caused by viral or bacterial infection, with *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis* being the most frequent bacterial pathogens. It is classified into acute otitis media (AOM), characterized by rapid-onset otalgia, fever, and bulging erythematous tympanic membrane with middle ear

effusion; otitis media with effusion (OME), in which non-purulent fluid persists in the middle ear without signs of acute infection, often causing conductive hearing loss and speech delay in children; and chronic suppurative otitis media (CSOM), defined by persistent otorrhea through a tympanic membrane perforation for more than 6 weeks. Eustachian tube dysfunction is the primary predisposing factor, as impaired drainage and ventilation of the middle ear allow pathogens to ascend from the nasopharynx. Treatment of AOM includes observation or antibiotics (amoxicillin 80-90 mg/kg/day for 10 days in children) depending on age and severity, while OME may require tympanostomy tube placement if effusion persists beyond 3 months with hearing loss. Complications include tympanic membrane perforation, mastoiditis, cholesteatoma, and intracranial spread.

Otolaryngology (ENT)

– The surgical specialty concerned with the diagnosis and treatment of disorders of the ear, nose, throat, head, and neck. Otolaryngologists (ENT surgeons) manage conditions ranging from otitis media and sinusitis to head and neck cancer, thyroid disease, and voice disorders. Subspecialties: otology/neurotology (ear disorders, hearing loss, balance), rhinology (sinus disease, anterior skull base), laryngology (voice, swallowing), head and neck oncology (cancer surgery including neck dissection, laryngectomy, thyroidectomy), paediatric ENT (cleft palate, cochlear implants), and facial plastic and reconstructive surgery. Training in the UK requires 2 years of core surgical training followed by 6 years of specialty training (ST3–ST8).

Otology

– The branch of medicine and surgery concerned with the study and treatment of ear disorders. Otology encompasses hearing loss (conductive, sensorineural, mixed), tinnitus, vertigo and balance disorders (Meniere disease, benign paroxysmal positional vertigo, vestibular neuritis), otitis media, otosclerosis, cholesteatoma, and ear trauma. Diagnostic tools: pure-tone audiometry, tympanometry, otoacoustic emissions, auditory brainstem response (ABR), and CT/MRI of the temporal bone. Surgical procedures include myringotomy, tympanoplasty, mastoidectomy, stapedectomy, cochlear implantation, and os-

ticuloplasty. Neurotology is a subspecialty addressing the interface between the ear and brain (acoustic neuroma, CSF leak repair, skull base surgery).

Otorrhea

– Discharge from the ear. Classification: acute otorrhea (<6 weeks) and chronic otorrhea (>6 weeks). Causes: acute otitis media with tympanic membrane perforation (purulent discharge, often in children), otitis externa (watery or mucoid discharge, ear canal inflammation), chronic suppurative otitis media (persistent purulent discharge through a non-healing perforation, associated with cholesteatoma), cerebrospinal fluid otorrhea (clear, watery, β -2 transferrin positive, indicates skull base fracture or surgical complication), and foreign body. Otorrhea with pain, fever, and mastoid tenderness raises concern for acute mastoiditis. Management: topical antibiotic drops (ciprofloxacin—first-line, avoids ototoxicity of aminoglycosides), aural toilet (microsuction), treatment of underlying cause; for CSF otorrhea, neurosurgical repair is required.

Otosclerosis

– An abnormal bony growth in the middle ear that causes hearing loss.

Otoscopy

– A clinical examination technique used to visualize the external auditory canal and tympanic membrane, and it is an essential component of the evaluation of ear complaints including hearing loss, ear pain, otorrhea, and tinnitus. Pneumatic otoscopy involves the use of a specialized otoscope with a sealed speculum that allows insufflation of air into the ear canal while observing the tympanic membrane, assessing the mobility of the membrane in response to pressure changes, which is reduced in otitis media with effusion and absent in middle ear fluid. The normal tympanic membrane appears as a translucent, pearly gray, cone-shaped membrane with a visible light reflex in the anteroinferior quadrant, and the handle of the malleus and the umbo (the central point of the tympanic membrane) are visible landmarks. Abnormal findings include bulging, erythema, effusion, perforation, retraction, cholesteatoma, and tympanostomy tubes, and proper otoscopic technique requires pulling the pinna superiorly and posteriorly.

Outer ear

- The external part of the ear, as well as the external ear canal and the eardrum.

Ozaena

- A chronic condition characterized by atrophic rhinitis with crusting, foul-smelling nasal discharge (fotor), and a sensation of nasal obstruction despite a patent airway. Ozaena is caused by progressive atrophy of the nasal mucosa and underlying bone, often associated with *Klebsiella ozaenae* infection. It is more common in women, typically presents in middle age, and is more prevalent in tropical and subtropical regions. The nasal mucosa is pale, dry, and crusted; removal of crusts reveals a widely patent nasal cavity. Atrophy may extend to the olfactory epithelium, causing anosmia. Treatment: nasal saline irrigation, topical antibiotics (neomycin, gentamicin), oral antibiotics (ciprofloxacin, rifampicin for *Klebsiella*), oestrogen nasal spray (improves mucosal blood flow), and surgical closure of the nasal cavity (Young procedure) in severe refractory cases.

Paranasal Sinuses

- The paranasal sinuses are four pairs of air-filled, mucosa-lined cavities within the facial bones that communicate with the nasal cavity through narrow drainage pathways called ostia, and they serve multiple functions including lightening the weight of the skull, humidifying and warming inspired air, producing mucus for nasal clearance, contributing to vocal resonance, and providing structural support for the face. The maxillary sinuses, the largest of the paranasal sinuses, are located in the maxillary bones beneath the orbits and lateral to the nasal cavity, with their ostia opening into the middle meatus. The frontal sinuses, located in the frontal bone above the orbits, drain through the frontonasal duct into the middle meatus. The ethmoidal sinuses, consisting of multiple small air cells within the ethmoid bone between the orbits, are divided into anterior and posterior groups, with the anterior cells draining into the middle meatus and the posterior cells draining into the superior meatus. The sphenoid sinuses, located in the sphenoid bone posterior to the ethmoidal sinuses, drain into the sphenoethmoidal recess. Sinusitis occurs when the ostia become obstructed, preventing mucus drainage and creating a favorable environment for bacterial infection.

Parotitis

- Inflammation of the parotid gland. Acute parotitis: most commonly caused by mumps virus (paramyxovirus—epidemic parotitis, typically in unvaccinated children, bilateral in 70%, resolves spontaneously over 7–10 days). Suppurative (bacterial) parotitis: *Staphylococcus aureus* (most common), streptococci, anaerobes—occurs in dehydrated, post-surgical, or immunocompromised patients; presents with painful, erythematous swelling, purulent discharge from Stensen duct, fever, and leukocytosis; treated with IV antibiotics (flucloxacillin), hydration, sialagogues, and surgical drainage if abscess forms. Chronic parotitis: recurrent episodes due to duct obstruction (sialolithiasis), Sjögren syndrome, sarcoidosis, or IgG4-related disease. Diagnosis: clinical, ultrasound, sialography, MRI. Complications of bacterial parotitis: parotid abscess, facial nerve palsy, extension to the parapharyngeal space. Mumps parotitis is prevented by MMR vaccination (two doses).

Peritonsillar Abscess

- Peritonsillar abscess, also known as quinsy, is a collection of pus in the peritonsillar space between the tonsillar capsule and the superior pharyngeal constrictor muscle, typically developing as a complication of acute tonsillitis, and it is the most common deep neck space infection. The condition presents with severe, unilateral sore throat, odynophagia, dysphagia, trismus (difficulty opening the mouth due to spasm of the pterygoid muscles), hot potato voice (muffled speech), and deviation of the uvula toward the contralateral side, with erythematous, bulging of the soft palate and tonsillar pillar on the affected side. The most common causative organisms.

Pharyngitis

- Inflammation of the pharynx, the most common presentation of which is sore throat (odynophagia) with or without fever, and it is classified as bacterial or viral based on the causative organism, with viral pharyngitis accounting for approximately eighty to ninety percent of cases and bacterial pharyngitis (primarily Group A *Streptococcus*) accounting for approximately ten to twenty percent. Viral pharyngitis typically presents with a gradual onset of sore throat, cough, rhinorrhea, conjunctivitis, and hoarseness, and is caused by adenoviruses, rhi-

noviruses, coronaviruses, influenza, and.

Pleomorphic Adenoma

– Pleomorphic adenoma, also known as benign mixed tumor, is the most common benign salivary gland tumor, accounting for approximately sixty to seventy percent of all parotid gland neoplasms and a significant proportion of minor salivary gland tumors, and it is characterized by a diverse histological appearance with a mixture of epithelial, myoepithelial, and mesenchymal-like components in a variable stroma that may be mucoid, chondroid, or osseous. The tumor typically presents as a slow-growing, painless, firm, mobile mass in the parotid gland, most commonly in the superficial lobe, and it is more common in women (female-to-male ratio of approximately 2:1), with a peak incidence in the fourth to.

Pneumatic Otoscopy

– A diagnostic technique that combines visualization of the tympanic membrane with assessment of its mobility in response to positive and negative air pressure changes, providing information about the presence of middle ear fluid and the condition of the Eustachian tube. The procedure uses a pneumatic otoscope with a soft rubber bulb that generates positive and negative pressure, and the examiner observes the tympanic membrane for movement in response to these pressure changes. Normal tympanic membranes move freely with pressure changes, while middle ear effusion reduces or eliminates mobility, and the degree of reduced mobility correlates with the presence and volume of middle ear fluid. Pneumatic otoscopy is recommended as the primary diagnostic tool for acute otitis media in children, as it provides both structural and functional information about the middle ear, and it can detect middle ear effusion with a sensitivity of approximately ninety percent when performed by experienced examiners. The technique is inexpensive, non-invasive, and does not require sedation, making it ideal for use in young children.

Prosthesis

– An artificial device such as a hearing aid, artificial joint, or dentures that substitutes for a missing body part.

Pure Tone Audiometry

– The standard behavioral test used to measure hearing sensitivity across the frequency range impor-

tant for speech perception, typically from 250 to 8000 Hertz, by determining the lowest intensity level at which a pure tone can be detected approximately fifty percent of the time (the hearing threshold). Air conduction thresholds are measured using headphones or insert earphones, and bone conduction thresholds are measured using a bone vibrator placed on the mastoid process or forehead, and the comparison between air and bone conduction thresholds distinguishes between conductive, sensorineural, and mixed hearing loss. The audiogram plots the hearing thresholds in decibels hearing level (dB HL) against frequency in Hertz (Hz), with normal hearing defined as thresholds of 25 dB HL or better. The degree of hearing loss is classified as normal (0-25 dB HL), mild (26-40 dB HL), moderate (41-55 dB HL), moderately severe (56-70 dB HL), severe (71-90 dB HL), and profound (greater than 90 dB HL). Pure tone audiometry is the foundation of audiometric assessment and is essential for diagnosing hearing loss, determining its type and degree, and guiding treatment decisions.

Quinsy

– See Peritonsillar Abscess.

Retropharyngeal Abscess

– A collection of pus in the retropharyngeal space, located between the posterior pharyngeal wall and the prevertebral fascia. Most common in children aged 2-4 years, arising from suppurative lymphadenitis of the retropharyngeal lymph nodes that drain the nasopharynx, adenoids, and sinuses. In adults, it typically results from direct extension of pharyngeal infection (tonsillitis, dental infection) or from penetrating trauma (foreign body, instrumentation). Presents with fever, sore throat, neck pain, dysphagia, drooling, cervical lymphadenopathy, and neck stiffness. In children, the classic presentation includes refusal to feed, stridor, or respiratory distress. Diagnosis is confirmed by contrast-enhanced CT of the neck showing a hypodense collection with rim enhancement in the retropharyngeal space. Lateral neck X-ray may show prevertebral soft tissue swelling (greater than 7 mm at C2 or greater than 14 mm at C6). Treatment: airway management, IV antibiotics (e.g., clindamycin or ampicillin-sulbactam), and surgical drainage via transoral incision or transcervical approach for larger abscesses or those not

responding to antibiotics. Complications include airway obstruction, mediastinitis, jugular vein thrombosis, and sepsis.

Rhinitis

– Inflammation of the nasal mucosa. Allergic rhinitis: IgE-mediated response to environmental allergens (pollen, dust mites, pet dander), presenting with sneezing, rhinorrhea, nasal congestion, and pruritus. Non-allergic rhinitis: vasomotor rhinitis (triggers: irritants, temperature changes, strong odors), infectious (viral URI), medication-induced (rhinitis medicamentosa from topical decongestant overuse), hormonal (pregnancy, hypothyroidism), and gustatory rhinitis (food-induced). Diagnosis: clinical, allergy testing. Treatment: intranasal corticosteroids (first-line), oral antihistamines, decongestants, saline irrigation, allergen immunotherapy for allergic rhinitis.

Rhinoplasty

– A surgical procedure to alter the shape, size, or function of the nose, performed for cosmetic reasons (aesthetic rhinoplasty—improving nasal appearance) or functional reasons (functional rhinoplasty—improving nasal airflow by correcting internal/external nasal valve collapse, deviated septum, or turbinate hypertrophy). Approaches: open rhinoplasty (transcolumellar incision—better exposure, preferred for complex cases) and closed (endonasal) rhinoplasty (incisions within the nostril—no external scar, less swelling). Components: hump reduction (dorsal bony and cartilaginous hump), osteotomies (narrowing the nasal bones), tip rhinoplasty (refinement of the nasal tip—cephalic trim, tip sutures, columellar strut graft), alar base reduction, and septoplasty (correction of septal deviation). Grafts: autologous cartilage (septal, auricular, costal) for structural support or contour augmentation. Post-operative: swelling and bruising (peaks at 48 hours, resolves over 1–2 weeks), nasal splint for 1 week, avoidance of glasses and strenuous activity for 4–6 weeks. Complications: bleeding, infection, nasal obstruction, asymmetry, saddle nose deformity (over-resection of dorsum), and need for revision (5–15%).

Rinne Test

– The Rinne test is a screening test that compares air conduction and bone conduction hearing using

a vibrating tuning fork (typically 512 Hz) to help differentiate between conductive and sensorineural hearing loss. The test is performed by first placing the vibrating tuning fork on the mastoid process to assess bone conduction, asking the patient to indicate when the sound is no longer heard, and then immediately holding the tuning fork adjacent to the external auditory canal to assess air conduction, asking the patient to indicate whether the sound is still audible. A positive Rinne test (normal result) occurs when air conduction is heard longer than bone conduction, indicating normal middle ear function or sensorineural hearing loss. A negative.

Salivary Gland Tumors

– Most salivary tumors are benign (80% in parotid, 50% in submandibular, 50% in minor glands). Benign: pleomorphic adenoma (most common overall), Warthin tumor (bilateral in 10%, smokers). Malignant: mucoepidermoid carcinoma (most common malignant), adenoid cystic carcinoma (perineural invasion), acinic cell carcinoma. Presents with painless, slow-growing mass. Malignant features: rapid growth, pain, facial nerve paralysis, skin fixation, and cervical lymphadenopathy. Diagnosis: fine needle aspiration (FNA), CT/MRI for staging. Treatment: superficial parotidectomy for benign; total parotidectomy with neck dissection for malignant, with postoperative radiation as needed.

Semicircular Canals

– The semicircular canals are three bony, fluid-filled, tube-like structures within the vestibular portion of the inner ear that detect rotational (angular) acceleration.

Sensorineural Hearing Loss

– Hearing loss from pathology of the cochlea or auditory (eighth cranial) nerve, characterized on pure-tone audiometry by elevated bone conduction thresholds and no air-bone gap. Causes are congenital (genetic syndromes, in utero infection) or acquired, with presbycusis most common, followed by noise-induced, ototoxic drugs, Meniere disease, and vestibular schwannoma. Management includes hearing aids, cochlear implantation, and corticosteroids for sudden loss.

Septal Hematoma

– Accumulation of blood between the perichondrium and the septal cartilage of the nose, typically fol-

lowing nasal trauma (nasal fracture). Presents with nasal obstruction, pain, and a bluish, boggy swelling of the nasal septum. An untreated septal hematoma causes avascular necrosis of the nasal cartilage (cartilage receives nutrition from perichondrium), leading to saddle nose deformity (septal perforation and collapse) within days. Diagnosis: nasal speculum exam. Treatment: immediate incision and drainage (small incision at the inferior aspect), packing to prevent re-accumulation, and antibiotics to prevent infection (septal abscess). Follow-up for re-accumulation.

Septoplasty

– A surgical procedure to straighten a deviated nasal septum, relieving obstruction, improving sinus drainage, and correcting related epistaxis or sleep disturbance, most often through an endonasal approach. It reshapes rather than resects the cartilaginous and bony septum while preserving support to avoid saddle nose deformity. Indications include symptomatic septal deviation refractory to medical therapy and access for transseptal surgery.

Sialolithiasis

– Sialolithiasis, commonly known as salivary stones, is the formation of calcified concretions within the salivary gland ducts or parenchyma, most commonly affecting the submandibular gland (approximately eighty percent of cases) due to the long, dependent course of the Wharton duct, the alkaline pH of submandibular saliva, and its higher mucin and calcium content, followed by the parotid gland (approximately ten percent) and the sublingual gland (approximately five percent). The stones are composed primarily of calcium phosphate and calcium carbonate, with an organic matrix of glycoproteins and bacteria, and they range in size from a few millimeters to several centimeters. Patients typically present with intermittent, recurrent episodes of glandular swelling and pain that worsen during meals (when salivary flow is stimulated), and the stone may be palpable in the floor of the mouth (submandibular stones) or intraorally. Diagnosis is confirmed by plain radiography (submandibular stones are radiopaque in approximately eighty percent), ultrasound, or CT imaging. Treatment depends on stone size and location, with small stones managed with sialagogues and hydration, and larger or impacted stones managed with sialendoscopy, lithotripsy, or

surgical removal.

Sialorrhoea

– See Drooling / Excessive Salivation.

Sinusitis

– Inflammation of the paranasal sinus mucosa. Acute sinusitis: viral (most common, resolves in <10 days) or bacterial (symptoms >10 days, double worsening, or severe: *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*). Chronic sinusitis: symptoms >12 weeks with radiographic evidence. Presents with nasal congestion, purulent rhinorrhea, facial pain/pressure, headache, and hyposmia. Diagnosis: clinical, CT sinus for chronic/recurrent. Treatment: analgesics, saline irrigation, intranasal corticosteroids; antibiotics for acute bacterial. Endoscopic sinus surgery for refractory chronic sinusitis.

Sinusitis and Sinus Problems

– Sinus problems refer to conditions affecting the paranasal sinuses, which are air-filled cavities in the skull that can become inflamed or infected. Acute sinusitis typically follows a viral upper respiratory infection and causes facial pain, nasal congestion, and headache, while chronic sinusitis persists for weeks or longer and may involve nasal polyps or allergic components. Treatment ranges from saline rinses and decongestants to intranasal corticosteroids, antibiotics for bacterial infection, and in refractory cases, endoscopic sinus surgery.

Sore Throat

– Pain, scratchiness, or irritation of the throat, most often caused by pharyngitis, typically viral but also bacterial, allergic, irritant, reflux, voice strain, traumatic, or neoplastic. Group A streptococcal pharyngitis is the important treatable bacterial cause, targeted by Centor criteria and confirmed by rapid antigen testing or culture. Red flags include severe pain, drooling, dysphagia, neck mass, and persistent hoarseness.

Speech Discrimination

– Speech discrimination testing, also known as word recognition scoring, measures the ability to understand speech at a comfortable listening level, and it is an important component of the audiometric evaluation that provides information about cochlear and neural function beyond what pure tone audiometry alone can reveal. The test typically uses a standardized list of phonetically balanced monosyllabic

words presented at a suprathreshold level (usually 40 dB above the speech recognition threshold), and the patient repeats the words, with the percentage of words correctly identified representing the speech discrimination score. Normal speech discrimination scores range from ninety to one hundred percent, while reduced scores indicate cochlear pathology (particularly in patients with high-tone sensorineural hearing loss) or retrocochlear pathology (as in acoustic neuroma, where scores may be disproportionately).

Sphenoidal Sinus

– The sphenoid sinuses are paired, air-filled cavities located within the body of the sphenoid bone, the most posterior of the paranasal sinuses, situated deep within the skull at the center of the cranial base, and they are in close proximity to critical neurovascular structures including the optic nerves, the internal carotid arteries, the cavernous sinuses, the pituitary gland, and the brainstem. The sphenoid sinuses vary considerably in size and pneumatization among individuals, and they drain through the sphenothmoidal recess located above and posterior to the superior turbinate into the superior meatus.

Stapedectomy

– A microsurgical procedure performed to treat otosclerosis, a condition characterized by abnormal bone remodeling in the otic capsule that fixes the stapes footplate in the oval window, preventing its normal vibratory movement and causing progressive conductive hearing loss. The procedure involves creating a small opening in the tympanic membrane, elevating the tympanomeatal flap to visualize the middle ear, identifying the fixed stapes, and either removing the entire stapes footplate (stapedectomy) or creating a small fenestration in the footplate (stapedotomy) and inserting a prosthetic device (typically a titanium or fluoroplastic piston) that connects the incus to the oval window, bypassing the fixed stapes and restoring the ossicular chain's ability to transmit sound vibrations. The procedure is performed under local or general anesthesia, and the success rate for hearing improvement is approximately ninety to ninety-five percent, with closure of the air-bone gap to within 10 decibels in most patients. Complications include sensorineural hearing loss (from perilymph leak or inner ear trauma),

vertigo, taste disturbance, and tympanic membrane perforation.

Stapes

– The stapes, commonly known as the stirrup, is the smallest bone in the human body and the most medially positioned ossicle in the middle ear, articulating with the incus at the incudostapedial joint and transmitting sound vibrations to the inner ear through its footplate, which is attached to the oval window by the annular ligament. The stapes consists of a head, two crura (anterior and posterior), and a footplate approximately 3.2 millimeters by 1.4 millimeters, and it acts as a piston, converting the lever action of the malleus and incus into a piston-like movement that transmits sound energy into the fluid-filled inner ear. The stapedius.

Stomatitis

– Inflammation of the oral mucosa, presenting as erythema, ulceration, pain, and difficulty eating. Causes: infections (viral—herpes simplex (herpetic gingivostomatitis), Coxsackie (hand-foot-and-mouth disease), herpes zoster; bacterial—acute necrotising ulcerative gingivitis (Vincent angina); fungal—*Candida albicans* (oral thrush, common in immunocompromised, infants, denture wearers, after antibiotics/inhaled corticosteroids)), physical trauma (biting, burns, ill-fitting dentures), chemical irritation (aspirin burn, alcohol, smoking), aphthous ulcers (recurrent aphthous stomatitis—minor, major, herpetiform; associated with stress, trauma, nutritional deficiencies, Crohn disease, Behçet disease), autoimmune (pemphigus vulgaris, mucous membrane pemphigoid, lichen planus), drug-induced (methotrexate, NSAIDs, chemotherapy—mucositis), and nutritional deficiencies (B vitamins, iron, folate, zinc). Diagnosis: clinical, swab for culture/PCR, patch testing, and biopsy. Treatment: treat underlying cause; symptomatic—topical analgesics (lidocaine), antiseptic mouthwashes (chlorhexidine), corticosteroids (topical or systemic), antifungals for *Candida*, antivirals for herpes.

Sublingual Gland

– The sublingual glands are the smallest of the major salivary glands, located in the floor of the mouth beneath the tongue, and they produce primarily mucous saliva that is delivered into the oral cavity through multiple small ducts (ducts of Rivinus) that

open along the sublingual fold, and through the major sublingual duct (Bartholin duct), which joins the Wharton duct of the submandibular gland. The sublingual glands are rarely affected by sialolithiasis due to the short, wide ducts, and they are more commonly involved in autoimmune conditions including.

Thyroid Cartilage

– The thyroid cartilage is the largest of the laryngeal cartilages, consisting of two laminae that fuse anteriorly at an angle of approximately ninety degrees in males and one hundred twenty degrees in females, creating the laryngeal prominence (commonly known as the Adam's apple), which is more prominent in males due to the acute angle and the effects of testosterone during puberty. The thyroid cartilage forms the anterior and lateral walls of the larynx and provides structural support and protection for the vocal cords and the intrinsic laryngeal muscles. The superior and inferior horns of the thyroid cartilage articulate with the hyoid bone and the cricoid cartilage, respectively, and the cricothyroid muscle, the only intrinsic laryngeal muscle innervated by the external branch of the superior laryngeal nerve, attaches to the thyroid cartilage and acts to tense the vocal cords, raising the pitch of the voice. The thyroid cartilage is prone to fracture in blunt neck trauma, and thyroid cartilage fractures can cause airway compromise, subcutaneous emphysema, and hoarseness.

Thyroid Nodule

– A thyroid nodule is a discrete lesion within the thyroid gland that is palpably or radiographically distinct from the surrounding thyroid parenchyma, and it is a common clinical finding, present in approximately five percent of palpable neck examinations and up to fifty percent of individuals on ultrasound imaging, with the vast majority being benign. The evaluation of thyroid nodules focuses on identifying the small minority that represent thyroid carcinoma, and it involves ultrasound assessment of nodule characteristics (size, composition, echogenicity, margins, shape, and calcifications), fine-needle aspiration biopsy of suspicious nodules, and thyroid function testing. The Thyroid Imaging Reporting.

Tinnitus

– The perception of sound in the absence of an ex-

ternal acoustic stimulus, commonly described as ringing, buzzing, hissing, or roaring in the ears, and it affects approximately fifteen to twenty percent of the global population, with a significant impact on quality of life in severe cases. Subjective tinnitus, the most common form, is perceived only by the patient and is most commonly associated with sensorineural hearing loss, noise ex-

TI-RADS

– The Thyroid Imaging Reporting and Data System is a standardized ultrasound-based risk stratification system developed by the American College of Radiology to evaluate thyroid nodules and guide recommendations for fine-needle aspiration biopsy, reducing unnecessary biopsies of benignappearing nodules while ensuring adequate sampling of suspicious nodules. The TI-RADS scoring system assigns points based on five ultrasound characteristics: composition (solid, mixed cystic-solid, predominantly cystic, or spongiform), echogenicity (anechoic, hypoechoic, isoechoic, or markedly hypoechoic), shape (wider-than-tall or taller-thanwide), margin (smooth, ill-defined, lobulated, or extra-thyroidal extension), and echogenic foci (none, macrocalcifications, rim calcifications, or microcalcifications). The total TI-RADS score determines the category from TR1 (benign, no biopsy needed) to TR5 (highly suspicious, biopsy recommended for nodules one centimeter or larger), and the system provides evidence-based size thresholds for biopsy recommendations at each TI-RADS level, optimizing the balance between cancer detection and unnecessary procedures.

Tonsillectomy

– The surgical removal of the palatine tonsils, and it is one of the most commonly performed surgical procedures in children, traditionally indicated for recurrent acute tonsillitis (seven episodes in one year, five per year for two years, or three per year for three years), chronic tonsillitis, and obstructive sleep apnea caused by tonsillar hypertrophy. The procedure is performed under general anesthesia, and the most commonly used techniques include cold dissection with electrocautery, bipolar diathermy, intracapsular tonsillectomy (partial tonsillectomy using a microdebrider or coblation), and total tonsillectomy. The most common complications include postoperative hemorrhage (the most significant complication,

occurring in approximately two to four percent of cases), dehydration from pain-related reduced oral intake, and velopharyngeal insufficiency. Postoperative pain is typically moderate to severe and lasts seven to ten days, and patients should avoid aspirin and non-steroidal anti-inflammatory drugs due to the increased risk of bleeding. The intracapsular technique preserves a thin rim of tonsillar tissue, reducing postoperative pain and hemorrhage rates, though with a small risk of tonsillar regrowth.

Tonsillitis

- Inflammation of the tonsils, most commonly the palatine tonsils, which are lymphoid tissue structures located in the oropharynx between the palatoglossal and palatopharyngeal.

Turbinates

- The nasal turbinates, also known as conchae, are three pairs of scroll-like bony projections on the lateral wall of the nasal cavity that are covered by a highly vascularized respiratory mucosa, and they function to increase the surface area available for air conditioning, create turbulent airflow for optimal filtration and warming of inspired air, and regulate nasal airflow through alternating congestion and decongestion of the venous sinusoids within the mucosa (nasal cycle). The inferior turbinate is the largest and is independently mobile, while the middle and superior turbinates are parts of the ethmoid bone. The inferior turbinate mucosa contains large venous sinusoids that can rapidly engorge with blood, causing nasal congestion, and its size fluctuates throughout the day in response to autonomic nervous system input, environmental temperature, allergens, and infection. Chronic enlargement of the inferior turbinates, called turbinate hypertrophy, is a common cause of nasal obstruction and may require medical treatment with topical corticosteroids and antihistamines, or surgical reduction procedures including turbinate cauterization, submucosal resection, or outfracture.

Turbinates Hypertrophy

- Chronic enlargement of the nasal turbinates, most commonly the inferior turbinates, resulting in nasal airway obstruction, which can be caused by chronic inflammation from allergic rhinitis, non-allergic rhinitis, chronic sinusitis, hormonal changes, or vasomotor dysfunction. The inferior turbinates contain

large venous sinusoids that can rapidly engorge with blood, and chronic stimulation from allergens, irritants, or infection leads to sustained engorgement and eventual hypertrophy of both the mucosal and bony components of the turbinate. The condition contributes to nasal obstruction, mouth breathing, snoring, and impaired quality of life, and it may be difficult to distinguish from the reversible congestion of acute rhinitis. Medical management includes intranasal corticosteroids, intranasal antihistamines, and avoidance of triggers, while surgical reduction may be considered for refractory cases and includes turbinate outfracture, submucosal resection (using radiofrequency, electrocautery, or microdebrider), and partial turbinectomy, with care taken to avoid excessive turbinate resection which can cause empty nose syndrome.

Tympanic membrane

- The tympanic membrane (eardrum) is a thin, cone-shaped, translucent membrane at the medial end of the external auditory canal that separates the external ear from the middle ear and serves as the interface for sound transmission by converting acoustic energy into mechanical vibrations of the ossicular chain. It is composed of three layers: an outer squamous epithelial layer continuous with the skin of the ear canal, a middle fibrous layer (lamina propria) containing radial and circular collagen fibers that provide structural integrity, and an inner mucosal layer continuous with the lining of the middle ear cavity. The pars tensa constitutes the majority of the membrane and contains a fibrous layer, while the smaller pars flaccida (Shrapnell membrane) lacks a fibrous layer and is more susceptible to retraction pocket formation and cholesteatoma development. Landmarks visible on otoscopy include the handle of the malleus (manubrium), the umbo at its tip, the cone of light reflex in the anteroinferior quadrant, and the pars flaccida superiorly. Perforation of the tympanic membrane may result from trauma, infection, or barotrauma and typically heals spontaneously within weeks, though persistent perforations may require tympanoplasty.

Tympanometry

- An objective, quantitative test that measures the compliance (mobility) of the tympanic membrane and the pressure within the middle ear as a function

of air pressure in the external auditory canal, providing information about middle ear function that supplements otoscopic examination. The test uses a tympanometer that delivers a probe tone (typically 226 Hz) into the sealed ear canal while varying the air pressure from positive to negative, measuring the reflected sound energy at each pressure level to generate a tympanogram.

Uvula

- A small, fleshy flap of tissue that hangs from the back of the throat over the root of the tongue.

Vertigo

- A false sensation of rotational or linear movement of the self or the environment, and it is a symptom rather than a disease, requiring differentiation from dizziness, disequilibrium, and presyncope. Peripheral vertigo, caused by dysfunction of the vestibular apparatus or vestibular nerve, is typically characterized by episodic, rotational vertigo that is severe, lasting seconds to hours, often with nausea and vomiting, and associated with nystagmus that is suppressed by visual fixation, hearing loss, and tinnitus. Central vertigo, caused by dysfunction.

Videostroboscopy

- A diagnostic technique used to evaluate the structure and function of the vocal cords by producing a slow-motion, composite image of vocal cord vibration using stroboscopic light flashes synchronized to the frequency of vocal cord vibration, allowing the assessment of vocal cord mucosal wave, amplitude, symmetry, phase closure, and.

Vocal Cord Nodules

- Vocal cord nodules, also known as singer's nodules or contact nodules, are bilateral, symmetric, benign epithelial thickenings that develop on the anterior third of the vocal cords at the junction of the membranous and cartilaginous portions, caused by chronic vocal abuse, misuse, or overuse that results in repeated mechanical trauma to the vocal cord mucosa. The nodules are composed of fibrosis, edema, and thickened epithelium in the superficial lamina propria, and they occur at the point of maximum vibration and contact stress on the vocal cords. Patients typically present with hoarseness, breathiness, and vocal fatigue, and the diagnosis is confirmed by laryngoscopy, which reveals bilateral, symmetric, sessile or pedunculated masses on the

vocal cords that may touch when the cords are adducted (kissing nodules). Treatment involves voice therapy with modification of vocal habits, avoidance of whispering and shouting, and hydration, and surgical removal is reserved for nodules that are refractory to voice therapy, are large enough to obstruct the glottis, or are suspected of harboring dysplasia.

Vocal Cord Paralysis

- Immobility of one or both vocal cords due to disruption of the recurrent laryngeal nerve (RLN). Unilateral vocal cord paralysis: hoarseness, breathy voice, aspiration, and ineffective cough. Causes: iatrogenic (thyroid, cardiac, spinal, thoracic surgery — most common), malignancy (lung, thyroid, esophageal, mediastinal), trauma, and idiopathic (10-20%). Bilateral vocal cord paralysis: stridor, dyspnea, airway obstruction, but the voice may be normal. Diagnosis: laryngoscopy, CT neck/chest to identify underlying cause, laryngeal EMG. Treatment: unilateral: voice therapy, vocal cord injection (temporary), medialization thyroplasty (permanent). Bilateral: tracheostomy, partial arytenoidectomy, or posterior cordotomy for airway.

Vocal Cord Paresis

- Partial paralysis or weakness of one or both vocal cords due to impaired function of the recurrent laryngeal nerve (RLN) or the vagus nerve. Unilateral paresis is more common and presents with hoarseness, breathy dysphonia, vocal fatigue, and sometimes aspiration. Causes include iatrogenic injury (thyroid, parathyroid, carotid, or thoracic surgery), neoplasms (lung, thyroid, esophageal), and idiopathic origin. Bilateral paresis presents with inspiratory stridor and dyspnea due to paramedian cord position, often requiring tracheostomy or cord lateralization. Diagnosis: laryngoscopy shows reduced or absent vocal cord movement on the affected side. Laryngeal electromyography can help differentiate neurogenic from mechanical causes. Management depends on severity: voice therapy for mild cases, medialization thyroplasty or injection laryngoplasty for glottic insufficiency, and arytenoid adduction for symptomatic unilateral paresis. Bilateral cases may require posterior cordotomy, arytenoidectomy, or tracheostomy.

Vocal Cord Polyp

– Vocal cord polyps are benign, unilateral, sessile or pedunculated lesions that arise from the vocal cord mucosa, typically as a result of a single traumatic vocal event such as shouting, screaming, or coughing, causing hemorrhage and edema in the superficial lamina propria (Reinke space). Unlike vocal cord nodules, which are bilateral and symmetric, polyps are typically unilateral and may be located anywhere along the vocal cord, though they are most common on the anterior third. The polyps may be translucent (edematous), hemorrhagic, or fibrotic, and they interfere with normal vocal cord vibration, causing hoarseness, breathiness, and a rough voice quality. Diagnosis is confirmed by laryngoscopy, which reveals a smooth, pedunculated or sessile mass protruding from the vocal cord. Treatment involves voice therapy for small polyps, surgical removal for larger polyps or those that are refractory to voice therapy, and avoidance of the vocal abuse that caused the initial trauma to prevent recurrence.

Vocal Cords

– The vocal cords, also known as vocal folds, are two pairs of horizontal folds of tissue within the.

Voice and Speech

– The products of complex coordinated activity of the respiratory, laryngeal, and articulatory systems. Voice (phonation) is produced by airflow from the lungs passing through the larynx causing vibration of the vocal cords (vocal folds); fundamental frequency (pitch) is determined by vocal cord length and tension, intensity (loudness) by subglottic air pressure, and quality by the pattern of vocal cord vibration. Speech (articulation) involves modification of the laryngeal sound by the pharynx, oral cavity, tongue, lips, teeth, and palate (resonance). Voice disorders (dysphonia): organic (vocal cord nodules, polyps, Reinke edema, laryngitis, laryngeal cancer, vocal cord paralysis/paresis) or functional (muscle tension dysphonia, psychogenic dysphonia, puberphonia). Speech disorders: dysarthria (neurological weakness/incoordination of articulators — stroke, Parkinson disease, ALS, cerebellar disease), apraxia of speech (motor planning deficit), and articulation disorders. Voice/speech assessment: laryngoscopy (direct or videostroboscopy) and acoustic analysis.

Weber Test

– The Weber test is a screening test for lateraliza-

tion of hearing that uses a vibrating tuning fork (typically 512 Hz) placed on the midline of the skull (vertex or forehead) to determine whether the sound is heard equally in both ears or louder in one ear, providing information about the type and side of hearing loss. In a patient with normal hearing, the sound is perceived equally in both ears or slightly louder in one ear due to normal asymmetry. In conductive hearing loss, the sound lateralizes to the affected ear because ambient noise is reduced on that side, enhancing the perception of bone-conducted sound. In sensorineural hearing loss, the sound lateralizes to the unaffected ear because the damaged cochlea is less sensitive to the bone-conducted sound.

Xerostomia (Dry Mouth)

– A subjective sensation of oral dryness resulting from reduced or absent saliva production (salivary gland hypofunction). Xerostomia affects approximately 20% of the general population, increasing with age and with the number of medications taken. Causes: medications (the most common cause, over 500 drugs cause xerostomia — anticholinergics, tricyclic antidepressants, SSRIs, antipsychotics, antihistamines, decongestants, antihypertensives, diuretics, opioids, and proton pump inhibitors), radiation therapy (head and neck cancer radiotherapy causes irreversible damage to salivary glands, dose-dependent, >30 Gy causes permanent hypofunction), systemic diseases (Sjogren syndrome, an autoimmune exocrinopathy affecting lacrimal and salivary glands; diabetes mellitus; HIV/AIDS; sarcoidosis; amyloidosis), and dehydration (poor fluid intake, vomiting, diarrhea, polyuria). Consequences: increased risk of dental caries (root caries, smooth surface caries), oral candidiasis (thrush), dysphagia (difficulty swallowing dry foods), dysgeusia (taste disturbance), oral mucosal discomfort and burning, halitosis, and difficulty wearing dentures. Diagnosis: sialometry (unstimulated whole salivary flow rate <0.1 mL/min is hyposalivation), minor salivary gland biopsy for suspected Sjogren syndrome. Treatment: symptomatic — frequent water sips, sugar-free chewing gum (stimulates residual salivary flow), artificial saliva substitutes (carboxymethylcellulose, mucin-based sprays, gels, and lozenges), and salivary stimulants (pilocarpine 5 mg tid, cevime-

line 30 mg tid — muscarinic agonists that stimulate residual salivary tissue, contraindicated in uncontrolled asthma, narrow-angle glaucoma, and iritis). Preventive: meticulous oral hygiene, regular fluoride application (high-fluoride toothpaste, fluoride varnish), chlorhexidine mouthwash for caries prevention, and antifungal therapy for oral candidiasis.

Chapter 11

Forensic Medicine & Medical Ethics

Adipocere (Grave Wax)

- Waxy, grayish-white substance formed postmortem in warm, moist, anaerobic environments (water, damp soil) by the hydrolysis and hydrogenation of body fat into free fatty acids; retards putrefaction and preserves anatomical details for months to years.

Admissibility

- The legal standard governing whether evidence may be received and weighed by a court. The Daubert standard requires expert scientific testimony to rest on testable methodology, peer review, a known error rate, and general acceptance, with the judge as gatekeeper; some state jurisdictions retain the older Frye standard. Improperly admitted evidence may constitute reversible error on appeal.

Air Embolism

- Presence of gas in the venous or arterial circulation, often fatal if massive. Causes: iatrogenic (central line insertion, surgery—especially neurosurgery in sitting position, dialysis, pressurized infusion), trauma (penetrating neck/chest wounds, diving), and procedures (abortion with irrigation, insufflation). Entry requires a vessel with pressure lower than atmospheric and a tract. Features: sudden cardiovascular collapse, cyanosis, mill-wheel murmur, or cutaneous marbling. Diagnosis: air in heart on CT or at autopsy (air aspiration test for right heart); findings significant in forensic evaluation of iatrogenic death.

Algor Mortis

- Post-mortem cooling of the body following death until it reaches ambient environmental temperature. Serves as one of the physical estimators of the post-mortem interval (time since death). Under standard conditions (20°C ambient temperature), the body cools at a rate of approximately 0.75–1.0°C (1.5°F)

per hour during the first 12 hours, and 0.5°C per hour thereafter. Influenced by ambient temperature, body habitus (obesity slows cooling), clothing, humidity, air movement, and immersion in water. Rectal temperature is recorded using a chemical thermometer.

Antemortem Injury

- Injury inflicted upon a body prior to death, characterized microscopically and macroscopically by physiological tissue responses including hemorrhage, blood clotting, inflammatory cell infiltration, tissue edema, and active healing reactions (differentiating it from postmortem artifact).

Asphyxia

- A condition of inadequate oxygenation due to impaired breathing or oxygen delivery, a common cause of death in forensic practice. Types: suffocation (airway obstruction by smothering—external, or choking—internal), strangulation (ligature, manual, or garroting—vascular/airway compression), hanging (self-suspension), drowning (aspiration of fluid), entrapment, and toxic asphyxia (carbon monoxide, cyanide—chemical interference with oxygen transport/use). General signs: cyanosis, petechiae (eyes, face), visceral congestion, edema, and fluidity of blood. Distinguishing cause requires careful scene examination and autopsy.

Autopsy

- A postmortem examination of a body to determine cause and manner of death, performed by a forensic pathologist (medical examiner/coroner) or, for hospital autopsies, a pathologist. Components: external examination (identification, injuries, scars, tattoos), internal examination (organ weights, findings), histology, toxicology, microbiology, and imaging. Forensic autopsies are conducted when death is sudden, unnatural, unexplained, or violent;

they document injuries, collect evidence (bullets, swabs), and issue a report addressing cause of death and manner (natural, accident, suicide, homicide, undetermined).

Autopsy (Medicolegal)

- Systematic external examination and surgical dissection of a deceased body performed under legal authority by a forensic pathologist to determine the Cause, Manner, and Mechanism of Death, document injuries, collect evidence, and assist judicial investigations.

Autopsy (Post-Mortem Examination)

- Specialized surgical procedure performed on a deceased body to determine the cause of death, mechanism of death, manner of death (natural, accidental, suicide, homicide, or undetermined), state of health prior to death, and to document injuries or disease processes. Types: Clinical Autopsy (hospital-based, requiring family consent, to study disease processes and audit medical care) and Forensic (Medico-Legal) Autopsy (ordered by a coroner, medical examiner, or magistrate under statutory authority, without requiring family consent, in cases of sudden, violent, suspicious, or unexplained death). Procedure involves external examination, full internal dissection of cranial, thoracic, and abdominal cavities, histopathology, toxicological sampling, and formal report generation.

Ballistics

- The science of the motion and behavior of projectiles (bullets, shot) and their effects on tissue. Forensic ballistics includes internal (within the firearm), external (in flight), and terminal (on target) ballistics. Firearm identification examines rifling marks (grooves/lands), firing pin impressions, and extractor/ejector marks to match bullets and cartridge cases to a specific weapon. Wound assessment (entry vs. exit, range—contact, close, intermediate, distant—and bullet path) informs reconstruction. Uses: gunshot wound interpretation, range estimation (powder stippling, soot), and weapon identification.

Battered Child Syndrome

- A pattern of repeated, non-accidental physical injury inflicted on a child by a caregiver, formally described by Kempe in 1962. Features include frac-

tures of differing ages, subdural and retinal hemorrhages, inconsistent histories, and delayed presentation; mandatory reporting is required in most jurisdictions. Forensic documentation with photographs, skeletal survey, and contemporaneous history is essential for protection and prosecution.

Beneficence and Non-Maleficence

- Core biomedical ethical principles guiding clinical practice and medical research. Beneficence requires healthcare providers to act in the best interest of the patient, taking positive steps to promote health, prevent harm, and relieve suffering. Non-Maleficence (expressed by the Latin phrase *primum non nocere*—"first, do no harm") obligates practitioners to avoid inflicting intentional harm, unnecessary pain, or undue risk on patients. Ethical dilemmas arise when balancing the potential benefits of a treatment against its inherent risks and side effects.

Bioethics

- Interdisciplinary study of the ethical, legal, philosophical, and social implications of advancements in medicine, biology, healthcare technology, and biotechnology. Key topics: autonomy, informed consent, end-of-life decision-making (euthanasia, advance directives, do-not-resuscitate orders), reproductive technologies (surrogacy, gene editing, IVF), organ transplantation ethics, allocation of scarce healthcare resources, genetic privacy, and clinical trial ethics.

Blood Spatter Analysis

- The forensic interpretation of bloodstain patterns to reconstruct events surrounding a violent incident. Types: passive (drops, pools, flows), transfer (contact patterns), and impact/expirated spatter. Spatter characteristics depend on droplet size, velocity (low—gravity, medium—blunt force, high—gunshot/explosion), angle of impact (elongated shapes), and surface. Analysis helps determine position of victim/assailant, number of blows or shots, movement, and events after injury. Strict protocol and documentation (photography, measurements) are required for court presentation.

Body Identification

- The process of establishing the identity of a deceased person, essential in forensic and mass-disaster contexts. Methods: visual recognition, personal effects, fingerprint comparison, dental records (dental

radiographs—best for single comparisons), DNA profiling (STR analysis, mitochondrial DNA for degraded samples), medical/surgical records (implants, scars, serial numbers), and serial-number records (pacemakers, prostheses). Anthropological analysis (skeletal features, age, sex, stature, ancestry) for decomposed or skeletal remains. Multiple methods combined provide certainty.

Bruise

– A contusion: localized hemorrhage into tissues due to blunt force trauma rupturing small blood vessels, with intact skin. Forensically significant for aging injuries: color changes (red/blue at 0-2 days, purple at 2-5 days, green at 5-7 days, yellow at 7-10 days, fading by 2-4 weeks) and pattern recognition (hand, belt, fingertip, bite) may indicate mechanism or abuse. Important variables: age, sex, site (loose skin bruising more readily), disease (bleeding disorders), and medications (anticoagulants). Not all bruises indicate inflicted injury; dating is approximate.

Bullet Track

– The path a projectile traverses through the body, defined by the entry wound, internal course (through organs, vessels, bones), and exit wound (or retained bullet). Forensic interpretation uses the track to determine trajectory (angle and direction of fire), shooter position, and sequence of events; multiple bullets require individual tracking. Ricochet and fragmentation alter tracks. Autopsy documentation includes measurement, X-ray/CT localization, and correlation with clothing damage and scene findings. Track analysis helps reconstruct shooting incidents and validate or refute witness accounts.

Blunt Force Trauma

– Injury produced when a blunt object strikes the body, or the body strikes a blunt surface, without a sharp edge penetrating the skin. Patterns include abrasions, contusions, lacerations with tissue bridging, and fractures; patterned injuries may reproduce the impacting object. Severity ranges from superficial damage to lethal organ rupture or intracranial hemorrhage. Mechanism, force, and direction inform manner-of-death determination.

Cadaveric Spasm

– Rare form of instantaneous post-mortem stiffening of a specific group of voluntary muscles at the exact moment of death, without an intervening period

of muscle relaxation. Unlike normal rigor mortis (which develops 2–4 hours post-mortem), cadaveric spasm occurs immediately, trapping objects held in the hand at death (e.g., a weapon in suicide, grass/twigs held by a drowning victim). Pathophysiology: severe physical or emotional stress combined with extreme exhaustion immediately preceding death, leading to rapid ATP depletion. Highly significant in forensic investigations for establishing suicide or struggle.

Capacity and Competence

– Decision-making capacity is a clinical evaluation performed by a physician to determine whether a patient understands the nature, consequences, risks, and alternatives of a specific proposed medical decision at a given time. Competence is a formal legal determination made by a judge regarding an individual's overall legal ability to manage their affairs or make decisions. A patient with capacity has the legal and moral right to grant or refuse consent for medical procedures, even if that refusal leads to harm or death.

Carbon Monoxide Poisoning

– Toxicity from inhalation of carbon monoxide (CO), a colorless, odorless gas binding hemoglobin 200–300 times more avidly than oxygen, forming carboxyhemoglobin (COHb) and reducing oxygen delivery. Sources: fires, faulty heaters, engine exhaust, suicide by car exhaust. Features: headache, nausea, cherry-red skin/lips (later), and loss of consciousness; severe exposure fatal. Diagnosis: COHb level (postmortem blood), classical pink lividity, and cherry-pink hypostasis. Forensic relevance: accidental vs. suicidal exposure; house-fire deaths often have significant COHb. Treatment (antemortem): 100% oxygen or hyperbaric oxygen.

Cause of Death

– The specific disease, injury, or toxic agent responsible for initiating the lethal physiological sequence leading directly to death (e.g., Gunshot wound to the head, Acute myocardial infarction).

Chain of Custody

– Meticulous paper trail and chronological documentation tracking the seizure, custody, control, transfer, analysis, and disposition of physical and electronic evidence in medico-legal investigations (e.g., blood samples for toxicology, bullets, sexual

assault kits, biological fluids). Essential in forensic science to demonstrate that evidence presented in a court of law is authentic, uncontaminated, and has remained unaltered since collection. Any breach in the chain of custody can render evidence inadmissible.

Concealed Pregnancy

- Pregnancy that is hidden or not recognized until delivery, often by denial (psychogenic) or deliberate concealment; a medicolegal concept relevant to infanticide. Forensic issues: determination of pregnancy (autopsy of fetus, hyoid, lungs), whether the infant was born alive (hydrostatic test of lungs, aeration) or stillborn, viability, and cause of death. Distinguishing live birth from stillbirth and establishing cause of infant death (e.g., suffocation, neglect) are central. Context: concealment of birth is a separate statutory offense in some jurisdictions.

Confidentiality

- The ethical and legal duty of healthcare professionals to protect patient information from unauthorized disclosure. Founded on the principle of respect for patient autonomy and trust, confidentiality is a core requirement of medical ethics (GMC guidelines) and law (GDPR, Data Protection Act, Caldicott principles). Information should only be shared with the patient's explicit consent, or when required by law (public health reporting, court order), or when necessary to protect the patient or others from serious harm (safeguarding, GMC duty of candor). Breach of confidentiality can result in disciplinary action, professional sanctions, and legal liability. Exceptions: serious communicable disease reporting (HIV, TB), child protection concerns, fitness to drive notification, and terrorism prevention. The duty of confidentiality continues after death (access to records of the deceased requires executor or next-of-kin consent).

Coroner

- An elected or appointed official responsible for investigating sudden, unexpected, violent, or suspicious deaths and determining identity, cause, and manner of death; the office historically required no medical training. Responsibilities include authorizing autopsies, issuing death certificates, holding inquests, and ordering death notifications. Many jurisdictions have replaced coroners with medical

examiner systems.

Corpse

- The dead body of a human being; the subject of medicolegal examination. Forensic assessment of a corpse includes identification, determination of death and time of death (rigor mortis, livor mortis, algor mortis, vitreous potassium, gastric emptying), external and internal examination, and collection of evidence. Corpses may be decomposed, mutilated, skeletalized, or otherwise altered, each requiring specialized techniques (entomology, anthropology, radiology). Preservation (cold storage, embalming) affects findings. The corpse is treated with dignity and handled under legal authority.

Criminal Abortion

- Abortion performed illegally, outside permitted legal indications and procedures (e.g., unsafe methods, unqualified practitioners, or non-medical settings), carrying high maternal risk. Methods historically included mechanical trauma, uterotonic drugs (oxytocin, prostaglandins), intrauterine solutions, and instrumentation—causing sepsis, hemorrhage, uterine perforation, and air embolism. Forensic evaluation: evidence of intervention (uterine injury, foreign material, products in the genital tract), pregnancy testing (hCG), complications, and the sequence of events. Overlaps with maternal death investigation.

Cyanide Poisoning

- Toxicity from cyanide compounds (hydrogen cyanide, potassium/sodium cyanide) that inhibit cytochrome oxidase (complex IV), blocking oxidative phosphorylation and cellular respiration despite adequate oxygen—histotoxic hypoxia. Sources: smoke inhalation (fires—plastic/acrylic), ingestion (industrial, suicidal), occupational exposure. Features: rapid collapse, seizures, bitter almond odor, rapid breathing then apnea, bright red lividity and venous blood (due to high venous oxygen). Diagnosis: blood cyanide levels, lactic acidosis, elevated anion gap. Death within minutes to hours. Antidotes (antemortem): sodium nitrite/thiosulfate, hydroxocobalamin.

Decapitation

- Separation of the head from the body, seen in severe trauma (vehicle accidents, train injuries, explosions), industrial accidents, hanging with judicial execution, or homicide. Complete decapitation is almost al-

ways rapidly fatal due to exsanguination and brain ischemia. Forensically: pattern of tissue/vertebral damage helps determine mechanism (sharp blade vs. blunt force avulsion); wound edges, tool marks, and associated injuries indicate whether accidental, suicidal, or homicidal. Scene reconstruction and identification are key.

Decomposition

- Postmortem breakdown of the body through autolysis and putrefaction. It begins within 24 to 72 hours at ambient temperature, producing green ceal discoloration, venous marbling, gas distension, skin slippage, and purge fluid. The sequence of fresh, bloated, active, advanced decay, and skeletal stages estimates the postmortem interval but depends on temperature, humidity, insect activity, and scavenging.

Defense Mechanisms (Forensic)

- Physical evidence patterns on a body demonstrating active resistance against an assailant prior to incapacitation.

Defense Wounds

- Injuries sustained by a victim attempting to ward off an attack, typically found on the flexor surfaces of hands, palms, wrists, and forearms (incised/stab wounds from knives or contusions/abrasions from blunt force).

Defense Wounds (Inscribed)

- Patterned incised or lacerated trauma localized to upper extremities indicating active physical defense.

Diatom Test

- Forensic technique used to support the diagnosis of drowning; microscopic silica-shelled diatoms present in drowning water enter lungs, penetrate alveolar capillaries, and circulate to distant closed organs (femur bone marrow, brain) only if active circulation was present at time of submersion.

Domestic Violence

- A pattern of coercive control and physical, sexual, psychological, or economic abuse by one intimate partner or household member against another. Forensic evaluation documents patterned injuries, defensive wounds, strangulation signs, burns, and injuries of differing ages. Providers have screening, safeguarding, and reporting obligations, and documentation records findings factually without attribution. Intimate partner homicide frequently

follows a documented escalation pattern.

Drowning (Dry/Wet Signs)

- Cause of death resulting from submersion or immersion in liquid causing primary respiratory impairment. Wet Drowning (85–90%): fluid enters the lungs, disrupting surfactant, causing alveolar collapse, ventilation-perfusion mismatch, hypoxia, cardiac arrest, and characteristic voluminous frothy foam emerging from the mouth and nostrils (Paltauf's foam). Dry Drowning (10–15%): severe laryngospasm triggered by initial water contact blocks fluid from entering the lungs, causing death by asphyxiation. Post-mortem signs: washerwoman skin (wrinkling of skin on palms and soles), cadaveric spasm holding debris, petechial hemorrhages in temporal bones (Wydler's sign), and water in the stomach and sphenoid sinus.

Drug Testing

- Laboratory analysis of biological specimens to detect drugs, metabolites, or poisons, used in clinical, workplace, sports, and forensic contexts. Specimens include blood, urine, oral fluid, hair, and postmortem tissues. The workflow is immunoassay screening followed by confirmatory GC-MS or LC-MS/MS, with strict chain of custody for forensic admissibility. Interpretation must account for pharmacokinetics, tolerance, and postmortem redistribution.

Entrance Wound

- A skin defect created where a projectile enters the body, distinguished from an exit wound by smaller size, rounded shape, and abraded inward margin. Contact wounds show a muzzle imprint and soot; close-range wounds show soot and powder tattooing; intermediate-range wounds show stippling; distant wounds show a clean abrasion ring. Caliber cannot be reliably estimated from the wound.

Euthanasia

- The deliberate act of ending a person's life to relieve suffering, typically performed by a physician. Active euthanasia involves directly administering a lethal substance (e.g., barbiturate overdose followed by neuromuscular blockade) at the patient's explicit request. Voluntary euthanasia is performed with the patient's informed consent. Physician-assisted suicide (PAS) involves the physician prescribing a lethal dose of medication that

the patient self-administers. Euthanasia is legal in a growing number of countries and jurisdictions under strict regulatory conditions (Belgium, Netherlands, Luxembourg, Canada, Colombia, Spain, New Zealand, and several Australian states, as well as PAS in Switzerland, Germany, Austria, and several US states). It is distinct from palliative sedation (using medication to relieve refractory suffering at the end of life, not intended to hasten death) and withdrawal of life-sustaining treatment (allowing natural death).

Euthanasia and Assisted Dying

– Ethical and legal concepts regarding intentional termination of life to relieve intractable pain and suffering. Active Euthanasia: deliberate administration of a lethal agent (e.g., lethal dose of barbiturates) by a physician to terminate a patient's life upon their explicit request. Passive Euthanasia: withdrawal or withholding of life-sustaining treatment (e.g., mechanical ventilation, artificial nutrition), allowing natural death to occur. Physician-Assisted Suicide (Assisted Dying): a physician prescribes a lethal dose of medication that the patient self-administers. Legal status varies widely by international jurisdiction.

Exhumation

– The lawful disinterment and removal of a buried body or remains for re-examination, re-testing, or identification. Indications: new evidence, suspicion of poisoning or foul play, DNA testing, paternity/maternity testing, exhumation of a wrongly buried body, or repatriation. Procedures require legal authorization (court order); careful recording of grave location, coffin condition, and body preservation. Autopsy of exhumed bodies can detect poisoning, injuries, or medical errors even years after burial (formalin fixation, embalming affect testing).

Exit Wound

– A skin defect produced where a projectile leaves the body, typically larger, irregular, and stellate, with everted edges, no abrasion ring or soot. Size depends on deformation, yaw, and fragmentation; small non-deformed bullets may produce shored exits, and an exit may be absent if the projectile is retained. Combined with the entrance wound, it allows trajectory reconstruction.

Expert Testimony

– Opinion evidence given by a witness qualified by knowledge, skill, experience, training, or education, admissible when it assists the trier of fact. Forensic physicians, pathologists, and toxicologists testify on cause and manner of death, injury, and toxicology, with opinions resting on reliable methods and adequate data. The role is educative and objective, distinguishing fact from opinion and disclosing limitations.

Fingerprint

– Friction-ridge skin pattern on fingers, palms, and soles that is individual, persistent, and classifiable; recording and comparing these patterns is a primary method of personal identification. Comparison of ridge minutiae between an unknown print and a known exemplar, with no unexplained differences, supports identification. Automated Fingerprint Identification Systems search large databases to generate candidate matches for examiner confirmation.

Forensic Anthropology

– The application of anthropological methods to identify human remains and analyze evidence, mainly skeletal material. Tasks: determination of biological profile (age at death, sex, ancestry, stature), distinguishing human from non-human bone, estimation of time since death (bone weathering, DNA), identifying trauma (perimortem vs. postmortem), and assisting mass-grave/disaster victim identification. Methods: osteometrics, radiography, histology, and stable isotope analysis. Works with forensic pathologists, odontologists, and entomologists in death investigation.

Forensic Entomology

– The study of insects and other arthropods in legal investigations, principally to estimate the postmortem interval (PMI) and to link suspects to scenes. Blow flies (*Calliphoridae*) and flesh flies colonize a corpse within minutes; the succession and developmental stages (eggs, larvae, pupae) are used to estimate time since death and season of death. Also: displacement of a body (different species in different habitats), presence of drugs in larvae, and neglect/myiasis in living victims. Collection must follow standardized protocols for legal admissibility.

Forensic Examination

– Structured medicolegal evaluation of a living or

deceased person, scene, or evidence to document findings relevant to a legal matter. Components include sexual assault examination with evidence collection, child abuse assessment, injury documentation, driving-impairment evaluation, and autopsy. Standardized protocols, contemporaneous charting, photography, and evidence kits with strict chain of custody preserve findings, conducted by trained forensic clinicians or pathologists.

Forensic Evidence

- Physical, biological, documentary, or testimonial material gathered, preserved, and analyzed to establish facts in a legal investigation. Categories include biological evidence (blood, semen, hair), trace evidence (fibers, glass, gunshot residue), pattern evidence (fingerprints, toolmarks, bloodstain patterns), and digital evidence. Reliability depends on validated methods, transparent error reporting, rigorous chain of custody, contamination control, and mitigation of contextual bias.

Forensic Medicine (Legal Medicine)

- Branch of medicine that applies medical, biological, and scientific knowledge to legal questions and the administration of justice. Sub-fields: Forensic Pathology (determination of cause and manner of death via autopsy), Clinical Forensic Medicine (evaluation of living victims of sexual assault, domestic abuse, child abuse, torture, and blood alcohol/drug testing in drivers), Forensic Toxicology (detection of drugs and poisons in legal contexts), Forensic Psychiatry (evaluation of criminal responsibility and competency to stand trial), and Forensic Odontology (identification via dental records).

Forensic Odontology

- The application of dental science in legal contexts. Main uses: human identification through comparison of dental records (restorations, radiographs, unique anatomy—antemortem vs. postmortem), age estimation (tooth eruption, development, root transparency), bite mark analysis (pattern matching to suspect dentition—now increasingly questioned scientifically), and postmortem dental examination. Dental identification is highly reliable and often the primary method for decomposed or burned remains. Expert testimony requires rigorous methodology.

Forensic Pathology

- A branch of pathology and medicine applying medical and pathological knowledge to legal questions, primarily determining cause and manner of death and documenting injuries. The forensic pathologist performs autopsies in sudden, unnatural, suspicious, or violent deaths, interprets injuries (blunt vs. sharp vs. gunshot vs. thermal), determines time of death, collects evidence, and provides expert testimony. Works with law enforcement, medical examiners, coroners, and specialists (anthropology, odontology, toxicology). Legal requirements govern performance and reporting.

Forensic Psychiatry

- The medical specialty at the interface of psychiatry and the law. Core activities: competency to stand trial, criminal responsibility/insanity defense (mental state at time of offense), dangerousness/risk assessment, civil commitment, testamentary capacity, and personal injury claims. Forensic psychiatrists provide expert opinions, write reports, and testify. Also involved in evaluation of sex offenders, malingering, and the psychiatric effects of trauma. Ethical framework emphasizes objectivity and boundaries, as the patient is often the court.

Forensic Radiography

- The use of imaging (X-ray, CT, MRI, ultrasound) in forensic and medico-legal investigation. Applications: identification (dental, skeletal features, medical devices with serial numbers), detection of injuries (fractures, projectiles, glass), age estimation, diagnosis of medical conditions, and examination of remains (radiology of decomposed/mummified bodies). Postmortem CT (PMCT) and virtual autopsy (virtopsy) complement conventional autopsy, providing non-invasive documentation, evidence preservation, and radiation-safe examination of potentially hazardous remains.

Forensic Toxicology

- The analysis of drugs, poisons, and their metabolites in biological specimens (blood, urine, vitreous humor, hair, tissues) to determine their role in intoxication, poisoning, or death. Uses: postmortem toxicology (cause of death—overdose, poisoning, lethal concentrations), human performance (driving under influence, drug-facilitated crime), and clinical/antemortem. Methods: immunoassay screen-

ing, GC-MS, LC-MS/MS, quantitative confirmation. Interpretation considers distribution, postmortem redistribution, metabolism, tolerance, and drug interactions. Central to forensic death investigation.

Gettler Test

- Historical quantitative chemical test for drowning, comparing chloride concentration in blood harvested from the left and right heart ventricles.

Gunshot Wound

- An injury produced by a projectile discharged from a firearm; forensic classification by range and direction. Entrance wound: rounded/ovoid defect with an abraded ring and often a zone of soot (close range) or stippling/tattooing (intermediate range); contact wounds show muzzle imprint. Exit wound: typically larger, irregular, with everted edges and no abrasion ring. Internal track depends on bullet velocity, yaw, fragmentation, and tissue. Shotgun wounds produce pellet spread patterns useful for range estimation. Interpretation determines range, angle, and manner.

Handwriting Analysis

- The scientific examination of handwriting (and documents) for the purpose of identifying the author or establishing authenticity. Compares individual features: letter formation, slant, spacing, pressure, line quality, and characteristic defects; questioned documents may involve signatures, alterations, erasures, or obliterations. Basis is the principle that no two people write identically and an individual's handwriting has consistency and variation. Limitations: skilled forgery, deliberate disguise, and examiner subjectivity; admissible with validated methodology and often complemented by other forensic evidence.

Hanging and Strangulation Signs

- Medico-legal findings resulting from mechanical constriction of the neck structures. Hanging: neck constriction by a ligature tightened by the weight of the victim's body. Ligature mark: pale, hard, parchment-like groove running obliquely upward toward the knot, usually situated above the thyroid cartilage. Strangulation: neck constriction by a ligature tightened by external force (ligature strangulation, horizontal mark around neck) or by hands/fingers (manual strangulation/throttling, showing fingernail abrasions and contusions). Internal autopsy findings: fracture of hyoid bone and thy-

roid cartilage cornua, intramuscular hemorrhages of neck muscles, mucosal petechiae, and Tardieu spots.

Hanging (Complete vs Incomplete)

- Form of violent asphyxial death produced by suspension of the body by a ligature around the neck. Complete Hanging: feet off ground, total body weight exerts pressure. Incomplete Hanging: part of body touches ground. Asphyxia results from occlusion of jugular veins (2 kg force) or carotid arteries (5 kg force).

Hesitation Wounds

- Multiple superficial, tentative parallel incised cuts surrounding a deeper primary fatal cut wound, classically observed in suicides involving sharp instruments (wrists, neck).

Incised Wound

- Clean-cut wound produced by a sharp-edged instrument (scalpel, knife, glass) that is longer on the skin surface than it is deep, featuring clean edges without tissue bridging or marginal abrasion.

Infanticide

- The killing of a child, in law typically defined as the killing of a newborn or infant (usually within the first year, or specifically within 24 hours of birth in some jurisdictions) by its mother while mentally disturbed by the effects of childbirth or lactation. Forensic evaluation: distinguishing live birth from stillbirth (lung aeration/hydrostatic tests, stomach gas), establishing viability, determining cause of death (suffocation, neglect, trauma), and assessing maternal mental state. Considered a separate, less-severely-punished offense in many jurisdictions.

Informed Consent

- Autonomous voluntary authorization given by a competent patient to undergo a specific medical intervention, procedure, or clinical trial. Core elements required for valid informed consent: (1) Disclosure of adequate information (nature of procedure, benefits, material risks, alternatives, and consequences of refusal), (2) Patient comprehension of the disclosed information, (3) Decision-making capacity of the patient, and (4) Voluntariness (freedom from coercion, manipulation, or undue influence). Exceptions: emergency situations where immediate intervention is required to save life or prevent severe harm and patient lacks capacity.

Injury Classification (Abrasion,

Laceration, Contusion, Incised Wounds)

- Forensic categorization of mechanical wounds. Abrasion: superficial friction injury affecting only the epidermis (e.g., scrape, graze, pattern abrasion). Contusion (Bruise): extravasation of blood into subcutaneous tissues caused by blunt trauma crushing blood vessels while leaving overlying skin intact; changes color over time (red/purple → blue/black → green → yellow). Laceration: tear or split of skin and deep tissues caused by blunt impact or crushing force, characterized by irregular, bruised edges, tissue bridging (intact nerves/vessels across the gap), and hair bulbs crushed. Incised Wound (Cut): sharp force injury caused by a blade, longer than it is deep, with clean-cut, unbruised margins and no tissue bridging.

Laceration (Forensic)

- Tear or disruption of tissue produced by blunt force trauma exceeding skin elasticity, featuring irregular bruised edges, tissue bridging (intact nerves, vessels across wound floor), and hair crushing.

Ligature

- Any cord, wire, rope, fabric, or flexible object used to constrict the neck, bind limbs, suspend the body, or inflict injury. The resulting pale groove-shaped abrasion may be horizontal with petechiae in homicidal strangulation, or oblique and upward in hanging. The mark may reproduce the implement's width and texture, and recovered ligatures are retained with knots intact for comparison.

Living Will (Advance Statements)

- A legally binding written document that specifies a person's preferences for medical treatment if they become unable to make decisions for themselves in the future (loss of capacity). Living wills are a type of advance directive (or advance decision/advance statement in the UK). They allow individuals to refuse specific treatments (e.g., cardiopulmonary resuscitation, mechanical ventilation, artificial nutrition and hydration, antibiotics) in specified future scenarios (e.g., terminal illness, permanent unconsciousness/vegetative state, severe dementia). Legal requirements: the document must be signed and witnessed, signed in the presence of a witness, and it must clearly state the treatments being refused and the circumstances in which the refusal applies.

In the UK: the Mental Capacity Act 2005 provides the legal framework for advance decisions. They are legally binding for refusing life-sustaining treatment if they are valid and applicable to the current circumstances. A valid advance decision can be overridden if the person has capacity and changes their mind when the situation arises. Related concepts: (1) Lasting Power of Attorney (LPA): allowed in the UK from 2007 for health and welfare decisions as well as decisions about property and financial affairs (in England and Wales), giving a named person legal authority to make decisions on behalf of the incapacitated patient. (2) Do Not Attempt Resuscitation (DNAR/DNACPR): a medical order signed by a senior clinician indicating that CPR should not be attempted in the event of cardiac arrest. (3) Physician Orders for Life-Sustaining Treatment (POLST): a medical order form used in the US that translates patient preferences into actionable medical orders. Advance care planning (ACP) discussions are encouraged to clarify patient values, goals, and preferences for future medical care.

Livor Mortis (Lividity)

- Post-mortem purplish-red discoloration of dependent body parts resulting from gravitational settling of blood in uncompressed capillaries and small veins following cessation of circulation. Onset: begins within 30 minutes to 2 hours after death; becomes fully developed and "fixed" (no longer blanches upon digital pressure due to hemolysis and extravasation) after 8–12 hours. Color variations provide forensic clues: cherry-red (carbon monoxide poisoning), bright pink (cyanide, cold exposure), brown (methemoglobinemia). Shifting of lividity patterns indicates that the body was moved post-mortem.

Livor Mortis (Postmortem Lividity)

- Purplish-red discoloration of dependent body parts following death, caused by gravitational pooling of blood in uncompressed capillaries and venules. Starts within 30 min–2 hours, becomes fixed after 6–12 hours. Color changes assist in diagnosing cause of death (cherry-red in CO, bright red in cold exposure/cyanide, chocolate brown in methemoglobinemia).

Manner of Death

– Legal classification of the circumstances surrounding a death, categorized into 5 official types: Natural, Accident, Suicide, Homicide, or Undetermined.

Mechanism of Death

– The physiologic or biochemical derangement that causes death (the final failure) as opposed to the underlying disease or injury (cause of death) and the circumstances (manner). Examples: ventricular fibrillation, cerebral hemorrhage, sepsis, respiratory failure, exsanguination, cardiac tamponade. The mechanism is an intermediate process; e.g., a cause of blunt force head trauma may act via the mechanism of cerebral edema and herniation. Correct certification distinguishes cause (disease/injury) from mechanism (physiologic derangement) from manner.

Medical Examiner

– An appointed physician, usually a board-certified forensic pathologist, charged with investigating sudden, unexpected, violent, or suspicious deaths, ordering autopsies, determining cause and manner of death, and certifying the death certificate. Unlike the elected coroner, a medical examiner must meet professional qualifications. Such systems coordinate with law enforcement, toxicology, and odontology and testify as expert witnesses.

Medical Jurisprudence

– The branch of law (and its study) that deals with the rights and duties of physicians and the legal aspects of medical practice, distinct from but overlapping with forensic medicine. Topics: consent (informed), confidentiality and privileged communication, professional negligence/malpractice, medical ethics, licensing, regulation of medical practice, medico-legal aspects of organ donation and transplantation, and expert testimony. Medical jurisprudence provides the legal framework within which forensic medicine operates.

Medical Negligence (Malpractice)

– Legal tort occurring when a healthcare provider fails to exercise the standard of reasonable care, skill, or diligence expected of a prudent practitioner of similar standing, resulting in injury, harm, or death to a patient. Legal elements required to establish medical negligence (the "4 Ds"): (1) Duty of care established between provider and patient, (2) Dereliction (breach) of that duty, (3) Direct causation (the breach directly caused the injury),

and (4) Damages (measurable physical, financial, or emotional harm suffered by the patient).

Medical Records

– A documented account of a patient's clinical history, examination, investigations, treatment, and outcome maintained by providers. In medicolegal practice, records are contemporaneous evidence in malpractice, injury, criminal, and death cases, so accuracy, timeliness, and unaltered amendments are essential. Access is governed by confidentiality statutes and court order. Forensic value is enhanced by detailed injury descriptions, timelines, and photographs.

Medicolegal

– Pertaining to the application of medical knowledge to legal questions and the intersection of medicine and the law. Covers forensic pathology, toxicology, psychiatry, and clinical issues: informed consent, malpractice, medical records, disability, personal injury, occupational disease, and public health law. Medicolegal investigation of death involves determining cause, manner, and time of death, and issuing death certificates. Documents (clinical records, expert reports) must meet evidentiary standards.

Morgue

– A facility (mortuary) where bodies are stored and medicolegal/hospital autopsies are performed. Features: refrigerated body storage, autopsy rooms with ventilation and safety (surgical instruments, saws), photographic and evidence-collection equipment, toxicology specimen handling, and secure chain-of-custody areas. Also: viewing rooms for identification and temporary holding pending burial/cremation. Standards govern hygiene, safety (blood-borne pathogens, chemicals), and legal documentation.

Multidisciplinary Disaster Victim Identification

– The coordinated process of identifying victims of mass-fatality incidents (natural disasters, transport crashes, terrorist attacks) using multiple disciplines: fingerprinting, dental records, DNA profiling, forensic anthropology/radiology, and personal effects, with ante-mortem data collection and comparison. Follows standardized protocols (Interpol DVI) with phases: scene management, body recovery, mortuary examination, ante-mortem data, reconciliation,

and family support. Priority is accurate, ethical, and timely identification of all victims.

Mummification

- Postmortem alteration occurring in hot, dry, arid, ventilated environments where rapid desiccation of tissues occurs before putrefaction can proceed, resulting in dry, leathery, dark brown skin clinging to underlying skeleton.

Paternity Testing

- The use of genetic markers to establish or exclude a biological parent-child relationship, the reference method being short tandem repeat DNA profiling of the child, alleged father, and mother. Modern STR analysis commonly yields paternity probability exceeding 99.99 percent for true fathers. Applications include child support, custody, inheritance, and remains identification. Collection and analysis follow chain-of-custody and accredited-laboratory standards.

Post-Mortem

- An examination of a body after death to determine the cause of death, identify disease processes, and evaluate the effects of medical or surgical treatment. Also called autopsy, necropsy. Types: hospital (clinical) post-mortem — performed with consent to investigate the cause of death, assess treatment, or advance medical knowledge; medico-legal (coroner's/forensic) post-mortem — ordered by a coroner or legal authority when the death is sudden, unexpected, suspicious, or unnatural (required by law; consent not needed). Procedure: external examination, internal examination (thoracic, abdominal, and cranial cavities), histopathology (tissue sampling), toxicology (blood, urine, vitreous humor), microbiology, and other specialized tests. The report includes: cause of death (immediate, underlying, and contributing factors), and relevant pathological findings. Post-mortem examination is essential for quality assurance in medicine (verification of clinical diagnosis, identification of missed diagnoses, and audit of surgical and medical care). In obstetrics, perinatal post-mortem is crucial for understanding stillbirth, congenital anomalies, and maternal death.

Postmortem Artifact

- Any structural, chemical, or physical change introduced into a body after death (e.g., embalming artifacts, insect activity, postmortem animal scavenging,

resuscitation trauma) that mimics antemortem disease or trauma.

Postmortem Interval

- The time elapsed since death, estimated by forensic scientists. Indicators: algor mortis (cooling—most accurate early), rigor mortis (onset 2-6 h, full 12-24 h, resolution 24-48 h), livor mortis (dependent lividity; fixed 4-12 h), vitreous potassium (increases after 12-24 h), gastric emptying, liver temperature, decomposition stage, and forensic entomology (insect succession). PMI estimation is approximate and affected by environmental temperature, body size, clothing, and circumstances. Used to establish a timeline and corroborate or refute accounts.

Postmortem Interval (PMI)

- Estimated elapsed time between actual death and the time of autopsy or body discovery, calculated utilizing algor mortis, livor mortis, rigor mortis, vitreous potassium levels, and insect succession patterns.

Pugilistic Stance

- The characteristic body position adopted by fire victims—flexed arms, elbows bent, fists clenched, knees flexed—resulting from heat-induced contraction (denaturation) of muscles (mainly flexors) and tendons, not from conscious movement. It occurs with thermal injury and can be present regardless of cause (even if death preceded fire). Its presence indicates the body was exposed to heat, not that the person was fighting. Important for distinguishing antemortem from postmortem burning and interpreting fire deaths.

Punctate Hemorrhages (Tardieu Spots)

- Small, pinpoint sub-ecchymotic hemorrhages (petechiae) resulting from the rupture of small capillaries under conditions of intense mechanical venous engorgement and asphyxia. Commonly observed on conjunctivae, sclerae, facial skin, epicardium, pleural surfaces, and thymus in deaths due to mechanical asphyxia (strangulation, hanging, suffocation, traumatic asphyxia). First described by Auguste Ambroise Tardieu in 1859.

Putrefaction

- Postmortem decomposition of body tissues brought about by bacterial and enzymatic action, characterized by green discoloration of lower abdomen

(cecum), marbling of cutaneous veins, gas distension, foul odor, and liquefaction.

Rape

– Sexual penetration of the mouth, vagina, or anus accomplished without consent or with a person unable to consent, often through force, threat, fraud, or impairment; many statutes subsume it under sexual assault. Forensic examination within about 120 hours documents injuries and collects biological evidence using a standardized kit with strict chain of custody. Prophylaxis and trauma-informed consent are central.

Res Ipsa Loquitur

– Latin legal doctrine meaning "the thing speaks for itself." Applied in medical malpractice cases where an injury is of a nature that ordinarily does not occur in the absence of negligence, the instrumentality causing harm was under the exclusive control of the defendant, and the plaintiff did not contribute to the injury. Examples: retaining a surgical sponge or instrument inside a patient's abdomen, or amputating the wrong limb. When invoked, it creates a rebuttable presumption of negligence, shifting the burden of proof to the defendant.

Rigor Mortis

– Post-mortem stiffening of body muscles resulting from loss of ATP synthesis following death. Without ATP, actin and myosin filaments remain permanently cross-linked in a rigid state. Onset: detectable in small muscles (jaw, eyelids) within 2–4 hours, becomes fully established in all voluntary muscles by 12 hours, remains fixed for 12 hours, and gradually resolves over the subsequent 12–24 hours as autolytic proteolytic enzymes break down muscle proteins ("rule of 12s": 12 hours onset, 12 hours duration, 12 hours resolution). Accelerated by high ambient temperature, fever, or violent exertion prior to death.

Sexual Assault

– A broad legal category of any non-consensual sexual contact or penetration, encompassing rape, indecent assault, and drug-facilitated assault. Examination documents general and anogenital injuries, collects biological and trace samples, and screens for drug-facilitated assault by extended-window testing. Consent capacity, intoxication, and coercion are central legal issues. Absence of genital injury

does not exclude assault, and delayed presentation is common.

Sharp Force Trauma

– Injury produced by an edged or pointed instrument that cuts or penetrates the skin, divided into incised wounds (longer than deep, clean margins) and stab wounds (deeper than wide). Wound length, depth, angle, hesitation marks, and defense injuries infer weapon type and manner. Tissue bridging distinguishes sharp-force from blunt-force lacerations. Penetration of major vessels may cause rapid exsanguination.

Skeletonization

– Final stage of postmortem decomposition where soft tissues, organs, and skin have completely decayed or been scavenged, leaving only clean osseous skeletal remains.

Stab Wound

– A penetrating sharp-force injury in which wound track depth exceeds skin defect length, produced by a pointed or sharp-edged implement. The skin defect approximates blade width only when perpendicular to Langer's lines, and a single-edged blade produces one sharp and one blunt end. Chest and abdominal stab wounds often cause fatal hemorrhage or tamponade despite a small external appearance.

Standard of Care

– The conduct, skill, diligence, and judgment a reasonably prudent practitioner of the same specialty would exercise under similar circumstances; the benchmark for medical negligence. It is established through guidelines, peer practice, and expert testimony rather than fixed statute. Breach is but one malpractice element, with duty, causation, and damages, and permits a range of acceptable options.

Stippling (Tattooing)

– Patterned dermal abrasions and punctate hemorrhages surrounding a firearm entrance wound, caused by unburned and partially burned gunpowder grains striking the skin at close range (15–75 cm).

Strangulation

– Compression of the neck causing occlusion of the airway (asphyxia) and/or cervical vessels (carotid/jugular), leading to unconsciousness and death. Types: ligature strangulation (cord, rope,

cloth—external mark above the larynx, often horizontal), manual (manual throttling—fingertip bruises, thumb imprint, often vertical), and garroting. Signs: petechial hemorrhages (face, conjunctivae), facial congestion/cyanosis, neck soft tissue hemorrhage, hyoid/laryngeal fractures, and ligation marks. High rate of homicidal cases; survivor evaluation requires careful examination and documentation.

Sudden Infant Death Syndrome (SIDS)

– Sudden, unexpected death of an infant under 1 year of age that remains unexplained after a thorough medico-legal investigation, including a complete autopsy, crime scene investigation, and review of clinical history. Peak incidence: 2–4 months of age. Pathophysiology: "triple-risk model" involving a vulnerable infant (brainstem respiratory control deficit), a critical developmental period, and an extrinsic stressor (prone sleeping position, soft bedding, exposure to cigarette smoke, overheating). Preventive campaign: "Back to Sleep" (placing infants supine for sleep) has reduced SIDS incidence by over 50% globally.

Suffocation

– Death or injury from failure of oxygen to reach the lungs, a category of asphyxia distinct from strangulation. Subtypes include smothering (airway obstruction), choking or foreign-body obstruction, mechanical asphyxia (positional, chest compression), and entrapment in oxygen-deficient environments. Findings may be subtle: facial and conjunctival petechiae, congestion, and patterned injuries. Investigation relies on scene findings and circumstantial reconstruction.

Thanatology

– Scientific study of death, dying, post-mortem phenomena, and the psychological, social, and ethical aspects of bereavement. In forensic medicine, thanatology focuses on establishing clinical and legal definitions of death (brain death vs. somatic death), post-mortem changes (algor mortis, livor mortis, rigor mortis, decomposition, adipocere, mummification), and estimating the post-mortem interval (PMI).

Time of Death

– The moment or estimated time at which biological

death occurred, a key medicolegal question. Estimated from postmortem changes: body cooling (algor mortis), rigor mortis, lividity (livor mortis), decomposition/putrefaction, insect colonization, and chemical changes (vitreal potassium, vitreal glucose, body temperature). Clinical evidence (last seen, medical records, stomach contents, personal effects) and scene findings contribute. Accuracy is limited; estimates are reported as ranges with confidence intervals. Legal importance: timeline, alibi corroboration, and manner determination.

Trajectory

– The path a projectile follows in flight and, in wound ballistics, the course it traverses through tissue from entrance to exit or rest. Internal trajectory is reconstructed from entrance and exit defects, the organ track, recovered fragments, and clothing damage; angles disclose shooter position and victim posture. Yaw, deformation, and fragmentation must be considered. Accurate analysis underpins shooting reconstruction.

Vitriolage

– The deliberate throwing or application of a corrosive chemical (vitriol—sulfuric acid, historically; now any strong acid/base) onto a person to disfigure, disable, or kill; a form of assault. Injuries: severe facial and body burns, scarring, blindness, respiratory injury from fumes, and psychological trauma. Forensic evaluation: chemical identification (burn pattern, cloth damage, laboratory analysis), extent/severity of injury, age and nature of scarring, and medicolegal reporting. Legal status varies; often treated as aggravated assault with life imprisonment in some jurisdictions.

Witness

– An individual who gives sworn testimony; a clinician may appear as a witness of fact (describing observations and care) or as an expert offering interpretive opinion. Testimony must be truthful, objective, and within personal knowledge or reliable methodology, distinguishing fact from opinion and avoiding advocacy. Prior statements and records are disclosable, and inconsistencies may be explored on cross-examination.

Wound

– An injury to living tissue caused by mechanical force; in forensic medicine, wounds are clas-

sified by mechanism: abrasion (scrape—loss of epidermis, no bleeding), laceration (tear from blunt force—ragged edges, tissue bridges), incised/incision (clean cut by sharp edge—linear, edges gape), stab/puncture (penetrating injury by pointed weapon—depth exceeds width), contusion (bruise), and gunshot wound. Wound interpretation (shape, edges, depth, location, associated findings) helps determine weapon type, force, angle, and manner (accident, suicide, homicide). Documentation includes measurement and photography.

Chapter 12

Gastroenterology

12.1 Esophageal & Gastric Medicine

Acute Pancreatitis

- Acute inflammatory process of the pancreas most commonly caused by gallstones and alcohol accounting for approximately eighty percent of cases. The pathogenesis involves premature trypsin activation within pancreatic acinar cells triggering autodigestion. Clinical presentation includes severe epigastric pain radiating to the back, nausea, and vomiting. Diagnosis requires two of three criteria: characteristic pain, serum lipase at least three times upper limit of normal, and characteristic imaging findings of pancreatic inflammation on CT.

Autoimmune Gastritis

- Chronic atrophic gastritis caused by antibodies against parietal cells leading to achlorhydria and vitamin B12 deficiency. Associated with pernicious anemia and increased risk of gastric carcinoid tumors and type 1 gastric neuroendocrine tumors. Anti-parietal cell antibodies are present in approximately ninety percent of patients. Diagnosis is by serology showing elevated gastrin levels and decreased pepsinogen I to II ratio, confirmed by endoscopic biopsy showing oxyntic gland atrophy. Management involves iron supplementation and endoscopic surveillance for gastric neuroendocrine tumors.

Barium Swallow

- Fluoroscopic examination of the esophagus after ingestion of barium contrast. Used to evaluate esophageal anatomy, motility, strictures, and structural abnormalities. The study demonstrates mucosal detail, filling defects, strictures, and motility disorders. A barium follow-through extends the

examination to the small bowel. Double-contrast technique using barium and air provides superior mucosal detail. The study has been largely replaced by upper endoscopy for direct visualization but remains useful in selected patients who cannot tolerate endoscopy.

Barrett Esophagus

- Metaplastic transformation of the normal stratified squamous epithelium of the distal esophagus to specialized intestinal-type columnar epithelium containing goblet cells, occurring as a consequence of chronic gastroesophageal reflux disease. This condition represents an important premalignant lesion because it confers a significantly increased risk of esophageal adenocarcinoma, estimated at approximately 0.5 percent per year in patients without dysplasia. The pathogenesis involves chronic acid exposure leading to inflammation, ulceration, and metaplastic change, with progression driven by bile reflux and inflammatory mediators.

Barrett Esophagus Surveillance

- Systematic endoscopic monitoring of patients with Barrett esophagus to detect dysplasia and early esophageal adenocarcinoma. Patients without dysplasia undergo surveillance every three to five years with four-quadrant biopsies every two centimeters throughout the Barrett segment. Patients with low-grade dysplasia should be offered endoscopic eradication therapy with radiofrequency ablation. Patients with high-grade dysplasia or intramucosal carcinoma should undergo endoscopic mucosal resection or oesophagectomy, depending on depth of invasion and patient fitness.

Bleeding Esophageal Varices

- Life-threatening hemorrhage from dilated submucosal veins in the lower esophagus, occurring as

a complication of portal hypertension, most commonly from cirrhosis. Varices form when the portal venous pressure gradient exceeds 10 mmHg (the threshold for variceal development). Risk of first variceal hemorrhage is approximately 15-25 percent per year, and each episode carries a mortality of 15-30 percent. Clinical presentation includes hematemesis (bright red blood or coffee-ground emesis), melena, and signs of hypovolaemic shock.

Boerhaave Syndrome

– Transmural spontaneous rupture of the esophagus typically occurring after forceful vomiting in the setting of a full stomach. Most commonly involves the left posterolateral wall of the distal esophagus. Presents with severe chest pain, subcutaneous emphysema, mediastinal emphysema, and rapidly progressive sepsis. This is a surgical emergency with mortality exceeding fifty percent when diagnosis and treatment are delayed. Diagnosis is suggested by chest radiography showing pneumomediastinum or pleural effusion on chest radiograph, and confirmed by CT showing esophageal wall thickening with extraluminal air.

Bouveret Syndrome

– Rare variant of gallstone ileus where a large gallstone erodes through a cholecystoduodenal fistula and impacts in the duodenum or pylorus causing gastric outlet obstruction. Represents approximately two to three percent of gallstone ileus cases. Presents with nausea, vomiting, epigastric pain, and anorexia. Diagnosis is by CT or upper gastrointestinal series showing gastric dilation with a filling defect in the duodenum and pneumobilia. Treatment is endoscopic or surgical removal of the impacted stone.

Cameron Lesions

– Linear gastric erosions or ulcers found on the mucosal folds at the diaphragmatic hiatus in patients with large hiatal hernias. They result from mechanical trauma as the gastric mucosa prolapses through the diaphragmatic crura during respiration and movement. May be a source of occult or overt gastrointestinal bleeding presenting with iron deficiency anemia or melena. Diagnosis requires careful endoscopic examination with particular attention to the hiatal hernia sac. Treatment involves proton pump inhibitors and treatment of the underlying

mechanical cause.

Cholelithiasis

– Presence of gallstones in the gallbladder. Types: cholesterol stones (80%, radiolucent, due to supersaturated bile), pigment stones (black: hemolysis, cirrhosis; brown: infection, bile stasis). Risk factors: female, fertile, fat, forty (5 Fs), obesity, rapid weight loss, hemolytic disorders, cirrhosis. Most are asymptomatic (incidental finding). Symptomatic cholelithiasis: episodic postprandial RUQ/epigastric pain (biliary colic). Complications: acute cholecystitis, choledocholithiasis, cholangitis, gallstone pancreatitis. Diagnosis: right upper quadrant ultrasound (gold standard). Treatment: laparoscopic cholecystectomy for symptomatic stones; observation for asymptomatic.

Cushing Ulcer

– Stress ulceration associated with central nervous system disease, trauma, or surgery. Caused by vagally mediated gastric acid hypersecretion, distinguishing it from Curling ulcer which results from mucosal ischemia. The ulcers are typically solitary, located in the stomach or duodenum, and present with gastrointestinal bleeding. Management involves acid suppression with proton pump inhibitors and treatment of the underlying neurological condition.

Dieulafoy Lesion

– Large caliber persistent submucosal artery in the stomach wall that can cause massive gastrointestinal bleeding. The artery is abnormally large and superficial, lacking the normal tapering into smaller arterioles. Presents with hematemesis or melena without a visible ulcer. The lesion is typically found within six centimeters of the gastroesophageal junction. Diagnosed and treated by endoscopic therapy with clips, thermal coagulation, or band ligation. Recurrent bleeding may occur and repeat endoscopy with hemostatic therapy.

Digestion

– The process by which the body breaks down ingested food into smaller molecules that can be absorbed and utilized. Digestion begins in the mouth (mechanical–mastication; enzymatic–salivary amylase for starch, lingual lipase). In the stomach: gastric acid (HCl) denatures proteins, pepsin digests proteins, and mechanical churning produces chyme. In the small intestine: pancreatic enzymes

(trypsin, chymotrypsin, amylase, lipase, nucleases) break down macromolecules; bile salts emulsify fats. Brush border enzymes (lactase, sucrase, maltase, peptidases) complete digestion. Absorption occurs primarily in the small intestine. The colon absorbs water and electrolytes and ferments undigested fiber.

Digestive Health

– The efficient functioning of the gastrointestinal tract in breaking down food, absorbing nutrients, and eliminating waste. Digestive health depends on factors such as diet, hydration, gut microbiome balance, and the integrity of the digestive mucosa. Common digestive disorders include irritable bowel syndrome, gastroesophageal reflux disease, and inflammatory bowel disease.

Dumping Syndrome

– Rapid gastric emptying of hypertonic contents into the small bowel after gastrectomy or gastric bypass surgery. Early dumping occurs within thirty minutes with vasomotor symptoms including flushing, palpitations, diarrhea, and dizziness from fluid shifts into the intestinal lumen. Late dumping occurs one to three hours later with reactive hypoglycemia from exaggerated insulin secretion. Managed with dietary modifications including small frequent meals, avoidance of simple sugars, and lying down after meals. Pharmacological therapy includes octreotide and acarbose to slow gastric emptying and blunt the insulin response.

Duodenal Ulcer

– Peptic ulcer in the duodenal mucosa strongly associated with *H. pylori* infection. Presents with epigastric pain relieved by food typically occurring several hours after meals and at night. Complications include hemorrhage, perforation, and gastric outlet obstruction. Diagnosis is by upper endoscopy. Treatment involves proton pump inhibitor therapy for four to eight weeks and *H. pylori* eradication. Duodenal ulcers have a lower risk of malignancy compared to gastric ulcers but require follow-up endoscopy to document healing.

Dyspepsia

– Chronic or recurrent pain or discomfort centered in the upper abdomen. Organic causes: peptic ulcer disease, GERD, gastritis, gastric cancer. Functional dyspepsia is diagnosed after exclusion of organic pathology with normal upper endoscopy. Rome IV

criteria define subtypes: epigastric pain syndrome and postprandial distress syndrome. Management: *H. pylori* test and treat, PPI trial, prokinetics, and low-dose antidepressants.

Dysphagia

– Difficulty swallowing, classified as oropharyngeal (difficulty initiating a swallow, choking, coughing, nasal regurgitation) or esophageal (sensation of food sticking retrosternally). Oropharyngeal causes: neurological (stroke, Parkinson's disease, motor neurone disease, myasthenia gravis), structural (pharyngeal pouch, tumors), and muscular (dermatomyositis). esophageal causes: mechanical obstruction (stricture, Schatzki ring, esophageal cancer, eosinophilic esophagitis) and motility disorders (achalasia, diffuse esophageal spasm, scleroderma). Investigations: videofluoroscopic swallow study for oropharyngeal; upper endoscopy, barium swallow, and esophageal manometry for esophageal. Complications: aspiration pneumonia, malnutrition, and dehydration.

EGD

– Esophagogastroduodenoscopy: upper endoscopy visualizing the esophagus, stomach, and duodenum using a flexible endoscope. Indications: dyspepsia with alarm features, dysphagia, GI bleeding (diagnosis and therapy— injection, clips, banding, cautery), biopsy (celiac, *H. pylori*, Barrett surveillance), dilation of strictures, and placement of feeding tubes. Complications: perforation, bleeding, sedation-related events. Preparation: fasting; sedation usually light. Alternatives for screening: capsule endoscopy. Essential for diagnosis and treatment of upper GI disorders.

Emesis (Vomiting)

– The forceful expulsion of gastric contents through the mouth, a complex reflex coordinated by the vomiting center in the medulla oblongata. The reflex involves: prodromal phase (nausea, salivation, autonomic activation—tachycardia, sweating), retching (rhythmic contractions of diaphragm and abdominal muscles against a closed glottis), and expulsion (forceful contraction of abdominal muscles with relaxation of the lower esophageal sphincter and diaphragm). Causes: gastrointestinal (gastroenteritis, gastroparesis, obstruction), vestibular (motion sickness, labyrinthitis), CNS (increased intracranial pressure, migraine), metabolic (pregnancy, ure-

mia, DKA, hypercalcemia), medications (chemotherapy, opioids, antibiotics), toxins (food poisoning, alcohol), and psychogenic. Complications: aspiration, dehydration, electrolyte disturbances, Mallory-Weiss tear. Antiemetics target different receptors: 5-HT₃, D₂, H₁, M₁, NK₁.

Endoscopic Mucosal Resection

– Advanced endoscopic technique for removal of superficial gastrointestinal neoplasms by lifting the lesion through submucosal injection and resecting with an electrosurgical snare. The technique involves injection of saline with vasoconstrictive agent into the submucosa, capturing the elevated lesion with a snare, and resecting with electrocautery. Indications include sessile colorectal polyps, early gastric cancer, Barrett esophagus with high-grade dysplasia, and large duodenal lesions. Complications include bleeding, perforation, and stricture formation, but these are uncommon in experienced hands.

Endoscopic Submucosal Dissection

– Advanced endoscopic technique for en bloc resection of large gastrointestinal neoplasms using specialized electrosurgical knives to dissect through the submucosa. The technique allows complete histological assessment and is particularly valuable for early gastric and colorectal cancers. Unlike piecemeal EMR, ESD achieves higher en bloc resection rates, lower recurrence rates, and accurate staging. Complications include bleeding in five to ten percent and perforation in three to five percent, though the risk of perforation is higher than with EMR and requires careful patient selection and operator expertise.

Endoscopic Ultrasound

– Diagnostic and therapeutic endoscopic procedure combining endoscopy with high-frequency ultrasound to provide detailed imaging of the gastrointestinal wall layers and adjacent organs. EUS is particularly valuable for evaluating pancreatic masses, staging gastrointestinal malignancies, evaluating submucosal lesions, and assessing the biliary tree. EUS-guided fine-needle aspiration allows tissue sampling of lesions not accessible by conventional biopsy. The staging accuracy for esophageal and rectal cancers, and for evaluating pancreatic lesions and mediastinal lymphadenopathy.

Endoscopy

– Visualization of the gastrointestinal tract using

flexible fiber-optic or video endoscopes. Upper endoscopy examines the esophagus, stomach, and duodenum. Colonoscopy examines the colon and terminal ileum. Both allow direct visualization, biopsy, and therapeutic interventions including polypectomy, hemostasis, and dilation. Endoscopic procedures require patient preparation, sedation, and monitoring. Complications are uncommon but include perforation, bleeding, and adverse reactions to sedation. Most procedures are safe when performed by trained endoscopists with appropriate monitoring.

Eosinophilic Esophagitis

– Chronic immune-mediated condition characterized by dense eosinophilic infiltration of the esophageal mucosa defined as fifteen or more eosinophils per high-power field, in the absence of other causes of esophageal eosinophilia. The condition is driven by a T helper type two inflammatory response and is strongly associated with atopic conditions. The clinical presentation varies by age: infants present with feeding difficulties; school-age children with dysphagia; and adults with progressive dysphagia, and food bolus impaction.

Eosinophilic Gastroenteritis

– Rare chronic inflammatory condition characterized by eosinophilic infiltration of the gastrointestinal tract beyond the esophagus involving any segment from stomach to rectum and extending beyond the mucosa to involve the muscularis propria or serosa. The condition is classified based on depth of infiltration: mucosal disease presents with pain and diarrhea; muscular disease causes obstruction; serosal disease causes eosinophilic ascites. Diagnosis is established by tissue biopsy demonstrating eosinophilic infiltration in the affected tissue.

Erosive Gastritis

– Inflammation of the stomach lining with superficial erosions but no full-thickness ulceration. Commonly caused by NSAIDs, alcohol, or critical illness. May present with epigastric pain or gastrointestinal bleeding. Diagnosis is by upper endoscopy showing erosions and erythema. Management involves proton pump inhibitors and removal of offending agents. Stress ulcer prophylaxis with proton pump inhibitors or H₂ blockers is indicated in critically ill patients at risk for stress-related mucosal disease.

Esophageal Achalasia

– Primary esophageal motility disorder characterized by failure of the lower esophageal sphincter to relax during swallowing and absent peristalsis in the distal esophagus, resulting from selective loss of inhibitory neurons in the myenteric plexus. The condition typically presents with progressive dysphagia to both solids and liquids, regurgitation, chest pain, and weight loss. Complications include aspiration pneumonia and increased risk of esophageal squamous cell carcinoma. Diagnosis is confirmed by high-resolution manometry showing incomplete lower esophageal sphincter relaxation and absent peristalsis.

Esophageal Candidiasis

– Fungal infection of the esophagus caused by *Candida* species common in immunocompromised patients including those with HIV, organ transplant recipients, and patients on inhaled corticosteroids. Presents with odynophagia and dysphagia. Diagnosed by endoscopy showing white adherent plaques and biopsy confirming fungal hyphae. Treated with oral fluconazole as first-line therapy. Esophageal candidiasis is an AIDS-defining illness when the CD4 count is below two hundred cells per microliter.

Esophageal Dilation

– Endoscopic passage of bougies or balloons to widen esophageal strictures. Used for symptomatic strictures from peptic disease, radiation, caustic injury, or eosinophilic esophagitis. Savary bougies are passed over a guidewire with progressive dilation. Through-the-scope balloons allow controlled radial dilation under direct visualization. Complications include perforation, which occurs in approximately one percent, and bleeding. Serial dilations are often required for refractory strictures. Dilation should be performed gradually over multiple sessions to reduce perforation risk.

Esophageal Diverticulum

– Outpouching of the esophageal wall classified by location. Zenker diverticulum occurs in the hypopharynx and is the most common esophageal diverticulum. Mid-esophageal diverticula are traction diverticula caused by extrinsic inflammatory disease including tuberculosis and histoplasmosis. Epiphrenic diverticula occur in the distal esophagus above the lower esophageal sphincter and are

associated with esophageal motility disorders including achalasia and diffuse esophageal spasm. Most diverticula are asymptomatic and discovered incidentally; symptomatic cases may require surgical diverticulectomy and myotomy.

Esophageal Intramural Pseudodiverticulosis

– Condition characterized by multiple small outpouchings of the esophageal submucosal glands seen on barium swallow as flask-shaped contrast collections oriented longitudinally along the esophagus. The pseudodiverticula are not true diverticula but rather dilated excretory ducts of submucosal glands. Associated with gastroesophageal reflux disease, diabetes mellitus, and chronic alcoholism. Most patients present with progressive dysphagia due to associated esophageal stricture formation. Diagnosis is confirmed by barium swallow showing characteristic flask-shaped outpouchings, and management focuses on treating the underlying stricture with dilation.

Esophageal Leukoplakia

– White plaques on the esophageal mucosa representing squamous cell hyperplasia with hyperkeratosis. Similar to oral leukoplakia it is considered a potentially premalignant condition. Associated with chronic irritation from smoking, alcohol, and gastroesophageal reflux. Diagnosis is by endoscopy with biopsy to exclude dysplasia or carcinoma. Management includes surveillance with endoscopy and biopsy, smoking and alcohol cessation, and treatment of reflux disease. The risk of malignant transformation is low, but regular surveillance with endoscopic biopsy is recommended.

Esophageal Manometry

– Diagnostic test measuring esophageal motor function by recording intraluminal pressures during swallowing. A catheter with pressure sensors is passed through the nose into the stomach and withdrawn to record pressures at multiple levels. High-resolution manometry using closely spaced sensors provides a spatiotemporal color plot. The Chicago classification categorizes esophageal motility disorders into major disorders including achalasia and distal esophageal spasm, and minor disorders including ineffective esophageal motility (IEM).

Esophageal Perforation

– Full-thickness rupture of the esophageal wall, most commonly Boerhaave syndrome from forceful vomiting occurring on the left posterolateral distal esophagus. Iatrogenic perforation during endoscopy is another common cause. Presents with chest pain, subcutaneous emphysema, and mediastinitis. A surgical emergency requiring emergent repair and drainage. Delayed diagnosis significantly increases mortality. Management includes nil per os, intravenous antibiotics, and surgical repair with tissue flap reinforcement for large defects.

Esophageal Spasm

– Esophageal motility disorder characterized by uncoordinated or excessive contractions impairing bolus transport. Diffuse esophageal spasm shows simultaneous contractions on manometry. Jackhammer esophagus features extremely high-amplitude peristaltic contractions. Patients present with episodic dysphagia and chest pain that may mimic cardiac pain. Diagnosis is by high-resolution manometry demonstrating characteristic pressure patterns. Barium swallow may show the corkscrew esophagus pattern. Treatment includes calcium channel blockers, nitrates, phosphodiesterase inhibitors, and endoscopic botulinum toxin injection for symptomatic relief.

Esophageal Stricture

– Narrowing of the esophageal lumen from chronic gastroesophageal reflux disease, caustic ingestion, or eosinophilic esophagitis. Presents with progressive dysphagia initially to solids then liquids. Diagnosed by upper endoscopy and barium swallow. Peptic strictures are the most common type and are treated with endoscopic balloon dilation combined with aggressive acid suppression. Recurrent strictures may require repeated dilations. Malignant strictures require stent placement or surgical resection with reconstruction.

Esophageal Varices

– Dilated, tortuous submucosal veins in the lower esophagus, most commonly caused by portal hypertension (cirrhosis—hepatic fibrosis with increased portal venous pressure >10 mmHg). They develop as portosystemic collaterals connecting the portal venous system (left gastric vein) to the systemic venous system (azygos vein). Prevalence: 50% of patients with cirrhosis, 30% of whom will

bleed within 2 years. Ruptured esophageal varices cause acute upper GI hemorrhage (hematemesis, melena, hemodynamic instability), with mortality of 15–20% per episode. Diagnosis: upper endoscopy—emergency for suspected variceal bleeding (red wale signs, cherry-red spots, fibrin plug). Management of acute bleeding: resuscitation, vasoactive drugs (terlipressin or octreotide), prophylactic antibiotics (ceftriaxone 1 g IV, reduces bacterial peritonitis and mortality), endoscopic band ligation (first-line, 90% hemostasis), and covered transjugular intrahepatic portosystemic shunt (TIPS) for refractory bleeding. Secondary prophylaxis: non-selective beta-blockers (propranolol, carvedilol) plus repeat band ligation every 2–4 weeks until varices obliterated. Primary prophylaxis for medium/large varices: beta-blockers or band ligation.

Esophageal Web

– Thin mucosal fold protruding into the esophageal lumen most commonly in the postcricoid region or upper esophagus. Webs may be asymptomatic or cause dysphagia particularly to solids. Multiple webs can occur in association with iron deficiency anemia as part of Plummer-Vinson syndrome or Paterson-Kelly syndrome. Diagnosis is by barium swallow showing thin filling defects and upper endoscopy which may inadvertently displace the web. Symptomatic webs are treated with endoscopic dilation. The significance of an esophageal web lies primarily in its association with Plummer-Vinson syndrome and the increased risk of postcricoid squamous cell carcinoma.

Esophagitis

– Inflammation of the esophageal mucosa. Causes: gastro-esophageal reflux disease (GERD—most common, 60–70% of cases), infectious (*Candida albicans*—most common in immunocompromised, HIV, diabetes, post-antibiotics; herpes simplex virus—painful ulcers; CMV—large ulcerations in immunocompromised), eosinophilic esophagitis (EoE—allergic/atopic, characteristic rings, furrows, and white plaques on endoscopy), pill-induced (doxycycline, bisphosphonates, NSAIDs, potassium chloride, quinidine—typically in the mid-esophagus at areas of extrinsic compression), and radiation esophagitis (during thoracic radiotherapy). Symptoms: heartburn, odynophagia (painful swallowing),

dysphagia (especially for solids in EoE and strictures), and retrosternal chest discomfort. Diagnosis: upper endoscopy with biopsy is the gold standard; biopsies from the distal and mid-esophagus help distinguish reflux esophagitis (basal hyperplasia, eosinophils $>15/\text{hpf}$ in EoE, neutrophilic infiltration in severe reflux). GERD esophagitis is graded by the Los Angeles classification (A–D). Management: lifestyle measures plus proton pump inhibitors (omeprazole 20 mg, lansoprazole 30 mg daily) for 4–8 weeks; EoE requires topical swallowed corticosteroids (fluticasone, budesonide) and dietary elimination; infectious esophagitis is treated with antifungals or antivirals as appropriate.

Esophagus (esophagus)

– A muscular tube approximately 25 cm long connecting the pharynx to the stomach, extending from the cricopharyngeus muscle (at the level of C6) to the gastroesophageal junction (T11). The esophagus has three anatomic constrictions: cervical (upper esophageal sphincter–cricopharyngeus at C6), thoracic (crossing of the aortic arch and left main bronchus), and diaphragmatic (hiatus). The wall consists of mucosa (non-keratinized stratified squamous epithelium), submucosa, muscularis propria (upper third: skeletal muscle; middle third: mixed; lower third: smooth muscle), and adventitia (no serosa). Functions: transport of swallowed food and liquid from pharynx to stomach via coordinated peristaltic contractions. The lower esophageal sphincter prevents gastric reflux. Common disorders: GERD, esophagitis, Barrett esophagus, esophageal cancer, achalasia, and strictures.

Feeding Jejunostomy

– Surgical or endoscopic placement of a feeding tube into the jejunum for enteral nutrition when upper gastrointestinal access is not feasible. Used in patients with head and neck cancers, esophageal obstruction, or severe dysphagia. Provides long-term nutritional support and avoids the complications of parenteral nutrition. The tube can be placed percutaneously using endoscopic or radiological guidance. Complications include tube displacement, occlusion, leakage, and local infection.

Functional Dyspepsia

– Chronic epigastric pain or discomfort without identifiable structural cause. The Rome IV criteria

include postprandial distress syndrome with early satiety and postprandial fullness, and epigastric pain syndrome with epigastric pain or burning unrelated to meals. Pathophysiology involves visceral hypersensitivity, altered gastric accommodation, and duodenal eosinophilia. Management includes dietary modifications, proton pump inhibitors, histamine H2 receptor antagonists, prokinetics, and neuro-modulators such as tricyclic antidepressants and serotonin-norepinephrine reuptake inhibitors.

Gastralgia

– Pain in the stomach or epigastric region. The term is non-specific and encompasses various causes of epigastric discomfort: functional dyspepsia (most common), peptic ulcer disease (gastric or duodenal), gastritis, gastro-esophageal reflux disease (GERD), gastric cancer, pancreatitis, cholecystitis, and referred pain (myocardial ischemia, pleurisy). Clinical assessment: quality (burning, gnawing, cramping), timing (postprandial, nocturnal, fasting), aggravating/relieving factors, associated symptoms (nausea, vomiting, weight loss, hematemesis, melena). Management: identify and treat underlying cause; *H. pylori* testing and eradication if present; trial of PPI if GERD or peptic ulcer suspected.

Gastrectomy

– Surgical removal of all (total gastrectomy) or part (partial/subtotal gastrectomy) of the stomach. Indications: gastric cancer (most common), severe peptic ulcer disease (rarely needed now due to PPIs and *H. pylori* treatment), gastric lymphoma, gastrointestinal stromal tumor (GIST), perforation, bleeding. Types: Billroth I (partial gastrectomy with gastroduodenostomy), Billroth II (partial gastrectomy with gastrojejunostomy), Roux-en-Y (total gastrectomy with oesophagojejunostomy). Complications: anastomotic leak (highest risk), dumping syndrome, bile reflux gastritis (post Billroth II), malabsorption (iron, B12, calcium, vitamin D, fat-soluble vitamins), bacterial overgrowth, weight loss, afferent/efferent loop syndrome. After total gastrectomy, intramuscular vitamin B12 supplementation is required lifelong due to loss of intrinsic factor.

Gastric Bezoar

– Accumulation of indigestible material in the stomach. Phytobezoars consist of vegetable fiber, trichobezoars of hair, and pharmacobezoars of medica-

tions. Associated with gastroparesis, prior surgery, and impaired gastric motility. Diagnosed by endoscopy. Treated with enzymatic dissolution using cellulase, papain, or cola, endoscopic fragmentation, or surgical removal for refractory cases. Bezoars are an important cause of gastric outlet obstruction and ulceration.

Gastric Carcinoid Tumor

- Neuroendocrine tumor arising from enterochromaffin-like cells in the gastric fundus. Type I gastric carcinoids are associated with autoimmune atrophic gastritis and hypergastrinemia, are typically small and multifocal, and carry a good prognosis. Type II gastric carcinoids are associated with Zollinger-Ellison syndrome and multiple endocrine neoplasia type 1. Type III gastric carcinoids are sporadic, solitary, larger, and more aggressive. Diagnosed by endoscopy with biopsy. Treatment depends on tumor size, type, and stage: small type I tumors can be managed by endoscopic resection and surveillance, while types II and III often require surgical resection with lymphadenectomy.

Gastric Emptying Study

- Nuclear medicine diagnostic test measuring the rate of gastric emptying. The protocol involves ingestion of a radiolabeled meal followed by serial gamma camera images obtained at one, two, and four hours. Gastric emptying is considered delayed if more than ten percent of the meal remains at four hours. The test is primarily used to diagnose gastroparesis, a condition of delayed gastric emptying without mechanical obstruction most commonly occurring as a complication of diabetes mellitus. The study may also help differentiate gastroparesis from functional dyspepsia.

Gastric Lymphoma

- Malignant proliferation of lymphoid tissue in the stomach most commonly mucosa-associated lymphoid tissue lymphoma. Strongly associated with *H. pylori* infection. Early disease may regress completely with *H. pylori* eradication therapy alone. More advanced disease may require chemotherapy with rituximab and cyclophosphamide, doxorubicin, vincristine, and prednisone. Surgery is rarely needed. Diffuse large B-cell lymphoma of the stomach is the other common type and requires

combination chemotherapy with R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisolone).

Gastric Outlet Obstruction

- Blockage of gastric outflow at the pylorus or duodenum. Causes include peptic ulcer scarring, gastric cancer, and pyloric stenosis in infants. Presents with projectile vomiting, dehydration, and metabolic alkalosis. Diagnosis is by upper endoscopy and CT scan. Management requires decompression with nasogastric tube, fluid resuscitation, correction of electrolyte abnormalities, and definitive treatment of the underlying cause. Pyloric stenosis in infants is treated surgically with pyloromyotomy.

Gastric Polyps

- Protruding lesions of the gastric mucosa classified by histological type. Fundic gland polyps are the most common type associated with long-term proton pump inhibitor use and familial adenomatous polyposis. Hyperplastic polyps are associated with chronic gastritis and *H. pylori* infection and carry a small risk of dysplasia. Adenomatous polyps are true neoplasms with malignant potential requiring complete removal and surveillance. Inflammatory polyps occur in the setting of inflammatory bowel disease and may regress with treatment of the underlying colitis.

Gastric Ulcer

- Peptic ulcer in the gastric mucosa associated with *H. pylori*, NSAIDs, and smoking. Pain is typically worsened by food. There is a higher risk of malignancy than duodenal ulcers. Diagnosis is by upper endoscopy with biopsy to exclude malignancy. Treatment involves proton pump inhibitors and *H. pylori* eradication. Follow-up endoscopy at eight weeks is recommended to confirm healing and exclude malignancy in gastric ulcers, particularly in patients over forty-five years.

Gastric Ulcer (see Peptic Ulcer)

- See Peptic Ulcer.

Gastric Volvulus

- Rotation of the stomach along its axis causing obstruction. It may present with Borchardt triad of epigastric pain, retching, and inability to pass a nasogastric tube. It is a surgical emergency requiring decompression and gastropexy. Organoaxial volvulus is the most common type where the stomach

rotates along its longitudinal axis. Mesenteroaxial volvulus involves rotation along an axis perpendicular to the long axis. Diagnosis is by CT scan or upper endoscopy.

Gastrin

– A peptide hormone produced by G cells in the gastric antrum and duodenum. Secreted in response to: (1) gastric distension, (2) amino acids and peptides (especially from protein-rich meals), (3) vagal stimulation (via gastrin-releasing peptide, GRP), (4) hypercalcaemia. Actions: stimulates gastric acid secretion by parietal cells (via histamine release from enterochromaffin-like cells and direct effect on CCK-B receptors), stimulates gastric motility, promotes growth of gastric mucosa (trophic effect). Inhibited by somatostatin (from D cells in response to low antral pH). Hypergastrinaemia: Zollinger-Ellison syndrome (gastrinoma, usually pancreatic), pernicious anemia (achlorhydria, loss of feedback inhibition), chronic PPI use. Fasting serum gastrin is measured in suspected gastrinoma.

Gastritis

– Inflammation of the gastric mucosa, classified by duration (acute or chronic), etiology, and histologic pattern. Acute gastritis is most commonly caused by *Helicobacter pylori* infection (acute *H. pylori* infection causes transient hypochlorhydria with epigastric pain, nausea, and vomiting), NSAIDs (inhibiting mucosal prostaglandin synthesis, especially in the gastric antrum, leading to erosions and bleeding), excessive alcohol consumption, severe physiologic stress (stress-related gastritis in critically ill patients). Chronic gastritis is most commonly caused by persistent *H. pylori* infection, which can progress to atrophic gastritis, intestinal metaplasia, and gastric adenocarcinoma.

Gastroduodenal Crohn Disease

– Involvement of the stomach and duodenum by Crohn disease occurring in approximately five percent of patients with Crohn. Gastric Crohn typically involves the antrum and pylorus and can cause gastric outlet obstruction from edema, fibrosis, or stricture. Duodenal Crohn presents with epigastric pain, nausea, vomiting, and weight loss. Diagnosis is by upper endoscopy with biopsy showing non-caseating granulomas and chronic inflammation. Treatment involves medical therapy with corticosteroids for

induction of remission, followed by immunomodulators or biologic therapy for maintenance.

Gastroenterology

– The medical specialty focused on the diagnosis and management of diseases of the gastrointestinal tract (esophagus, stomach, small intestine, colon, rectum, pancreas, gallbladder, bile ducts, liver). Subspecialties: hepatology (liver), pancreatology, inflammatory bowel disease, gastrointestinal oncology, neurogastroenterology. Diagnostic tools: upper endoscopy (esophagogastroduodenoscopy, OGD), colonoscopy, capsule endoscopy, endoscopic retrograde cholangiopancreatography (ERCP), endoscopic ultrasound (EUS), breath tests (*H. pylori*, lactose intolerance, SIBO), manometry, pH metry. Therapeutic procedures: polypectomy, mucosal resection, hemostasis (injection, cautery, clips, banding), dilation, stent placement, percutaneous endoscopic gastrostomy (PEG).

Gastroesophageal Reflux Disease (GERD)

– A chronic condition in which gastric contents reflux backward into the esophagus, causing troublesome symptoms and/or complications. Epidemiology: affects 10–20% of adults in Western countries. Pathophysiology: transient lower esophageal sphincter relaxations (TLESRs) are the primary mechanism; contributing factors include a hypotensive lower esophageal sphincter, hiatal hernia, impaired esophageal clearance, delayed gastric emptying, and obesity. Symptoms: classic symptoms include heartburn (retrosternal burning) and acid regurgitation; atypical symptoms include non-cardiac chest pain, chronic cough, laryngitis, asthma exacerbation, and globus sensation. Complications: erosive esophagitis, esophageal stricture, Barrett esophagus (metaplasia from squamous to columnar epithelium, increasing risk of esophageal adenocarcinoma). Diagnosis: clinical evaluation, PPI trial, upper endoscopy (for alarm symptoms such as dysphagia, weight loss, GI bleeding, anemia, or age > 55), and 24-hour ambulatory pH/impedance monitoring for refractory cases. Management: lifestyle modifications (weight loss, elevation of head of bed, avoiding trigger foods and late meals), proton pump inhibitors (PPIs like omeprazole 20 mg daily), H2 receptor antagonists, and laparoscopic Nissen fun-

duplication or magnetic sphincter augmentation for refractory cases.

Gastrointestinal Bleeding

- Hemorrhage from any part of the gastrointestinal tract classified as upper or lower based on location relative to the ligament of Treitz. Upper gastrointestinal bleeding originating proximal to this landmark typically presents with hematemesis or melena. Common causes include peptic ulcer disease, esophageal and gastric varices from portal hypertension, Mallory-Weiss tears, and erosive gastritis. Lower gastrointestinal bleeding originating distal to the ligament of Treitz usually presents with haematochezia or bright red blood per rectum, along with abdominal pain.

Gastroparesis

- Delayed gastric emptying without mechanical obstruction most commonly caused by diabetes mellitus, post-surgical changes, or idiopathic causes. Presents with nausea, vomiting of undigested food, early satiety, bloating, and abdominal pain. Diagnosed by gastric emptying scintigraphy showing more than ten percent retention at four hours. Complications include poor glycemic control, bezoar formation, and malnutrition. Managed with dietary modifications including small frequent meals and low-fat low-fibre diet, prokinetic agents such as metoclopramide and domperidone, and antiemetics. In severe cases, gastric electrical stimulation or jejunostomy tube placement may be considered.

Gastrostomy

- Surgical creation of an opening (stoma) through the abdominal wall into the stomach for enteral feeding or decompression. Methods: percutaneous endoscopic gastrostomy (PEG, most common–pull or introducer technique), radiologically inserted gastrostomy (RIG, under fluoroscopic guidance), surgical gastrostomy (open or laparoscopic; Stamm or Witzel technique). Indications: neurological dysphagia (stroke, motor neuron disease, dementia), head and neck cancer, esophageal obstruction, major trauma/burns, prolonged mechanical ventilation. Contraindications: gastric outlet obstruction, severe ascites, gastric varices, coagulopathy, previous abdominal surgery (relative). Complications: peristomal infection (most common, 5-30%), tube displacement, buried bumper syndrome, gastrocolic

fistula, peritonitis, pneumoperitoneum, bleeding.

Gavage

- Feeding through a tube passed into the stomach (nasogastric, orogastric, or gastrostomy tube). Used when oral feeding is impossible or inadequate. In neonates: gavage feeding is used for premature infants unable to coordinate suck-swallow-breathe. Types: bolus (intermittent, 100-400 mL over 10-30 minutes) or continuous (drip, 50-150 mL/hour via pump). Complications: tube misplacement (aspiration), tube blockage, nasal erosion, sinusitis, gastro-esophageal reflux, diarrhea (hyperosmolar feeds).

Halitosis

- An unpleasant odour of the breath that may be socially distressing. The most common cause (85-90%) is poor oral hygiene– accumulation of bacteria on the tongue, dental plaque, periodontitis, and gingivitis. The odour arises from volatile sulphur compounds (VSCs–hydrogen sulphide, methyl mercaptan, dimethyl sulphide) produced by Gram-negative anaerobic bacteria (especially *Porphyromonas gingivalis*, *Treponema denticola*, *Tannerella forsythia*) that break down sulphur-containing amino acids (cysteine, methionine). Other oral causes: dry mouth (xerostomia, reduced salivary cleansing), dental caries, oral infections, tongue coating, poorly fitting dentures. Non-oral causes: sinusitis (post-nasal drip), tonsillitis/tonsilloliths, gastro-esophageal reflux disease (GERD), *Helicobacter pylori* infection, liver failure (feto hepaticus–a sweet, musty odour), renal failure (uraemic fetor–ammoniacal/urine-like), diabetic ketoacidosis (fruity/acetone), lung abscess, bronchiectasis (putrid odour), and trimethylaminuria (fish malodour syndrome). Diagnosis: clinical assessment (oral examination), organoleptic scoring (sensory assessment by clinician), gas chromatography, BANA test (benzoyl-DL-arginine naphthylamide for bacterial enzymes). Management: good oral hygiene (tongue scraping, toothbrushing, flossing), treatment of underlying dental/medical conditions, mouthwash (chlorhexidine, zinc-containing, chlorine dioxide), avoidance of tobacco and alcohol.

Helicobacter pylori

- Gram-negative, microaerophilic, spiral-shaped bacterium specifically adapted to colonize the human

gastric mucosa. It is estimated that approximately half the world's population is infected, making it one of the most common chronic bacterial infections globally. *H. pylori* colonizes the gastric antrum and body, surviving the extremely acidic environment by producing large quantities of the enzyme urease, which converts urea to ammonia and carbon dioxide, creating a protective alkaline microenvironment around the organism that neutralizes gastric acid and allows colonization.

Hematemesis

– Vomiting of blood, indicating upper gastrointestinal bleeding proximal to the ligament of Treitz. Blood may be bright red (acute, brisk bleeding) or resemble coffee grounds (altered blood that has been in contact with gastric acid). Common causes: peptic ulcer disease (most common, 50%), esophageal varices (15%), Mallory-Weiss tears (10%), erosive gastritis, esophagitis, and gastric cancer. Initial management: ABC approach, large-bore IV access, fluid resuscitation, blood transfusion (target Hb >80 g/L in hemodynamically stable patients), and proton pump inhibitor infusion. Prognostic scoring: Rockall score and Glasgow-Blatchford score predict need for intervention and mortality. Upper endoscopy within 24 hours is both diagnostic and therapeutic (hemostatic clips, adrenaline injection, thermal coagulation, or band ligation for varices).

Hematochezia

– The passage of bright red or maroon blood per rectum, usually indicating active lower gastrointestinal (LGI) bleeding distal to the ligament of Treitz (e.g., diverticulosis, arteriovenous malformations/angiodysplasia, colorectal polyps/cancer, inflammatory bowel disease, hemorrhoids). Massive upper GI bleeding (e.g., esophageal varices, peptic ulcer disease) with rapid intestinal transit (< 2 hours) can also present with hematochezia and hemodynamic instability. Diagnostic evaluation: colonoscopy (first-line), CTA, or red blood cell scan.

Hiatal Hernia

– Protrusion of part of the stomach through the esophageal hiatus into the thoracic cavity. Type I (sliding, 95%): gastroesophageal junction above the diaphragm. Types II-IV (paraesophageal): fundus or other portions herniate alongside the esophagus.

Sliding hernias are associated with GERD. Paraesophageal hernias can cause obstruction, volvulus, and ischemia. Treatment: PPIs for GERD; surgical repair for symptomatic paraesophageal hernias.

Hiccough (Hiccup)

– An involuntary, repetitive, spasmodic contraction of the diaphragm followed by sudden closure of the glottis, producing the characteristic 'hic' sound. Hiccups are caused by irritation or stimulation of the phrenic nerve (C3-C5, innervates the diaphragm) or the vagus nerve (CN X). Acute (<48 hours): most are benign and self-limiting, triggered by: carbonated beverages, eating too quickly, spicy foods, alcohol, sudden temperature change (hot then cold), excitement, stress. Persistent (>48 hours) or intractable (>1 month): underlying pathology should be sought. Causes: (1) Gastrointestinal: GORD, hiatus hernia, gastric distension, gastritis, hepatitis, pancreatitis, bowel obstruction. (2) Central nervous system: stroke, multiple sclerosis, brainstem tumor, encephalitis, meningitis. (3) Thoracic: pneumonia, pleurisy, pericarditis, myocardial infarction, aortic aneurysm, mediastinal mass, lung cancer. (4) Metabolic: uraemia, hyponatraemia, diabetes, alcohol use disorder. (5) Drugs: corticosteroids, benzodiazepines, barbiturates, methyldopa, chemotherapy (platinum-based). (6) Psychogenic: anxiety, conversion disorder, malingering. Management: acute: breath-holding, drinking cold water, Valsalva manoeuvre, pulling knees to chest, eating a spoonful of sugar, or using a paper bag (re-breathing). Persistent/intractable: chlorpromazine (dopamine antagonist, 25-50 mg IM/IV or 25 mg PO TID, first-line, FDA approved), metoclopramide, baclofen, gabapentin, nifedipine, omeprazole. In severe cases: phrenic nerve block or surgical phrenic nerve crush (rare).

Hiccups (Singultus)

– Involuntary, spasmodic contractions of the diaphragm and intercostal muscles followed by sudden glottic closure, producing the characteristic "hic" sound. The reflex arc involves the phrenic nerve (C3-C5), vagus nerve, and brainstem centers. Acute hiccups (<48 hours) are common and benign, triggered by gastric distension (overeating, carbonated beverages, aerophagia), temperature changes (hot/cold food or drink), alcohol, excite-

ment, or stress. Persistent hiccups (>48 hours) and intractable hiccups (>1 month) require evaluation for underlying pathology: gastrointestinal (GERD, hiatal hernia, gastritis), neurologic (stroke, brainstem tumor, multiple sclerosis, meningitis), thoracic (pneumonia, pleurisy, pericarditis, myocardial infarction), metabolic (uremia, hyponatremia, diabetes), or drug-induced (dexamethasone, benzodiazepines, opioids, barbiturates, chemotherapy). Imaging: chest X-ray, CT head/chest/abdomen, upper endoscopy, and brain MRI when neurologic signs are present. Treatment for acute hiccups: vagal maneuvers (breath-holding, Valsalva, drinking water rapidly, swallowing dry sugar, pulling knees to chest, carotid sinus massage), and rebreathing into a bag (raises CO₂, may suppress the reflex arc). Pharmacotherapy for persistent hiccups: chlorpromazine (first-line, FDA-approved), metoclopramide, baclofen, gabapentin, or haloperidol; severe refractory cases may require phrenic nerve block or vagus nerve stimulation.

Internal Hernia

– Herniation of bowel through a mesenteric defect common after Roux-en-Y gastric bypass creating a defect at the jejunojejunostomy. May cause intermittent or acute small bowel obstruction. Presents with episodic abdominal pain, nausea, and vomiting. Diagnosed by CT showing clustered dilated small bowel loops and the swirling pattern of mesenteric vessels. Treated surgically with reduction of the hernia and closure of the mesenteric defect. Internal hernias after bariatric surgery are a surgical emergency requiring prompt operative intervention to prevent bowel ischemia and infarction.

Intestinal Perforation

– Full-thickness breach in the bowel wall allowing luminal contents to enter the peritoneal cavity. Causes include diverticulitis, appendicitis, peptic ulcer disease, and trauma. Presents with acute abdomen, peritonitis, and free air on imaging. A surgical emergency requiring emergent laparotomy with primary repair or resection depending on location and degree of contamination. Postoperative management includes broad-spectrum antibiotics and intensive care support.

Intramural Hematoma

– Collection of blood within the wall of the gas-

trointestinal tract most commonly the duodenum. Caused by trauma, anticoagulation, or coagulopathy. Presents with abdominal pain, vomiting, and sometimes obstructive symptoms. Diagnosis is by CT showing circumferential wall thickening with high-attenuation hematoma. Managed conservatively with bowel rest, nasogastric decompression, and correction of coagulopathy. Most resolve spontaneously without surgical intervention.

Lynch Syndrome

– Hereditary nonpolyposis colorectal cancer syndrome caused by mismatch repair gene mutations including MLH1, MSH2, MSH6, and PMS2 with autosomal dominant inheritance. It increases the risk of colorectal, endometrial, ovarian, gastric, and urinary tract cancers. Diagnosis is suggested by microsatellite instability testing and immunohistochemistry showing loss of mismatch repair proteins, confirmed by genetic testing. Management involves intensive colonoscopic surveillance every one to two years starting at age 20-25, and prophylactic hysterectomy and salpingo-oophorectomy after completion of childbearing for women with Lynch syndrome.

Mallory-Weiss Tear

– Longitudinal mucosal laceration at the gastroesophageal junction caused by forceful vomiting or retching. It typically presents with hematemesis. Most bleeds spontaneously within twenty-four to forty-eight hours. Diagnosis is made by upper endoscopy showing a linear mucosal tear. Management includes observation, proton pump inhibitors, and endoscopic hemostasis with clips or thermal therapy if active bleeding is identified. Recurrence is uncommon and the prognosis is generally excellent.

Meckel Diverticulum

– Congenital remnant of the omphalomesenteric duct located on the antimesenteric border of the distal ileum approximately sixty centimeters from the ileocecal valve. It follows the rule of twos: occurs in approximately two percent of the population, located approximately two feet from the ileocecal valve, approximately two inches in length, and may contain two types of ectopic tissue most commonly gastric and pancreatic mucosa. The most common presentation in children is painless lower gastrointestinal bleeding from ulceration of ectopic gastric

mucosa.

Meconium Peritonitis

– Sterile chemical peritonitis resulting from in utero intestinal perforation allowing meconium to spill into the peritoneal cavity. Most commonly associated with cystic fibrosis causing inspissated meconium obstruction, intestinal atresia, and volvulus. May be detected prenatally as fetal ascites with echogenic peritoneal calcifications. After birth presents with abdominal distension, vomiting, and signs of peritonitis. Diagnosis is by abdominal radiography showing intraperitoneal calcifications. Treatment is supportive with bowel rest, nasogastric decompression, and parenteral nutrition; surgery is reserved for ongoing perforation or obstruction.

melena

– Passage of black, tarry, foul-smelling stools due to the presence of digested blood, indicating upper gastrointestinal bleeding (usually proximal to the ligament of Treitz). The black color results from oxidation of haemoglobin to haematin by intestinal enzymes and bacteria. At least 200 mL of blood is typically required in the upper GI tract to produce melena. Common causes: peptic ulcer disease (most common), esophageal varices, Mallory-Weiss tear, erosive gastritis, Dieulafoy lesion, and gastric cancer. melena may persist for several days after a single bleeding episode. Differentiation from black stools caused by iron supplements, bismuth, or liquorice is important (these are not tarry and test negative for occult blood). Management: same as for hematemesis (resuscitation, PPI, urgent upper endoscopy).

Nonalcoholic Fatty Liver Disease

– NAFLD: hepatic steatosis (>5 percent of hepatocytes) in the absence of significant alcohol use, associated with the metabolic syndrome (obesity, type 2 diabetes, dyslipidemia, hypertension). Spectrum: simple steatosis (non-progressive in most) to nonalcoholic steatohepatitis (NASH—steatosis + inflammation + hepatocyte injury) leading to fibrosis, cirrhosis, and hepatocellular carcinoma. Often asymptomatic; elevated ALT/AST (mild) or discovered incidentally. Diagnosis: imaging (ultrasound—fatty liver), elastography (fibrosis), liver biopsy (NASH diagnosis). Management: weight loss (7-10 percent), exercise, control of metabolic comorbidities; pioglitazone/vitamin E in selected NASH;

avoid alcohol. Now termed metabolic dysfunction-associated steatotic liver disease (MASLD).

Occult Blood

– Blood present in feces that is not visible to the naked eye, detectable only by chemical or immunochemical testing. fecal occult blood testing (FOBT) is used for colorectal cancer screening. Guaiac-based FOBT (gFOBT) detects haem peroxidase activity (requires dietary restriction—avoid red meat, horseradish, vitamin C). fecal immunochemical test (FIT) uses antibodies specific for human haemoglobin (no dietary restriction, more sensitive, quantitative; threshold typically 10–20 μg Hb/g feces). Positive FIT requires follow-up colonoscopy. Screening with FIT every 1–2 years reduces colorectal cancer mortality by 15–33%. False positives can occur with upper GI bleeding, NSAIDs, anticoagulants, and menstrual blood. Other causes of occult GI bleeding include peptic ulcer disease, angiodysplasia, and inflammatory bowel disease.

Odynophagia

– Painful swallowing, characterized by a burning, squeezing, or sticking sensation behind the sternum during deglutition. Strongly suggests mucosal inflammation or ulceration of the esophagus. Major causes: Infectious Esophagitis (*Candida albicans*, Herpes Simplex Virus, Cytomegalovirus in immunocompromised/HIV patients), Pill-Induced Esophagitis (tetracyclines, bisphosphonates, NSAIDs, iron), Radiation Esophagitis, and severe GERD. Evaluation: upper endoscopy (EGD) with biopsy.

Ogilvie Syndrome

– Acute colonic pseudo-obstruction characterized by massive colonic dilation in the absence of mechanical obstruction typically occurring in hospitalized patients with serious comorbidities including post-surgical states, severe infections, and medication effects. Pathophysiology involves autonomic imbalance with sympathetic overactivity causing inhibition of colonic motility. The cecum is disproportionately dilated carrying risk of perforation which occurs when the cecal diameter exceeds twelve centimetres, with management including nasogastric decompression, correction of electrolyte abnormalities, discontinuation of exacerbating medications, neostigmine administration, and colonoscopic decompression for refractory cases.

Peptic Ulcer Disease

- Condition characterized by ulceration of the gastrointestinal mucosa extending through the muscularis mucosae into the submucosa or deeper layers, occurring most commonly in the duodenal bulb and gastric antrum. The two predominant etiologies are *Helicobacter pylori* infection and nonsteroidal anti-inflammatory drug use, which together account for the vast majority of peptic ulcers. Duodenal ulcers are strongly associated with *H. pylori* and present with epigastric pain that is classically relieved by food and antacids, whereas gastric ulcers cause pain that is worsened by eating.

Peutz-Jeghers Syndrome

- An autosomal dominant neurocutaneous disorder caused by germline loss-of-function mutations in the STK11 (LKB1) tumor suppressor gene on chromosome 19p13. Characterized by: 1) Mucocutaneous hyperpigmented macules (dark brown/blue freckle-like spots on lips, buccal mucosa, perioral skin, and digits), and 2) Multiple hamartomatous polyps throughout the gastrointestinal tract (most dense in small intestine/jejunum). Complications: recurrent intussusception, GI bleeding, and markedly increased lifetime risk of GI (colorectal, gastric, pancreatic) and extra-GI malignancies (breast, ovarian, uterine). Surveillance: capsule endoscopy, colonoscopy, mammography, and pelvic MRI.

Plummer-Vinson Syndrome

- Triad of iron deficiency anemia, esophageal web, and dysphagia occurring predominantly in middle-aged women. The esophageal webs are thin mucosal folds typically located in the postcricoid region of the hypopharynx and proximal esophagus. The pathogenesis is thought to involve epithelial atrophy from chronic iron deficiency affecting rapidly dividing mucosal cells. The syndrome is considered a premalignant condition with increased risk of postcricoid squamous cell carcinoma. Diagnosis is established by barium swallow demonstrating the characteristic thin mucosal web in the proximal esophagus, and treatment consists of iron replacement therapy and endoscopic dilation of the web.

Portal Hypertension

- Elevated pressure in the portal venous system defined as hepatic venous pressure gradient exceeding five millimeters of mercury with clinically significant

portal hypertension occurring when the gradient exceeds ten. The most common cause is cirrhosis where increased intrahepatic resistance combined with splanchnic vasodilation creates a hyperdynamic circulatory state. Consequences include esophageal variceal hemorrhage, ascites, splenomegaly with hypersplenism, and hepatic encephalopathy. Diagnosis is established by measurement of the hepatic venous pressure gradient, upper gastrointestinal endoscopy to evaluate for varices, and imaging to assess for features of portal hypertension such as splenomegaly and portosystemic collaterals.

Portal Hypertensive Gastropathy

- Diffuse mucosal changes in the stomach due to portal hypertension causing chronic blood loss. Characterized by mosaic pattern and cherry red spots on endoscopy representing dilated mucosal vessels. Most common in patients with advanced cirrhosis and portal hypertension. Managed with beta-blockers to reduce portal pressure and iron supplementation for anemia. Argon plasma coagulation may be used for severe bleeding. The condition is distinct from gastritis and does not respond to acid suppression therapy.

Portopulmonary Syndrome

- Development of pulmonary arterial hypertension in the setting of portal hypertension or liver disease. Results from increased cardiac output and splanchnic vasodilation leading to pulmonary vascular remodeling. Classified as mild, moderate, or based on hemodynamic parameters with mean pulmonary artery pressure greater than twenty millimeters of mercury. Presents with exertional dysphagia, fatigue, and exercise intolerance. Diagnosis requires right heart catheterization confirming elevated pulmonary artery pressure on right heart catheterisation, with treatment including pulmonary vasodilator therapy and liver transplantation in selected cases.

Pyloric Stenosis

- Hypertrophy of the pyloric sphincter muscle causing gastric outlet obstruction most common in young infants. Presents with non-bilious projectile vomiting typically beginning at two to eight weeks of age. Dehydration and metabolic alkalosis with hypochloremia and hypokalemia develop as the condition progresses. Diagnosis is by ultrasound show-

ing pyloric muscle thickness greater than three millimeters and length greater than fifteen millimeters. Treated surgically with Ramstedt pyloromyotomy, which typically resolves with full recovery.

Schatzki Ring

- Thin circumferential mucosal ring located at the squamocolumnar junction of the distal esophagus at the superior margin of a hiatal hernia. The ring is composed of mucosa and submucosa. May be asymptomatic or cause episodic dysphagia particularly to solid food and acute food bolus impaction. Diagnosis is by barium swallow showing a thin circumferential narrowing at the gastroesophageal junction. Upper endoscopy may miss the ring if the esophagus is overdistended with air. Treatment of symptomatic Schatzki rings is endoscopic dilation or disruption of the ring with biopsy forceps or electrocautery.

Small Bowel Obstruction

- Mechanical blockage of the small intestine most commonly caused by adhesions from prior surgery accounting for sixty to seventy-five percent, followed by hernias and malignancy. Clinical presentation includes colicky abdominal pain, bilious vomiting, distension, and obstipation. Diagnosis is established by abdominal CT demonstrating the transition point. Management involves nasogastric decompression, intravenous fluids, and monitoring for ischemia. Complete obstruction with strangulation require emergency laparotomy with resection of non-viable bowel.

Somatostatinoma

- Rare pancreatic or duodenal tumor producing somatostatin causing diabetes, gallstones, steatorrhea, and hypochlorhydria from suppression of insulin, gallbladder contraction, pancreatic enzymes, and gastric acid respectively. Diagnosed by elevated somatostatin levels. Treatment is surgical resection for localized disease. Somatostatin analogs may control symptoms but do not treat the underlying tumor. The prognosis depends on tumor stage and completeness of surgical resection.

Steatorrhea

- The passage of excess fat in the stool, causing greasy, pale, foul-smelling, floating stools—a hallmark of fat malabsorption. Causes: pancreatic insufficiency (chronic pancreatitis, cystic fibrosis—impaired lipase), biliary obstruction (gallstones,

cholangiocarcinoma—reduced bile salts), mucosal disease (celiac disease, tropical sprue), and lymphatic obstruction. Associated symptoms: weight loss, malnutrition, fat-soluble vitamin (A, D, E, K) deficiencies. Diagnosis: fecal fat (qualitative or 72-hour quantitative), elastase (pancreatic), anti-transglutaminase (celiac), imaging; management treats the underlying cause with pancreatic enzyme replacement and diet.

Stomach Cancer

- Gastric adenocarcinoma, a malignancy of the stomach; a leading cause of cancer death worldwide (more common in East Asia). Risk factors: *Helicobacter pylori* infection (major), diet (smoked/preserved foods, nitrates), smoking, pernicious anemia, familial syndromes (HDGC, Lynch). Types: intestinal (distal, *H. pylori*-associated, from chronic gastritis/intestinal metaplasia) and diffuse (limits plastica). Features: dyspepsia, early satiety, weight loss, anemia, melena, vomiting; often advanced at diagnosis. Diagnosis: endoscopy with biopsy, staging CT/endoscopic ultrasound. Management: surgical resection ($\pm$ neoadjuvant chemo), chemotherapy, targeted therapy (HER2, PD-1); prognosis depends on stage.

Stomach Ulcer

- See Gastric Ulcer.

Variceal Hemorrhage

- Life-threatening complication of portal hypertension involving rupture of dilated esophageal or gastric varices. The risk is determined by variceal size, red color signs, liver disease severity, and portal hypertension degree. Acute management involves hemodynamic resuscitation, vasoactive drugs, prophylactic antibiotics, and emergent endoscopic band ligation. Transjugular intrahepatic portosystemic shunt is indicated for refractory bleeding. Prevention involves screening endoscopy and prophylactic non-selective beta-blockers or endoscopic variceal ligation for primary prophylaxis, depending on variceal size and patient tolerance.

Whipple Procedure

- Pancreaticoduodenectomy for cancers of the pancreatic head, distal bile duct, or ampulla. Involves removal of the pancreatic head, duodenum, distal bile duct, and gallbladder with three anastomoses: hepaticojejunostomy, pancreaticojejunostomy, and

gastrojejunostomy. The pylorus-preserving variant maintains the entire stomach. Mortality at high-volume centers is approximately two to five percent. Complications include pancreatic fistula, delayed gastric emptying, and hemorrhage. Adjuvant chemotherapy with gemcitabine or 5-fluorouracil-based regimens is given after resection to improve survival, but the prognosis remains poor.

Wireless Motility Capsule

– Ingestible capsule that measures pH, pressure, and temperature throughout the gastrointestinal tract. Provides regional transit times through the stomach, small bowel, and colon in a single test. The pH sensor identifies transition points between segments based on characteristic pH changes. Useful for evaluating gastric emptying, small bowel transit, and colonic transit in patients with suspected motility disorders. Non-invasive alternative to scintigraphy with the advantage of providing whole gut transit assessment in a single non-invasive study.

Zenker Diverticulum

– Pulsion diverticulum at the junction of the thyropharyngeus and cricopharyngeus muscles in the proximal esophagus. It presents with dysphagia, regurgitation of undigested food, halitosis, and aspiration. Diagnosis is by barium swallow showing the characteristic outpouching. Treatment is surgical with diverticulectomy or cricopharyngeal myotomy. The endoscopic approach with cricopharyngeal myotomy is increasingly used. Complications include aspiration pneumonia and, rarely, perforation.

Zollinger-Ellison Syndrome

– Gastrin-secreting tumor called gastrinoma causing gastric acid hypersecretion, severe peptic ulcers, and diarrhea. Most tumors are located in the pancreas or duodenum with approximately sixty percent being malignant. Presents with multiple or refractory peptic ulcers, diarrhea, and esophageal reflux. Diagnosed by elevated fasting gastrin levels greater than one thousand picograms per milliliter and positive secretin stimulation test. Treatment involves high-dose proton pump inhibitors and surgical resection for localized gastrinoma, with a cure rate of approximately 30 percent.

12.2 Intestinal & Colorectal Medicine

Abdominal Compartment Syndrome

– Condition defined by sustained intra-abdominal pressure greater than twenty millimeters of mercury associated with new organ dysfunction. Causes include massive ascites, bowel distension from obstruction or ileus, hemorrhage, and post-surgical conditions particularly after large abdominal wall hernia repairs. Elevated intra-abdominal pressure impairs venous return reducing cardiac output, restricts diaphragmatic excursion causing respiratory failure, compresses the renal veins causing oliguria, and can progress to abdominal compartment syndrome with multi-organ failure.

Abdominal Pain

– Discomfort within the abdomen classified as visceral (dull, midline, poorly localized), parietal (sharp, well localized, worsened by movement), or referred from a distant source. Characterization by SOCRATES guides the differential, which varies by location—right lower quadrant suggests appendicitis; epigastric, pancreatitis or peptic ulcer. Distinguishing surgical from medical causes relies on history, examination, and targeted imaging and laboratory tests.

Acute Liver Failure

– Rapid deterioration of liver function in a previously healthy individual without prior liver disease. Causes include acetaminophen toxicity, viral hepatitis, drug reactions, autoimmune hepatitis, and Wilson disease. Features include coagulopathy, encephalopathy, and multiorgan failure. Presents with jaundice, confusion, and bleeding. Management in intensive care includes monitoring, treatment of reversible causes, and consideration for liver transplantation which is the definitive treatment for irreversible acute liver failure.

Adenoma-Carcinoma Sequence

– Established model of stepwise colorectal carcinogenesis progressing from normal epithelium through adenomas to carcinoma over ten to fifteen years. The sequence begins with APC tumor suppressor gene inactivation, followed by KRAS oncogene activation promoting adenoma growth, and TP53 in-

activation associated with progression to invasive carcinoma. This model explains why polyp removal during colonoscopy prevents colorectal cancer. It accounts for seventy to eighty percent of colorectal cancers. The pathway underscores the importance of screening colonoscopy and polypectomy for cancer prevention.

Anal Abscess

- Collection of pus in the perianal or ischiorectal space usually from infected anal glands. Presents with throbbing anal pain, swelling, fever, and difficulty sitting. Diagnosed clinically with tenderness and fluctuance. Treatment is incision and drainage under local anesthesia. Antibiotics are not routinely required for simple abscesses. Anoscopy should be performed to evaluate for an underlying fistula. Recurrence is common if an associated fistula is not identified and treated.

Anal Fissure

- Linear tear in the distal anal mucosa usually posterior in the midline. Presents with painful defecation and bright red blood on wiping or in the toilet. Associated with constipation, hard stools, and chronic diarrhea. The internal anal sphincter spasm perpetuates the fissure by reducing blood flow to the posterior midline. Managed with stool softeners, dietary fiber, topical nitrates or calcium channel blockers, botulinum toxin injection, and lateral internal sphincterotomy for refractory cases.

Anal Fistula

- Abnormal tract connecting the anal canal to the perianal skin usually following a drained abscess. Presents with recurrent drainage, pain, and pruritus. Parks classification categorizes fistulae by relationship to the sphincter muscles. Diagnosed by examination under anesthesia and MRI. Treated surgically with fistulotomy for low fistulae, seton placement for high fistulae, advancement flap repair, or the LIFT procedure. Crohn-related fistulae require medical optimization with biologic agents before surgical intervention to optimise wound healing and reduce recurrence.

Anastomotic Leak

- Breakdown of a surgical anastomosis in the gastrointestinal tract causing spillage of luminal contents into the peritoneal cavity. Presents with fever, tachycardia, abdominal pain, leukocytosis, and peri-

tonitis. Diagnosed by CT with oral or rectal contrast showing extraluminal contrast or fluid collection. Risk factors include malnutrition, steroid use, obesity, and distal anastomosis. Managed with broad-spectrum antibiotics, percutaneous drainage of abscesses, and possible reoperation for diffuse peritonitis.

Angiodysplasia

- Vascular ectasia consisting of dilated fragile blood vessels in the gastrointestinal mucosa and submucosa, most commonly found in the cecum and ascending colon. They are the most common cause of acute lower gastrointestinal bleeding in elderly patients over sixty years of age. Patients typically present with intermittent painless hematochezia or melena and chronic iron deficiency anemia. Diagnosis is best achieved by colonoscopy revealing cherry-red spots. Management of actively bleeding lesions includes endoscopic therapy with cautery, argon plasma coagulation, or clipping.

Anorectal Manometry

- Measurement of pressures in the anal canal and rectum to assess sphincter function and rectal sensation. A pressure-sensing catheter is inserted into the rectum and slowly withdrawn through the anal canal. Measures resting and squeeze pressures reflecting internal and external sphincter function respectively. Rectal sensation is assessed by balloon inflation. Used to evaluate fecal incontinence, chronic constipation, and to screen for Hirschsprung disease in children. The study helps guide treatment decisions for these conditions.

Anorexia

- Loss of appetite, distinct from anorexia nervosa (the eating disorder). Causes include: infections (most common), malignancies (especially GI, pancreatic, lung), chronic diseases (CKD, COPD, heart failure, liver disease), medications (chemotherapy, opioids, antibiotics), psychological disorders (depression, anxiety), and endocrine disorders (Addison's disease, hypothyroidism). Pathophysiology involves cytokines (TNF- α , IL-6), leptin dysregulation, and altered hypothalamic appetite centers. Consequences: malnutrition, weight loss, sarcopenia, and immune dysfunction. Management: treat underlying cause, nutritional support (oral supplements, enteral feeding if severe), appetite stimulants

(megestrol acetate, corticosteroids, dronabinol), and dietary modifications (small frequent meals, preferred foods).

APACHE II Score

- Severity scoring system for critically ill patients incorporating physiological variables, age, and chronic health status to generate scores from zero to seventy-one. Higher scores indicate greater severity and higher mortality. In acute pancreatitis, scores of eight or greater indicate severe disease. The score is calculated within twenty-four hours of ICU admission. It is validated across multiple ICU populations and used for severity assessment, quality improvement, and research. Limitations include the complexity of calculation and the need for accurate physiological data.

Appendicitis

- Inflammation of the vermiform appendix, most commonly due to luminal obstruction by fecalith, lymphoid hyperplasia, or foreign body. Presents with periumbilical pain migrating to the right lower quadrant, nausea, anorexia, and low-grade fever. Diagnosis: clinical, elevated WBC, CT scan. Treatment: laparoscopic appendectomy. Complications: perforation, peritonitis, abscess formation if untreated.

Ascites

- Pathological accumulation of fluid within the peritoneal cavity representing the most common decompensating event in cirrhosis. The pathogenesis involves splanchnic arterial vasodilation reducing effective arterial blood volume and activating neurohormonal mechanisms leading to sodium and water retention. Diagnosis is established by clinical examination and confirmed by ultrasonography. Diagnostic paracentesis determines the serum-ascites albumin gradient, with a gradient of one point one grams per decilitre or greater indicates portal hypertension.

Autoimmune Hepatitis

- Chronic hepatitis caused by immune-mediated destruction of hepatocytes characterized by interface hepatitis with lymphoplasmacytic infiltrate, elevated transaminases, hypergammaglobulinemia, and autoantibodies. Type 1 autoimmune hepatitis is associated with anti-nuclear and anti-smooth muscle antibodies while type 2 is associated with

anti-liver kidney microsomal antibodies. Diagnosis is based on the International Autoimmune Hepatitis Group scoring system. Treatment involves corticosteroids with azathioprine as steroid-sparing agents for maintenance therapy.

Autoimmune Pancreatitis

- Chronic inflammatory condition characterized by dense lymphoplasmacytic infiltrate with IgG4-positive plasma cells representing the pancreatic manifestation of IgG4-related disease. Type 1 is more common affecting older men with elevated serum IgG4 and extrapancreatic involvement. Type 2 affects younger patients with higher prevalence of inflammatory bowel disease. Clinical presentation includes painless obstructive jaundice and new-onset diabetes. Imaging shows a sausage-shaped pancreas with peripancreatic fat stranding and capsule-like rim enhancement.

Bile Salt Malabsorption

- Condition characterized by impaired reabsorption of bile acids in the terminal ileum leading to excessive bile acids entering the colon where they stimulate water and electrolyte secretion causing chronic watery diarrhea. Normally approximately ninety-five percent of bile acids are reabsorbed in the terminal ileum through the apical sodium-dependent bile acid transporter. When this mechanism is disrupted by surgical resection, inflammatory bowel disease, or idiopathic causes, excess bile acids in the colon stimulate colonic secretion causing watery diarrhea, which responds to bile acid sequestrants such as colestyramine.

Biliary Atresia

- A progressive, obliterative cholangiopathy of the extrahepatic bile ducts in neonates, leading to biliary obstruction, cholestasis, and ultimately biliary cirrhosis if untreated. It is the most common cause of neonatal jaundice requiring surgery and the leading indication for pediatric liver transplantation, with an incidence of approximately 1 in 10,000 to 15,000 live births. The etiology is unknown but likely involves an inflammatory insult (possible viral trigger: rotavirus, reovirus) superimposed on a developmental susceptibility of the neonatal bile duct epithelium.

Biliary Dyskinesia

- Functional gallbladder disorder with impaired gall-

bladder ejection fraction in the absence of gallstones. Presents with biliary colic-like right upper quadrant pain. Diagnosed by CCK-HIDA scan showing ejection fraction less than thirty-five percent. The diagnosis requires exclusion of other causes of biliary-type pain. Treatment is cholecystectomy, which provides symptom relief in approximately eighty percent of patients with confirmed biliary dyskinesia.

Bowel Incontinence

- The involuntary loss of solid or liquid stool through the anus, also known as fecal incontinence, affecting approximately 2-15 percent of the general population and increasing in prevalence with age. Causes are classified by mechanism: structural sphincter damage (obstetric anal sphincter injury from vaginal delivery, the most common cause in women; anorectal surgery; trauma), neurogenic dysfunction (diabetic neuropathy, spinal cord injury, stroke, multiple sclerosis, cauda equina syndrome), and cognitive impairment.

Budd-Chiari Syndrome

- Obstruction of hepatic venous outflow at any level from small hepatic venules to the inferior vena cava junction with the right atrium. The most common predisposing condition is myeloproliferative disorders accounting for forty to fifty percent of cases. Other risk factors include thrombophilia and oral contraceptive use. Clinical presentation varies from acute right upper quadrant pain with ascites to chronic presentation mimicking cirrhosis. Diagnosis is established by Doppler ultrasonography showing absent or reversed hepatic venous flow, and confirmed by venography.

C282Y Mutation

- Most common genetic cause of hereditary hemochromatosis, a C to T transition in the HFE gene resulting in cysteine to tyrosine substitution at position 282. Homozygosity occurs in approximately one in two hundred individuals of Northern European descent. The mutation disrupts HFE protein interaction with transferrin receptor leading to inappropriately low hepcidin production and unregulated iron absorption. Penetrance is incomplete with only approximately twenty-eight percent of male and one per cent of female C282Y homozygotes develop clinical iron overload.

Cambridge Classification

- ERCP-based grading system for chronic pancreatitis severity evaluating the main pancreatic duct, branches, and common bile duct. Normal pancreas shows smooth duct without abnormalities. Equivocal shows fewer than three abnormal side branches. Mild shows three or more abnormal side branches. Moderate shows abnormal main duct. Severe shows calculi, cavities, or strictures. The classification has been largely superseded by MRCP and endoscopic ultrasound which provide both ductal and parenchymal assessment.

Capsule Endoscopy

- Non-invasive diagnostic technique using a swallowable wireless endoscopic device to capture images of the small intestinal mucosa. The capsule contains a miniature video camera and transmitter that sends images to a receiver worn on the patient's belt. The procedure is primarily used to evaluate the small bowel for obscure gastrointestinal bleeding, suspected Crohn disease, small bowel tumors, and celiac disease. The patient ingests the capsule after an overnight fast and it is passed naturally in the stool within 24 to 48 hours.

Carcinoid Syndrome

- Serotonin-secreting neuroendocrine tumor causing flushing, diarrhea, bronchospasm, and right-sided heart disease. Occurs when vasoactive substances bypass hepatic metabolism through venous drainage or liver metastases. Diagnosis is with twenty-four hour urine 5-hydroxyindoleacetic acid or serum chromogranin A. Octreotide controls symptoms by suppressing hormone release. Surgical debulking reduces tumor burden. Telotristat ethyl inhibits serotonin synthesis for refractory diarrhea. Right-sided valvular heart disease, particularly tricuspid regurgitation and pulmonary stenosis, is managed with valve replacement in severe cases.

Celiac Crisis

- Acute life-threatening presentation of celiac disease characterized by severe dehydration, electrolyte imbalances, metabolic acidosis, hypocalcemic tetany, and hypovolemic shock. Most commonly occurs in infants and young children after a viral illness or introduction of gluten-containing foods. Presents with profuse watery diarrhea, vomiting, abdominal distension, and signs of severe dehydration. Treatment

requires aggressive fluid and electrolyte resuscitation, correction of hypocalcemia and hypoglycaemia, and administration of intravenous corticosteroids.

Celiac Disease

– An immune-mediated enteropathy triggered by gluten ingestion in genetically predisposed individuals (HLA-DQ2/DQ8). Gliadin peptides from wheat, barley, and rye activate an autoimmune response against tissue transglutaminase (tTG), causing villous atrophy, crypt hyperplasia, and intraepithelial lymphocytosis in the small intestine. Presents with diarrhea, steatorrhea, weight loss, bloating, iron deficiency anemia, and failure to thrive in children. Extraintestinal: dermatitis herpetiformis, osteoporosis, infertility, and neuropathy. Diagnosis: positive tTG-IgA, EMA, and duodenal biopsy showing villous atrophy. Management: strict lifelong gluten-free diet. Complications: refractory celiac disease, enteropathy-associated T-cell lymphoma (rare).

Celiac Trunk Stenosis

– Narrowing of the celiac trunk typically caused by extrinsic compression from the median arcuate ligament of the diaphragm, known as median arcuate ligament syndrome or celiac artery compression syndrome. Causes chronic abdominal pain particularly after eating and weight loss due to postprandial mesenteric ischemia. Diagnosis is by CT angiography or conventional angiography showing characteristic hook-shaped narrowing of the celiac trunk and collateral vessel formation. Treatment is surgical division of the median arcuate ligament with or without celiac artery reconstruction.

Charcot Triad

– Clinical constellation of fever, right upper quadrant pain, and jaundice representing the classic presentation of ascending cholangitis, infection of the biliary tree from common bile duct obstruction by a gallstone. The full triad is found in approximately fifty to seventy percent of patients. When hypotension and altered mental status are added, it constitutes Reynolds pentad indicating suppurative cholangitis. Initial management involves intravenous fluids, broad-spectrum antibiotics, and urgent biliary drainage by ERCP with endoscopic sphincterotomy.

Charcot Triad (Cholangitis)

– Classic diagnostic triad of acute ascending cholangitis: (1) Fever, (2) Right Upper Quadrant abdominal

pain, and (3) Jaundice. Reynolds Pentad adds Hypotension and Altered Mental Status. *See Acute Cholangitis.*

Child-Pugh Classification

– Clinical scoring system assessing prognosis of chronic liver disease by evaluating five parameters: total bilirubin, serum albumin, international normalized ratio, ascites, and hepatic encephalopathy. Each parameter is scored one to three points. Child-Pugh A with five to six points represents well-compensated cirrhosis with one-year survival exceeding ninety-five percent. Child-Pugh B with seven to nine points represents significant functional compromise with one-year survival approximately eighty percent. Child-Pugh C with ten to fifteen points represents decompensated cirrhosis with one-year survival of approximately fifty percent.

Cholangitis

– Bacterial infection of the biliary tree, most commonly caused by choledocholithiasis (common bile duct stones) obstructing bile flow, but also from biliary strictures, stent occlusion, and malignancy. The classic clinical presentation is Charcot triad: fever, right upper quadrant pain, and jaundice (present in 50-70 percent of cases). Suppurative cholangitis with Reynolds pentad (Charcot triad plus hypotension and altered mental status) indicates severe disease requiring urgent decompression. Complications include pancreatitis, perforation, bleeding, and cholangitis.

Choledochal Cyst

– Congenital dilatation of the biliary tree classified into five types according to the Todani classification. Type I involving dilation of the common bile duct is the most common. Presents with the classic triad of abdominal pain, jaundice, and palpable mass though all three are present in less than twenty percent of cases. Risk of cholangiocarcinoma is significantly increased. Diagnosed by MRCP or CT showing biliary dilation. Treated with complete surgical excision of the cyst and biliary reconstruction with Roux-en-Y hepaticojejunostomy.

Choledocholithiasis

– The presence of gallstones within the common bile duct, occurring in approximately 10-20 percent of patients with cholelithiasis. Stones may form primarily in the common bile duct (primary

stones, brown pigment stones, associated with biliary stasis and infection) or migrate from the gallbladder (secondary stones, most common, identical to gallbladder stones). Clinical presentation ranges from asymptomatic (incidental finding on imaging) to classic biliary colic, obstructive jaundice, and cholangitis. Endoscopic retrograde cholangiopancreatography is both diagnostic and therapeutic, allowing stone extraction after sphincterotomy.

Chronic Intestinal Pseudo-Obstruction

- Chronic condition of recurrent episodes of intestinal obstruction without mechanical blockage due to neuromuscular dysfunction of the gastrointestinal tract. May involve the small bowel, colon, or both. Causes include systemic sclerosis, diabetes, Parkinson disease, amyloidosis, and paraneoplastic syndromes. Presents with abdominal distension, pain, nausea, vomiting, constipation, and malabsorption. Diagnosed by imaging showing dilated bowel loops without transition point, and antroduodenal manometry showing abnormal motility patterns in the small bowel.

Chronic Mesenteric Ischemia

- Recurrent abdominal pain occurring after eating resulting from insufficient blood flow to meet the metabolic demands of the gastrointestinal tract. Most commonly caused by atherosclerotic stenosis of at least two of the three major mesenteric arteries. Classic presentation is sitophobia, fear of eating due to postprandial abdominal pain typically beginning thirty minutes to two hours after meals and lasting one to two hours. Patients develop food avoidance and significant weight loss. Diagnosis is confirmed by CT angiography or conventional angiography demonstrating stenosis of at least two mesenteric vessels.

Chronic Pancreatitis

- Progressive irreversible inflammatory condition characterized by permanent structural damage causing exocrine and endocrine impairment. The most common cause is chronic alcohol consumption. Other causes include hereditary pancreatitis, autoimmune pancreatitis, and metabolic factors. Clinical manifestations include chronic abdominal pain, steatorrhea, and diabetes mellitus. Diagnosis is established by imaging showing calcifications, ductal

dilatation, and parenchymal atrophy. The Cambridge classification is used for staging severity.

Clostridioides difficile Infection

- Bacterial infection of the colon caused by *C. difficile* toxin, usually following antibiotic use that disrupts normal colonic flora. Presents with watery diarrhea, fever, and abdominal pain. Diagnosed by stool toxin assay or nucleic acid amplification test. Treatment involves discontinuation of the offending antibiotic and initiation of oral vancomycin or fidaxomicin. Fecal microbiota transplantation is highly effective for recurrent infection. Complications include toxic megacolon, perforation, and death.

CMV Colitis

- Colonic inflammation caused by cytomegalovirus reactivation in immunocompromised patients including those with HIV and organ transplant recipients. Presents with bloody diarrhea and abdominal pain. Diagnosed by colonoscopy with biopsy showing characteristic owl-eye intranuclear inclusions in enlarged cells. Treated with intravenous ganciclovir or oral valganciclovir. CMV colitis should be considered in any immunocompromised patient with colitis unresponsive to standard therapy.

Colitis

- Inflammation of the colon, with a broad differential diagnosis and diverse clinical presentations. Acute colitis presents with diarrhea (often bloody), abdominal pain, tenesmus, and urgency. The most common causes include infectious colitis (bacterial: *Shigella*, *Salmonella*, *Campylobacter*, *E. coli* O157:H7, *C. difficile*; viral: CMV; parasitic: amebiasis), ischemic colitis (from hypoperfusion, typically at watershed areas of splenic flexure and rectosigmoid), and idiopathic inflammatory bowel disease (ulcerative colitis and Crohn disease).

Collagenous Colitis

- Chronic inflammatory bowel disease characterized by thickening of the subepithelial collagen band in the colonic mucosa to greater than ten micrometers normally less than five micrometers with preservation of the epithelial surface. Presents with chronic watery non-bloody diarrhea primarily in middle-aged women. The collagen band disrupts water and electrolyte absorption leading to secretory diarrhea. Diagnosis requires colonoscopy with random colonic biopsies demonstrating the characteristic subepithe-

lial collagen deposition.

Colonic Ischemia

- Decreased blood flow to the colon causing mucosal or transmural injury. Most commonly affects watershed areas particularly the splenic flexure and rectosigmoid junction. Causes include non-occlusive hypoperfusion from cardiogenic shock, vasoconstrictive medications, and vasculitis. Presents with sudden onset crampy left lower quadrant pain followed by bloody diarrhea within twenty-four hours. Most cases are self-limited with mucosal ischemia resolving within one to two weeks. Severe transmural infarction requires surgical resection.

Colonoscopy

- Visualization of the entire colon and terminal ileum using a flexible colonoscope. It is the gold standard for colorectal cancer screening and the preferred method for evaluating colonic pathology. The procedure requires bowel preparation with purgative solution to clear the colon. Therapeutic capabilities include polypectomy, hemostasis, dilation, and stent placement. Complications include perforation, bleeding, and post-polypectomy syndrome. Adequate adenoma detection rate is a key quality metric in colonoscopy.

Colorectal Cancer Screening

- Public health strategy to detect colorectal cancer and precancerous polyps in asymptomatic individuals. Current guidelines recommend screening beginning at age forty-five. Options include fecal immunochemical test annually, multi-target stool DNA test every three years, colonoscopy every ten years, CT colonography every five years, and flexible sigmoidoscopy every five years. The choice depends on patient preference, access, risk assessment, and shared decision-making. Screening reduces cancer incidence and mortality.

Constipation

- A common symptom-based disorder defined by the Rome IV criteria as having two or more of the following for at least 3 months: straining during more than 25 percent of bowel movements, lumpy or hard stools, sensation of incomplete evacuation, sensation of anorectal obstruction, manual maneuvers to facilitate defecation, or fewer than 3 bowel movements per week. Constipation is classified as primary (normal transit, slow transit, or defecatory

dysfunction from pelvic floor dyssynergia or structural abnormalities of the anorectum.

Courvoisier Sign

- Clinical finding of a palpable non-tender gallbladder in obstructive jaundice suggesting malignant biliary obstruction. In gallstone disease, the gallbladder is typically fibrotic and not palpable, whereas in malignant obstruction it is distended because the wall is initially normal and compliant. The most common cause is pancreatic head carcinoma. The sign has a positive predictive value of approximately eighty-five to ninety percent. Physical examination requires careful right upper quadrant palpation.

Crohn Disease

- Chronic transmural inflammatory condition that can affect any segment of the gastrointestinal tract from the oral cavity to the perianal region, though the terminal ileum and ileocolonic region are most commonly involved. Unlike ulcerative colitis, Crohn disease is characterized by transmural inflammation that extends through all layers of the bowel wall, segmental or skip lesions with intervening normal bowel, and a cobblestone mucosal appearance resulting from intersecting lines of ulceration. The transmural nature of inflammation predisposes to fistula formation, abscesses, and strictures.

Crohn Disease Cobblestoning

- Endoscopic appearance of the colonic or small bowel mucosa in Crohn disease characterized by a bumpy, irregular surface resembling cobblestones. This distinctive appearance results from intersecting lines of deep linear and serpiginous ulceration that surround areas of relatively preserved or edematous but intact mucosa. The combination of raised mucosal islands between ulcer tracks creates the characteristic cobblestone pattern. This finding is highly suggestive of Crohn disease and reflects the underlying pathology of the disease.

CT Colonography

- CT imaging of the colon after bowel preparation and insufflation with air or carbon dioxide. Used for colorectal cancer screening in patients unable to undergo optical colonoscopy and for evaluating complete colonoscopy when the cecum was not reached. Detects polyps greater than six millimeters with high sensitivity. Advantages include non-invasiveness and examination of extracolonic struc-

tures. Disadvantages include radiation exposure, need for adequate bowel preparation, and inability to perform polypectomy or biopsy at the time of imaging.

CT Enterography

– CT imaging of the small bowel after administration of large volumes of neutral oral contrast distending the small bowel with IV contrast. Excellent for evaluating Crohn disease, small bowel tumors, and obscure gastrointestinal bleeding. Demonstrates bowel wall thickening, hyperenhancement, mesenteric fat stranding, lymphadenopathy, and complications including strictures, fistulae, and abscesses. The technique provides high spatial resolution and rapid acquisition. It is limited by ionizing radiation exposure.

Curling Ulcer

– Stress ulceration of the stomach or duodenum associated with severe burns. Part of the Curling triad with hypovolemia and sepsis. The pathogenesis involves reduced mucosal blood flow during the systemic inflammatory response to burn injury. Prevention with stress ulcer prophylaxis using proton pump inhibitors or H₂ blockers is standard in burn unit patients. Treatment of established Curling ulcers involves acid suppression and surgical intervention for complications including hemorrhage and perforation.

Defecography

– Dynamic imaging of the rectum and pelvic floor during defecation using fluoroscopy or MRI. The rectum is filled with contrast paste and the patient performs defecation while images are captured. Evaluates rectal prolapse, intussusception, rectocele, enterocele, and pelvic floor dyssynergia. MR defecography provides superior soft tissue detail without radiation and is the preferred modality when available. The study is particularly useful in evaluating patients with obstructed defecation syndrome, particularly when standard therapies have failed.

Diarrhea

– Frequent passage of loose, watery stools, typically defined as more than 3 bowel movements per day with stool weight exceeding 200 grams. Acute diarrhea (less than 14 days) is most commonly infectious in etiology: viral (norovirus, rotavirus, adenovirus), bacterial (*Campylobacter*, *Salmonella*, *Shigella*, *E.*

coli, *C. difficile*), and parasitic (*Giardia*, *Cryptosporidium*, *Entamoeba*). Chronic diarrhea (more than 4 weeks) requires evaluation for malabsorption syndromes (celiac disease, pancreatic insufficiency, bile acid malabsorption, and microscopic colitis).

Diarrhea, Constipation, Gas, and Bloating

– These common gastrointestinal symptoms arise from disruptions in normal digestive function caused by diet, infections, medications, or underlying conditions like irritable bowel syndrome. Diarrhea involves increased stool frequency and water content, while constipation involves infrequent or difficult passage of stool. Gas and bloating result from swallowed air or colonic fermentation of undigested food and may cause abdominal distension and discomfort.

Diverticular Disease

– Condition characterized by the presence of diverticula, which are outpouchings of the colonic mucosa and submucosa through defects in the muscularis propria at sites where vasa recta penetrate the bowel wall. Diverticulosis, the presence of diverticula without inflammation, is extremely common in Western populations, affecting more than half of individuals over age sixty, and is thought to result from a combination of low dietary fiber intake, increased intraluminal pressure from straining, and age-related weakening of the colonic wall.

Diverticulitis

– Inflammation and infection of colonic diverticula, a common complication of diverticulosis affecting 10-25 percent of individuals with diverticula. The pathophysiology involves microperforation of a diverticulum with fecal contents entering the pericolic tissues, inciting inflammation and potential abscess formation. Clinical presentation includes acute onset of left lower quadrant abdominal pain (typically constant, localized, worsened by movement), fever, nausea, vomiting, and altered bowel habit, and anorexia.

Diverticulosis

– The presence of diverticula, small mucosal outpouchings through the colonic wall at sites of vascular penetration, most commonly in the sigmoid colon (90 percent of cases). Prevalence increases with age, affecting over 50 percent of individuals

older than 60 years and nearly 70 percent by age 85. The pathogenesis involves a combination of low dietary fiber intake leading to increased intraluminal pressure, segmental colonic muscle hypertrophy, and weakening of the colonic wall at points of nutrient arteries at the point of vasa recta penetration through the circular muscle layer.

Diverticulosis and Diverticulitis

– Diverticulosis is a condition in which small, bulging pouches (diverticula) form in the lining of the digestive tract, most commonly in the colon. Diverticulitis occurs when these pouches become inflamed or infected, causing abdominal pain, fever, and changes in bowel habits. Treatment ranges from dietary modification and antibiotics for mild cases to surgical intervention for severe or recurrent episodes.

Double-Balloon Enteroscopy

– Advanced endoscopic technique using an enteroscope equipped with balloons at the tip of both the endoscope and an overtube allowing systematic advancement and visualization of the entire small bowel. The balloons are alternately inflated and deflated to anchor the bowel wall and advance the endoscope. This technique allows deep intubation of the small bowel from both oral and anal approaches. Double-balloon enteroscopy is the most comprehensive method for evaluating small bowel pathology, with the ability to perform biopsies and therapeutic interventions throughout the entire small bowel.

Dubin-Johnson syndrome

– A benign, autosomal recessive disorder of conjugated hyperbilirubinemia caused by mutations in the *ABCC2* gene encoding the multidrug resistance-associated protein 2 (MRP2), which transports conjugated bilirubin from hepatocytes into bile. This results in impaired excretion of conjugated bilirubin and other organic anions, leading to elevated serum conjugated bilirubin levels (typically 2-5 mg/dL). The liver has a characteristic gross black appearance due to accumulation of dark pigment (epinephrine metabolites) deposited in the hepatocytes.

Dysentery

– Severe diarrheal illness with blood and mucus in stool, typically caused by *Shigella*, *Salmonella*, *Campylobacter*, or *Entamoeba histolytica*. Presents with frequent bloody stools, abdominal cramps,

tenesmus, and fever. Diagnosis: stool culture, microscopy, PCR. Treatment: rehydration and targeted antibiotics based on pathogen and sensitivity. Complications: toxic megacolon, hemolytic uremic syndrome (Shiga toxin-producing *E. coli*).

Endoscopic Retrograde Cholangiopancreatography

– Combined endoscopic and fluoroscopic procedure used to visualize and treat disorders of the biliary and pancreatic ducts. A duodenoscope is advanced to the second portion of the duodenum and the ampulla of Vater is cannulated. Contrast dye is injected under fluoroscopic guidance creating cholangiograms and pancreatograms. Therapeutic interventions include endoscopic sphincterotomy, stone extraction using baskets and balloons, stent placement for strictures, and nasobiliary drainage. The most common complication is post-ERCP pancreatitis, occurring in 3-10 percent of cases.

Enema

– The introduction of fluid into the rectum and colon through the anus for diagnostic or therapeutic purposes. Types: cleansing enema (warm water, saline, or soap solution to relieve constipation or prepare for colonoscopy/surgery), retention enema (mineral oil for fecal impaction, corticosteroid or mesalamine for inflammatory bowel disease), barium enema (radiographic contrast study of the colon—now largely replaced by colonoscopy and CT colonography), and medicinal enema (administration of drugs such as laxatives, anti-inflammatories, or anesthetics). Potential complications: electrolyte disturbance (with excessive tap water enemas), bowel perforation (rare, with improper technique), and vagal reaction.

Enteritis

– Inflammation of the small intestine, most commonly caused by infectious agents (viral, bacterial, or parasitic). Viral enteritis (norovirus, rotavirus, adenovirus, astrovirus) presents with acute onset of watery diarrhea, nausea, vomiting, and abdominal cramps, typically self-limited over 2–7 days. Bacterial enteritis (*Campylobacter*, *Salmonella*, *Shigella*, *E. coli*, *Yersinia*) more often presents with fever, bloody diarrhea, and tenesmus. Chronic enteritis occurs in Crohn disease, celiac disease, radiation enteritis, and eosinophilic gastroenteritis. Diagnosis: clinical history, stool studies (culture, PCR, ova and

parasites), and imaging. Management: rehydration (oral or IV), antiemetics, and antibiotics only for specific bacterial infections.

Familial Adenomatous Polyposis

– Hereditary condition with hundreds to thousands of adenomas throughout the colon caused by germline APC gene mutations with autosomal dominant inheritance. Polyps develop during the second decade and colorectal cancer occurs by age forty if untreated. Diagnosis is by colonoscopy showing numerous polyps and genetic testing. Management requires prophylactic colectomy typically in the second decade. Upper gastrointestinal endoscopy surveillance is needed for duodenal and periampullary polyps. Genetic counselling and testing of at-risk family members are essential components of management.

Fatty Liver Disease (MASLD)

– A condition characterized by the accumulation of excess fat in liver cells, most commonly associated with obesity, insulin resistance, and metabolic syndrome. Non-alcoholic fatty liver disease (NAFLD) is the most common form and ranges from simple steatosis to non-alcoholic steatohepatitis (NASH), which can progress to fibrosis and cirrhosis. Management focuses on weight loss, dietary modification, exercise, and control of metabolic risk factors.

Fecal Calprotectin

– Neutrophil-derived protein measured in stool as a marker of intestinal inflammation. It is stable in stool at room temperature for up to seven days. Useful for differentiating inflammatory from functional bowel disease and monitoring inflammatory bowel disease activity. Levels above fifty micrograms per gram suggest intestinal inflammation. Fecal calprotectin has high sensitivity and specificity for detecting endoscopically active inflammatory bowel disease and can reduce the need for endoscopic surveillance when used as a triage tool.

Fecal Elastase

– Pancreatic enzyme measured in stool as a marker of exocrine pancreatic function. Low levels below two hundred micrograms per gram indicate pancreatic insufficiency, and levels below one hundred are consistent with severe exocrine insufficiency. Useful for diagnosing chronic pancreatitis and cystic fibrosis-related pancreatic insufficiency. The test is

not affected by enzyme supplementation. Fecal elastase has good sensitivity and specificity for detecting moderate to severe pancreatic exocrine insufficiency.

Fecal Incontinence

– Inability to control bowel movements ranging from minor soiling to complete loss of continence. Causes include sphincter injury from obstetric trauma or surgery, neuropathy from diabetes or spinal cord injury, diarrhea, rectal prolapse, and cognitive impairment. Diagnosed by anorectal manometry, endoanal ultrasound, and pudendal nerve terminal motor latency testing. Managed with pelvic floor exercises and biofeedback as first-line therapy, dietary modification to optimize stool consistency, bulk-forming laxatives as initial management, with prescription medications such as loperamide for diarrhea-predominant symptoms and linaclotide for constipation-predominant symptoms.

Fecal Microbiota Transplantation

– Transfer of stool from a healthy donor into the gastrointestinal tract of a recipient to restore microbiome diversity. Highly effective for recurrent *Clostridioides difficile* infection with cure rates exceeding eighty-five percent. Administered via colonoscopy, enema, nasoduodenal tube, or oral capsules. The procedure is generally safe with rare complications including aspiration during administration. Donor screening is essential to prevent transmission of infectious diseases. Research is ongoing into the role of FMT in other conditions such as inflammatory bowel disease and metabolic syndrome.

FibroScan

– Non-invasive transient elastography technique measuring liver stiffness to assess hepatic fibrosis. Values correlate with fibrosis stage with higher values indicating more advanced fibrosis. The technique avoids the need for liver biopsy in many patients. Results may be unreliable in obesity, ascites, and narrow intercostal spaces. Controlled attenuation parameter measures hepatic steatosis simultaneously. FibroScan is useful for screening, diagnosis, and monitoring of liver fibrosis in chronic liver disease, particularly in patients with chronic hepatitis B, non-alcoholic fatty liver disease, and recurrent alcohol-related liver disease.

Fistula-in-Ano

– Abnormal epithelialized tract connecting the anal canal to the perianal skin, representing a common and distressing complication of Crohn disease and also occurring following perianal abscess drainage or from cryptoglandular infection. In Crohn disease, fistulae result from transmural inflammation that penetrates through the bowel wall and tracks to the skin surface. Parks classification categorizes fistulae based on their relationship to the anal sphincter muscles: intersphincteric fistulae course between the internal and external anal sphincters, trans-sphincteric fistulae pass through the external sphincter, supra-sphincteric fistulae loop over the puborectalis, and extrasphincteric fistulae track outside the sphincter complex entirely.

Fitz-Hugh-Curtis Syndrome

– Perihepatitis associated with pelvic inflammatory disease caused by ascension of *Neisseria gonorrhoeae* or *Chlamydia trachomatis* from the pelvis to the liver capsule along the right paracolic gutter. Presents with right upper quadrant pain, fever, and tender hepatomegaly often in young sexually active women. May mimic cholecystitis or hepatitis. Diagnosis requires demonstration of pelvic inflammatory disease with cervical cultures or nucleic acid amplification testing and imaging showing perihepatic enhancement on CT or MRI.

Focal Nodular Hyperplasia

– Benign liver lesion with a characteristic central stellate scar visible on imaging. The lesion represents a hyperplastic response to a pre-existing vascular malformation rather than a true neoplasm. Associated with oral contraceptive use though it also occurs in men and children. No risk of hemorrhage or malignant transformation. Diagnosed by imaging showing a well-circumscribed enhancing mass with central scar. Managed expectantly with no treatment required. Differentiation from hepatic adenoma, which carries risk of hemorrhage and malignant transformation and is managed differently.

Foodborne Illness

– Any illness resulting from the ingestion of contaminated food, encompassing infections and intoxications caused by pathogens, toxins, or chemical contaminants. It affects millions annually and poses particular risks to pregnant women, young children, older adults, and immunocompromised individuals.

Prevention relies on proper food handling, cooking temperatures, hand hygiene, and safe storage practices.

Food Poisoning

– Illness caused by consuming food contaminated with bacteria, viruses, parasites, or their toxins. Common pathogens include *Salmonella*, *Escherichia coli*, *Listeria*, and norovirus, with symptoms such as nausea, vomiting, diarrhea, abdominal cramps, and fever. Most cases resolve without treatment, but severe infections may require hospitalization and supportive care.

Gall-Bladder

– A pear-shaped sac located beneath the liver on the visceral surface, in the gallbladder fossa between the right and quadrate lobes of the liver. Capacity: approximately 30-50 mL. Functions: (1) concentrates and stores bile (10-fold concentration by absorption of water and electrolytes), (2) releases bile into the duodenum via the cystic duct and common bile duct in response to cholecystokinin (CCK) released after a fatty meal, (3) secretes mucus (protects gallbladder mucosa from bile acids). The gallbladder is absent in some species (rat, horse) and can be removed (cholecystectomy) without significant digestive impairment. Bile composition: bile salts, bilirubin, cholesterol, phospholipids.

Gall-Bladder, Diseases of

– Pathological conditions affecting the gallbladder. Types: (1) Cholelithiasis (gallstones)—most common, affects 10-15% of adults in Western countries. (2) Acute cholecystitis—inflammation of the gallbladder, usually due to stone obstruction of the cystic duct (90%). (3) Chronic cholecystitis—persistent inflammation with fibrosis, almost always associated with stones. (4) Acalculous cholecystitis—inflammation without stones, seen in critically ill patients, burns, trauma, total parenteral nutrition. (5) Gallbladder polyps—most are benign cholesterol polyps; adenomatous polyps have malignant potential. (6) Gallbladder carcinoma—rare (1-2% of gallstone patients), more common with large stones (>3 cm), porcelain gallbladder, and chronic *Salmonella typhi* carriage. (7) Choledocholithiasis—stones in the common bile duct. (8) Mirizzi syndrome—stone impacted in the cystic duct causing extrinsic compression of the common hepatic duct.

Gallstone Ileus

– Large gallstone eroding through the gallbladder wall into the duodenum causing mechanical small bowel obstruction. Diagnosed by CT showing Rigler triad of small bowel obstruction, pneumobilia, and ectopic gallstone. The most common site of obstruction is the ileum where the bowel caliber narrows. Treatment is surgical with enterolithotomy to relieve the obstruction. Cholecystectomy and fistula repair may be performed simultaneously or as a staged procedure depending on the patient's condition.

Gallstones

– Also known as cholelithiasis, crystalline deposits that form in the gallbladder composed predominantly of cholesterol (80 percent of stones in Western populations, yellow-green, radiolucent on plain x-ray, develop when bile is supersaturated with cholesterol) or bilirubin pigment (black pigment stones: sterile bile with high unconjugated bilirubin from hemolysis, cirrhosis, age; brown pigment stones: infected bile from bacterial beta-glucuronidase activity, associated with biliary stasis and parasitic infection in East Asian populations).

Gallstones (Cholelithiasis)

– See Gallstones.

Gastrocnemius

– The large superficial muscle of the posterior calf, forming the bulk of the calf contour. Origin: medial and lateral femoral condyles. Insertion: calcaneus via the Achilles tendon. Nerve: tibial nerve (S1-S2). Action: plantar flexion of the ankle (standing, walking, running, jumping); also flexes the knee. The gastrocnemius works with the soleus as the triceps surae. Clinical relevance: medial gastrocnemius strain (tennis leg), gastrocnemius rupture, deep vein thrombosis (DVT) may cause calf swelling and must be distinguished from muscle injury. Power: can generate up to 3-4 times body weight during running.

Gastroenteritis

– Inflammation of the stomach and intestinal mucosa, most commonly caused by viral infections (norovirus, rotavirus, adenovirus), bacterial pathogens (*E. coli*, *Salmonella*, *Campylobacter*), or parasites. Presents with diarrhea, vomiting, abdominal cramps, and dehydration. Self-limited in most cases. Management: oral rehydration, antiemet-

ics, and symptomatic care. Antibiotics reserved for specific bacterial infections.

Gastrointestinal Stromal Tumor

– Mesenchymal tumor arising from interstitial cells of Cajal in the gastrointestinal wall most commonly in the stomach. Often driven by gain-of-function mutations in the KIT proto-oncogene or PDGFRA gene. The majority are but approximately twenty to thirty percent are malignant. Diagnosed by endoscopic ultrasound with fine-needle aspiration and immunohistochemistry showing CD117 or DOG1 positivity. Treated with imatinib a tyrosine kinase inhibitor for unresectable or metastatic disease and surgical resection for localized disease, with imatinib as first-line therapy for advanced or metastatic GIST.

Giardiasis

– Infection with *Giardia lamblia* (*G. intestinalis*), a protozoan parasite causing diarrheal illness. Transmission via contaminated water (fecal-oral). Presents with foul-smelling, greasy diarrhea, bloating, abdominal cramps, weight loss, and steatorrhea. Diagnosis: stool antigen testing or microscopy. Treatment: metronidazole or tinidazole. Prevention: water purification, hand hygiene.

Gilbert Syndrome

– A common, benign autosomal recessive hereditary hyperbilirubinemia caused by a promoter mutation in the UGT1A1 gene leading to reduced activity (~30% of normal) of UDP-glucuronosyltransferase. Characterized by mild, transient unconjugated (indirect) hyperbilirubinemia (total bilirubin typically < 3 mg/dL) triggered by physical stress, fasting, illness, dehydration, or strenuous exercise. Asymptomatic with normal liver enzymes (ALT, AST, alkaline phosphatase) and no hemolysis. Excellent prognosis requiring no treatment; reassurance is key.

Gluten

– A complex of storage proteins (prolamins and glutelins) found in wheat (gliadin), barley (hordein), and rye (secalin). Gluten provides elasticity to dough. In susceptible individuals, gluten triggers an autoimmune response (celiac disease) or non-autoimmune sensitivity (non-celiac gluten sensitivity, NCGS). Gluten-free diet is the treatment for celiac disease. Oats contain avenin (structurally different) and are tolerated by most celiac patients if certified gluten-free (avoid cross-contamination).

Gluten is also implicated in: dermatitis herpetiformis (cutaneous manifestation of celiac disease), gluten ataxia, and wheat allergy (IgE-mediated, different pathogenesis).

Gluten-Sensitive Enteropathy (Celiac Disease)

– An autoimmune enteropathy triggered by ingestion of gluten (wheat, barley, rye) in genetically predisposed individuals. Incidence: 1% worldwide, higher in HLA-DQ2 (90%) and HLA-DQ8 carriers. Pathophysiology: gluten peptides (especially 33-mer alpha-gliadin) are deamidated by tissue transglutaminase (tTG), presented by HLA-DQ2/DQ8, activating T-cell-mediated damage to small intestinal villi (villous atrophy, crypt hyperplasia, increased intraepithelial lymphocytes). Symptoms: (1) Classical: chronic diarrhea, steatorrhea, weight loss, bloating, abdominal pain, failure to thrive (children). (2) Non-classical: iron-deficiency anemia, fatigue, osteoporosis, elevated transaminases, infertility, neuropathy, dermatitis herpetiformis. (3) Asymptomatic: detected by screening in at-risk groups (family history, type 1 diabetes, Down syndrome, autoimmune thyroiditis). Diagnosis: positive serology (IgA anti-tTG, confirm with anti-EMA or anti-DGP), duodenal biopsy (Marsh grade 0-IIIc). Treatment: lifelong strict gluten-free diet. Complications: refractory celiac disease (unresponsive to >12 months of diet), enteropathy-associated T-cell lymphoma (EATL), ulcerative jejunoileitis, increased mortality (hazard ratio 1.2-1.4).

Graft-Versus-Host Disease

– Immunological reaction where donor T cells attack recipient tissues after allogeneic bone marrow transplant. Affects the skin, liver, and gastrointestinal tract. GI manifestations include diarrhea, abdominal pain, nausea, anorexia, and gastrointestinal bleeding. Acute graft-versus-host disease occurs within the first hundred days and chronic occurs after day hundred. Diagnosis is by endoscopy with biopsy showing characteristic apoptosis and crypt abscesses. Treated with corticosteroids, calcineurin inhibitors (tacrolimus), mycophenolate mofetil, and anti-TNF agents.

Gripping (see Colic)

– Severe abdominal pain, typically spasmodic in

nature. See Colic.

Gut Microbiome

– The complex community of trillions of microorganisms, including bacteria, viruses, and fungi, residing in the gastrointestinal tract. The gut microbiome plays a crucial role in digestion, immune function, vitamin synthesis, and protection against pathogens. Its composition is influenced by diet, medications, and lifestyle, and imbalances have been linked to conditions such as obesity, inflammatory bowel disease, and metabolic disorders.

Hartmann Procedure

– Surgical resection of the rectosigmoid colon with creation of an end colostomy and rectal stump. Used for emergency resection of complicated diverticulitis with peritonitis and colorectal cancer with obstruction or perforation. The procedure avoids primary anastomosis in a contaminated field. Reversal with restoration of intestinal continuity is performed electively when the patient recovers, though not all patients are candidates for reversal. Laparoscopic reversal may be technically demanding due to adhesions and fibrosis and carries significant morbidity.

Hemochromatosis

– Iron overload disorder characterized by excessive intestinal iron absorption leading to progressive iron deposition in parenchymal organs. Hereditary hemochromatosis is most commonly caused by homozygous C282Y mutations in the HFE gene affecting approximately one in two hundred individuals of Northern European descent. Clinical manifestations include hepatic cirrhosis, cardiomyopathy, diabetes mellitus, arthropathy, and hypogonadism. Diagnosis is established by elevated transferrin saturation, elevated serum ferritin, and confirmatory genetic testing for HFE mutations.

Hemorrhoids

– Dilated veins in the rectal and anal canal. Internal hemorrhoids are above the dentate line, innervated by visceral nerves, and present with painless bright red bleeding. External hemorrhoids are below the dentate line, innervated by somatic nerves, and may thrombose causing severe pain. Grading: first degree bleed but do not prolapse; second degree prolapse with straining but reduce spontaneously; third degree require manual reduction; fourth degree are irreducible. Managed with dietary fiber,

increased fluid intake, stool softeners, and topical treatments. Surgical intervention including haemorrhoidectomy, stapled haemorrhoidopexy, or rubber band ligation is reserved for advanced grades and refractory symptoms.

Hepatic Cyst

- Fluid-filled cavity in the liver most commonly congenital and asymptomatic. Simple hepatic cysts are lined by biliary epithelium and contain clear fluid. May cause pain or compressive symptoms if large or complicated by hemorrhage, infection, or rupture. Simple cysts require no treatment. Polycystic liver disease is an autosomal dominant condition associated with autosomal dominant polycystic kidney disease and may cause significant hepatomegaly and symptoms requiring surgical intervention including fenestration, aspiration sclerotherapy, or surgical resection for symptomatic giant cysts.

Hepatic Encephalopathy

- Neuropsychiatric syndrome occurring in advanced liver disease resulting from accumulation of neurotoxic substances, particularly ammonia. Ammonia crosses the blood-brain barrier and is metabolized by astrocytes into glutamine causing osmotic swelling and impaired neurotransmission. The West Haven grading classifies severity from grade one with mild confusion to grade four with coma. Precipitating factors include gastrointestinal bleeding, infection, constipation, and dehydration. Diagnosis is primarily clinical, supported by elevated serum ammonia, and exclusion of other causes of altered mental status. Management includes lactulose, rifaximin, dietary protein restriction, and treatment of precipitating factors.

Hepatic Hemangioma

- Most common benign liver tumor composed of dilated blood-filled vascular spaces lined by endothelial cells. Usually asymptomatic and found incidentally on imaging. Most are small and require no treatment. Giant hemangiomas exceeding five centimeters may cause pain, compression of adjacent structures, or rarely consumptive coagulopathy with Kasabach-Merritt syndrome. Diagnosed characteristically on imaging showing peripheral nodular enhancement with centripetal fill-in on contrast-enhanced CT or MRI, with a characteristic discontinuous centripetal filling pattern.

Hepatic Hydrothorax

- Large pleural effusion occurring in patients with cirrhosis and portal hypertension in the absence of primary cardiac or pulmonary disease. Most commonly right-sided resulting from transit of ascitic fluid through small defects in the diaphragm into the pleural space driven by the pressure gradient between the abdomen and thorax. Presents with dyspnea, cough, and hypoxemia. Diagnosis requires thoracentesis demonstrating transudative fluid with a high ascitic fluid to pleural fluid protein gradient, along with treatment of the underlying liver disease and portal hypertension.

Hepatitis A Virus

- Picornavirus transmitted through the fecal-oral route most commonly via contaminated food or water. The incubation period is fifteen to fifty days. Clinical presentation ranges from asymptomatic infection in young children to symptomatic acute hepatitis with jaundice, fatigue, nausea, elevated transaminases, dark urine, and pale stools. Unlike hepatitis B and C, hepatitis A does not cause chronic infection. Fulminant hepatitis occurs in approximately zero point one to zero point three percent with overall mortality increasing with age and underlying liver disease.

Hepatitis B Virus

- Hepadnavirus transmitted through percutaneous exposure, sexual contact, and perinatally causing acute and potentially chronic hepatitis. The virus has a partially double-stranded circular DNA genome. Chronic hepatitis B affects approximately two hundred forty million people worldwide, increasing the risk of cirrhosis and hepatocellular carcinoma. Diagnosis is made by serological testing: surface antigen indicates infection, surface antibody indicates immunity, core antibody indicates past or current infection. Vaccination is recommended for all susceptible individuals and is highly effective at preventing infection and its complications.

Hepatitis C Virus

- Flavivirus transmitted primarily through percutaneous exposure with injection drug use being the most common route. Approximately seventy to eighty percent of acute infections progress to chronic hepatitis C, the leading cause of cirrhosis, hepatocellular carcinoma, and liver transplantation in many

Western countries. Diagnosis involves anti-hepatitis C antibody screening followed by confirmatory RNA measurement. Treatment with direct-acting antivirals achieves sustained virological response rates exceeding 95 percent, with minimal side effects.

Hepatitis D Virus

- Defective RNA virus requiring co-infection with hepatitis B to replicate, using hepatitis B surface antigen for its envelope. Hepatitis D causes more severe liver disease than hepatitis B alone with accelerated progression to cirrhosis and higher risk of hepatocellular carcinoma. Co-infection with hepatitis D and B during acute hepatitis B is generally self-limited, but superinfection of chronic hepatitis B carriers leads to chronic hepatitis D in seventy to ninety percent of cases. Diagnosis is by serological testing for anti-hepatitis D antibodies and confirmed by HDV RNA detection.

Hepatitis E Virus

- Non-enveloped RNA virus transmitted through the fecal-oral route most commonly via contaminated drinking water. It is the most common cause of acute viral hepatitis worldwide. Clinical presentation is similar to hepatitis A with jaundice and elevated transaminases. The infection is usually self-limited in immunocompetent individuals, but fulminant hepatic failure occurs in approximately one to two percent overall with significantly higher mortality in pregnant women reaching twenty-five percent in the third trimester.

Hepatocellular Jaundice

- Jaundice caused by dysfunction of hepatocytes, impairing the liver's ability to take up, conjugate, or excrete bilirubin. See Jaundice for complete overview. Causes: viral hepatitis (A, B, C, D, E), alcoholic hepatitis, drug-induced liver injury (paracetamol, isoniazid), cirrhosis, autoimmune hepatitis, Wilson disease, haemochromatosis. Laboratory features: mixed elevation of unconjugated and conjugated bilirubin, elevated transaminases (ALT/AST), and impaired synthetic function (low albumin, prolonged INR). Differentiated from obstructive jaundice by normal bile ducts on imaging.

Hepatoma

- See Hepatocellular Carcinoma.

Hepatopulmonary Syndrome

- Triad of liver disease, intrapulmonary vascular

dilatation, and impaired oxygenation causing hypoxemia. Presents with platypnea which is dyspnea worsening in the upright position and orthodeoxia which is oxygen desaturation in the upright position. Diagnosed by contrast-enhanced echocardiography showing right-to-left shunt or macroaggregated albumin lung perfusion scan. The condition is an indication for liver transplantation as it may improve or resolve after transplant. There is no effective medical therapy beyond supportive care and oxygen supplementation.

Hepatorenal Syndrome

- Functional renal failure in advanced liver disease characterized by intense renal vasoconstriction in the setting of splanchnic vasodilation. Type 1 hepatorenal syndrome is rapidly progressive with median survival of approximately two weeks without treatment. Type 2 is slowly progressive associated with refractory ascites. Diagnosis requires exclusion of other causes of renal failure. Treatment options include vasoconstrictor therapy with terlipressin and albumin, transjugular intrahepatic portosystemic shunt (TIPS) for refractory cases, and liver transplantation as definitive treatment.

Hirschsprung Disease

- Congenital condition characterized by the absence of enteric ganglion cells in a segment of the distal colon, resulting from failure of neural crest cell migration during embryonic development. The aganglionic segment, which most commonly involves the rectosigmoid colon, remains tonically contracted because it lacks the inhibitory neural input required for relaxation, causing functional bowel obstruction. Affected infants typically present with failure to pass meconium within forty-eight hours of birth, along with abdominal distension, bilious vomiting, and delayed passage of meconium. Diagnosis is confirmed by barium enema showing a transition zone between the dilated proximal ganglionic segment and the narrow distal aganglionic segment, and definitive treatment is surgical resection of the aganglionic segment with pull-through anastomosis.

Hirschsprung's Disease

- A congenital disorder characterized by the absence of parasympathetic ganglion cells (aganglionosis) in the distal colon, resulting in failure of relaxation and functional obstruction. Incidence: 1 in 5,000 live

births, male predominance (4:1). The aganglionic segment extends proximally from the internal anal sphincter for a variable distance: short-segment (most common, 80%, rectosigmoid), long-segment (15%, extends beyond the sigmoid), total colonic aganglionosis (5%). Pathophysiology: during embryonic development (weeks 5-12), neural crest cells fail to migrate completely along the hindgut. The aganglionic segment has absent submucosal (Meissner) and myenteric (Auerbach) plexuses, causing tonic contraction and functional obstruction. Mutation in RET proto-oncogene is the most common genetic cause (50% of familial, 15% of sporadic cases). Associated with Down syndrome (5-10%) and other genetic syndromes (Waardenburg, MEN IIA). Clinical presentation: neonates—failure to pass meconium in the first 24-48 hours (99% of normal infants pass meconium within 24 hours), abdominal distension, bilious vomiting, enterocolitis (fever, explosive diarrhea, sepsis). Older infants/children—chronic constipation, abdominal distension, failure to thrive, enterocolitis. Diagnosis: barium enema (transition zone—narrow aganglionic segment proximal to dilated ganglionic colon), anorectal manometry (absent rectoanal inhibitory reflex), full-thickness rectal biopsy (golden standard—absent ganglion cells, hypertrophied nerve trunks on acetylcholinesterase staining). Treatment: surgical resection of the aganglionic segment with pull-through procedure (Soave, Swenson, Duhamel). Laparoscopic-assisted and transanal endorectal pull-through are preferred. Prognosis: excellent for short-segment disease; long-term issues with constipation, soiling, and enterocolitis in some patients.

Ileal Pouch-Anal Anastomosis

– Surgical creation of a J-pouch from the terminal ileum after proctocolectomy to preserve intestinal continuity for ulcerative colitis. Avoids permanent ileostomy by allowing defecation through the anal route. The procedure involves removal of the entire colon and rectum with construction of a reservoir from distal ileum. Complications include pouchitis, which is the most common complication, cuffitis, anastomotic stricture, and pouch failure. Pouchitis typically responds to antibiotic therapy with metronidazole or ciprofloxacin, and chronic pouchitis may require probiotic therapy, topical steroids,

or biologic agents.

Inflammatory Bowel Disease

– Chronic relapsing inflammatory conditions of the gastrointestinal tract encompassing Crohn disease and ulcerative colitis, resulting from a dysregulated immune response in genetically susceptible individuals triggered by environmental factors and alterations in the gut microbiome. The incidence and prevalence of IBD have increased substantially over recent decades, particularly in newly industrialized countries, suggesting important roles for urbanization, dietary changes, and reduced microbial diversity, which collectively drive the chronic inflammatory response.

Inflammatory Bowel Disease (IBD)

– A group of chronic inflammatory conditions affecting the gastrointestinal tract, primarily Crohn's disease and ulcerative colitis. Crohn's disease can involve any part of the digestive tract with transmural inflammation, while ulcerative colitis is confined to the colonic mucosa. Symptoms include abdominal pain, diarrhea, rectal bleeding, and weight loss, managed with anti-inflammatory medications, immunosuppressants, and sometimes surgery.

Intestinal Ganglioneuromatosis

– Benign proliferation of ganglion cells and nerve fibers in the gastrointestinal tract wall. May be diffuse involving the entire gastrointestinal tract or localized as ganglioneuromas. Associated with multiple endocrine neoplasia type 2B where intestinal ganglioneuromatosis may precede the development of medullary thyroid carcinoma. Can cause constipation, diarrhea, abdominal pain, or pseudo-obstruction. Diagnosis is by endoscopic biopsy showing ganglion cells within the lamina propria and muscularis mucosae, often associated with nerve fibre hypertrophy.

Intestinal Obstruction

– A mechanical or functional blockage of intestinal contents. Small bowel obstruction (SBO): most common cause is adhesions (60%), followed by hernias, tumors, and Crohn disease. Large bowel obstruction (LBO): most common is colorectal cancer, volvulus (sigmoid most common), and diverticulitis. Symptoms: abdominal pain (crampy, colicky), vomiting, abdominal distension, and obstipation. In SBO, vomiting is early and prominent. In LBO, distension

is prominent and vomiting is late. Diagnosis: plain abdominal X-ray (air-fluid levels, dilated loops), CT scan (gold standard, identifies etiology and strangulation). Treatment: NPO, NG decompression, IV fluids, and electrolyte correction. Complete SBO often requires surgery (laparoscopy or laparotomy with adhesiolysis). LBO: resection, Hartmann procedure, or colonic stenting as bridge to surgery.

Intestinal Pseudo-Obstruction

– Acute or chronic dilation of the bowel without mechanical obstruction due to neuromuscular dysfunction. Acute colonic pseudo-obstruction also called Ogilvie syndrome occurs in hospitalized or post-surgical patients. Chronic intestinal pseudo-obstruction may be idiopathic or secondary to systemic diseases including scleroderma, diabetes, and Parkinson disease. Managed with decompression, prokinetic agents including metoclopramide and erythromycin, and treatment of underlying conditions. Neostigmine is the first-line pharmacological treatment for acute colonic pseudo-obstruction, with resolution rates exceeding 80 percent, but requires cardiac monitoring due to risk of bradycardia.

Intra-Abdominal Abscess

– Localized collection of pus within the abdomen commonly in the pelvis, between bowel loops, or beneath the diaphragm. Results from intra-abdominal infection or surgery. Presents with fever, abdominal pain, and leukocytosis. Diagnosed by CT with contrast showing rim-enhancing fluid collection. Treated with percutaneous CT-guided drainage and broad-spectrum antibiotics. Surgery is reserved for multiloculated abscesses not amenable to percutaneous drainage or failure of percutaneous management.

Intra-Abdominal Hypertension

– Sustained elevation of intra-abdominal pressure above twelve millimeters of mercury measured through the urinary bladder. Graded as grade one twelve to fifteen, grade two sixteen to twenty, grade three twenty-one to twenty-five, and grade four greater than twenty-five millimeters of mercury. Causes include fluid resuscitation, abdominal surgery, ileus, ascites, and abdominal hemorrhage. Intra-abdominal hypertension can progress to abdominal compartment syndrome with organ dysfunction. Monitoring of intra-abdominal pressure is essential in critically ill and post-surgical patients

to guide interventions and prevent progression to abdominal compartment syndrome.

Intussusception

– Condition in which a segment of intestine telescopes into the adjacent distal segment causing bowel obstruction and compromise of the mesenteric blood supply. It is the most common cause of intestinal obstruction in infants and children between six months and three years of age. Classic presentation includes episodic colicky abdominal pain, vomiting, a sausage-shaped abdominal mass, and current jelly stool. Diagnosis is confirmed by ultrasound demonstrating a target sign or donut sign. In stable patients with non-ischemic intussusception, air or contrast enema reduction is both diagnostic and therapeutic, with success rates exceeding 80 percent in children.

Irritable Bowel Syndrome

– Functional gastrointestinal disorder characterized by recurrent abdominal pain associated with altered bowel habits without identifiable structural abnormalities. The Rome IV criteria define IBS as recurrent abdominal pain occurring at least one day per week associated with changes in defecation or stool form. Subtypes include IBS with constipation, IBS with diarrhea, and IBS with mixed bowel habits. Pathophysiology involves visceral hypersensitivity, altered gut motility, gut-brain axis dysfunction, and psychosocial factors. Management includes dietary modifications, stress reduction, fibre supplementation, antispasmodics, and neuromodulators.

Irritable Bowel Syndrome (IBS)

– A chronic functional gastrointestinal disorder characterized by recurrent abdominal pain and altered bowel habits (diarrhea, constipation, or mixed) without identifiable structural pathology. Pathophysiology involves dysregulation of the gut–brain axis, visceral hypersensitivity, altered motility, and imbalances in the gut microbiome. Diagnosis is clinical based on Rome IV criteria: recurrent abdominal pain at least 1 day/week for 3 months, associated with defecation or change in stool frequency/form. Management includes dietary modifications (low-FODMAP diet), fiber supplementation, antispasmodics, probiotics, and neuromodulators (tricyclic antidepressants, SSRIs) for refractory symptoms.

Ischemic Colitis

– Colonic mucosal ischemia resulting from reduced blood flow through the marginal artery and end arteries, most commonly occurring at watershed areas between vascular territories, particularly the splenic flexure. Unlike acute mesenteric ischemia affecting the small bowel, ischemic colitis most often occurs with non-occlusive hypoperfusion from cardiac failure or dehydration. The clinical presentation includes sudden onset crampy left-sided abdominal pain followed by bloody diarrhea. Most cases are self-limiting and resolve with supportive care and bowel rest, with full recovery expected within one to two weeks without specific intervention.

Jaundice

– Yellowish discoloration of the skin, sclerae, and mucous membranes caused by hyperbilirubinemia (serum bilirubin greater than 2-3 mg/dL), resulting from an imbalance between bilirubin production and clearance. Bilirubin metabolism: heme from senescent red blood cells is converted by heme oxygenase to biliverdin, then to unconjugated (indirect) bilirubin, which is transported to the liver bound to albumin. Unconjugated bilirubin is taken up by hepatocytes and conjugated with glucuronic acid by uridine diphosphate glucuronosyltransferase (UGT) in the hepatocyte. Conjugated (direct) bilirubin is water-soluble and excreted into bile. Hyperbilirubinaemia is classified as predominantly unconjugated (pre-hepatic or hepatic) or conjugated (hepatic or post-hepatic/obstructive).

Jaundice (Icterus)

– See Jaundice.

Kayser-Fleischer Rings

– Golden-brown copper deposition rings in Descemet membrane of the cornea representing a pathognomonic finding of Wilson disease. These rings are visible on slit lamp examination and present in virtually all patients with neurological manifestations of Wilson disease though they may be absent in isolated hepatic disease. The rings typically begin at the superior and inferior poles and progress circumferentially. They may gradually diminish after initiation of chelation therapy. Detection requires slit-lamp examination by an experienced ophthalmologist.

Lactose

– The primary disaccharide found in milk and dairy products (glucose + galactose, beta-1,4 glycosidic bond). See Lactose Intolerance.

Lactose intolerance

– A common digestive disorder caused by lactase deficiency leading to malabsorption of lactose, the primary disaccharide in milk and dairy products. The lactase enzyme is produced by enterocytes of the small intestinal brush border and hydrolyzes lactose into glucose and galactose for absorption. Three types exist: primary lactase deficiency (most common, involves the genetically programmed decline in lactase activity after weaning, affecting 70-75 percent of the world's adult population, with highest prevalence in individuals of East Asian, African, and Middle Eastern descent where lactase persistence is less common).

Large Bowel Obstruction

– Mechanical blockage of the colon most commonly caused by colorectal cancer, volvulus, or diverticular stricture. Clinical presentation includes progressive abdominal distension, constipation, and obstipation. The cecum is at highest risk of perforation with distal obstruction. Diagnosis is by CT scan identifying the site and cause. Management depends on cause: sigmoid volvulus may be managed by endoscopic detorsion, cecal volvulus requires emergent surgery, and colorectal cancer obstruction may require a diverting colostomy or colonic stent as a bridge to elective resection.

Liver Abscess

– Focal collection of pus within the liver parenchyma. Pyogenic abscesses are most commonly from biliary tract infection or hematogenous spread from portal or systemic infection. Amoebic abscesses are caused by *Entamoeba histolytica* predominantly in tropical regions. Presents with fever, right upper quadrant pain, and hepatomegaly. Diagnosed by CT showing rim-enhancing fluid collection. Treatment involves percutaneous CT-guided drainage and broad-spectrum antibiotics for pyogenic abscesses. Metronidazole is the treatment of choice for amoebic liver abscesses, with aspiration reserved for large abscesses at risk of rupture.

Liver Biopsy

– Percutaneous, transjugular, or laparoscopic sampling of liver tissue for histological evaluation. Indi-

cated for staging fibrosis, diagnosing specific liver diseases, and assessing treatment response. The procedure is guided by ultrasound for accuracy. Complications include bleeding, pain, and pneumothorax. Contraindications include uncorrected coagulopathy and thrombocytopenia. Transjugular biopsy is performed when percutaneous biopsy is contraindicated due to coagulopathy or ascites. Histologic evaluation remains the gold standard for assessing fibrosis stage and grade of inflammatory activity in chronic liver disease.

Liver Cirrhosis

- Advanced hepatic fibrosis with regenerative nodules surrounded by dense fibrous septa representing the end result of chronic liver injury. Common etiologies include chronic viral hepatitis, alcoholic liver disease, and nonalcoholic steatohepatitis. The pathogenesis involves activation of hepatic stellate cells producing excessive extracellular matrix. Cirrhosis progresses through compensated and decompensated phases. Decompensation manifests with ascites, variceal hemorrhage, encephalopathy, and ultimately hepatic failure.

Liver Diseases

- A broad category of pathological conditions affecting the structure and function of the liver. See individual entries: Hepatitis, Liver Cirrhosis, Fatty Liver, Hepatocellular Carcinoma, etc.

Liver Health

- Essential for metabolism, detoxification, protein synthesis, bile production, and immune function. Common liver disorders include nonalcoholic fatty liver disease (NAFLD, now termed metabolic dysfunction–associated steatotic liver disease or MASLD) affecting 30% of adults, alcoholic liver disease (steatosis, hepatitis, cirrhosis), viral hepatitis (HAV, HBV, HCV), drug-induced liver injury (acetaminophen toxicity most common), and autoimmune hepatitis. MASLD progresses from steatosis to steatohepatitis (NASH/MASH) with fibrosis and cirrhosis, driven by insulin resistance, obesity, and metabolic syndrome. Screening: liver enzymes (ALT, AST), viral serologies, abdominal ultrasound, FibroScan for fibrosis, and liver biopsy when indicated. Management: weight loss $\geq 7\%$ improves steatohepatitis in MASLD, alcohol cessation, antiviral therapy for HBV/HCV (direct-acting

antivirals cure $>95\%$ of HCV), and vaccination for HAV/HBV.

Liver Transplantation

- Surgical replacement of a diseased liver with a healthy donor organ indicated for end-stage liver disease, acute liver failure, and select hepatocellular carcinomas within Milan criteria. Requires lifelong immunosuppression with calcineurin inhibitors, antimetabolites, and corticosteroids. Living donor liver transplantation uses a portion of a living donor's liver which regenerates in both donor and recipient. Complications include rejection, infection, vascular complications, biliary complications (anastomotic strictures, bile leaks), and hepatic artery thrombosis.

Low FODMAP Diet

- Dietary intervention for irritable bowel syndrome that restricts fermentable oligosaccharides, disaccharides, monosaccharides, and polyols, which are short-chain carbohydrates poorly absorbed in the small intestine and rapidly fermented by colonic bacteria producing gas and drawing water into the intestinal lumen. The approach involves an elimination phase of two to six weeks, a reintroduction phase identifying personal triggers, and a long-term personalization phase. Studies demonstrate symptom improvement in 50-80 percent of patients with irritable bowel syndrome.

Lymphocytic Colitis

- Chronic inflammatory bowel disease characterized by increased intraepithelial lymphocytes exceeding twenty per one hundred surface epithelial cells in the colonic mucosa without significant subepithelial collagen band thickening. Shares clinical features with collagenous colitis including chronic watery non-bloody diarrhea primarily in middle-aged women. The pathogenesis may involve an immune response to luminal antigens. Diagnosis requires colonoscopy with random colonic biopsies showing increased intraepithelial lymphocytes on histology.

Malabsorption

- Defective absorption of nutrients from the small intestine. Causes: celiac disease, pancreatic insufficiency, bacterial overgrowth, Crohn disease, short bowel syndrome, and infections. Presents with diarrhea, steatorrhea, weight loss, and deficiency of specific nutrients (iron, B12, vitamin D, calcium).

Diagnosis: stool studies, D-xylose test, breath tests, small bowel biopsy. Treatment: address underlying cause and replace deficient nutrients.

Meconium Ileus

– Intestinal obstruction in neonates caused by inspissated meconium most commonly associated with cystic fibrosis. Presents with abdominal distension, bilious vomiting, and failure to pass meconium within forty-eight hours. Diagnosis is suggested by abdominal radiography showing a ground-glass appearance and may be confirmed by CT showing calcified meconium. Treatment includes water-soluble contrast enema which can be both diagnostic and therapeutic by loosening the inspissated meconium. Surgical intervention is required when non-operative management fails, with laparotomy and enterotomy for meconium removal and possible bowel resection for complicated cases.

MELD Score

– Model for End-Stage Liver Disease predicting three-month mortality in advanced liver disease used for liver transplant allocation. The score is calculated using serum bilirubin, creatinine, and international normalized ratio generating a continuous score from approximately six to forty points. Higher scores indicate more severe disease and higher mortality risk. The updated MELD score includes serum sodium. MELD exception points are granted for conditions including hepatocellular carcinoma within the Milan criteria (single tumor up to 5 cm, or up to 3 tumors each up to 3 cm, without extrahepatic spread or major vascular invasion).

Microscopic Colitis

– Umbrella term encompassing both collagenous colitis and lymphocytic colitis which share the clinical presentation of chronic watery non-bloody diarrhea and the pathophysiological feature of colonic mucosal inflammation. Endoscopic appearance is typically normal necessitating random biopsies for diagnosis. More common in women and associated with autoimmune diseases, celiac disease, and certain medications including proton pump inhibitors, selective serotonin reuptake inhibitors, and nonsteroidal anti-inflammatory drugs (NSAIDs), which can cause mucosal injury through inhibition of cyclooxygenase and prostaglandin synthesis.

Mirizzi Syndrome

– Condition where a gallstone impacted in the cystic duct or Hartmann pouch extrinsic compression of the common hepatic duct causing obstructive jaundice. Classified into four types based on the degree of erosion and fistula formation. Type one is extrinsic compression without fistula. Types two through four involve cholecystobiliary fistula of increasing size. Presents with obstructive jaundice, cholangitis, and abdominal pain. Diagnosis is by MRCP or endoscopic ultrasound demonstrating the impacted gallstone on the bile duct, and cholecystectomy with fistula repair is the definitive management.

MR Enterography

– MRI of the small bowel after oral contrast administration. Superior soft tissue contrast for evaluating Crohn disease activity, fistulas, and abscesses without ionizing radiation. Demonstrates mural thickening, edema, enhancement patterns, and extraintestinal complications. Diffusion-weighted imaging helps assess disease activity. Preferred imaging modality for young patients requiring serial follow-up due to absence of radiation. The technique is limited by longer examination time, availability, and susceptibility to motion artefact.

Neuroendocrine Tumors

– Heterogeneous group of neoplasms arising from neuroendocrine cells throughout the gastrointestinal tract and pancreas. May be functional producing hormones or non-functional. Graded by Ki-67 index and mitotic count into well-differentiated low-grade, intermediate-grade, and poorly differentiated high-grade tumors. Functional tumors include gastrinomas, insulinomas, glucagonomas, VIPomas, and carcinoid tumors secreting serotonin. Diagnosis is by hormone levels, imaging with CT, MRI, or octreotide scintigraphy (OctreoScan), and tissue biopsy for histological grading. Management includes somatostatin analogues for symptom control, peptide receptor radionuclide therapy (PRRT), and surgical resection for localised disease.

Non-Alcoholic Fatty Liver Disease

– Hepatic steatosis in the absence of significant alcohol consumption, strongly associated with metabolic syndrome, obesity, and type 2 diabetes. NAFLD includes simple steatosis and non-alcoholic steatohepatitis (NASH) with inflammation and fibrosis. NASH can progress to cirrhosis and hepatocellular

carcinoma. Diagnosis: abdominal ultrasound, elevated liver enzymes, transient elastography, and liver biopsy for staging. Management: weight loss, exercise, vitamin E, and pioglitazone for NASH.

Nonalcoholic Steatohepatitis

– Progressive form of NAFLD characterized by hepatic steatosis with lobular inflammation and hepatocyte ballooning with significant risk of progression to fibrosis, cirrhosis, and hepatocellular carcinoma. NASH affects approximately three to five percent of the general population. The histological features include macrovesicular steatosis, inflammation, hepatocyte ballooning, and perisinusoidal fibrosis. Progressive fibrosis is the most important predictor of liver-related mortality. Management involves lifestyle modification with weight loss, dietary changes, exercise, vitamin E therapy in non-diabetic patients with biopsy-proven NASH, and consideration of obeticholic acid or GLP-1 receptor agonists in selected patients.

Obstructive Jaundice

– Jaundice caused by obstruction of bile flow from the liver to the duodenum, resulting in accumulation of conjugated bilirubin in the blood. See Jaundice for complete overview. Causes: (1) Extrahepatic obstruction: choledocholithiasis (common bile duct stones, most common), pancreatic head carcinoma (painless jaundice, Courvoisier law), cholangiocarcinoma, ampullary tumor, primary sclerosing cholangitis, biliary stricture (post-surgical, post-ERCP), Mirizzi syndrome. (2) Intrahepatic obstruction: primary biliary cholangitis (now PBC), drug-induced cholestasis, infiltrative diseases (sarcoidosis, amyloidosis), sepsis, total parenteral nutrition. Laboratory features: elevated conjugated (direct) bilirubin, raised ALP and GGT (cholestatic enzymes), transaminases may be normal or mildly elevated. Imaging: ultrasound (dilated bile ducts, stone, mass), MRCP, ERCP (therapeutic). Complications: cholangitis, secondary biliary cirrhosis, fat-soluble vitamin deficiency (A, D, E, K), pruritus.

Pancreatic Cancer

– Aggressive malignancy with pancreatic ductal adenocarcinoma accounting for approximately eighty-five percent of cases. It is the fourth leading cause of cancer-related death with a five-year survival of approximately ten percent. Risk factors include

smoking, chronic pancreatitis, diabetes, and genetic syndromes. The most common presentation is painless obstructive jaundice from head of pancreas tumors. The Courvoisier sign suggests malignant biliary obstruction. Diagnosis involves CT, endoscopic ultrasound with fine-needle aspiration for tissue diagnosis, and tumor marker CA 19-9. Staging uses CT and endoscopic ultrasound.

Paracentesis

– Percutaneous needle aspiration of ascitic fluid from the peritoneal cavity. Used for diagnostic analysis to determine the cause of ascites and for therapeutic removal of large volumes for symptom relief. The serum-ascites albumin gradient is calculated to differentiate portal hypertensive from non-portal hypertensive causes. A gradient of one point one grams per deciliter or greater indicates portal hypertension. Diagnostic paracentesis with cell count, culture, and cytology should be performed before initiating treatment in all patients with new-onset ascites.

Peak Flow Meter

– See Peak Expiratory Flow Rate.

Peritoneal Carcinomatosis

– Diffuse metastatic seeding of the peritoneal cavity from gastrointestinal or ovarian malignancies. Presents with ascites, bowel obstruction, and cachexia. Diagnosed by CT and paracentesis showing malignant cells. Prognosis is generally poor. Management includes systemic chemotherapy, palliative care, and in selected cases, cytoreductive surgery with hyperthermic intraperitoneal chemotherapy. The peritoneal cancer index assesses disease distribution for surgical planning.

Peritoneal Dialysis Catheter

– Flexible tube surgically placed into the peritoneal cavity for peritoneal dialysis. The Tenckhoff catheter is the most commonly used type with one or two cuffs that promote tissue ingrowth and anchor the catheter. Placement can be done surgically, laparoscopically, or percutaneously under radiological guidance. Complications include peritonitis, catheter-related infection, tunnel infection, outflow failure, and hernia formation. Proper catheter placement technique and exit site care are essential for preventing infectious complications and ensuring catheter longevity.

Pilonidal Disease

– A chronic inflammatory condition of the sacrococcygeal region involving hair follicles. Pilonidal sinus: epithelialized tract containing hair and debris. Pilonidal abscess: acute infection of the sinus. Most common in young, hirsute males, exacerbated by prolonged sitting, obesity, and local trauma. Presents with pain, swelling, and purulent drainage in the natal cleft. Treatment: incision and drainage for acute abscess; definitive surgical treatment (excision with secondary healing, flap closure, or pit-picking) for chronic disease. Recurrence is common without good hygiene and hair removal.

Pneumatosis Cystoides Intestinalis

– Gas-filled cysts within the bowel wall that may be primary or secondary to bowel ischemia, infection, chronic lung disease, or medications. Often an incidental finding on imaging. Primary pneumatosis is benign and asymptomatic. Secondary pneumatosis may indicate serious underlying disease. Managed by treating the underlying condition. Surgery is reserved for complications including pneumoperitoneum, obstruction, or hemorrhage.

Pneumatosis Intestinalis

– Presence of gas within the bowel wall appearing as linear or cystic radiolucencies on imaging. Primary pneumatosis is benign and idiopathic accounting for approximately fifteen percent of cases. Secondary pneumatosis is associated with intestinal ischemia, necrotizing enterocolitis in neonates, obstructive pulmonary disease, and connective tissue diseases. The cystic form appears as clusters of gas-filled cysts in the submucosa or subserosa. The linear form suggests intramural gas tracking along the mesenteric vessels, which may indicate bowel necrosis and requires urgent surgical intervention.

Polyp Surveillance Colonoscopy

– Interval-based endoscopic follow-up of patients with previously identified colorectal polyps. Intervals are determined by polyp number, size, and histological features. One to two small adenomas require surveillance at seven to ten years. Three to four adenomas at three to five years. Five to ten adenomas or adenomas with villous features or high-grade dysplasia at three years. More than ten adenomas at one year. Sessile serrated polyps greater than ten millimeters require three to five year surveillance

intervals.

Porcelain Gallbladder

– Calcification of the gallbladder wall visible on imaging representing chronic inflammatory condition associated with cholelithiasis and chronic cholecystitis. Historically considered a strong risk factor for gallbladder carcinoma, recent studies suggest the cancer risk may be lower than previously estimated. Most patients are asymptomatic and the condition is discovered incidentally. When cholecystectomy is performed, the gallbladder should be carefully examined for occult malignancy. Management is cholecystectomy, preferably by the laparoscopic approach.

Postcholecystectomy Syndrome

– Persistence or recurrence of symptoms after cholecystectomy. Causes include retained common bile duct stones, sphincter of Oddi dysfunction, bile salt malabsorption, irritable bowel syndrome, and other gastrointestinal conditions. Evaluation includes liver function tests, MRCP, and endoscopic ultrasound. Treatment depends on the identified cause. Bile salt malabsorption responds to bile acid sequestrants. Sphincter of Oddi dysfunction may require endoscopic sphincterotomy.

Prebiotics and Probiotics

– Prebiotics are nondigestible food ingredients (fiber and oligosaccharides—inulin, fructooligosaccharides, galactooligosaccharides) that selectively stimulate the growth and activity of beneficial gut bacteria (*Bifidobacterium*, *Lactobacillus*), promoting host health. Probiotics are live microorganisms that confer a health benefit when administered in adequate amounts—commonly *Lactobacillus* species, *Bifidobacterium*, *Saccharomyces boulardii* (yeast), and *Streptococcus thermophilus*. Evidence supports probiotics for prevention of antibiotic-associated diarrhea (50% risk reduction), reduction of *C. difficile* infection recurrence (alongside standard antibiotics), management of irritable bowel syndrome (bloating, pain), treatment of acute infectious gastroenteritis (reduces duration by 1 day), and prevention of necrotizing enterocolitis in preterm infants. Synbiotics combine prebiotics and probiotics. The microbiome modulates immune function, metabolism, and gut–brain signaling. Quality control varies widely; products should specify genus, species, strain, and

colony-forming units (CFU) per dose. Fermented foods (yogurt, kefir, kimchi, sauerkraut) naturally provide beneficial microbes.

Primary Biliary Cholangitis

– Chronic autoimmune cholestatic liver disease characterized by progressive destruction of small intrahepatic bile ducts. The disease predominantly affects middle-aged women. Anti-mitochondrial antibodies are found in approximately ninety-five percent of patients. The hallmark histological finding is florid duct lesion with granulomatous destruction of interlobular bile ducts. Clinical presentation includes fatigue and pruritus. Diagnosis is established by elevated alkaline phosphatase, positive anti-mitochondrial antibodies, elevated serum IgM, and characteristic histology on liver biopsy. First-line treatment is ursodeoxycholic acid, which improves liver biochemistry and delays disease progression.

Primary Sclerosing Cholangitis

– Chronic cholestatic liver disease characterized by progressive fibrosis and strictures of intrahepatic and extrahepatic bile ducts. The disease has a strong association with ulcerative colitis occurring in seventy to eighty percent of patients. Diagnosis is established by MRCP showing multifocal strictures and dilatations giving a beaded appearance. Patients have a significantly increased risk of cholangiocarcinoma developing in ten to fifteen percent. There is no proven effective medical therapy, and liver transplantation is the definitive treatment for end-stage disease.

Proctitis

– Inflammation of the rectal mucosa causing tenesmus, rectal pain, and bloody discharge. Causes include inflammatory bowel disease, sexually transmitted infections including gonorrhea, chlamydia, and herpes, radiation therapy, and ischemia. Diagnosed by proctoscopy with biopsy. Treatment is directed at the underlying etiology. Empiric treatment for sexually transmitted infections should be initiated while awaiting culture results. Inflammatory proctitis responds to topical mesalamine or corticosteroid enemas.

Pruritus Ani

– Persistent itching around the anus with multiple potential causes including hemorrhoids, fissures, in-

fections such as pinworms and candidiasis, dermatologic conditions including psoriasis and lichen sclerosus, and idiopathic causes. Managed by addressing the underlying cause, strict hygiene measures with gentle cleansing after bowel movements, avoiding scratching, and topical treatments including hydrocortisone cream and barrier preparations. Cotton underwear and avoidance of irritating foods such as coffee, spicy foods, and citrus fruits should also be advised.

Pseudomembranous Colitis

– Colonic inflammation caused by *C. difficile* infection showing yellow-white plaques on colonoscopy. The plaques consist of fibrin, inflammatory cells, and necrotic epithelial debris overlying mucosal ulceration. Presents with profuse watery diarrhea and abdominal pain. Diagnosis is confirmed by endoscopy with biopsy showing characteristic pseudomembranes. Treated with oral vancomycin or fidaxomicin. Severe cases may require intravenous metronidazole and surgical intervention for fulminant colitis unresponsive to medical therapy.

Psoas Abscess

– Collection of pus in the iliopsoas muscle compartment. Primary psoas abscess results from hematogenous spread of *Staphylococcus aureus* typically in immunocompromised patients. Secondary psoas abscess results from contiguous spread from adjacent structures including Crohn disease, diverticulitis, appendicitis, and vertebral osteomyelitis. Presents with fever, flank or abdominal pain, and characteristic hip flexion posture. Diagnosis is by CT of the abdomen and pelvis showing the psoas collection. Treatment is CT-guided percutaneous drainage and intravenous antibiotics directed at the causative organism.

Push Enteroscopy

– Endoscopic technique using a longer endoscope to visualize and intervene in the proximal small bowel beyond the reach of standard upper endoscopy. Unlike capsule endoscopy, push enteroscopy allows direct visualization with the ability to obtain biopsies and perform hemostasis. The procedure is performed with the endoscope advanced through the mouth into the proximal and mid-jejunum. The primary indication is evaluation of obscure gastrointestinal bleeding identified on capsule endoscopy.

The diagnostic yield of push enteroscopy is highest when performed within 24-48 hours of active bleeding, and it enables targeted therapeutic intervention.

Ranson Criteria

- Clinical scoring system for acute pancreatitis severity incorporating eleven parameters at two time points. Admission parameters include age, white blood cell count, glucose, LDH, and AST. Forty-eight hour parameters include hematocrit drop, BUN increase, calcium, oxygen tension, base deficit, and fluid sequestration. A score of three or more indicates severe pancreatitis with mortality increasing with score. The Ranson criteria require forty-eight hours to complete, making them less useful for early severity assessment, and the Bedside Index for Severity in Acute Pancreatitis (BISAP) score is increasingly preferred for early risk stratification.

Rectal Prolapse

- Protrusion of rectal tissue through the anal opening. Complete prolapse involves all layers of the rectal wall and presents as a concentric cylindrical mass with visible mucosal folds. Partial prolapse involves only the mucosa. Associated with chronic straining, pelvic floor dysfunction, and neurological conditions. Treatment is surgical with rectopexy being the preferred approach. Perineal approaches including Delorme procedure and Altemeier procedure are options for elderly or high-risk patients.

Rectovaginal Fistula

- Abnormal connection between the rectum and vagina causing passage of stool or gas through the vagina. Causes include obstetric injury particularly third and fourth degree perineal tears, Crohn disease, radiation therapy, and surgical complications. Presents with vaginal discharge of stool, flatus, or recurrent vaginal infections. Classified by location as low involving the anal sphincter or high above the sphincter. Treated surgically with approaches including transanal advancement flap, transperineal repair, or with gracilis muscle flap interposition for complex recurrent fistulae.

Reynolds Pentad

- Extension of the Charcot triad to include hypotension and altered mental status representing suppurative cholangitis, a severe life-threatening form of ascending cholangitis. Patients present with high

fever, rigors, right upper quadrant pain, jaundice, hypotension, and confusion. Management involves aggressive fluid resuscitation, vasopressor support, broad-spectrum antibiotics, and emergent biliary decompression by ERCP. Without prompt treatment, suppurative cholangitis carries mortality exceeding 50 percent without prompt intervention.

Rovsing Sign

- Physical exam sign of acute appendicitis: palpation of the left lower quadrant elicits pain in the right lower quadrant due to displacement of gas stretching the inflamed appendix. *See Appendicitis.*

Salmonellosis

- Infection with *Salmonella* bacteria (non-typhoidal), typically acquired from contaminated food (eggs, poultry, meat). Presents with acute gastroenteritis: diarrhea, fever, and abdominal cramps within 6-72 hours of ingestion. Self-limited in immunocompetent patients. Bacteremia can occur, especially in immunocompromised. Treatment: supportive care; antibiotics reserved for severe disease, bacteremia, or immunocompromised hosts.

Serrated Pathway

- Alternative molecular pathway to colorectal carcinogenesis accounting for fifteen to thirty percent of cases. It involves serrated polyps as precursors including sessile serrated lesions with dysplasia. Molecular features include CpG island methylator phenotype, BRAF mutations, and microsatellite instability from MLH1 silencing. Sessile serrated lesions tend to be flat, sessile, mucus-covered, and located in the proximal colon making them difficult to detect. Recognition has led to updated colonoscopic screening and surveillance guidelines that emphasize careful inspection of the proximal colon.

Shigellosis

- Acute infectious colitis caused by *Shigella* species (*S. sonnei* most common in developed countries). Presents with fever, abdominal cramps, tenesmus, and frequent bloody, mucoid stools. Highly contagious with low infectious dose. Diagnosis: stool culture. Treatment: azithromycin, ciprofloxacin, or ceftriaxone (resistance patterns vary). Complications: reactive arthritis, hemolytic uremic syndrome (*S. dysenteriae* type 1).

Short Bowel Syndrome

- Clinical condition resulting from surgical resection

or functional loss of a significant portion of the small intestine leading to inadequate absorption of nutrients. Clinical manifestations depend on the length and location of the remaining bowel, the presence or absence of the ileocecal valve, and the adaptability of the remaining intestine. Patients typically experience profuse diarrhea, dehydration, electrolyte imbalances, and progressive malnutrition. Those losing the terminal ileum lack vitamin B12 absorption, requiring lifelong parenteral supplementation, while those with an intact colon can absorb short-chain fatty acids and salvage some calories and fluid.

Spontaneous Bacterial Peritonitis

- Infection of ascitic fluid without an identifiable intra-abdominal source representing a serious complication of cirrhosis with ascites. The pathogenesis involves impaired immune function, bacterial translocation from the intestinal lumen, and seeding of ascitic fluid which provides a favorable medium for bacterial growth. The most common causative organism is *Escherichia coli*. Patients present with fever, abdominal pain, and altered mental status, though symptoms may be absent in thirty percent of cases, necessitating a high index of suspicion and a low threshold for diagnostic paracentesis.

Tenesmus

- A sensation of incomplete defecation, characterized by a constant feeling of needing to pass stool accompanied by straining, pain, and cramping, despite little or no stool being passed. Tenesmus is a symptom, not a diagnosis. Causes: inflammatory bowel disease (ulcerative colitis—most common, Crohn disease), infectious colitis (*Shigella*, *Salmonella*, *Campylobacter*, *Clostridioides difficile*, amoebic dysentery), radiation proctitis (post-pelvic radiotherapy), colorectal cancer (especially rectal cancer—should be excluded), anorectal conditions (hemorrhoids, anal fissure, solitary rectal ulcer syndrome, proctalgia fugax), and irritable bowel syndrome. Pathophysiology: inflammation, infiltration, or irritation of the rectal mucosa and nerve endings (S2–S4, pelvic splanchnic nerves) triggers the urge to defecate. Assessment: proctoscopy/sigmoidoscopy or colonoscopy with biopsy, stool culture, and imaging (CT, MRI) if tumor suspected. Treatment: directed at the underlying cause—mesalazine, steroids,

and biologic therapy for IBD; antibiotics for infectious colitis; surgery for malignancy; topical anaesthetics, biofeedback, and amitriptyline for functional disorders.

Toxic Megacolon

- Acute life-threatening dilation of the colon associated with systemic toxicity, representing one of the most serious complications of inflammatory bowel disease, particularly ulcerative colitis. It can also occur in infectious colitis caused by *Clostridioides difficile* and cytomegalovirus. The pathophysiology involves transmural inflammation extending beyond the mucosa, causing destruction of the myenteric plexus and smooth muscle dysfunction leading to loss of colonic tone. The diagnosis requires radiologic evidence of colonic dilation exceeding 6 cm in diameter, with loss of haustrations, accompanied by clinical signs of toxicity including fever, tachycardia, leukocytosis, and systemic inflammatory response.

Tropical Sprue

- Chronic diarrhea and malabsorption syndrome of uncertain etiology occurring predominantly in tropical and subtropical regions. The condition is characterized by villous atrophy of the small intestinal mucosa leading to malabsorption of nutrients including folate, iron, and vitamin B12. The exact pathogenesis remains unclear but may involve an infectious etiology, altered gut microbiota, or nutritional deficiencies. The clinical presentation includes chronic diarrhea, steatorrhea, weight loss, and anemia. Treatment includes a prolonged course of tetracycline or doxycycline with folic acid supplementation, and the condition responds well to antibiotic therapy if diagnosed early.

Typhlitis

- Inflammation of the cecum in immunocompromised patients particularly those with neutropenia from chemotherapy. Also known as neutropenic enterocolitis. Presents with right lower quadrant pain, fever, and diarrhea. Diagnosis is by CT showing cecal wall thickening. Managed with bowel rest, broad-spectrum antibiotics covering gram-negative and anaerobic organisms, and resolution of neutropenia. Surgery is reserved for complications including perforation and hemorrhage.

Typhoid Fever

- A systemic infection caused by *Salmonella typhi*,

acquired through contaminated food or water. Incubation 7-14 days. Presents with prolonged fever, headache, abdominal pain, rose spots, and relative bradycardia. Diagnosis: blood culture (first week), stool culture (second week), Widal test. Treatment: azithromycin, ceftriaxone, or fluoroquinolones. Complications: intestinal perforation, hemorrhage. Prevention: vaccination and water sanitation.

Ulcerative Colitis

- Chronic inflammatory disease limited to the colon and rectum, characterized by continuous mucosal and submucosal inflammation that invariably begins in the rectum and extends proximally in an uninterrupted pattern. The distribution follows a predictable anatomical pattern classified as proctitis when confined to the rectum, left-sided colitis extending to the splenic flexure, or extensive colitis extending beyond the splenic flexure. Unlike Crohn disease, the inflammation in ulcerative colitis is confined to the mucosa and submucosa, without transmural involvement.

Volvulus

- Twisting of a loop of intestine around its mesenteric attachment point causing luminal obstruction and compromise of the mesenteric blood supply which can rapidly progress to bowel ischemia. The two most common sites are the sigmoid colon accounting for approximately seventy-five percent of colonic volvulus in elderly patients with chronic constipation and redundant sigmoid, and the cecum accounting for approximately twenty-five percent in younger patients with a mobile cecum. Sigmoid volvulus presents with abdominal distension, pain, and obstipation, and is initially managed with endoscopic detorsion using a sigmoidoscope, followed by elective sigmoid resection to prevent recurrence.

Whipple Disease

- A rare systemic bacterial infection caused by *Tropheryma whipplei*, affecting the small intestine and multiple organ systems. Presents with arthralgias (prodromal, years before GI symptoms), weight loss, chronic diarrhea, steatorrhea, and abdominal pain. Extraintestinal: endocarditis, neurologic symptoms (dementia, ophthalmoplegia, myoclonus), and lymphadenopathy. Diagnosis: small bowel biopsy showing PAS-positive macrophages contain-

ing rod-shaped bacteria, PCR of tissue or CSF. Treatment: prolonged antibiotic therapy (ceftriaxone IV induction, followed by TMP-SMX or doxycycline + hydroxychloroquine for 1-2 years). Untreated is fatal.

Whipple Triad

- Diagnostic criteria for Insulinoma: (1) Symptoms of hypoglycemia (diaphoresis, confusion), (2) Documented low plasma glucose (< 55 mg/dL), and (3) Prompt relief of symptoms following glucose administration. See *Insulinoma*.

Zieve's Syndrome

- A triad of haemolytic anemia, hyperlipidaemia, and jaundice occurring in the setting of chronic alcohol use disorder and alcoholic liver disease (acute alcoholic steatohepatitis or alcoholic cirrhosis). First described by Leslie Zieve in 1958 in patients with alcoholic liver disease presenting with transient haemolytic anemia (Coombs-negative, likely due to oxidative damage to erythrocyte membranes from acetaldehyde and lipid peroxidation products), markedly elevated serum triglycerides (hyperlipidaemia, often severe, >1000 mg/dL, due to alcohol-induced increase in hepatic VLDL secretion and reduced lipoprotein lipase activity), and jaundice (from alcoholic hepatitis, intrahepatic cholestasis, and haemolysis). The syndrome is typically self-limited, resolving with alcohol abstinence over 2-4 weeks, but recurrence is common if alcohol consumption resumes. Management: supportive care, alcohol cessation, and management of hypertriglyceridaemia (dietary fat restriction, fibrates) to prevent acute pancreatitis.

Chapter 13

Genetics

Aneuploidy

- An abnormal number of chromosomes in a cell, differing from the wild-type diploid number (46,XX or 46,XY). Caused primarily by meiotic non-disjunction during gametogenesis. Common autosomal trisomies: Down syndrome (trisomy 21), Edwards syndrome (trisomy 18), Patau syndrome (trisomy 13). Sex chromosome aneuploidies: Turner syndrome (45,X0), Klinefelter syndrome (47,XXY).

Autosomal Dominant

- A pattern of inheritance in which a single copy of a mutated gene on a non-sex chromosome (autosomal) is sufficient to cause disease. Each child of an affected parent has a 50% chance of inheriting the mutation. Characteristics: vertical transmission across generations, equal male and female frequency. Examples: Marfan syndrome, Huntington disease, Achondroplasia, Familial Hypercholesterolemia.

Autosomal Recessive

- A pattern of inheritance requiring two copies of a mutated gene (one from each heterozygous carrier parent) for disease manifestation. Carriers are clinically asymptomatic. Each child of two carrier parents has a 25% chance of disease, 50% chance of carrier status, and 25% chance of non-carrier. Characteristics: horizontal transmission (affected siblings), increased frequency in consanguineous marriages. Examples: Cystic Fibrosis, Sickle Cell Anemia, Tay-Sachs Disease, Phenylketonuria.

Birth Defect

- A structural, functional, or metabolic abnormality present at birth (congenital anomaly), caused by genetic (chromosomal, single-gene), environmental (teratogens: alcohol, valproate, rubella, radiation), or multifactorial factors. Major birth defects affect 2-3 percent of newborns and are a leading cause of infant mortality. Examples: neural tube

defects, congenital heart defects, cleft lip/palate, Down syndrome. Prevention includes folic acid supplementation, avoidance of teratogens, and prenatal screening/diagnosis.

Carrier

- An individual who possesses one copy of an altered gene (heterozygote) for a recessive or X-linked condition but does not express the disease phenotype. Carriers can transmit the mutation to offspring: two carrier parents have a 25 percent risk of an affected child and 50 percent risk of carrier offspring (autosomal recessive). Carrier screening (cystic fibrosis, Tay-Sachs, thalassemia, sickle cell) and carrier detection are important in genetic counseling and reproductive planning.

Chromosomal Abnormality

- Any deviation from the normal number (46 chromosomes, 23 pairs) or structure of chromosomes. Numerical abnormalities: aneuploidy (trisomy 21/Down syndrome, trisomy 18/Edwards syndrome, trisomy 13/Patau syndrome, monosomy X/Turner syndrome), polyploidy (triploidy, tetraploidy). Structural abnormalities: deletions (Cri-du-chat, 22q11.2 deletion), duplications, translocations (Robertsonian, reciprocal), inversions, and ring chromosomes. Mosaicism: presence of two or more genetically different cell lines in the same individual. Screening: combined test (nuchal translucency, hCG, PAPP-A), NIPT (cell-free fetal DNA), quadruple test. Diagnosis: chorionic villus sampling (11-14 weeks), amniocentesis (15+ weeks). Karyotype, FISH, or chromosomal microarray confirms the diagnosis.

Chromosomes

- The thread-like structures within the cell nucleus that carry genetic information in the form of DNA. Humans have 46 chromosomes arranged in 23 pairs:

22 pairs of autosomes and 1 pair of sex chromosomes (XX in females, XY in males). Each parent contributes one chromosome to each pair. Chromosomes are visible under a light microscope during cell division and are arranged in a standardized format called a karyotype (ordered by size, centromere position, and banding pattern, using G-banding or spectral karyotyping). The short arm is designated p (petit) and the long arm is q. Chromosomal abnormalities can involve number (aneuploidy) or structure (deletions, duplications, translocations, inversions). Telomeres: protective caps at chromosome ends. Centromere: region where sister chromatids are joined and spindle fibers attach during cell division.

Cloning

– The production of genetically identical copies of DNA sequences, cells, or organisms. Molecular cloning: inserting a DNA fragment into a plasmid/vector for amplification in bacteria (recombinant DNA). Cellular cloning: generating identical cells from a single cell. Reproductive cloning (e.g., Dolly the sheep) uses somatic cell nuclear transfer. Therapeutic cloning aims to produce embryonic stem cells for regenerative medicine. Applications and ethics of human cloning are debated and largely regulated.

Codon

– A sequence of three nucleotides (triplet) in mRNA that specifies a single amino acid or a stop signal during translation. The genetic code has 64 codons: 61 sense codons encoding amino acids and 3 stop (nonsense) codons (UAA, UAG, UGA). The code is degenerate (multiple codons per amino acid) and nearly universal. The start codon (AUG, methionine) initiates translation; reading frame is critical—frameshift mutations alter codon grouping. Codon-anticodon base pairing occurs on the ribosome.

Congenital Disorder

– See Birth Defect. A condition present at birth, whether inherited (genetic), developmental, or acquired in utero. Includes structural anomalies (cardiac, neural tube, limb), inborn errors of metabolism, and functional disorders. Etiology: chromosomal abnormalities, single-gene mutations, teratogen exposure, maternal infections, and mul-

tifactorial inheritance. Diagnosis may be prenatal (ultrasound, screening, amniocentesis/CVS) or postnatal. Management ranges from surgical correction to lifelong medical therapy and genetic counseling.

CRISPR-Cas9

– A bacterial adaptive immune mechanism adapted as a targeted genome editing tool. Uses a synthetic single guide RNA (sgRNA) to direct the Cas9 endonuclease to a specific target DNA sequence adjacent to a protospacer adjacent motif (PAM). Introduces double-strand breaks repaired by non-homologous end joining (NHEJ, gene knockout) or homology-directed repair (HDR, precise insertion/edit).

Cystic Fibrosis

– An autosomal recessive multisystem disorder caused by mutations in the CFTR gene on chromosome 7q31.2, encoding the cystic fibrosis transmembrane conductance regulator, a cAMP-regulated chloride channel expressed on epithelial surfaces. Over 2,000 CFTR mutations have been identified; the most common is F508del (deletion of phenylalanine at position 508), accounting for approximately 70 percent of alleles worldwide. CFTR mutations are classified by defect type: Class I (no protein production – nonsense, frameshift); Class II (defective trafficking and degradation – F508del); Class III (defective gating – G551D); Class IV (defective chloride conductance); Class V (reduced synthesis); Class VI (accelerated turnover). Clinical features: chronic suppurative lung disease (bronchiectasis, *Pseudomonas aeruginosa*, progressive obstructive airways disease), exocrine pancreatic insufficiency (steatorrhea, fat-soluble vitamin deficiency), meconium ileus in neonates, congenital bilateral absence of the vas deferens (male infertility), and elevated sweat chloride (>60 mmol/L, measured by pilocarpine iontophoresis). Management: chest physiotherapy, mucolytics (dornase alfa), inhaled antibiotics (tobramycin), pancreatic enzyme replacement, fat-soluble vitamin supplementation, and CFTR modulator therapy (ivacaftor for Class III; lumacaftor/ivacaftor and tezacaftor/ivacaftor for Class II; elxacaftor/tezacaftor/ivacaftor triple therapy). Lung transplantation in end-stage disease.

Deletion

– A chromosomal or DNA mutation in which a seg-

ment of DNA is lost. Deletions may involve a single base (frameshift if not a multiple of 3) or large chromosomal regions. Examples: 22q11.2 deletion (DiGeorge syndrome), 5p deletion (cri du chat), and cystic fibrosis most common mutation (delta-F508, 3-base deletion). Large deletions may be visible on karyotype; small ones require FISH or microarrays. Consequences: loss of gene function, haploinsufficiency, or contiguous gene syndromes.

DNA Sequencing

– The determination of the order of nucleotide bases (A, T, G, C) in a DNA molecule. Methods: Sanger (chain-termination) sequencing for targeted/gene-level analysis and next-generation sequencing (NGS) for high-throughput, genome-wide analysis (whole exome/genome). Applications: diagnosing genetic disorders, identifying mutations (including somatic mutations in cancer), pharmacogenomics, and microbial identification. Bioinformatics analysis and variant interpretation are essential; results require confirmation and genetic counseling.

Duplication

– A chromosomal or DNA mutation in which a segment of DNA is copied one or more times, increasing gene dosage. May be intrachromosomal or interchromosomal. Examples: Charcot-Marie-Tooth disease type 1A (PMP22 duplication), Potocki-Lupski syndrome (17p11.2 duplication). Large duplications may be detected on karyotype; smaller ones by FISH, microarrays, or sequencing. Effects depend on gene content and dosage sensitivity; duplications can be benign or pathogenic.

Embryonic Stem Cell

– Pluripotent stem cells derived from the inner cell mass of the blastocyst (5-7 days post-fertilization). Capable of self-renewal and differentiation into all three germ layers (ectoderm, mesoderm, endoderm) and thus all cell types of the body. Used in research for developmental biology, drug testing, and potential regenerative therapies. Derivation requires destruction of the embryo, raising ethical considerations. Contrast with adult stem cells and induced pluripotent stem cells (iPSCs).

Epigenetics

– Heritable changes in gene expression or cellular phenotype caused by mechanisms other than alterations in the underlying DNA sequence. Mechanisms

include DNA methylation (typically silences gene expression at CpG islands), histone modification (acetylation relaxes chromatin to activate transcription; methylation can activate or repress), and non-coding RNA regulation. Influenced by environmental factors, aging, and diet.

Exon

– The coding segment of a gene that is retained in mature mRNA and translated into protein (or forms untranslated regions). Exons are interrupted by introns in the genome; during splicing, introns are removed and exons are joined. Alternative splicing of exons produces multiple protein isoforms from one gene (estimated 95 percent of human genes). Mutations in exons cause missense, nonsense, and frameshift changes. Exon structure is central to the Human Genome Project and gene therapy (exon skipping).

Expressivity

– The degree or severity to which a genetic trait or phenotype is expressed in individuals with the same genotype. Variable expressivity means affected individuals (same mutation) show a range of clinical severity (e.g., neurofibromatosis type 1: café-au-lait spots alone to multiple tumors). Expressivity differs from penetrance (whether the phenotype appears at all). Both are influenced by other genes (modifiers) and environment, complicating genotype-phenotype correlation and genetic counseling.

Fluorescent In Situ Hybridization (FISH)

– A cytogenetic technique using fluorescently labeled DNA probes that bind complementary sequences on chromosomes to detect and localize specific DNA regions. Applications: aneuploidy detection, microdeletion syndromes (22q11.2), gene rearrangements (BCR-ABL, MLL), HER2 amplification in breast cancer, and chromosomal translocations. Performed on metaphase spreads or interphase nuclei; rapid results. Complementary to karyotyping and chromosomal microarray.

Frameshift Mutation

– An insertion or deletion of nucleotides that is not a multiple of three, shifting the reading frame of the coding sequence. This alters the grouping of codons downstream, usually producing a nonfunctional protein with a truncated or abnormal amino acid sequence.

quence and often an early stop codon. Example: cystic fibrosis delta-F508 is a 3-base deletion (in-frame, not frameshift); many pathogenic mutations in tumor suppressor genes are frameshifts. Consequences: loss of function, often disease-causing.

Friedreich Ataxia

– The most common inherited ataxia, an autosomal recessive disorder caused by GAA trinucleotide repeat expansion in the FXN gene on chromosome 9q13, encoding frataxin, a mitochondrial protein essential for iron-sulfur cluster biogenesis. The repeat expansion (typically 66-1,700 repeats; normal is 5-30) causes gene silencing through heterochromatin formation, leading to frataxin deficiency (20-30 percent of normal levels). Frataxin deficiency impairs mitochondrial iron metabolism, causing iron accumulation within mitochondria, defective iron-sulfur cluster assembly, impaired oxidative phosphorylation, and increased oxidative stress. Clinical triad: progressive ataxia (cerebellar and sensory), hypertrophic cardiomyopathy (most common cause of premature death), and diabetes mellitus or glucose intolerance. Additional features: dysarthria, lower limb areflexia, loss of vibration and proprioception (dorsal columns), pyramidal weakness, pes cavus, scoliosis, and optic atrophy. Age of onset typically 5-25 years; earlier onset correlates with larger repeat expansions. Diagnosis: genetic testing for GAA expansion in the FXN gene. Management is supportive: physical therapy, speech therapy, cardiac monitoring (annual echocardiogram, ECG), diabetes screening. No disease-modifying therapy available; omaveloxolone approved in some populations. Prognosis: loss of ambulation 10-20 years after onset; death usually from cardiomyopathy.

Gamete

– A mature haploid reproductive cell (23 chromosomes) that fuses with another gamete during fertilization to form a diploid zygote. Male gamete: spermatozoon (flagellated, motile, produced by spermatogenesis in testes, approximately 100 million per day). Female gamete: oocyte (ovum, non-motile, larger, produced by oogenesis in ovaries; approximately 1 million present at birth, reduced to 400-500 ovulated in a lifetime). Gametogenesis involves meiosis (reduction division) to achieve haploidy. Abnormal gametes may occur from meiotic

non-disjunction, leading to aneuploidy in offspring (Down syndrome, Turner syndrome, Klinefelter syndrome).

Gaucher Disease

– Most common lysosomal storage disorder caused by glucocerebrosidase deficiency. Results in accumulation of glucocerebroside in macrophages. Type 1 is the most common and affects the liver, spleen, and bones.

Gene

– The fundamental physical and functional unit of heredity. A gene is a segment of DNA (or RNA in some viruses) that encodes a functional product (typically a protein or, in the case of non-coding RNA genes, a functional RNA molecule). The human genome contains 20,000-25,000 protein-coding genes. Structure: promoter region (regulatory sequence upstream, binds RNA polymerase and transcription factors), exons (coding sequences), introns (non-coding intervening sequences, spliced out), and untranslated regions (UTRs, 5 and 3 prime). Gene expression is regulated at multiple levels: transcriptional (transcription factors, enhancers, silencers, epigenetic modifications), post-transcriptional (splicing, RNA editing, mRNA stability), translational (initiation factors, miRNA, ribosome binding), and post-translational (phosphorylation, ubiquitination, glycosylation). Gene nomenclature: official symbols assigned by HGNC (HUGO Gene Nomenclature Committee), e.g., CFTR, BRCA1, TP53.

Gene Expression

– The process by which information in a gene is used to produce a functional product (protein or functional RNA), comprising transcription (DNA to mRNA) and translation (mRNA to protein). Regulated at multiple levels: chromatin structure and epigenetic modifications (methylation, histone modification), transcription factors, RNA processing/splicing, mRNA stability, and translation. Gene expression differs by cell type and condition (spatial and temporal regulation). Dysregulation underlies cancer, developmental disorders, and many diseases.

Genetic Code

– The set of rules by which information encoded in nucleotide sequences (DNA and RNA) is translated into proteins. The code is: (1) Triplet: three con-

secutive nucleotides (codon) specify one amino acid. (2) Degenerate: 64 possible codons encode 20 amino acids and 3 stop codons (UAA, UAG, UGA). (3) Universal: nearly identical across all organisms. (4) Non-overlapping: each nucleotide belongs to only one codon. (5) Commaless: codons are read sequentially without gaps. Key features: start codon (AUG, methionine, also sets reading frame), wobble hypothesis (third base pairing is flexible, allowing fewer tRNAs to decode all codons).

Genetic Counseling

– The process of helping individuals and families understand and adapt to the medical, psychological, and familial implications of genetic contributions to disease. Components: risk assessment and inheritance pattern explanation, interpretation of genetic test results, discussion of reproductive options and management, and psychosocial support. Provided by genetic counselors/medical geneticists. Indications: family history of genetic disease, birth defects, prenatal screening anomalies, cancer predisposition, and consanguinity.

Genetic Disorder

– A disease caused by an abnormality in the genome. Categories: single-gene (Mendelian) disorders (autosomal dominant/recessive, X-linked: cystic fibrosis, Huntington, hemophilia), chromosomal disorders (Down, Turner, Klinefelter), mitochondrial disorders, multifactorial/polygenic disorders (diabetes, heart disease, cancer), and somatic (acquired) mutations (cancer). Manifestations vary by gene function, inheritance, penetrance, and expressivity. Diagnosis uses genetic testing; management may be symptomatic, preventive, or targeted (gene therapy emerging).

Genetic Engineering

– The direct manipulation of an organism's genes using biotechnology. Techniques include: (1) Recombinant DNA technology: insertion of foreign DNA into a vector (plasmid, virus) for expression in a host organism (bacteria, yeast, mammalian cells). (2) CRISPR-Cas9: RNA-guided nuclease that cuts DNA at a specific sequence, enabling gene knockout, knock-in, and precise editing. (3) Gene silencing: RNA interference (siRNA, shRNA) to reduce gene expression. (4) Gene therapy: delivery of functional genes to treat genetic disorders. Applications:

production of therapeutic proteins (insulin, growth hormone, clotting factors, monoclonal antibodies), genetically modified organisms (GMOs, crop improvement), gene therapy (SCID, hemophilia, sickle cell disease, Leber congenital amaurosis), synthetic biology, and xenotransplantation. Ethical and safety concerns: off-target effects, germline editing consequences, ecological impact of GMOs.

Genetics

– The branch of biology concerned with the study of genes, genetic variation, and heredity in living organisms. Major subdisciplines: (1) Mendelian genetics: patterns of inheritance of single-gene traits (autosomal dominant, autosomal recessive, X-linked, Y-linked, mitochondrial). (2) Molecular genetics: structure and function of DNA, RNA, and proteins at the molecular level. (3) Population genetics: allele frequency distribution and change under the influence of natural selection, genetic drift, mutation, and gene flow (Hardy-Weinberg equilibrium). (4) Quantitative genetics: inheritance of complex traits influenced by multiple genes and environment (heritability estimates). (5) Genomics: the comprehensive study of entire genomes (structural, functional, comparative, epigenomics). (6) Clinical genetics: diagnosis and management of genetic disorders, genetic counseling, prenatal diagnosis, and carrier screening.

Genetic Screening

– The systematic testing of populations or high-risk groups to identify individuals at risk of or affected by genetic disorders, before or regardless of symptoms. Types: newborn screening (PKU, hypothyroidism, sickle cell), carrier screening (cystic fibrosis, Tay-Sachs), preconception/prenatal screening (NIPT), and predictive testing for late-onset disorders (BRCA, Huntington) and pharmacogenomics. Principles: benefit, informed consent, confidentiality, and follow-up counseling. Screening requires confirmation with diagnostic testing.

Genome

– The complete set of genetic material (DNA) of an organism. Human genome: approximately 3.2 billion base pairs, 20,000-25,000 protein-coding genes (only 1-2% of total DNA), organized into 23 pairs of chromosomes (22 autosomes + sex chromosomes). Non-coding DNA (98%) includes: regulatory se-

quences (promoters, enhancers), transposable elements, introns, telomeres, centromeres, pseudogenes, microRNAs, long non-coding RNAs, and repetitive sequences. The Human Genome Project (1990-2003) sequenced the human genome. Genomic medicine uses genome sequencing for diagnosis, pharmacogenomics, and prediction of disease risk.

Genome Sequencing

- The determination of the complete DNA sequence of an organism's genome (3.2 billion base pairs in humans). Whole genome sequencing (WGS) covers coding and noncoding regions; whole exome sequencing (WES) covers the 1-2 percent coding exons. Used for undiagnosed genetic disease, cancer genomics, pharmacogenomics, and prenatal diagnosis (NIPT, WGS in acute neonatal settings). Cost has fallen dramatically; challenges include variant interpretation, incidental findings, and data privacy.

Genotype

- The genetic constitution of an organism, determined by the specific alleles present at a given genetic locus. The genotype is the inherited genetic information carried by an individual, as distinct from the phenotype (observable physical or biochemical characteristics). Genotype is influenced by genotype-environment interactions. In Mendelian genetics, a homozygous genotype has two identical alleles at a locus (e.g., AA or aa), while a heterozygous genotype has two different alleles (Aa). Genotype frequency in a population is determined by Hardy-Weinberg equilibrium. Genotyping methods: PCR, DNA sequencing, microarray, SNP analysis.

Hardy-Weinberg Equilibrium

- A fundamental principle of population genetics stating that allele and genotype frequencies remain constant across generations in the absence of evolutionary influences (mutation, selection, migration, genetic drift, non-random mating). Equations: $p + q = 1$ (allele frequencies) and $p^2 + 2pq + q^2 = 1$ (genotype frequencies), where $2pq$ represents carrier frequency for autosomal recessive diseases.

Hemizygous

- Having only one copy of a gene or chromosomal region instead of the normal two. Males are hemizygous for genes on the X chromosome (XY)—therefore X-linked recessive disorders (hemophilia A, Duchenne muscular dystrophy) af-

fect males preferentially; females can be affected if homozygous or with skewed X-inactivation. Hemizygosity also occurs for deletions or loss of one allele. Genetic testing can identify hemizygous states.

Hemochromatosis

- Hereditary hemochromatosis (HH) is an autosomal recessive disorder of iron metabolism caused most commonly by homozygosity for the C282Y mutation in the HFE gene on chromosome 6p21.3, leading to inappropriately low hepcidin production and excessive intestinal iron absorption (1.5-2 mg/day normally, increasing to 3-4 mg/day in HH). Iron accumulates progressively in parenchymal organs (liver, pancreas, heart, pituitary, joints, skin), causing tissue damage through oxidative stress (Fenton reaction generating hydroxyl radicals that damage lipids, proteins, and DNA). Clinical features: bronze or gray skin pigmentation (bronze diabetes), diabetes mellitus, cirrhosis (increased risk of hepatocellular carcinoma), dilated or restrictive cardiomyopathy, hypogonadotropic hypogonadism, arthritis (typically second and third metacarpophalangeal joints), and osteoporosis. Penetrance is incomplete; many homozygotes show only biochemical abnormalities without clinical disease. Diagnosis: elevated transferrin saturation (>45 percent) and serum ferritin; HFE genetic testing confirms; liver MRI or biopsy quantifies iron burden. Treatment: graded phlebotomy (500 mL weekly until ferritin <50 mcg/L, then maintenance every 2-4 months). Iron chelation (deferasirox, deferoxamine) for patients who cannot tolerate phlebotomy. First-degree relatives should be screened with iron studies and HFE genotyping.

Hemophilia A

- X-linked recessive bleeding disorder caused by deficiency of coagulation factor VIII. Severity correlates with factor activity level. Characterized by hemarthrosis, soft tissue bleeding, and prolonged aPTT.

Hemophilia B

- X-linked recessive bleeding disorder caused by deficiency of coagulation factor IX. Also known as Christmas disease. Clinically indistinguishable from hemophilia A. Diagnosed by factor IX activity assay.

Heterozygous

- Having two different alleles at a given gene locus on homologous chromosomes. For a recessive disorder,

a heterozygous individual is an unaffected carrier; for an autosomal dominant disorder, a heterozygote is affected (penetrance permitting). Heterozygosity enables genetic variation; compound heterozygotes carry two different mutant alleles (e.g., cystic fibrosis). Heterozygous advantage: sickle cell trait carriers have malaria resistance. Contrast with homozygous and hemizygous.

Homozygous

– Having two identical alleles at a given gene locus on homologous chromosomes. Homozygotes for a recessive mutation are affected (e.g., homozygous delta-F508 in cystic fibrosis); homozygotes for a dominant mutation usually have severe/earlier disease. Homozygosity increases with consanguinity (related parents). Genotype-phenotype correlation and genetic counseling depend on the zygosity state. Contrast with heterozygous and hemizygous.

Huntington Disease

– An autosomal dominant neurodegenerative disorder caused by an expanded CAG trinucleotide repeat in the HTT gene on chromosome 4p16.3, encoding huntingtin protein. Normal alleles have fewer than 26 CAG repeats; 27–35 repeats are intermediate (not pathogenic but may expand in offspring); 36–39 repeats show reduced penetrance; 40 or more repeats cause full penetrance disease. The expanded polyglutamine tract causes mutant huntingtin to misfold, aggregate, and disrupt cellular processes (transcription, mitochondrial function, axonal transport, synaptic transmission), leading to neuronal death (most prominently in the caudate nucleus, putamen, and cerebral cortex). Clinical triad: chorea (involuntary, dance-like movements; the most characteristic motor feature), progressive dementia (executive dysfunction, memory loss, visuospatial deficits), and psychiatric disturbance (depression (most common), anxiety, irritability, obsessive-compulsive symptoms, psychosis). Mean age of onset 35–44 years; juvenile-onset HD (CAG >60 repeats) presents with rigidity, bradykinesia, and seizures rather than chorea. Anticipation occurs – the CAG repeat expands during male meiosis (paternal transmission), resulting in earlier onset in successive generations. Diagnosis: genetic testing for CAG repeat expansion in the HTT gene (with pre-test and post-test genetic counseling). Treatment is symptomatic: tetrabenazine

or deutetrabenazine for chorea; antidepressants; antipsychotics. No disease-modifying therapy exists. Prognosis: mean survival 15–20 years from onset.

Imprinting

– An epigenetic phenomenon in which a gene is expressed only from one parental allele, the other being silenced by DNA methylation and histone modifications established during gametogenesis. Examples: Prader-Willi syndrome (loss of paternal 15q11-q13 expression) and Angelman syndrome (loss of maternal allele). Imprinted genes influence growth and development; imprinting defects cause disease despite normal gene sequence. Contrast with biallelic expression of most genes.

Induced Pluripotent Stem Cell (iPSC)

– A pluripotent stem cell generated from an adult somatic cell (fibroblast, blood cell) by introducing transcription factors (Oct4, Sox2, Klf4, c-Myc—Yamanaka factors) that reprogram it to an embryonic-like state. iPSCs can differentiate into all cell types, enabling patient-specific disease modeling, drug screening, and regenerative medicine without embryo destruction. Limitations: reprogramming efficiency, genomic instability, and tumorigenicity risk.

Inherited Disorder

– A genetic disorder transmitted from parents to offspring through germline mutations (as opposed to somatic/acquired mutations). Follows Mendelian patterns (autosomal dominant, autosomal recessive, X-linked) or non-Mendelian (mitochondrial, imprinting, trinucleotide repeat expansion, multifactorial). Present from conception; may manifest at birth or later (late-onset Huntington). Risk counseling uses pedigree analysis and genetic testing; implications include recurrence risks for siblings and offspring.

Intron

– A noncoding segment of a gene that is transcribed into pre-mRNA but removed during RNA splicing and not present in the mature mRNA. Introns interrupt exons and may contain regulatory elements. They allow alternative splicing (producing protein diversity) and exon shuffling. Intronic mutations can disrupt splicing (creating cryptic splice sites) or regulatory function, causing disease (e.g., factor VIII intron 22 inversion in severe hemophilia A).

Karyotype

- The complete visual profile of an individual's chromosomes in metaphase, arranged in homologous pairs by size, centromere position, and banding pattern (Giemsa staining). Used to detect numerical chromosomal abnormalities (trisomies, monosomies) and large structural rearrangements (translocations, inversions, deletions).

Lesch-Nyhan Syndrome

- An X-linked recessive metabolic disorder caused by a complete deficiency of hypoxanthine-guanine phosphoribosyltransferase (HGPRT), a key enzyme in the purine salvage pathway. Results in accumulation of uric acid and impaired purine recycling. Classic clinical mnemonic HGPRT: Hyperuricemia (gout, uric acid orange "sand" in diapers), Gout, Pissed off (compulsive self-mutilation: biting of lips and fingers), Retardation (intellectual disability), Dystonia/Hypotonia. Lab findings: hyperuricemia, elevated urinary uric acid-to-creatinine ratio. Treatment: allopurinol or febuxostat (inhibits xanthine oxidase to manage hyperuricemia and prevent renal stones; does not reverse neurological deficits).

Li-Fraumeni Syndrome

- Autosomal dominant cancer predisposition syndrome most commonly caused by TP53 mutations. Characterized by early-onset cancers including sarcomas, breast cancer, brain tumors, and adrenocortical carcinoma. Very high lifetime cancer risk.

Marfan Syndrome

- An autosomal dominant connective tissue disorder caused by mutations in the FBN1 gene on chromosome 15q21.1, encoding fibrillin-1, a major component of microfibrils that form the scaffold for elastin in connective tissue. Fibrillin-1 mutations also lead to increased transforming growth factor-beta (TGF-beta) signaling, contributing to the pathogenesis. The Ghent nosology (2010 revision) diagnoses Marfan syndrome when aortic root dilation (Z-score ≥ 2) AND ectopia lentis are present; or aortic root dilation AND a pathogenic FBN1 mutation; or aortic root dilation AND a sufficient systemic score (points for wrist and thumb signs, pectus carinatum, hindfoot deformity, pneumothorax, dural ectasia, protrusio acetabuli, facial features, skin striae, myopia, mitral valve prolapse). Skeletal features: tall stature, arachnodactyly, pectus deformities, scol-

iosis, joint hypermobility. Cardiovascular: aortic root aneurysm (leading cause of mortality), aortic regurgitation, mitral valve prolapse, aortic dissection (type A). Ocular: ectopia lentis (upward lens dislocation), myopia, retinal detachment. Diagnosis: revised Ghent criteria; FBN1 genetic testing; serial echocardiography for aortic root measurement; slit-lamp ophthalmology. Management: beta-blockers (atenolol) and losartan to slow aortic root growth; serial echocardiography; annual ophthalmology review; avoidance of contact sports and heavy exertion. Elective prophylactic aortic root replacement (Bentall procedure) when aortic root diameter reaches 50 mm (or 45 mm with rapid progression or family history of dissection).

Meiosis

- A specialized form of cell division in germ cells that reduces the chromosome number by half, producing four genetically distinct haploid gametes (sperm or ova) from one diploid progenitor. Consists of two rounds: Meiosis I (reductional division; homologous chromosomes pair, undergo crossing over/recombination, and segregate) and Meiosis II (equational division; sister chromatids segregate).

Mendelian Inheritance

- Biological inheritance patterns obeying Gregor Mendel's laws: Law of Segregation (allele pairs separate during gamete formation) and Law of Independent Assortment (genes for different traits segregate independently). Includes autosomal dominant, autosomal recessive, and X-linked inheritance patterns.

Methylation

- An epigenetic modification in which a methyl group is added to cytosine residues (typically CpG dinucleotides) by DNA methyltransferases. DNA methylation regulates gene expression (promoter methylation generally silences genes), genomic imprinting, X-inactivation, and silencing of transposons. Aberrant methylation is implicated in cancer (tumor suppressor silencing, global hypomethylation) and developmental disorders. Methylation patterns are heritable across cell divisions and can be modified by environment and diet.

Microarray

- A technology that measures the expression or copy number of thousands of genes (or DNA sequences) simultaneously. DNA microarrays (gene chips) hy-

bridize labeled cDNA to probes for gene expression profiling. Chromosomal microarrays (CMA/aCGH, SNP arrays) detect copy number variants (deletions, duplications) genome-wide and are first-line for many neurodevelopmental and congenital disorders. Applications: cancer classification, pharmacogenomics, and diagnosis of microdeletion syndromes. Replaced partly by sequencing.

Mitosis

– Process of somatic cell division resulting in two genetically identical diploid daughter cells from a single parent cell. Phases: Prophase (chromatin condenses), Prometaphase (nuclear envelope breaks down), Metaphase (chromosomes align at equatorial plate), Anaphase (sister chromatids separate to opposite poles), Telophase (nuclear envelopes reform), followed by Cytokinesis.

Monosomy

– The presence of only one copy of a chromosome instead of two ($2n-1$), usually lethal in autosomes except for Turner syndrome (45,X). Monosomy arises from meiotic nondisjunction and causes severe developmental consequences from gene dosage imbalance. Contrast with trisomy (an extra copy) and other aneuploidies. Prenatal diagnosis by karyotype or NIPT. Most monosomies result in early miscarriage.

Non-disjunction

– The failure of homologous chromosomes (Meiosis I) or sister chromatids (Meiosis II or Mitosis) to separate properly during cell division. Results in daughter cells with abnormal chromosome numbers (nullisomy, monosomy, disomy, trisomy). Advanced maternal age (>35 years) is the primary risk factor for meiotic non-disjunction.

PCR

– Polymerase chain reaction; a molecular technique that amplifies a specific DNA sequence exponentially through repeated cycles of denaturation, primer annealing, and extension by a heat-stable DNA polymerase (Taq). Each cycle doubles the target, producing millions of copies. Clinical applications: diagnosis of infections (HIV, hepatitis C, COVID-19 via RT-PCR), genetic testing (mutation detection), forensic DNA analysis, and quantification of viral load. Real-time PCR (qPCR) measures amplification as it occurs; RT-PCR detects RNA via reverse transcriptase.

Penetrance

– The proportion of individuals carrying a specific disease-causing gene mutation who actually express the associated clinical phenotype. Expressed as a percentage. Complete penetrance (100%): all mutation carriers show disease (e.g., Huntington disease). Incomplete/Reduced penetrance ($<100\%$): some carriers remain asymptomatic (e.g., BRCA1/BRCA2 hereditary breast cancer).

Phenotype

– The composite observable physical, physiological, biochemical, and behavioral traits of an organism, resulting from the interaction of its genotype with environmental influences.

Phenylketonuria

– An autosomal recessive aminoacidopathy caused by deficiency of phenylalanine hydroxylase (PAH), the enzyme that converts phenylalanine to tyrosine. PAH deficiency leads to toxic accumulation of phenylalanine and its metabolites (phenylketones: phenylacetate, phenyllactate, phenylpyruvate) in blood and brain, causing irreversible intellectual disability if untreated. PKU is caused by mutations in the PAH gene on chromosome 12q23.2, with over 1,000 mutations identified. Classic PKU: blood phenylalanine $>1,200$ micromol/L (20 mg/dL) on normal diet; mild PKU: 600-1,200 micromol/L; mild hyperphenylalaninaemia: 120-600 micromol/L (no treatment required). Newborn screening by tandem mass spectrometry (Guthrie test) detects elevated phenylalanine levels in all developed countries; prompt initiation of dietary therapy prevents neurological damage. Treatment: lifelong low-phenylalanine diet (phenylalanine-free medical formula and restricted natural protein); tetrahydrobiopterin (BH₄, sapropterin) response in some mutation types; pegvaliase (PEGylated recombinant phenylalanine ammonia lyase) for adults with poorly controlled PKU. Maternal PKU: women with PKU must maintain strict phenylalanine control before conception and throughout pregnancy to prevent fetal damage (microcephaly, intellectual disability, congenital heart disease, low birth weight).

Point Mutation

– A change in a single nucleotide base in DNA. Types: substitution (missense—changes an amino acid; nonsense—creates a stop codon; silent—no amino acid

change), transition (purine-purine or pyrimidine-pyrimidine), and transversion (purine-pyrimidine). Point mutations cause disease (sickle cell: single missense in beta-globin; many cancers) or benign variation (SNPs). Detected by sequencing; effects depend on location (coding, regulatory, splice site).

Polymerase Chain Reaction (PCR)

– A molecular technique that amplifies a specific DNA sequence exponentially using a thermostable DNA polymerase (Taq), primers flanking the target, and thermal cycling (denaturation, annealing, extension). Applications: infectious disease diagnosis (COVID-19 RT-PCR), genetic testing, forensic DNA analysis, detection of minimal residual disease, and cloning. Variants: RT-PCR (RNA templates), real-time/qPCR (quantification), and digital PCR. Sensitivity and specificity are high; contamination is a concern.

Polyploidy

– The presence of more than two complete sets of chromosomes (3n triploidy, 4n tetraploidy), usually lethal in humans—triploidy causes early miscarriage; rarely, mosaic survival with severe anomalies. Polyploidy is common in plants (agriculturally valuable). Arises from fertilization errors (two sperm, diploid gamete). Contrast with aneuploidy (single chromosome imbalance). Prenatal detection via karyotype/ultrasound.

Prenatal Diagnosis

– The detection of genetic or structural disorders in a fetus before birth. Noninvasive: maternal serum screening, cell-free fetal DNA (NIPT), and ultrasound (nuchal translucency, anomaly scan). Invasive (diagnostic): amniocentesis (15+ weeks), chorionic villus sampling (10-13 weeks), and cordocentesis, enabling karyotype, microarray, or sequencing. Used for high-risk pregnancies, abnormal screening, or family history; carries miscarriage risk. Genetic counseling accompanies testing.

Promoter

– A DNA regulatory region upstream of a gene where RNA polymerase and transcription factors bind to initiate transcription. Core elements: TATA box, initiator, and transcription start site. Promoters are cell- and tissue-specific and regulated by enhancers and repressors. Mutations or hypermethylation of promoters silence genes (e.g., tumor suppressor si-

lencing in cancer). Viral promoters (CMV) are used in gene therapy vectors and expression systems.

Recombinant DNA

– DNA molecules formed by joining genetic material from different sources, produced using restriction enzymes and DNA ligase in cloning vectors (plasmids, viruses). Applications: production of therapeutic proteins (insulin, growth hormone, factor VIII, monoclonal antibodies), vaccines (recombinant hepatitis B), gene therapy, genetic engineering of crops, and research. Underlies biotechnology and molecular medicine; regulated for safety and ethics.

Restriction Enzyme

– A bacterial enzyme that cuts DNA at specific recognition sequences (e.g., EcoRI recognizes GAATTC), producing sticky or blunt ends. Used in recombinant DNA technology to cut vectors and inserts, in restriction fragment length polymorphism (RFLP) analysis, and for DNA fingerprinting. Thousands of enzymes are available with varying specificity. Named by organism (Eco = *E. coli*, R = strain).

Sex-Linked

– Refers to traits or disorders determined by genes on the sex chromosomes (X or Y), most commonly X-linked. X-linked recessive (hemophilia, Duchenne muscular dystrophy, red-green color blindness): males affected (hemizygous), females carriers—transmission from carrier mothers; affected males do not transmit to sons. X-linked dominant (fragile X, Rett—usually lethal in males): affected females and males. Y-linked traits are rare (male-limited). Contrast with autosomal inheritance.

Sickle Cell Disease

– A group of inherited hemoglobinopathies caused by a point mutation (glutamic acid to valine at position 6) in the beta-globin gene (HBB) on chromosome 11, producing hemoglobin S (HbS). Homozygous HbSS is the most common and severe form. Under conditions of deoxygenation, HbS polymerizes, causing red blood cells to assume a rigid sickle shape. Sickled cells are less deformable, leading to vaso-occlusion, microvascular ischemia, and hemolytic anemia. SCD manifests through acute and chronic complications: vaso-occlusive crises (bone pain, dactylitis, priapism), acute chest syndrome (fever, chest pain, pulmonary infiltrates, hypoxia), stroke (overt or silent cerebral infarction), bacterial in-

fection risk (functional asplenia, encapsulated organisms – *Streptococcus pneumoniae*, *Haemophilus influenzae*), aplastic crisis (parvovirus B19-induced temporary arrest of erythropoiesis), splenic sequestration, pulmonary hypertension, leg ulcers, avascular necrosis of femoral head, and chronic kidney disease. Diagnosis: hemoglobin electrophoresis or high-performance liquid chromatography (HPLC) showing HbS (typically >80 percent in HbSS). Newborn screening (isoelectric focusing) universal in high-prevalence regions. Treatment: hydroxyurea (increases fetal hemoglobin HbF, reducing sickling); regular blood transfusion for stroke prevention; penicillin prophylaxis and pneumococcal vaccination (functional asplenia); pain management; acute chest syndrome management (antibiotics, transfusion, bronchodilators). hematopoietic stem cell transplantation is curative; gene therapy (LentiGlobin, CRISPR-based approaches) is emerging. Prognosis: mean survival 40-50 years in high-income countries.

Sporadic

– Occurring in isolated, random, or scattered instances, without a predictable pattern or clear cause. In medical genetics, sporadic cases of a disease occur in individuals with no family history of the condition, resulting from *de novo* (new) mutations rather than inherited germline mutations. Sporadic cancers arise from acquired (somatic) mutations. Examples: most cases of breast, ovarian, and colorectal cancers are sporadic. Many genetic syndromes can occur sporadically through *de novo* mutations (e.g., neurofibromatosis type 1, CHARGE syndrome, Cornelia de Lange syndrome). Sporadic cases have a low recurrence risk in siblings unless gonadal mosaicism is present.

Stem Cells

– Undifferentiated cells capable of self-renewal (producing identical daughter cells) and differentiation into specialized cell types. Classification by potency: totipotent (zygote—can form all cell types including extraembryonic tissues), pluripotent (embryonic stem cells—can form all three germ layers: ectoderm, endoderm, mesoderm), multipotent (adult/somatic stem cells—limited to a specific lineage: hematopoietic stem cells → all blood cells; mesenchymal stem cells → bone, cartilage, fat; neural stem cells → neurons, glia), and

oligopotent/unipotent. Sources: embryonic stem cells (derived from the inner cell mass of blastocysts—ethical concerns), induced pluripotent stem cells (iPSCs—somatic cells reprogrammed by Yamanaka factors: OCT4, SOX2, KLF4, c-MYC), adult stem cells (bone marrow, adipose tissue, umbilical cord blood), and perinatal stem cells (amniotic fluid, placenta). Clinical applications: hematopoietic stem cell transplantation (bone marrow transplant for leukemia, lymphoma, multiple myeloma, aplastic anemia), mesenchymal stem cells (orthopedics—cartilage repair, graft-versus-host disease, Crohn disease—clinical trials), limbal stem cell transplantation (corneal regeneration), and iPSC-derived cell therapies (retinal pigment epithelium for macular degeneration—clinical trials). Challenges: teratoma formation (pluripotent cells), immune rejection, ethical controversies (embryonic stem cells), and regulatory hurdles.

Tay-Sachs Disease

– Autosomal recessive lysosomal storage disorder caused by hexosaminidase A deficiency. Results in accumulation of GM2 ganglioside in neurons causing progressive neurodegeneration. Most common in Ashkenazi Jewish populations.

Teratogenesis

– The process by which congenital malformations (birth defects) are produced in a developing fetus by exposure to teratogens—agents that interfere with normal embryonic or fetal development. Teratogenesis is most sensitive during the period of organogenesis (weeks 3–8 of gestation), when major organs are forming. Principles: (1) Susceptibility depends on the genotype of the embryo and the timing, dose, and duration of exposure. (2) Different teratogens produce characteristic patterns of malformations. (3) The critical period for each organ system is when it is undergoing rapid differentiation. Major teratogens: (1) Medications—thalidomide (limb defects—phocomelia, amelia), isotretinoin (CNS, cardiac, craniofacial defects), valproic acid (neural tube defects, learning difficulties), warfarin (nasal hypoplasia, stippled epiphyses), methotrexate (CNS, skeletal), ACE inhibitors (renal dysplasia, oligohydramnios), tetracycline (bone and tooth discoloration, bone growth suppression), and androgens/lithium/carbamazepine/phenytoin. (2)

Maternal infections—rubella (deafness, cataracts, congenital heart disease), cytomegalovirus, toxoplasmosis, varicella, Zika virus. (3) Maternal conditions—diabetes (neural tube defects, congenital heart disease, macrosomia), phenylketonuria (microcephaly, intellectual disability). (4) Environmental exposures—alcohol (fetal alcohol syndrome—facial dysmorphism, growth restriction, neurodevelopmental impairment), ionizing radiation (microcephaly, intellectual disability), methylmercury (cerebral palsy, blindness), tobacco smoke (IUGR, cleft palate, preterm birth). Prevention: preconception counseling, folic acid supplementation (4–5 mg/day in high-risk women—reduces neural tube defects by 70%), and avoidance of known teratogens during pregnancy.

Thalassemia

- Group of autosomal recessive disorders characterized by reduced or absent globin chain synthesis. Alpha thalassemia results from mutations in the HBA genes. Beta thalassemia results from mutations in the HBB gene.

Translocation

- A chromosomal rearrangement in which a segment of one chromosome is transferred to another. Reciprocal translocations exchange segments between two nonhomologous chromosomes. Balanced translocations are often phenotypically normal but produce unbalanced gametes (recurrent miscarriage, abnormal offspring). Examples: Philadelphia chromosome t(9;22) in CML, t(8;14) in Burkitt lymphoma, t(15;17) in APL. Detected by karyotype/FISH. Robertsonian translocations involve acrocentric chromosomes (Down syndrome risk).

Trisomy

- The presence of an extra chromosome (three copies instead of the normal pair), resulting in a total of 47 chromosomes. Trisomy is the most common type of aneuploidy and usually arises from non-disjunction during meiosis (failure of homologous chromosomes or sister chromatids to separate). Trisomies involving autosomes (non-sex chromosomes) are generally incompatible with life, except for trisomy 21, 18, and 13. Trisomy 21 (Down syndrome): most common viable autosomal trisomy (incidence 1 in 700 live births), associated with intellectual disability, congenital heart disease (AVSD, VSD, ASD), hy-

potonia, characteristic facial features (flat facies, upslanting palpebral fissures, epicanthal folds, protruding tongue), increased risk of leukemia (ALL), Alzheimer disease (by age 40), and atlantoaxial instability. Trisomy 18 (Edwards syndrome): incidence 1 in 5,000, severe intellectual disability, rocker-bottom feet, clenched hands with overlapping fingers, congenital heart disease, and omphalocele; median survival <1 year. Trisomy 13 (Patau syndrome): incidence 1 in 15,000, severe intellectual disability, cleft lip/palate, polydactyly, holoprosencephaly, and congenital heart disease; median survival 7–10 days. Sex chromosome trisomies: XXY (Klinefelter syndrome), XXX (triple X syndrome), XYY (Jacob syndrome)—generally milder phenotypes. Prenatal screening: combined test (nuchal translucency, β -hCG, PAPP-A) at 11–13 weeks, NIPT (cell-free fetal DNA), and diagnostic testing (CVS or amniocentesis).

Variable Expressivity

- See Expressivity.

Whole Exome Sequencing (WES)

- A genomic technique sequencing the protein-coding exons of all genes (1–2 percent of the genome, 20,000 genes). Used to diagnose rare and undiagnosed genetic disorders, identify disease-causing variants, and for research. Less expensive and easier to interpret than whole genome sequencing but misses intronic, regulatory, and structural variants. Yield varies by phenotype (higher for neurodevelopmental disorders). Requires trio (parent-child) analysis and careful variant interpretation.

Whole Genome Sequencing (WGS)

- A genomic technique determining the complete DNA sequence of an individual's genome, including coding and noncoding regions, single-nucleotide variants, indels, and structural variants. Used for undiagnosed genetic disease (especially neonatal), cancer genomics, pharmacogenomics, and infectious disease epidemiology. Increasingly first-line in undiagnosed disease due to falling costs. Challenges: data volume, variant interpretation, incidental findings, and privacy. WES covers only exons.

Wilson Disease

- An autosomal recessive disorder of copper metabolism caused by mutations in the ATP7B gene on chromosome 13q14.3, encoding a copper-

transporting ATPase. The defective ATP7B protein cannot incorporate copper into ceruloplasmin or excrete excess copper into bile, leading to toxic copper accumulation primarily in the liver and brain (basal ganglia, particularly the putamen and globus pallidus), with secondary deposition in the cornea (Kayser-Fleischer rings – golden-brown copper deposits in Descemet’s membrane at the limbus, visible on slit-lamp examination, pathognomonic for Wilson disease). Hepatic presentation: acute hepatitis, fulminant hepatic failure (with Coombs-negative hemolytic anemia), chronic hepatitis, cirrhosis, and portal hypertension. Neuropsychiatric presentation: movement disorders (tremor, dysarthria, dystonia, chorea, parkinsonism), dysphagia, personality changes, depression, psychosis, and cognitive decline. Other features: renal tubular dysfunction (Fanconi syndrome), arthropathy, and cardiomyopathy. Diagnosis: reduced serum ceruloplasmin (<0.2 g/L), elevated 24-hour urinary copper excretion (>1.6 micromol/24h), elevated hepatic copper on liver biopsy (>250 mcg/g dry weight); Kayser-Fleischer rings on slit-lamp examination; ATP7B genetic testing. The Leipzig diagnostic scoring system aids diagnosis. Treatment: lifelong copper chelation (D-penicillamine as first-line, trientine as second-line) and zinc acetate (blocks intestinal copper absorption, used as maintenance or for pre-symptomatic patients). Avoid copper-rich foods (shellfish, liver, nuts, chocolate). Liver transplantation for fulminant hepatic failure or decompensated cirrhosis. Prognosis: excellent with lifelong treatment; progressive and fatal without treatment.

X-Linked Recessive

– Inheritance of a gene mutation located on the X chromosome. Expressed in all hemizygous males (XY) and homozygous females (XX). Females carrying one mutant copy are asymptomatic carriers. Carrier mothers have a 50% chance of passing disease to sons and 50% chance of carrier status in daughters. Affected fathers pass the mutation to 100% of daughters (carriers) and 0% of sons. Examples: Hemophilia A/B, Duchenne Muscular Dystrophy, Glucose-6-Phosphate Dehydrogenase Deficiency.

Chapter 14

Geriatrics & Gerontology

Age-Related Macular Degeneration (AMD)

- Progressive degenerative disease of the central retina (macula) causing bilateral, irreversible loss of central vision in adults aged > 50 years, while preserving peripheral vision. Classified into dry (non-exudative, 85–90%, characterized by drusen accumulation beneath the retinal pigment epithelium and geographic atrophy) and wet (exudative, 10–15%, characterized by choroidal neovascularization leaking blood and fluid into the subretinal space). Risk factors: advanced age, cigarette smoking, hypertension, and genetic susceptibility (CFH gene mutations). Treatment: antioxidant/vitamin supplementation (AREDS2 formula) for intermediate dry AMD; intravitreal anti-VEGF injections (ranibizumab, aflibercept) for wet AMD.

Age-Related Physiological Changes

- Progressive structural and functional decline occurring across organ systems with advancing age. Cardiovascular: decreased arterial compliance, left ventricular hypertrophy, reduced responsiveness to beta-adrenergic stimulation. Respiratory: decreased chest wall compliance, loss of elastic recoil, decreased forced expiratory volume (FEV₁). Renal: loss of functioning nephrons, decreased glomerular filtration rate (GFR declines by 1 mL/min/year after age 40). Gastrointestinal: slowed gastric emptying, decreased colonic motility. Nervous system: neuronal loss, brain volume reduction, decreased neurotransmitter synthesis. Endocrine: impaired glucose tolerance, decreased growth hormone and sex steroids (andropause/menopause). Immunosenescence: impaired cell-mediated immunity.

Agitation in Dementia

- Behavioral and psychological symptom of demen-

tia (BPSD) characterized by emotional distress, pacing, aggression, and motor restlessness; non-pharmacological interventions (environmental modification, music therapy) are first-line.

Alzheimer Disease

- The most common neurodegenerative cause of dementia, accounting for approximately sixty to seventy percent of all dementia cases. It is characterized by progressive cognitive decline, memory loss, and functional impairment, with pathologic hallmarks of extracellular amyloid-beta (A-beta) plaques and intracellular neurofibrillary tangles composed of hyperphosphorylated tau protein. The pathophysiology begins decades before clinical symptoms, with accumulation of amyloid-beta (A-beta) plaques, followed by tau hyperphosphorylation, neurofibrillary tangle formation, synaptic dysfunction, neuronal loss, and brain atrophy, particularly affecting the hippocampus, entorhinal cortex, and temporoparietal association areas. Clinical presentation includes progressive impairment of short-term memory as the earliest and most prominent feature, followed by deficits in language (anomia, fluent aphasia), visuospatial function (topographical disorientation), executive function (poor judgement, impaired planning), and apraxia. Diagnosis is based on clinical criteria, cognitive testing (MMSE, MoCA), and supportive biomarkers including CSF analysis (reduced A-beta-42, elevated total tau and phospho-tau) and amyloid PET imaging. Management includes acetylcholinesterase inhibitors (donepezil, rivastigmine, galantamine) for mild-to-moderate disease and the NMDA receptor antagonist memantine for moderate-to-severe disease, along with behavioural interventions and caregiver support.

Alzheimer's Disease

– A progressive neurodegenerative disorder and the most common cause of dementia, accounting for 60 to 80 percent of cases. It is characterized pathologically by accumulation of extracellular amyloid-beta plaques and intracellular tau-containing neurofibrillary tangles in the cerebral cortex and hippocampus, along with progressive neuronal loss and cerebral atrophy. The disease typically begins with insidious memory impairment, particularly of recent events, and progresses over years with declining cognitive function, behavioural changes, and loss of independence. APOE epsilon-4 is the strongest genetic risk factor for late-onset Alzheimer disease. Definitive diagnosis requires pathological examination, though clinical criteria and biomarkers have high diagnostic accuracy.

Atypical Disease Presentation

– Phenomenon in older adults where acute serious medical conditions (e.g., pneumonia, UTI, myocardial infarction) present with non-specific geriatric syndromes (acute delirium, functional decline, anorexia, falls) rather than classic signs like fever or chest pain.

Beers Criteria

– Expert consensus guidelines developed by the American Geriatrics Society (AGS) identifying potentially inappropriate medications (PIMs) that should generally be avoided in older adults due to unfavorable risk-benefit ratios. Categories: medications to avoid in most older adults (e.g., first-generation antihistamines, long-acting benzodiazepines, tricyclic antidepressants, NSAIDs, muscle relaxants), medications to avoid in patients with specific diseases or syndromes (e.g., NSAIDs in heart failure), and medications to be used with caution. The criteria aim to reduce adverse drug events, polypharmacy, and healthcare costs in geriatric care.

Caregiver Burden

– Multidimensional strain, exhaustion, and psychological distress experienced by informal family caregivers providing long-term care to frail, chronically ill, or cognitively impaired older adults (particularly those with Alzheimer's disease). Physical, emotional, financial, and social burdens increase the caregiver's risk for depression, anxiety, cardiovascular illness, and premature mortality. Interventions: caregiver education, support groups, respite care ser-

vices, adult day health programs, and psychological counseling.

Comprehensive Geriatric Assessment (CGA)

– Multidisciplinary diagnostic process used to evaluate the medical, psychological, functional, and social capabilities of vulnerable older individuals to create an integrated management plan. Core domains assessed: medical status (comorbidities, polypharmacy, nutrition, vision/hearing), physical function (ADLs, mobility, fall risk), cognitive and affective status (Mini-Mental State Exam, Geriatric Depression Scale), and social/environmental support. Proven to improve functional status, decrease hospital readmissions, and lower institutionalization rates.

Debility

– A state of generalized weakness, loss of strength, and reduced functional capacity, often associated with chronic illness, malnutrition, prolonged bed rest, or advanced age. Debility is a nonspecific term that may reflect underlying conditions such as sarcopenia, cachexia, deconditioning, or frailty. Management focuses on addressing the underlying cause, nutritional support, physical therapy, and gradual mobilization to prevent further functional decline.

Delirium

– Acute, fluctuating decline in attention, awareness, and cognition, typically developing over hours to days. Differentiated from dementia by its sudden onset, fluctuating course, and marked impairment of attention. Subtypes: hyperactive (agitation, hallucinations), hypoactive (lethargy, withdrawal, often missed), and mixed. Common precipitating factors in vulnerable older adults (mnemonic "I WATCH CONFUSED"): Infection (UTI, pneumonia), Withdrawal, Acute metabolic disturbance, Trauma/pain, CNS pathology, Hypoxia, Opioids/medications, Nutrition, Subdural hematoma, Endocrine, and Sensory deprivation. Non-pharmacological management (reorientation, early mobilization, sleep hygiene) is first-line; low-dose antipsychotics are reserved for severe agitation threatening safety.

Delirium (Geriatric)

– Acute, fluctuating disturbance in attention, awareness, and cognition, highly prevalent in hospitalized

elderly patients. Triggered by underlying medical illness, infections (UTI, pneumonia), medications (anticholinergics, sedatives), or surgery. Subtypes: Hyperactive, Hypoactive (frequently missed), and Mixed.

Dementia

– Chronic, global, usually progressive impairment of cognitive functions (memory, language, executive function, visuospatial skills, orientation) severe enough to interfere with daily social and occupational functioning. Major etiologies in the elderly: Alzheimer's disease (60–70%, neurofibrillary tangles and amyloid beta plaques), Vascular dementia (15–20%, lacunar infarcts, multi-infarct brain injury), Dementia with Lewy Bodies (10–15%, visual hallucinations, parkinsonism, REM sleep disorder), and Frontotemporal dementia (behavioral/personality changes). Reversible causes (hypothyroidism, vitamin B₁₂ deficiency, normal pressure hydrocephalus, neurosyphilis) must be excluded.

Deprescribing

– Planned, supervised process of dose reduction or discontinuation of potentially inappropriate, ineffective, or harmful medications in elderly patients to reduce polypharmacy and lower adverse event risks.

Elder Abuse and Neglect

– Intentional act or failure to act by a caregiver or trusted individual that causes harm or serious risk of harm to a vulnerable older adult. Categories: physical abuse, psychological/emotional abuse, financial exploitation (most common), sexual abuse, neglect (withholding food, shelter, medical care), and self-neglect. Risk factors: cognitive impairment, physical dependency, caregiver stress, isolation, and substance abuse. Signs: unexplained bruises, fractures, malnutrition, poor hygiene, sudden changes in financial assets, and withdrawal. Mandatory reporting laws require healthcare providers to report suspected elder mistreatment to adult protective services.

Fall Risk Assessment

– Systematic clinical evaluation of intrinsic and extrinsic factors predisposing an older adult to falls, which represent a leading cause of injury, hip fractures, loss of independence, and accidental death in geriatrics. Intrinsic risk factors: gait and balance impairment, muscle weakness (sarcopenia), pe-

ripheral neuropathy, visual impairment, orthostatic hypotension, cognitive decline, and polypharmacy (particularly sedatives, antihypertensives, and anticholinergics). Extrinsic risk factors: poor lighting, slippery floors, throw rugs, lack of grab bars, and improper footwear. Screening tests: Timed Up and Go (TUG) test, Berg Balance Scale, and functional reach test.

Falls in the Elderly

– Leading cause of accidental injury and death in adults aged 65 and older. Multifactorial etiology: muscle weakness, gait instability, sensory deficits, environmental hazards, and psychotropic/antihypertensive medications.

Frailty

– A clinical syndrome in older adults characterized by decreased physiologic reserve and increased vulnerability to stressors, resulting in increased risk of falls, hospitalization, disability, and death. Fried frailty phenotype: ≥ 3 of 5 criteria present — unintentional weight loss (>10 lbs in past year), exhaustion (self-reported), weakness (grip strength), slow gait speed, and low physical activity. Frailty is distinct from disability and comorbidity. Pre-frail: 1-2 criteria. Management: multi-domain intervention (exercise including resistance training, nutritional optimization with protein supplementation, medication review, and management of comorbidities). Frailty is potentially reversible with appropriate intervention.

Frailty Syndrome

– Biologic syndrome of decreased physiological reserve and vulnerability to stressors, resulting from dysregulated multi-system decline. Fried frailty phenotype criteria (≥ 3 present for diagnosis): unintentional weight loss (> 10 lbs in past year), exhaustion, muscle weakness (reduced grip strength), slow walking speed, and low physical activity level. Frail older adults are at significantly higher risk for falls, hospitalization, disability, institutionalization, and mortality. Management: progressive resistance exercise training, nutritional optimization (protein supplementation), and reduction of polypharmacy.

Frontotemporal Dementia

– A group of neurodegenerative disorders characterized by progressive degeneration of the frontal and temporal lobes, presenting with personality changes, behavioral abnormalities, language impair-

ment, and cognitive decline. FTD is the most common cause of dementia in patients under sixty years of age and accounts for approximately five to ten percent of all dementia cases. The three main clinical variants are behavioral variant FTD (bvFTD), which presents with progressive personality changes such as apathy, disinhibition, loss of empathy, perseverative behaviours, hyperorality, and dietary changes (bvFTD), semantic variant primary progressive aphasia (svPPA) with loss of word meaning and object knowledge, and non-fluent/agrammatic variant PPA (nfvPPA) with effortful, agrammatic speech. The pathophysiology involves accumulation of abnormal proteins: about 50 percent of FTD cases have tau inclusions (tauopathy), 40 percent have TDP-43 inclusions (TDP-43 proteinopathy), and 10 percent have FUS inclusions. Approximately 30-50 percent of FTD cases have a family history, with autosomal dominant mutations in the MAPT (tau), GRN (progranulin), and C9orf72 genes being the most common. C9orf72 hexanucleotide repeat expansions are the most common genetic cause of both FTD and ALS, and these conditions may co-occur. Diagnosis is by clinical criteria (Rascovsky criteria for bvFTD, Gorno-Tempini criteria for PPA variants), neuropsychological testing, and MRI brain showing focal atrophy of the frontal and/or temporal lobes. There is no disease-modifying treatment; management is symptomatic with SSRIs for behavioural symptoms, antipsychotics for agitation, and speech therapy for language deficits. Prognosis is poor, with median survival of 6-10 years from diagnosis.

Functional Incontinence

- Urinary incontinence in patients with normal lower urinary tract function who are unable to reach the toilet in time due to physical mobility limitations, severe cognitive impairment, or environmental barriers.

Geriatric Anesthesia

- Geriatric patients have decreased physiologic reserve and increased anesthesia risk. Age-related changes include decreased cardiac output, reduced pulmonary function, decreased renal function, altered pharmacokinetics (reduced volume of distribution, decreased hepatic metabolism), and increased brain sensitivity to anesthetics. Frailty assessment

predicts postoperative complications. Delirium is a common postoperative complication, particularly in patients with dementia. Minimally invasive techniques, regional anesthesia, and multimodal analgesia improve outcomes. Preoperative optimisation of comorbidities reduces perioperative risk. Postoperative cognitive dysfunction and functional decline are concerns requiring appropriate discharge planning and follow-up.

Geriatric Delirium

- Acute, fluctuating disturbance in attention, awareness, and cognition, highly prevalent in hospitalized elderly patients. Triggered by underlying medical illness, infections (UTI, pneumonia), medications (anticholinergics, sedatives), or surgery. Subtypes: Hyperactive, Hypoactive (frequently missed), and Mixed.

Geriatric Depression Scale (GDS)

- Validated 30-item (or short 15-item) self-report screening tool specifically designed to detect depression in older adults. Unlike general depression scales, the GDS minimizes somatic symptoms (fatigue, sleep disturbance) that often overlap with normal aging or physical illness, focusing instead on psychological symptoms (feelings of helplessness, hopelessness, loss of interest). A score of > 5 on the 15-item GDS warrants further clinical evaluation for major depressive disorder.

Geriatric Dermatology

- Geriatric dermatology addresses skin changes and diseases of aging. Senile purpura (easy bruising from fragile vessels). Actinic keratoses (premalignant from sun exposure). Seborrheic keratoses (benign proliferations). Pruritus senilis (generalized itching from xerosis). Skin cancer incidence increases with age. Impaired wound healing and increased infection risk. Polypharmacy increases adverse drug reactions. Careful medication review and skin cancer screening are essential.

Geriatric Failure to Thrive

- Complex syndrome in older adults characterized by weight loss (> 5%), decreased appetite, poor nutrition, physical inactivity, depression, and cognitive decline, associated with increased mortality.

Geriatrician

- A physician who specializes in the care of older patients.

Geriatric Psychiatry

- The subspecialty of psychiatry focused on the prevention, evaluation, diagnosis, and treatment of mental and emotional disorders in older adults. Geriatric patients often present atypically, with depression manifesting as somatic complaints and cognitive decline. Common conditions include late-life depression, dementia, delirium, and late-onset psychosis. Polypharmacy, medical comorbidity, and altered drug metabolism complicate treatment.

Geriatrics (see Medicine of Ageing)

- The medical specialty concerned with the health and care of older adults. See Medicine of Ageing.

Gerontology & Geriatrics

- Gerontology is the multidisciplinary scientific study of the biological, psychological, and social aspects of aging. Geriatrics is the specialized branch of medicine focused on the health care, disease prevention, diagnosis, and treatment of medical conditions in older adults. Core principles of geriatric care emphasize maintaining functional independence, optimizing quality of life, preserving cognition, and minimizing adverse outcomes from polypharmacy and hospitalization.

Instrumental Activities of Daily Living (IADLs)

- Complex cognitive and physical tasks required to live independently within a community, evaluated using Lawton scale: Using the telephone, Shopping, Food preparation, Housekeeping, Laundry, Mode of transportation, Responsibility for own medications, and Ability to handle finances.

Lewy Body Dementia

- The second most common neurodegenerative cause of dementia after Alzheimer disease and is characterized by the presence of alpha-synuclein-containing Lewy bodies in cortical and subcortical neurons. LBD encompasses two clinical entities: dementia with Lewy bodies (DLB), where dementia occurs within one year of the onset of parkinsonism, and Parkinson disease dementia (PDD), where dementia occurs after at least one year of established Parkinson disease. The core clinical features include dementia (typically with prominent fluctuations in cognition and alertness, well-formed recurrent visual hallucinations, and parkinsonism), REM sleep behaviour disorder (acting out dreams, often a pro-

dromal feature), and autonomic dysfunction. Other supportive features include severe neuroleptic sensitivity (a critical clinical point: antipsychotics can precipitate severe rigidity and autonomic instability in LBD), repeated falls, syncope, and depression. The diagnostic criteria include the presence of two or more core features for probable DLB and one core feature for possible DLB. Diagnosis is clinical, supported by dopamine transporter (DaT) SPECT imaging showing reduced presynaptic dopamine uptake in the basal ganglia (the most useful diagnostic test), and polysomnography may confirm REM sleep behaviour disorder. Management includes cholinesterase inhibitors (rivastigmine, donepezil) for cognition and visual hallucinations—these are more effective than in Alzheimer disease—and careful use of atypical antipsychotics (quetiapine, clozapine) for severe hallucinations or agitation, with avoidance of typical antipsychotics due to neuroleptic sensitivity. Levodopa may be used for parkinsonism but has limited efficacy. Prognosis is poor, with progressive decline over several years, parkinsonism worsening, and eventual death from complications of immobility and dysphagia.

MIND Diet

- The MIND diet (Mediterranean-DASH Intervention for Neurodegenerative Delay) is a hybrid eating pattern combining elements of the Mediterranean and DASH diets, specifically designed to preserve cognitive function and reduce dementia risk. Emphasis is on green leafy vegetables (≥ 6 servings/week), berries (≥ 2 servings/week, specifically blueberries and strawberries for their flavonoid content), nuts, whole grains, fish, poultry, olive oil, and wine (≤ 1 glass/day); red meat, butter/margarine, cheese, pastries/sweets, and fried foods are limited. The MIND diet trial (Morris et al.) showed that higher adherence was associated with significantly slower cognitive decline equivalent to 7.5 years of younger age; observational data suggest even moderate adherence reduces Alzheimer disease risk by 35%. Protective mechanisms: antioxidant (vitamin E, flavonoids), anti-inflammatory (polyunsaturated fats, polyphenols), and vascular (blood pressure reduction, improved cerebral blood flow) effects.

Multi-Infarct Dementia

- Subtype of vascular dementia resulting from cu-

mulative stroke damage due to multiple recurrent ischemic cerebral cortical and subcortical strokes. Clinical presentation is classically characterized by a stepwise deterioration in cognitive function, where each sudden drop in performance corresponds to a discrete vascular event, accompanied by focal neurological deficits (hemiparesis, pseudobulbar palsy, gait apraxia, exaggerated deep tendon reflexes). Brain MRI demonstrates multiple lacunar and cortical infarcts with extensive white matter hyperintensities (leukoaraiosis). Management focuses on secondary stroke prevention (antithrombotics, blood pressure control, statins).

Normal Pressure Hydrocephalus (NPH)

– Reversible cause of dementia characterized by enlarged cerebral ventricles with normal or transiently elevated cerebrospinal fluid (CSF) pressure on lumbar puncture. Pathophysiology: impaired CSF absorption by arachnoid villi. Classic triad (mnemonic "Wet, Wobbly, Weird"): (1) Gait apraxia (magnetic, broad-based, short-stepped gait—usually the first and most prominent symptom), (2) Urinary incontinence (urgency and loss of control), and (3) Dementia (subcortical, psychomotor slowing). Brain MRI shows ventriculomegaly out of proportion to sulcal atrophy. Diagnostic test: high-volume lumbar puncture (tap test) showing temporary improvement in gait. Treatment: surgical placement of a ventriculoperitoneal (VP) shunt.

Osteoporosis

– Systemic skeletal disorder characterized by low bone mineral density (BMD), microarchitectural deterioration of bone tissue, and increased bone fragility, predisposing to low-trauma (fragility) fractures of the hip, vertebrae, and distal radius. Most common in postmenopausal women due to estrogen deficiency accelerating osteoclast-mediated bone resorption. Diagnosis: Dual-energy X-ray absorptiometry (DEXA) scan showing a BMD T-score ≤ -2.5 at the femoral neck or lumbar spine. Prevention and treatment: weight-bearing exercise, calcium and vitamin D supplementation, bisphosphonates (alendronate, zoledronic acid), denosumab, and anabolic agents (teriparatide).

Overflow Incontinence

– Involuntary loss of urine associated with overdisten-

sion and incomplete emptying of the bladder, caused by bladder outlet obstruction (BPH) or detrusor underactivity (diabetic neuropathy).

Polypharmacy

– Concurrent use of multiple medications by a single patient, typically defined as taking 5 or more prescription drugs daily. Highly prevalent in older adults with multiple chronic comorbidities. Consequences: increased risk of adverse drug reactions, drug-drug interactions, prescribing cascades (treating drug side effects with additional drugs), cognitive impairment, falls, non-adherence, and hospitalization. Management involves routine medication reconciliation, structured deprescribing, and adherence to guidelines such as the Beers Criteria.

Presbycusis

– Age-related, progressive, bilateral, symmetrical sensorineural hearing loss resulting from degeneration of cochlear hair cells, spiral ganglion neurons, and the stria vascularis in the inner ear. Typically affects high-frequency sounds first, causing difficulty understanding speech in noisy environments and loss of consonant discrimination (e.g., distinguishing "s", "f", "t"). Audiometry demonstrates a characteristic sloping high-frequency hearing loss. Management: hearing aids, assistive listening devices, and auditory rehabilitation.

Presbyopia

– Age-related decline in the eye's accommodative ability, resulting in difficulty focusing on near objects. Pathophysiology: loss of crystalline lens elasticity and decreased power of the ciliary muscle, typically becoming clinically noticeable around age 40–45. Patients present with eye strain, headaches, and the need to hold reading material at arm's length. Corrected with convex reading glasses, bifocal/progressive lenses, or accommodative contact lenses.

Pressure Sore (Decubitus Ulcer)

– Decubitus ulcer (bedsores, pressure ulcers) are localised areas of tissue necrosis caused by prolonged pressure over bony prominences, most commonly in immobile patients. Sites: sacrum (most common), heels, elbows, hips, and occiput. Pathophysiology: pressure exceeding capillary closing pressure (32 mmHg) causes ischaemia, followed by reperfusion injury, inflammation, and necrosis. Risk fac-

tors: immobility, sensory loss, malnutrition, moisture (incontinence), advanced age, and poor perfusion. NPUAP Staging: Stage 1 (non-blanchable erythema), Stage 2 (partial-thickness skin loss), Stage 3 (full-thickness loss without bone exposure), Stage 4 (full-thickness loss with bone/tendon/muscle involvement), Unstageable (eschar or slough covering base), Deep Tissue Injury (purple/maroon intact skin). Management: pressure redistribution (turn q2h, specialized mattresses), wound debridement, moist wound care, infection control, nutritional support, and surgical repair for advanced stages. Prevention is paramount: risk assessment (Braden scale), regular repositioning, pressure-relieving surfaces, skin care, and nutrition.

Pressure Ulcer

- Localized injury to skin and underlying soft tissue, typically over a bony prominence (sacrum, ischium, calcaneus), resulting from sustained pressure or pressure in combination with shear. Staged 1–4 (Stage 1: non-blanchable erythema; Stage 4: full-thickness skin loss exposing bone, muscle, or tendon).

Pressure Ulcers (Decubitus Ulcers)

- Localized injury to the skin and underlying soft tissue, usually over a bony prominence (sacrum, ischium, trochanter, calcaneus), resulting from sustained mechanical pressure combined with friction and shear forces. Staging: Stage 1 (non-blanchable erythema of intact skin), Stage 2 (partial-thickness skin loss with exposed dermis), Stage 3 (full-thickness skin loss with visible subcutaneous fat), Stage 4 (full-thickness skin and tissue loss with exposed muscle, tendon, or bone), Unstageable (obscured by eschar/slough), and Deep Tissue Injury. Risk factors evaluated by the Braden Scale: immobility, incontinence, malnutrition, and impaired sensation. Prevention: repositioning every 2 hours, pressure-relieving mattresses, moisture management, and nutritional support.

Sarcopenia

- Age-associated progressive loss of skeletal muscle mass, strength, and functional capacity. Primary sarcopenia is driven by intrinsic aging processes (decline in anabolic hormones, motor neuron loss, chronic low-grade inflammation, mitochondrial dysfunction); secondary sarcopenia results from disuse, disease, or malnutrition. Diagnosis

requires demonstration of low muscle strength (reduced grip strength) combined with low muscle quantity/quality (measured by DXA or BIA). Sarcopenia increases the risk of physical disability, falls, frailty, and mortality. Treatment: progressive resistance exercise training combined with adequate dietary protein intake (1.2–1.5 g/kg/day).

Senile Gait

- Altered gait pattern commonly observed in very old adults, characterized by decreased walking speed, shortened step length, widened base of support, increased double-support time, and diminished arm swing. Resulting from a combination of subclinical neurological, musculoskeletal, and sensory impairments (decreased proprioception, sarcopenia, joint stiffness, subtle frontal lobe dysfunction). Differentiated from specific pathological gaits (parkinsonian, ataxic, hemiparetic). Evaluation requires screening for reversible causes (cataracts, joint pain, B12 deficiency) and physical therapy gait training.

STOPP/START Criteria

- Evidence-based screening tool for elderly drug regimens. STOPP (Screening Tool of Older Persons' Prescriptions) identifies inappropriate medications; START (Screening Tool to Alert doctors to Right Treatment) identifies omitted evidence-based medications.

Stress Incontinence

- Involuntary urinary leakage occurring during activities that acutely increase intra-abdominal pressure (coughing, sneezing, laughing, exercise), resulting from urethral hypermobility or intrinsic sphincter deficiency.

Sundowning Syndrome

- Neuropsychiatric phenomenon characterized by increased confusion, disorientation, anxiety, agitation, and restlessness appearing in the late afternoon or evening, commonly affecting individuals with Alzheimer's disease or other dementias.

Urge Incontinence

- Involuntary leakage of urine accompanied or immediately preceded by a sudden, intense urge to void, caused by detrusor muscle overactivity ('overactive bladder'). Common in elderly patients; managed with bladder training, antimuscarinics (solifenacin), or beta-3 agonists (mirabegron).

Vascular Dementia

– The second most common cause of dementia after Alzheimer disease and results from cerebrovascular disease causing sufficient brain injury to impair cognitive function. It is caused by large vessel cerebrovascular disease (multi-infarct dementia from multiple cortical and subcortical infarcts), small vessel cerebrovascular disease (subcortical ischemic vascular dementia from lacunar infarcts and white matter changes), strategic single infarct (infarction in a cognitively critical area such as the dominant thalamus, angular gyrus, or medial temporal lobe), or global hypoperfusion injury from cardiac arrest or hypotension causing watershed infarcts between vascular territories. Clinical presentation of vascular dementia is characterized by a stepwise deterioration and a patchy pattern of cognitive deficits, in contrast to the gradual progressive decline of Alzheimer disease. The cognitive profile includes executive dysfunction (impaired planning, organisation, and abstraction) more than memory loss, slowness of processing (bradyphrenia), and subcortical features (apathy, emotional lability, depression). Focal neurological signs (hemiparesis, sensory loss, visual field deficits, pseudobulbar palsy, gait disturbance) are common. The Hachinski ischemic Score helps differentiate vascular dementia from Alzheimer disease. Diagnosis is by clinical assessment, cognitive testing, and neuroimaging (CT or MRI) showing multiple infarcts, extensive white matter disease (leukoaraiosis), or a strategically located infarct. Management includes control of vascular risk factors (hypertension, diabetes, hyperlipidaemia, smoking cessation, antiplatelet therapy), and symptomatic treatment of cognitive and behavioural symptoms. Acetylcholinesterase inhibitors have limited benefit in vascular dementia, unlike their use in Alzheimer disease. Prognosis is variable and depends on the progression of underlying cerebrovascular disease.

Chapter 15

Hematology

Acanthocytes (Spur Cells)

– Abnormal red blood cells with irregular, spiky, thorn-like membrane projections of varying length and width. Caused by alterations in membrane lipid composition (increased cholesterol-to-phospholipid ratio). Associated with Abetalipoproteinemia (APOB mutation, loss of chylomicrons/VLDL), severe liver disease (spur cell anemia in end-stage cirrhosis), and McLeod syndrome (X-linked neuroacanthocytosis).

Acute leukemia

– leukemia characterized by a rapid onset, clonal proliferation of immature blast cells (>20% of bone marrow cells), and rapid progression without treatment. Subtypes: acute lymphoblastic leukemia (ALL, B-cell or T-cell, most common childhood cancer, peak age 2-5) and acute myeloid leukemia (AML, more common in adults, median age 65-70). Clinical features: bone marrow failure (anemia–fatigue, pallor; thrombocytopenia–bruising, petechiae, bleeding; neutropenia–fever, recurrent infections), organ infiltration (lymphadenopathy, hepatosplenomegaly, bone pain, gum hypertrophy in AML M4/M5, skin infiltration). Emergency complications: hyperleukocytosis (blast count >100,000, risk of leukostasis, requiring urgent leukapheresis), tumor lysis syndrome, disseminated intravascular coagulation (especially in AML M3/promyelocytic). Diagnosis: full blood count and blood film, bone marrow aspirate and trephine biopsy, flow cytometry (immunophenotyping), cytogenetics (karyotype, FISH), and molecular genetics (NPM1, FLT3-ITD, CEBPA, RUNX1, BCR-ABL for ALL, PML-RARA for APL).

Acute Lymphoblastic Leukemia

– A clonal malignancy of lymphoid progenitor cells, most common in children (peak age 2-5 years) but

also occurring in adults with a worse prognosis with increasing age. B-cell ALL (85 percent of childhood, 75 percent of adult ALL) is classified by immunophenotype: early pre-B (CD19+, CD10-, TdT+), common ALL (CD19+, CD10+, TdT+), pre-B (CD19+, cytoplasmic mu heavy chain+), and mature B-cell (Burkitt-type, CD19+, surface immunoglobulin+, CD10+). T-cell ALL (15% of childhood, 25% of adult ALL) presents with mediastinal mass and has a poorer prognosis.

Acute Megakaryoblastic Leukemia

– A rare subtype of acute myeloid leukemia characterized by the proliferation of megakaryoblasts in the bone marrow and peripheral blood. It accounts for approximately 1-2 percent of AML in adults but is the most common AML subtype in children with Down syndrome (trisomy 21), where it occurs in 1-5 percent of cases (called transient abnormal myelopoiesis in neonates, which often resolves spontaneously). AMKL is associated with extensive bone marrow fibrosis and a poor prognosis.

Acute Promyelocytic Leukemia

– A distinct subtype of acute myeloid leukemia (AML) characterized by the t(15;17)(q24;q21) translocation, which fuses the promyelocytic leukemia (PML) gene on chromosome 15 with the retinoic acid receptor alpha (RARA) gene on chromosome 17. This PML-RARA fusion protein blocks myeloid differentiation at the promyelocyte stage, leading to accumulation of abnormal promyelocytes in the bone marrow and peripheral blood. APL accounts for approximately 5-10 percent of AML cases.

Anaemia

– A condition in which the number of red blood cells or the hemoglobin concentration is below the

normal range, reducing the oxygen-carrying capacity of the blood. Classified by etiology: blood loss (acute or chronic), decreased production (iron deficiency, vitamin B12/folate deficiency, bone marrow failure, anemia of chronic disease), and increased destruction (hemolytic anemias). Classified by morphology: microcytic (low MCV — iron deficiency, thalassemia, anemia of chronic disease), normocytic (normal MCV — acute blood loss, hemolysis, renal failure), macrocytic (high MCV — B12/folate deficiency, alcohol, MDS, hypothyroidism). Symptoms: fatigue, pallor, dyspnea, dizziness, tachycardia. Severe anemia can cause heart failure. Diagnosis: CBC, reticulocyte count, iron studies, vitamin B12/folate, and peripheral smear. Treatment: address underlying cause, iron supplementation, B12/folate replacement, erythropoietin, and blood transfusion for severe symptomatic anemia.

Anemia

– A reduction in the oxygen-carrying capacity of the blood, defined by a hemoglobin concentration below the normal range for age and sex: less than 13.5 g/dL in adult males, less than 12.0 g/dL in adult females. Anemia is classified by mechanism into three categories: decreased production (iron deficiency, vitamin B12 deficiency, folate deficiency, chronic disease, aplastic anemia, myelodysplastic syndrome), increased destruction (hemolytic anemias including hereditary spherocytosis, sickle cell disease, paroxysmal nocturnal haemoglobinuria), or blood loss.

Antiphospholipid Syndrome

– A systemic autoimmune thrombophilia characterized by arterial and venous thrombosis, pregnancy morbidity, and persistent antiphospholipid antibody positivity. Antiphospholipid antibodies are a heterogeneous group of autoantibodies targeting phospholipid-binding proteins: lupus anticoagulant (LA, detected by prolongation of phospholipid-dependent coagulation assays that fails to correct with mixing study, paradoxically associated with thrombosis), anticardiolipin antibodies (aCL, IgG or IgM, detected by ELISA), and anti-beta-2 glycoprotein I antibodies.

Antithrombin Deficiency

– A rare (1 in 2,000-5,000), strongly thrombophilic inherited disorder (autosomal dominant). Antithrom-

bin (previously antithrombin III) is a serine protease inhibitor that inactivates thrombin and factors Xa, IXa, XIa, and XIIa. Heterozygous: 10-50 fold increased VTE risk, more severe than factor V Leiden. Presents with DVT and PE at a young age (<30), recurrent thrombosis, and unusual sites (mesenteric, cerebral veins). Diagnosis: low antithrombin activity (type I: reduced antigen and activity; type II: reduced activity). Heparin resistance is a clue. Management: anticoagulation for acute VTE; may require high-dose heparin; lifelong anticoagulation. Prophylaxis in high-risk situations is essential.

Aplastic Anemia

– A bone marrow failure syndrome characterized by pancytopenia (anemia, leukopenia, thrombocytopenia) and a hypocellular bone marrow with replacement by fat cells, resulting from immune-mediated destruction of hematopoietic stem cells. Acquired aplastic anemia accounts for 80-90 percent of cases, with autoimmune T-cell-mediated destruction of CD34+ hematopoietic progenitors as the primary mechanism, supported by response to immunosuppressive therapy. Causes include idiopathic (60-70%), drugs, toxins, viruses, and pregnancy.

Auer Rods

– Pathognomonic intracellular crystalline inclusions formed by the fusion of azurophilic granules, seen in the cytoplasm of leukemic myeloblasts. Strongly diagnostic of Acute Myeloid Leukemia (AML), particularly Acute Promyelocytic Leukemia (APL, FAB M3 classification, *t*(15;17) PML-RARA translocation). APL myeloblasts often contain multiple Auer rods ("faggot cells") and trigger severe Disseminated Intravascular Coagulation (DIC) upon cell lysis. Treated urgently with All-Trans Retinoic Acid (ATRA) and arsenic trioxide.

Autoimmune Hemolytic Anemia

– AIHA: hemolytic anemia due to antibodies directed against red blood cells. Warm AIHA (IgG, 37C—idiopathic, SLE, CLL, drugs: methyldopa, penicillin): splenic sequestration, spherocytes, positive direct antiglobulin (DAT). Cold AIHA/cold agglutinin disease (IgM, <30C—mycoplasma, EBV, lymphoma): complement-mediated, acrocyanosis; cold hemolysin (paroxysmal cold hemoglobinuria, Donath-Landsteiner). Features: anemia, jaundice, reticulocytosis, raised LDH/bilirubin,

low haptoglobin, DAT positive. Management: warm—corticosteroids first-line, rituximab, splenectomy, immunosuppression; cold—avoid cold, rituximab; transfuse cautiously (compatibility at 37°C).

Bleeding

– The escape of blood from the vascular system, which may be external (visible hemorrhage from a wound, orifice, or natural opening) or internal (bleeding into a body cavity, organ, or tissue). Bleeding is classified by source: arterial bleeding (bright red, pulsatile, and difficult to control due to high pressure), venous bleeding (dark red, steady flow), and capillary bleeding (slow oozing from superficial wounds). The clinical significance of bleeding depends on the rate and volume of blood loss, as well as the location of bleeding, with hemorrhage in critical areas such as the intracranial cavity, pericardium, or airway being immediately life-threatening even with relatively small volumes of blood loss.

Bleeding Disorders

– A heterogeneous group of conditions characterized by abnormal hemostasis, resulting from defects in blood vessels, platelets, or coagulation factors. They are classified into three categories: vascular disorders (Ehlers-Danlos syndrome, Henoch-Schonlein purpura, hereditary hemorrhagic telangiectasia), platelet disorders (thrombocytopenia from immune destruction [immune thrombocytopenia], decreased production [aplastic anemia, chemotherapy], or sequestration [hypersplenism]; and platelet function disorders (von Willebrand disease, uraemia, aspirin, NSAIDs)), and coagulation disorders (hemophilia A and B, von Willebrand disease, factor deficiencies, vitamin K deficiency, liver disease, anticoagulant therapy, and DIC).

Blood Group

– The classification of blood based on the presence or absence of specific antigens (agglutinogens) on the surface of red blood cells. The ABO system has four groups: A (A antigen), B (B antigen), AB (both A and B), and O (neither A nor B). The Rh system: RhD-positive (85% of population) or RhD-negative (15%). Blood type compatibility is critical for transfusion: group O RhD-negative is the universal donor (no ABO/RhD antigens); group AB RhD-positive is the universal recipient (no ABO/RhD antibodies). In pregnancy, RhD-negative women carrying

RhD-positive fetuses may develop anti-D antibodies, causing hemolytic disease of the newborn in subsequent pregnancies — prevented by antenatal and postnatal anti-D immunoglobulin (RhoGAM).

Blood Smear

– Peripheral blood film: a thin blood smear on a slide stained (Wright/Giemsa) and examined microscopically for cell morphology, aiding diagnosis. Findings: spherocytes (AIHA, hereditary spherocytosis), schistocytes (MAHA—TTP, HUS, DIC), sickle cells, target cells (thalassemia, liver disease), teardrop cells (myelofibrosis), nucleated RBCs, blast cells (leukemia), toxic granulation (infection), platelet clumps (pseudothrombocytopenia), and parasites (malaria, babesia). Essential for anemia, cytopenia, and leukemia evaluation; confirms automated differential and identifies abnormal cells.

Blood Transfusion

– The administration of whole blood or blood components (packed red blood cells, platelets, fresh frozen plasma, cryoprecipitate) to restore or maintain adequate circulating blood volume and oxygen-carrying capacity. Indications: packed red blood cells for symptomatic anemia (hemoglobin less than 7-8 g/dL in stable patients; higher thresholds for patients with acute coronary syndrome, hemoglobin less than 10 g/dL, or ongoing hemorrhage); platelets for active bleeding with thrombocytopenia less than $50 \times 10^9/L$; FFP for coagulopathy with INR >1.5 ; cryoprecipitate for fibrinogen <100 mg/dL.

Bone Marrow Biopsy

– A procedure sampling bone marrow (typically posterior iliac crest) via aspiration (cytology, flow cytometry, cultures) and trephine core biopsy (histology, architecture, fibrosis, cellularity). Indications: evaluation of cytopenias/pancytopenia, suspected leukemia/lymphoma/myeloma/metastasis, staging, fever of unknown origin, marrow failure, and monitoring response to therapy. Provides cellularity, lineage assessment, blast counts, iron stores, and cytogenetic/molecular studies (FISH, cytogenetics). Complications: pain, bleeding, infection (rare). Contraindications: severe coagulopathy (correct first). Essential for hematologic diagnosis.

Burkitt Lymphoma

– A highly aggressive B-cell lymphoma characterized by MYC translocation (t(8;14) IGH-

MYC, t(8;22) IGL-MYC, t(2;8) IGK-MYC) and a "starry sky" morphology (tingible body macrophages). Three variants: endemic (African, EBV+, jaw/facial bones), sporadic (abdominal, ileocecal), immunodeficiency-associated (HIV). Clinical: rapidly growing mass, LDH extremely high, TLS risk. Treatment: intensive short-course chemotherapy (CODOX-M/IVAC, hyper-CVAD, LMB) + rituximab + CNS prophylaxis with intrathecal methotrexate.

Chronic leukemia

- leukemia characterized by an insidious onset, clonal proliferation of relatively mature blood cells, and a more indolent clinical course. Subtypes: chronic lymphocytic leukemia (CLL, most common adult leukemia, median age 72, monoclonal B-cell proliferation CD5+, CD23+, often asymptomatic, managed with watchful waiting in early stage) and chronic myeloid leukemia (CML, characterized by Philadelphia chromosome t(9;22) BCR-ABL fusion, trilineage myeloproliferation, progresses through chronic phase to accelerated phase to blast crisis).

Chronic Lymphocytic Leukemia

- The most common leukemia in Western countries, characterized by the clonal proliferation of mature-appearing but functionally incompetent B lymphocytes that accumulate in blood, bone marrow, and lymphoid tissues. Diagnosis requires a monoclonal B-lymphocyte count of 5,000 per microliter or greater with a characteristic immunophenotype: CD5+, CD19+, CD23+, CD200+, with weak surface immunoglobulin expression and weak CD20. CLL has a highly variable clinical course, with some patients having indolent disease and others progressing rapidly.

Chronic Myeloid Leukemia

- A myeloproliferative neoplasm characterized by the Philadelphia chromosome [t(9;22)(q34;q11.2)], which creates the BCR-ABL1 fusion gene encoding a constitutively active tyrosine kinase. CML has three phases: chronic phase (most common at diagnosis, 85-90 percent, characterized by low blast count less than 10 percent, thrombocytosis, and basophilia), accelerated phase (increasing blasts 10-19 percent, basophilia greater than 20 percent, or additional cytogenetic abnormalities), and blast phase (>20% blasts, acute leukemia-like, poor prognosis).

Chronic Leukemia

- A rare myelodysplastic/myeloproliferative neoplasm characterized by persistent monocytosis (absolute monocyte count greater than 1,000 per microliter and greater than 10 percent of white blood cells) in the peripheral blood and bone marrow, with dysplastic features and variable blast count. CMML bridges the categories of MDS and myeloproliferative neoplasm, with clinical features of both: cytopenias and dysplasia (MDS features) plus splenomegaly and monocytosis, and increased risk of transformation to AML (15-30%).

Coagulation Factor Deficiencies

- Rare factor deficiencies: Factor VII (most common rare bleeding disorder, prolonged PT, normal aPTT, mucosal bleeding, hemarthrosis; recombinant FVIIa for treatment), Factor X (prolonged PT/aPTT), Factor XI (Ashkenazi Jews, prolonged aPTT, bleeding with surgery/trauma, FFP for replacement), Factor XIII (normal PT/aPTT, clot solubility test, umbilical stump bleeding, intracranial hemorrhage; FXIII concentrate), Fibrinogen (afibrinogenemia, hypofibrinogenemia, dysfibrinogenemia; cryoprecipitate, fibrinogen concentrate).

Dacrocytes (Teardrop Cells)

- Teardrop-shaped red blood cells formed as erythrocytes are squeezed and deformed while exiting a fibrotic or infiltrated bone marrow space. Characteristic feature of Primary Myelofibrosis (JAK2 V617F mutation), bone marrow infiltration (myelophthitic anemia from metastatic cancer, granulomas, or leukemia), and severe thalassemia.

Direct Oral Anticoagulants

- Direct oral anticoagulants (DOACs) target specific coagulation factors: dabigatran (direct thrombin inhibitor, factor IIa), rivaroxaban, apixaban, edoxaban (direct factor Xa inhibitors). Indications: VTE treatment/prevention, stroke prevention in atrial fibrillation (non-valvular), post-orthopedic surgery prophylaxis. Advantages: fixed dosing, no routine monitoring, rapid onset/offset, fewer drug/food interactions (vs warfarin). Reversal: idarucizumab (anti-dabigatran monoclonal antibody), andexanet alfa (anti-Xa reversal). DOACs are preferred over warfarin for most indications.

Disseminated Intravascular Coagu-

lation

– A pathological state of simultaneous systemic activation of coagulation and fibrinolysis, leading to widespread microvascular thrombosis that causes organ ischemia and dysfunction, paradoxically accompanied by consumptive coagulopathy and increased bleeding risk. DIC is triggered by conditions that expose tissue factor to the circulation: sepsis (most common trigger, especially gram-negative and fungal), trauma (tissue factor release), malignancy (particularly adenocarcinomas and acute promyelocytic leukemia),.

Dyscrasia

– An historic term broadly referring to any abnormal condition of the blood or bone marrow, now used primarily in the context of plasma cell dyscrasias (also called monoclonal gammopathies). These include multiple myeloma, monoclonal gammopathy of undetermined significance (MGUS), Waldenstrom macroglobulinemia, AL amyloidosis, and POEMS syndrome. The term indicates a disorder of blood cell production or function, often involving the overproduction of a monoclonal immunoglobulin (M protein) by a clonal plasma cell population. Diagnosis: serum protein electrophoresis, immunofixation, serum free light chain assay, and bone marrow biopsy.

Echinocytes (Burr Cells)

– Red blood cells with uniform, small, evenly spaced serrated or spiky membrane projections along the entire erythrocyte circumference. Most commonly caused by End-Stage Renal Disease (Uremia), pyruvate kinase deficiency, severe hypokalemia, or in vitro artifact (crenation due to glass slides or prolonged storage).

Erythropoietin

– A glycoprotein hormone (EPO) that regulates erythropoiesis—the production of red blood cells in the bone marrow. Produced primarily by interstitial peritubular cells in the kidney (90%) and hepatocytes (10%) in response to tissue hypoxia. EPO binds to EPOR receptors on erythroid progenitor cells in the bone marrow, promoting their survival, proliferation, and differentiation into mature erythrocytes. Deficiency causes anemia of chronic kidney disease (the most clinically significant EPO deficiency). Recombinant human EPO (epoetin

alfa, darbepoetin alfa) is used to treat anemia in CKD, chemotherapy-induced anemia, and before elective surgery to reduce transfusion needs. Adverse effects: hypertension, thrombosis (especially when hemoglobin targets are too high), and pure red cell aplasia (rare, antibody-mediated, associated with subcutaneous administration of certain epoetin formulations).

Essential Thrombocythemia

– A chronic myeloproliferative neoplasm characterized by sustained platelet count elevation (greater than 450,000 per microliter) due to clonal megakaryocytic proliferation, with a risk of both thrombotic and hemorrhagic complications. The JAK2 V617F mutation is present in 50-60 percent of cases, CALR mutations in 20-30 percent, and MPL mutations in 3-5 percent; approximately 10-15 percent are triple-negative. Clinical presentation ranges from asymptomatic (incidentally found on routine blood count) to thrombotic events (DVT, PE, microvascular occlusions including erythromelalgia and TIAs) and hemorrhagic complications (GI bleeding, epistaxis).

Factor V Leiden

– The most common inherited thrombophilia, caused by a point mutation in the factor V gene (G1691A, R506Q) resulting in resistance to activated protein C (APC resistance). Heterozygous: 5-fold increased VTE risk; homozygous: 50-80 fold increased risk. Most common in Caucasians (3-7% prevalence). Clinical significance: increased risk of DVT, PE, and recurrent pregnancy loss. Less clear association with arterial thrombosis. Management: anticoagulation for VTE (consider DOACs); asymptomatic individuals generally do not require prophylaxis except in high-risk situations (surgery, pregnancy, prolonged immobilization).

Folate Deficiency

– Folate (vitamin B9) deficiency causes megaloblastic anemia identical to B12 deficiency but without neurologic manifestations (except possible cognitive changes). Dietary sources: leafy greens, legumes, liver; daily requirement 400 mcg. Absorption in jejunum. Causes: inadequate intake (alcoholism, malnutrition, elderly), malabsorption (celiac, short bowel), increased demand (pregnancy, hemolysis, dialysis), drugs (methotrexate, trimetho-

prim, phenytoin, sulfasalazine). Lab: macrocytic anemia, hypersegmented neutrophils on peripheral smear, low folate levels.

Folate-deficiency anemia

– A type of megaloblastic anemia caused by insufficient folic acid, a B vitamin essential for DNA synthesis, cell division, and red blood cell production. Folate deficiency impairs thymidylate synthesis, causing defective DNA replication in rapidly dividing cells of the bone marrow, resulting in megaloblastic erythropoiesis with large, abnormally shaped erythrocyte precursors. Causes include inadequate dietary intake (most common in alcohol use disorder, older adults, fad diets, and anorexia), increased requirements (pregnancy, hemolysis, malignancy, chronic inflammatory disorders), and impaired absorption (short bowel, celiac disease, gastric bypass). Diagnosis confirmed by low serum folate and elevated homocysteine; methylmalonic acid is normal (distinguishes from B12 deficiency).

Follicular Lymphoma

– The most common indolent non-Hodgkin lymphoma, accounting for 20-25 percent of NHL cases, characterized by t(14;18) translocation leading to BCL2 overexpression and follicular growth pattern. Clinical presentation: painless lymphadenopathy, often widespread, with bone marrow involvement in 60-70 percent. Grading: 1-2 (follicular, indolent), 3A (centrocytes + centroblasts), 3B (centroblasts only, aggressive). FLIPI (Follicular Lymphoma International Prognostic Index) incorporates five adverse prognostic factors: age >60, serum LDH > normal, number of nodal sites >4, hemoglobin <12 g/dL, and Ann Arbor stage III-IV.

G6PD Deficiency

– Glucose-6-phosphate dehydrogenase (G6PD) deficiency is an X-linked enzymopathy affecting the pentose phosphate pathway, leading to impaired NADPH production and reduced glutathione regeneration, rendering erythrocytes susceptible to oxidative hemolysis. Common variants: African A- (mild), Mediterranean (severe), Mahidol (SE Asia). Triggers: fava beans, oxidant drugs (primaquine, dapsone, sulfonamides, rasburicase, methylene blue), infections. Clinical: acute hemolytic anemia (back pain, dark urine (haemoglobinuria), jaundice, anemia); self-limiting within 1-2 weeks of trigger re-

moval.

Granulocyte

– A type of white blood cell (leukocyte) containing cytoplasmic granules that are visible on light microscopy. Granulocytes are produced in the bone marrow (myelopoiesis, 3-4 days maturation) and are part of the innate immune system. Three types: (1) Neutrophils (40-70% of WBCs): bilobed nucleus, pale pink granules, primary defence against bacteria and fungi, short half-life (6-8 hours). (2) Eosinophils (1-4%): bilobed nucleus, orange-red granules, defence against parasites and involvement in allergic inflammation. (3) Basophils (<1%): bilobed nucleus, large dark purple granules, release histamine and heparin in allergic reactions. Granulocyte count (total): $2.0-7.5 \times 10^9/L$. Neutropenia (ANC <1.5) increases infection risk; agranulocytosis (ANC <0.5) is a medical emergency.

Haemangioma

– A benign vascular tumor composed of proliferating endothelial cells, the most common soft tissue tumor of infancy. Haemangiomas present shortly after birth (not usually visible at birth), undergo a proliferative phase (first 6-12 months, rapid growth), followed by involution (slow regression over 5-10 years with replacement by fibrofatty tissue). 60% occur in the head and neck region. Most are superficial (strawberry naevus), but can be deep (blue-hued) or mixed. Complications: ulceration (10-20%, most common), bleeding, infection, visual axis obstruction (periocular), airway obstruction (subglottic), Kasabach-Merritt phenomenon (platelet trapping, consumptive coagulopathy). Treatment options: observation (majority involute spontaneously), topical timolol for superficial lesions, oral propranolol (2-3 mg/kg/day, first-line for problematic lesions), laser therapy for residual telangiectasia after involution, surgical excision for complications or residual deformity.

Haemarthrosis

– Bleeding into a joint cavity. Causes: trauma (most common), hemophilia (spontaneous haemarthrosis is characteristic, especially in severe deficiency of factor VIII or IX, common in knees, elbows, ankles), anticoagulant therapy, pigmented villonodular synovitis (PVNS, recurrent haemarthrosis), joint surgery, and vascular malformations. In hemophilia,

recurrent haemarthrosis leads to synovitis, cartilage damage, joint space narrowing, and ultimately haemophilic arthropathy (chronic pain, stiffness, deformity, ankylosis). Management: factor replacement (aim for 50-100% activity), joint aspiration only if tense and painful (risk of infection), rest, ice, splinting, physiotherapy to prevent contractures.

Haematocrit

– The proportion of blood volume occupied by red blood cells (RBCs), expressed as a percentage or decimal fraction. Normal reference range: men 42-50%, women 37-47% (varies by altitude, age, and laboratory). Haematocrit is measured by centrifugation of whole blood in a microhaematocrit tube (PCV–packed cell volume) or calculated from mean corpuscular volume (MCV) and RBC count ($\text{Hct} = \text{MCV} \times \text{RBC count} / 10$). Clinical interpretation: low haematocrit (anemia–decreased RBC production, increased destruction, or blood loss), high haematocrit (polycythemia–primary: polycythemia vera; secondary: chronic hypoxia, high altitude, COPD, cyanotic heart disease, EPO-secreting tumors, smoking). The haematocrit is used to assess the severity of anemia and to guide transfusion decisions (trigger typically $<21\text{-}24\%$ or $<7\text{-}8 \text{ g/dL}$ hemoglobin depending on clinical context).

Haematologist

– A medical doctor who specializes in the diagnosis, treatment, and prevention of diseases of the blood and blood-forming organs. Conditions managed: anemia, bleeding disorders (hemophilia, von Willebrand disease), thrombophilia, hematologic malignancies (leukemia, lymphoma, myeloma, MDS, MPN), and hemoglobinopathies (sickle cell disease, thalassemia). Hematologists interpret laboratory tests (CBC, coagulation studies, bone marrow biopsy, flow cytometry, cytogenetics, molecular testing) and administer treatments including chemotherapy, targeted therapy, immunotherapy, anticoagulation, clotting factor replacement, and stem cell transplantation.

Haematoma

– A localised collection of blood outside blood vessels, usually clotted, within an organ or tissue. Haematomas form when trauma or disease causes a blood vessel to rupture. They are classified by location: subcutaneous (ecchymosis/bruise), intra-

muscular, subdural, epidural, intracerebral, subungual (under nail), perianal, rectus sheath, psoas, septal (nasal), subchorionic/retroplacental (pregnancy), and retroperitoneal. A haematoma may expand (especially in anticoagulated patients) and can cause complications: compression of adjacent structures (nerve compression, compartment syndrome), infection if it becomes secondarily infected, organisation and fibrosis, or calcification. Management depends on size and location: most small haematomas resorb spontaneously over weeks; large or expanding haematomas may require drainage (surgical or percutaneous) and reversal of any coagulopathy.

Haematuria

– The presence of blood in the urine. Classification: gross (visible to the naked eye, indicates bleeding beyond the nephron) vs microscopic (detected only on urinalysis or microscopy, >3 RBCs per high-power field). Aetiologies: (1) Glomerular: IgA nephropathy (most common cause of macroscopic haematuria), post-streptococcal GN, membranoproliferative GN, Alport syndrome, thin basement membrane nephropathy. Glomerular haematuria often presents with dysmorphic RBCs (acanthocytes) and RBC casts. (2) Non-glomerular: urinary tract infection (most common cause), urolithiasis (renal calculi), malignancy (bladder cancer, RCC, prostate cancer), benign prostatic hyperplasia (BPH), trauma, exercise-induced haematuria, anticoagulation. (3) Factitious: menstrual contamination, factitious haematuria. Evaluation: history (timing, associated symptoms, smoking history, anticoagulant use), urinalysis and culture, urine cytology, imaging (CT urogram or ultrasound), cystoscopy (for persistent or unexplained haematuria, especially in older adults).

Haem- / Haema- / Haemato- / Haemo- (Prefixes relating to blood)

– Prefixes derived from the Greek word haima (blood), used in medical terminology to denote blood-related conditions and procedures. Examples: hemoglobin (oxygen-carrying protein), hemorrhage (bleeding), hemostasis (stopping bleeding), hematology (study of blood), haematuria (blood in urine), hemoptysis (coughing blood), haemangioma (blood vessel tumor), haematocrit (percentage of

blood volume occupied by red cells), hemophilia (bleeding disorder), haemarthrosis (blood in a joint), haemodialysis (blood filtration), haemolysis (break-down of red cells), hemolytic anemia (anemia from red cell destruction), haemopoietic (blood-forming). In American English, the prefix is typically spelled hem-, hema-, hemato-, hemo-.

Haemodialysis

– A medical procedure that filters waste products, toxins, and excess fluid from the blood when the kidneys are unable to do so (end-stage renal disease, ESRD). Mechanism: blood is pumped through an extracorporeal circuit and passes through a dialyser (artificial kidney) containing thousands of hollow fibers with a semipermeable membrane. Dialysis accomplishes: diffusion (removal of small solutes—urea, creatinine, potassium, phosphate down a concentration gradient), ultrafiltration (removal of excess fluid by applying hydrostatic pressure), and convection (removal of middle molecules by solvent drag). Access: arteriovenous fistula (AVF, gold standard), arteriovenous graft (AVG), or central venous catheter (tunnelled, non-tunnelled). Typical schedule: 3-4 hours, 3 times per week. Complications: hypotension (most common, due to ultrafiltration), muscle cramps, disequilibrium syndrome, air embolism, access complications (stenosis, thrombosis, aneurysm, infection), dialyser reactions (hypersensitivity to ethylene oxide or heparin), amyloidosis (beta-2 microglobulin accumulation).

Haemophilia

– An X-linked recessive bleeding disorder caused by deficiency of coagulation factor VIII (hemophilia A, 80-85%) or factor IX (hemophilia B, Christmas disease, 15-20%). Incidence: 1 in 5,000 male births (hemophilia A), 1 in 30,000 (hemophilia B). Severity correlates with residual factor activity: severe (<1% activity, spontaneous bleeding into joints and muscles), moderate (1-5%, bleeding after minor trauma), mild (6-40%, bleeding after major trauma or surgery). Clinical features: spontaneous haemarthrosis (knees, elbows, ankles—most characteristic), intramuscular haematomas (iliopsoas, calf, forearm), easy bruising, prolonged bleeding after dental extractions or surgery, haematuria, intracranial hemorrhage (most common cause of death). Diagnosis: prolonged aPTT with normal

PT and platelet count, factor VIII and IX assays (low). Treatment: factor replacement (recombinant or plasma-derived, on-demand or prophylaxis), desmopressin (DDAVP, releases von Willebrand factor, effective in mild hemophilia A), emicizumab (bispecific monoclonal antibody, mimics factor VIII function, subcutaneous prophylaxis for hemophilia A). Complications: development of inhibitors (alloantibodies against factor VIII/IX, 20-30% of severe hemophilia A, renders standard replacement ineffective), haemophilic arthropathy (chronic joint damage), transfusion-transmitted infections (HIV, hepatitis B/C—now rare due to viral inactivation and recombinant products).

Haemoptysis

– Coughing up blood or blood-stained sputum from the lower respiratory tract. Aetiologies: bronchitis (most common, 25-50%, acute or chronic), bronchiectasis (dilated airways, chronic inflammation), lung cancer (squamous cell most commonly, 20% present with haemoptysis), tuberculosis (especially cavitary or endobronchial), pulmonary embolism (haemoptysis with pleuritic chest pain and dyspnoea), pneumonia (especially *Klebsiella*—currant jelly sputum), lung abscess, bronchiectasis, aspergilloma (fungus ball in a cavity), mitral stenosis (pulmonary venous hypertension causing rupture of bronchial varices), iatrogenic (bronchoscopy, lung biopsy, anticoagulation), and vasculitides (Wegener granulomatosis, Goodpasture syndrome). Massive haemoptysis (>200 mL/24 hours or >50 mL/hour) is life-threatening due to asphyxiation rather than exsanguination. Diagnostic workup: chest X-ray, CT chest, bronchoscopy, sputum culture and cytology, complete blood count, coagulation profile. Management: ABC, position patient with bleeding side down, bronchial artery embolisation (BAE) for massive haemoptysis, surgery (lobectomy, pneumonectomy) for refractory cases.

Hairy Cell Leukemia

– A rare, indolent B-cell chronic lymphoproliferative disorder characterized by the accumulation of mature B lymphocytes with characteristic cytoplasmic projections ("hairy cells") in the bone marrow, peripheral blood, and spleen. It accounts for less than 2 percent of adult leukemias and predominantly affects middle-aged men (male-to-female ratio ap-

proximately 4-5:1). Classic HCL is driven by the BRAF V600E mutation, present in virtually all cases. Clinical presentation includes pancytopenia, splenomegaly (often massive), recurrent infections, and fatigue.

Heinz Bodies

– Inclusions within red blood cells composed of denatured, oxidized hemoglobin. Formed under severe oxidative stress when protective reducing agents (glutathione) are depleted. Classically seen in Glucose-6-Phosphate Dehydrogenase (G6PD) deficiency following exposure to oxidative triggers (fava beans, primaquine, sulfonamides, infection). Identified using supravital stains (crystal violet or new methylene blue). Macrophages in the spleen bite out the inclusions, forming characteristic "bite cells" (degmacytes) on peripheral blood smear.

Hematocrit

– The percentage of total blood volume composed of packed red blood cells, one of the most commonly ordered laboratory tests in clinical medicine. The hematocrit is measured by centrifugation of anticoagulated whole blood in a capillary tube or automated analyzer, separating the cellular elements from plasma; the normal range is 41-53 percent in adult men and 36-46 percent in adult women, with lower values in children and during pregnancy (physiologic hemodilution). The hematocrit reflects both the packed cell volume and the plasma volume, so it is influenced by both the red blood cell mass and the plasma volume, with a low haematocrit indicating anemia and a high haematocrit suggesting polycythemia.

hematology

– The branch of medicine concerned with the study, diagnosis, treatment, and prevention of disorders of the blood and blood-forming organs (bone marrow, lymph nodes, spleen). Subspecialties: benign hematology (anemia, haemoglobinopathies–sickle cell disease, thalassemia, hemostatic disorders–hemophilia, von Willebrand disease, immune thrombocytopenia), malignant hematology (acute and chronic leukemias, myelodysplastic syndromes, myeloproliferative neoplasms, lymphoma, multiple myeloma, amyloidosis), transfusion medicine (blood banking, donor management, component therapy, apheresis, stem cell transplantation), haemato-oncology

(chemotherapy, targeted therapy, immunotherapy, CAR-T cells, HSCT). Diagnostic tools: full blood count (FBC), blood film, bone marrow aspiration and trephine biopsy, flow cytometry, cytogenetics, molecular genetics (PCR, NGS), coagulation studies, hemoglobin electrophoresis, serum protein electrophoresis.

Hemoglobin

– The oxygen-carrying metalloprotein in red blood cells, composed of four globin subunits each containing an iron-porphyrin (heme) group. Adult hemoglobin (HbA): alpha2-beta2 tetramer (two alpha chains, two beta chains). Fetal hemoglobin (HbF): alpha2-gamma2, higher oxygen affinity for oxygen transfer across the placenta. hemoglobin reversibly binds oxygen (4 O₂ molecules per tetramer) through cooperative binding (sigmoidal oxygen dissociation curve, p₅₀ = 26 mmHg). The Bohr effect: decreased pH and increased CO₂ shift the curve rightward, increasing oxygen unloading in tissues. Normal: men 13.5-17.5 g/dL, women 12.0-16.0 g/dL. Abnormal haemoglobins: sickle cell disease (HbS, Glu6Val in beta-globin), HbC, HbE, metHb, carboxyHb (CO poisoning, cherry-red appearance). HbA_{1c}: glycated hemoglobin, measures average blood glucose over 2-3 months, used for diabetes monitoring. Buffy coat: anticoagulated blood centrifuged shows three layers: plasma (top), buffy coat (middle, WBCs and platelets), packed RBCs (bottom).

Hemoglobinopathies:

Thalassemias

– Thalassemias are inherited disorders of globin chain synthesis imbalance: alpha-thalassemia (HBA1/HBA2 deletions) and beta-thalassemia (HBB mutations). Beta-thalassemia major (transfusion-dependent): severe anemia presenting in infancy, ineffective erythropoiesis, marrow expansion, extramedullary hematopoiesis, iron overload from transfusions. Management: chronic transfusions (maintain Hb >9-10 g/dL), iron chelation (deferasirox, deferoxamine, deferiprone), splenectomy if hypersplenism, luspatercept (activin receptor ligand trap for beta-thalassemia), and allogeneic HSCT as definitive therapy.

hemolysis

– The premature destruction of red blood cells, re-

leasing hemoglobin into the plasma. Extravascular hemolysis (most common): RBCs are destroyed by macrophages in the spleen and liver — causes unconjugated hyperbilirubinemia, increased LDH, and decreased haptoglobin. Intravascular hemolysis: RBCs rupture within the circulation — causes hemoglobinemia, hemoglobinuria, and decreased haptoglobin. Causes: inherited (hereditary spherocytosis, G6PD deficiency, sickle cell disease, thalassemia) and acquired (autoimmune hemolytic anemia, microangiopathic hemolytic anemia — DIC, TTP, HUS; mechanical heart valves, infection, drugs, transfusion reaction). Lab findings: reticulocytosis, elevated LDH, unconjugated bilirubin, decreased haptoglobin, and abnormal peripheral smear (spherocytes, schistocytes, sickle cells). Treatment: address underlying cause, folic acid supplementation, corticosteroids for AIHA, and splenectomy for selected cases.

Hemolytic Anemia

– Anemia due to accelerated destruction of red blood cells (RBCs), classified as intrinsic (RBC defect) or extrinsic (external factors). Intrinsic: hereditary spherocytosis, G6PD deficiency, sickle cell disease, thalassemia. Extrinsic: autoimmune hemolytic anemia (warm or cold agglutinin), microangiopathic hemolytic anemia (TMA, DIC, TTP/HUS), drug-induced, and mechanical (prosthetic valves). Laboratory: elevated LDH, indirect bilirubin, reticulocyte count; decreased haptoglobin; positive direct Coombs test in immune-mediated. Treatment depends on cause: corticosteroids for warm AIHA, splenectomy, and immunosuppressants.

Hemolytic Anemias: Autoimmune

– Autoimmune hemolytic anemia (AIHA): warm (IgG, 70-80%, extravascular hemolysis in spleen, DAT positive for IgG +/- C3, associated with CLL, SLE, drugs, idiopathic), cold agglutinin disease (IgM, complement-mediated, intravascular/extravascular, DAT positive for C3 only, associated with lymphoproliferative, Mycoplasma), mixed (both warm and cold), paroxysmal cold hemoglobinuria (Donath-Landsteiner antibody, biphasic hemolysin, post-viral in children). Drug-induced (penicillins, cephalosporins, methyl-dopa). Treatment: corticosteroids (prednisone 1 mg/kg/day) for warm AIHA; rituximab, splenec-

tomy, IVIG, and immunosuppressants for refractory cases; avoid transfusions if possible; keep patient warm for cold agglutinin disease.

Hemolytic Anemias: Hereditary

– Hereditary spherocytosis (HS): cytoskeletal protein defects (ankyrin, band 3, protein 4.2, alpha/beta spectrin) -> spherical RBCs, splenic trapping, hemolysis. AD (75%) or AR. Clinical: anemia, jaundice, splenomegaly, gallstones. Spherocytes on smear, increased MCHC, osmotic fragility test, eosin-5-maleimide (EMA) binding (flow cytometry). Treatment: folic acid, splenectomy (if moderate/severe, after age 5-6, pneumococcal/meningococcal/Hib vaccines pre-op), partial splenectomy. Hereditary elliptocytosis: milder, usually asymptomatic; hereditary pyropoikilocytosis: severe hemolysis.

hemolytic Disease of the Newborn

– A condition in which maternal antibodies destroy fetal/neonatal red blood cells (RBCs), causing hemolytic anemia, hyperbilirubinaemia, and in severe cases hydrops fetalis. Most commonly due to Rh incompatibility: an RhD-negative mother carries an RhD-positive fetus; fetomaternal hemorrhage at delivery (or during pregnancy) sensitises the mother to produce anti-D IgG antibodies; subsequent pregnancies with RhD-positive fetuses are vulnerable. ABO incompatibility (mother O, baby A or B) is more common but typically milder. Pathophysiology: maternal IgG crosses the placenta, coats fetal RBCs, and causes extravascular hemolysis in the fetal spleen. Severity ranges from mild jaundice to severe anemia, hepatosplenomegaly, hydrops (anasarca, ascites, pleural effusion, heart failure), and intrauterine death (hydropic). Diagnosis: maternal antibody screening (indirect Coombs test), paternal zygosity testing, fetal genotyping (cell-free fetal DNA), serial MCA-PSV Doppler ultrasound to detect fetal anemia. Management: intrauterine transfusion (IUT) for severe anemia, early delivery, phototherapy for neonatal jaundice, exchange transfusion for severe hyperbilirubinaemia (neurotoxicity-kernicterus). Prevention: routine antenatal anti-D prophylaxis (RAADP) at 28 weeks and postpartum anti-D IgG within 72 hours of delivery for all non-sensitised RhD-negative women. Screening and prophylaxis have reduced HDN incidence by 90%.

Hemolytic Jaundice

– Jaundice resulting from excessive hemolysis (break-down of red blood cells) causing overproduction of unconjugated bilirubin that exceeds the liver's capacity for conjugation and excretion. See Jaundice for complete overview. Causes: hereditary spherocytosis, G6PD deficiency, sickle cell disease, thalassemia, autoimmune hemolytic anemia, hemolytic transfusion reaction, malaria, and microangiopathic hemolytic anemia (MAHA). Laboratory features: elevated unconjugated (indirect) bilirubin, increased reticulocyte count, low haptoglobin, elevated LDH, raised urobilinogen in urine, and evidence of hemolysis on blood film (spherocytes, schistocytes, bite cells).

Hemolytic Uremic Syndrome

– A thrombotic microangiopathy characterized by microangiopathic hemolytic anemia, thrombocytopenia, and acute kidney injury. Typical (Shiga toxin-producing *E. coli*, STEC-HUS): O157:H7 (most common), non-O157; follows diarrheal prodrome; children; supportive care (no antibiotics, may increase toxin release); eculizumab not routinely recommended. Atypical (aHUS): complement dysregulation (mutations in CFH, CFI, MCP/CD46, C3, CFB, THBD, or autoantibodies to CFH); requires eculizumab (anti-C5 monoclonal antibody) and plasma exchange. Management of both types includes supportive care with transfusion and plasma exchange.

hemorrhoids (Piles)

– Vascular cushions in the anal canal composed of arteriovenous anastomoses (normal structures present from birth), which become symptomatic when they bleed, prolapse, or thrombose. Anatomy: internal hemorrhoids (above the dentate line, 3 primary positions—left lateral, right anterior, right posterior, covered by columnar epithelium, visceral innervation—painless), external hemorrhoids (below the dentate line, covered by squamous epithelium, somatic innervation—painful if thrombosed). Grading of internal hemorrhoids: grade 1 (confined to anal canal, no prolapse), grade 2 (prolapses on defecation but reduces spontaneously), grade 3 (prolapses and requires manual reduction), grade 4 (irreducible, permanently prolapsed). Risk factors: chronic constipation/straining, prolonged sitting,

pregnancy, obesity, low-fibre diet, cirrhosis (portal hypertension). Symptoms: painless rectal bleeding (bright red blood on toilet paper or dripping into the bowl, typically coating stools), prolapse, pruritus ani, mucoid discharge, thrombosis (acute severe pain, perianal lump). Diagnosis: clinical (inspection of external hemorrhoids, digital rectal examination, anoscopy, proctoscopy). Management: lifestyle (high-fibre diet, adequate hydration increased fibre, avoid straining), topical treatments (anaesthetics, steroids, astringents), rubber band ligation (grade 1-2), sclerotherapy, infrared coagulation, haemorrhoidectomy (Milligan-Morgan open, Ferguson closed, stapled, THD—transanal haemorrhoidal dearterialisation).

hemostasis

– The physiological process that stops bleeding at the site of vascular injury. Three phases: (1) Primary hemostasis: vasoconstriction (reflex, endothelin-mediated), platelet adhesion (to exposed subendothelial von Willebrand factor via platelet glycoprotein Ib/IX/V, to collagen via GPVI), platelet activation (shape change, granule release—ADP, thromboxane A₂, serotonin), and platelet aggregation (fibrinogen bridges between platelet GPIIb/IIIa receptors), forming a platelet plug. (2) Secondary hemostasis: coagulation cascade, culminating in cross-linked fibrin stabilising the platelet plug. (3) Fibrinolysis: tissue plasminogen activator (tPA) converts plasminogen to plasmin, which degrades fibrin into D-dimers and FDPs. The coagulation cascade is classically described as intrinsic (surface contact—factors XII, XI, IX, VIII) and extrinsic (tissue factor—factor VII) pathways converging on the common pathway (factor X, V, II, I). In vivo, the cell-based model of hemostasis more accurately describes initiation on tissue factor-bearing cells, amplification on platelets, and propagation on platelet surfaces. Disorders: hemophilia (deficiency of VIII or IX), von Willebrand disease (deficiency or dysfunction of vWF), thrombocytopenia, platelet function disorders, anticoagulation therapy.

Heparin-Induced Thrombocytopenia

– An immune-mediated adverse drug reaction caused by IgG antibodies against platelet factor 4 (PF4)-heparin complexes, leading to platelet activation,

thrombocytopenia, and a prothrombotic state. HIT typically occurs 5-14 days after heparin exposure (unfractionated heparin > low molecular weight heparin). Clinical: thrombocytopenia (fall >50% from baseline, nadir rarely <20k), thrombosis (venous: DVT/PE; arterial: limb ischemia, stroke, MI) in 20-50%, skin necrosis at injection sites (50%), and adrenal hemorrhage. Diagnosis: 4Ts score, HIT ELISA (PF4-heparin ELISA), serotonin release assay (SRA). Treatment: stop heparin, start non-heparin anticoagulant (argatroban, bivalirudin, fondaparinux, danaparoid). Avoid warfarin until platelets >150 (risk of venous limb gangrene).

Hereditary Hemorrhagic Telangiectasia (Osler-Weber-Rendu Disease)

– An autosomal dominant vascular dysplasia characterized by malformed blood vessels lacking smooth muscle layers. Mutations in ENG (endoglin) or ACVRL1 (ALK1) genes. Classic clinical triad: 1) Recurrent spontaneous epistaxis (nosebleeds), 2) Mucocutaneous telangiectasias (lips, tongue, oral mucosa, fingertips), and 3) Arteriovenous malformations (AVMs) in lungs, liver, and brain. Pulmonary AVMs act as right-to-left shunts, causing hypoxemia and risk of paradoxical embolic brain abscesses. Treatment: local hemostatics, anti-angiogenic therapy (bevacizumab), and AVM embolization.

Hereditary Spherocytosis

– The most common inherited hemolytic anemia in Northern Europeans (autosomal dominant 75%, recessive 25%). Caused by defects in RBC membrane proteins (spectrin, ankyrin, band 3, protein 4.2), leading to loss of membrane surface area, reduced deformability, and premature destruction in the spleen. Presents with hemolytic anemia, jaundice, splenomegaly, and reticulocytosis. Lab findings: spherocytes on peripheral smear, increased MCHC, negative direct Coombs test, elevated osmotic fragility. Complications: aplastic crisis (parvovirus B19), hemolytic crisis, gallstones (pigment stones), and leg ulcers. Treatment: folic acid supplementation; splenectomy for severe anemia.

Hodgkin Lymphoma

– A B-cell lymphoma characterized by the presence of Reed-Sternberg cells (large, binucleate or multinucleate cells with owl-eye nuclei) in a background of reactive inflammatory

cells. Classical HL (cHL) accounts for 95 percent of cases and is subdivided into nodular sclerosis (most common, mediastinal predominance, young adults), mixed cellularity, lymphocyte-rich, and lymphocyte-depleted subtypes. Nodular lymphocyte-predominant HL (NLPHL, 5 percent) features lymphocyte-predominant (LP) cells (CD20+, CD15-, CD30-) instead of Reed-Sternberg cells. Staging with PET-CT. Treatment: ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine) or escalated BEACOPP for advanced disease; involved-field radiation for bulky disease; brentuximab vedotin for relapsed/refractory CD30+ disease.

Hodgkin's Lymphoma

– See Hodgkin Lymphoma.

Howell-Jolly Bodies

– Basophilic nuclear remnants (clusters of DNA) normally removed from circulating red blood cells by splenic macrophages (pitting). Presence on peripheral blood smear indicates functional asplenia or anatomical splenectomy (e.g., trauma, sickle cell auto-splenectomy). Also seen in severe megaloblastic anemia. Patients require vaccination against encapsulated organisms (*Streptococcus pneumoniae*, *Neisseria meningitidis*, *Haemophilus influenzae* type b).

Immune Thrombocytopenia

– An autoimmune disorder characterized by isolated thrombocytopenia (platelet count <100 x10⁹/L) due to autoantibody-mediated platelet destruction and impaired platelet production. Primary ITP (no identifiable cause) vs secondary (SLE, CLL, HIV, HCV, drugs). Clinical: petechiae, purpura, epistaxis, menorrhagia; intracranial hemorrhage rare (<1%). Diagnosis: exclusion of other causes (CBC, blood smear, HIV/HCV, TSH, ANA, bone marrow if >60 or atypical features). First-line: corticosteroids (prednisone). Second-line: TPO receptor agonists (eltrombopag, romiplostim), rituximab, mycophenolate mofetil. Splenectomy reserved for refractory cases. Platelet transfusion for life-threatening bleeding.

Immune Thrombocytopenic Purpura (ITP)

– An autoimmune bleeding disorder characterized by isolated thrombocytopenia (platelet count <

100,000/ μ L) with normal white blood cell count and hemoglobin. Caused by autoantibodies (primarily IgG) directed against platelet surface glycoproteins (IIb/IIIa or Ib/IX), leading to splenic macrophage phagocytosis of platelets. Acute ITP: self-limited, common in children following viral infection. Chronic ITP: common in adult females (20-40 years), insidious onset. Clinical features: petechiae, purpura, epistaxis, gingival bleeding; splenomegaly is notably absent. Management: IVIG or Rho(D) immune globulin (first-line for rapid platelet rise), oral corticosteroids (prednisone), rituximab, TPO receptor agonists (eltrombopag, romiplostim), or splenectomy for refractory cases.

INR

– International normalized ratio: a standardized measure of the prothrombin time (PT), calculated as (patient PT/mean normal PT)^{ISI}, to ensure consistent monitoring of vitamin K antagonist (warfarin) therapy across laboratories. Target INR: 2-3 for most indications (AF, VTE); 2.5-3.5 for mechanical heart valves. Elevated INR: warfarin effect, vitamin K deficiency, liver disease, DIC, and drug interactions. Management of high INR: hold warfarin, vitamin K, and fresh frozen plasma/4-factor PCC for bleeding or very high INR. Routine monitoring is essential for warfarin safety.

Iron Deficiency Anemia

– The most common anemia worldwide, affecting over 1 billion people, resulting from insufficient iron for hemoglobin synthesis. Iron balance requires adequate dietary intake (heme iron from animal sources better absorbed than non-heme iron from plant sources), efficient absorption (duodenal and proximal jejunal enterocytes, regulated by hepcidin), and minimal losses (menstruation, GI bleeding, pregnancy). Causes include chronic blood loss (menorrhagia, GI bleeding from GI lesions), malabsorption, and increased requirements (pregnancy, growth). Lab: microcytic hypochromic anemia, low ferritin, low serum iron, low transferrin saturation, increased TIBC, increased RDW. Diagnosis: iron studies with ferritin <30 ng/mL. Treatment: oral iron (ferrous sulfate 325 mg daily); IV iron for intolerance, malabsorption, severe deficiency, or chronic blood loss. Response measured by reticulocyte count increase within 7-10 days and Hb rise of 1-2 g/dL over 3-4

weeks.

Leucocyte (White Blood Cell)

– See White Blood Cell / Leucocyte.

Leucopenia

– A decreased total white blood cell count below the normal reference range ($<4.0 \times 10^9$ /L). Leucopenia is often due to a decrease in neutrophils (neutropenia) or lymphocytes (lymphopenia). Causes: infection (viral–HIV, EBV, influenza, hepatitis; overwhelming bacterial sepsis–endotoxin-induced bone marrow suppression; typhoid), bone marrow failure (aplastic anemia, myelodysplasia, leukemia, myelofibrosis), chemotherapy/radiotherapy (most common cause of moderate-severe neutropenia), drugs (carbimazole, methimazole, clozapine, sulfonamides, immunosuppressants, antipsychotics, anticonvulsants), autoimmune (SLE, Felty syndrome–neutropenia with RA and splenomegaly), hypersplenism (cirrhosis, portal hypertension), nutritional deficiency (vitamin B12, folate, copper), and ethnic/benign variants (pseudoneutropenia, Afro-Caribbean and African descent, stable neutrophil count $1.0\text{--}2.5 \times 10^9$ /L with no increased infection risk). Clinical significance: increased risk of infection, especially when absolute neutrophil count (ANC) falls $<1.0 \times 10^9$ /L. Severe neutropenia (ANC <0.5) requires urgent evaluation. Management: treat underlying cause, stop offending drug, G-CSF (filgrastim) for chemotherapy-induced neutropenia, antibiotic prophylaxis for severe chronic neutropenia.

Leukemia

– A group of hematological malignancies characterized by the clonal proliferation of abnormal white blood cells (blasts) in the bone marrow and peripheral blood. leukemia is classified by: (1) clinical course: acute (rapid onset, $>20\%$ blasts in bone marrow) vs chronic (insidious onset, more differentiated cells). (2) cell lineage: lymphoblastic (T-cell or B-cell precursor) vs myeloid (granulocytic, monocytic, erythroid, megakaryocytic). The four main subtypes are: acute lymphoblastic leukemia (ALL, most common in children), acute myeloid leukemia (AML, more common in adults), chronic lymphocytic leukemia (CLL, most common adult leukemia in Western countries), and chronic myeloid leukemia (CML, characterized by Philadelphia chromosome t(9;22) BCR-ABL fusion).

Leukocytosis

– An increased total white blood cell count above the normal reference range ($>11 \times 10^9/\text{L}$ in adults). Causes: physiological (exercise, stress, pregnancy, labor), infectious (most common, especially bacterial–neutrophilia; viral–lymphocytosis; parasitic–eosinophilia), inflammatory (autoimmune disease, vasculitis, gout, pancreatitis), tissue necrosis (myocardial infarction, burns, trauma, surgery), malignancy (myeloproliferative neoplasms–CML, polycythemia vera; solid tumors with bone marrow involvement), medications (corticosteroids, lithium, G-CSF), hematologic (hemolytic anemia, hemorrhage), and post-splenectomy. Leukocytosis is further characterized by the specific cell line increased: neutrophilia (neutrophils $>7.5 \times 10^9/\text{L}$, bacterial infection, stress, steroids, CML), lymphocytosis (lymphocytes $>4.0 \times 10^9/\text{L}$, viral infection, CLL, pertussis), monocytosis (monocytes $>0.8 \times 10^9/\text{L}$, TB, endocarditis, CMML), eosinophilia (eosinophils $>0.5 \times 10^9/\text{L}$, parasitic infection, asthma, allergy, eosinophilic granulomatosis with polyangiitis, drug reaction), and basophilia (basophils $>0.1 \times 10^9/\text{L}$, CML, polycythemia vera). A normal peripheral blood smear and lack of abnormal cells distinguishes reactive leukocytosis from leukemia.

Lymphocytopenia

– A reduced lymphocyte count ($<1.0 \times 10^9/\text{L}$). Causes: acute (stress, steroids, sepsis, trauma, burns), infections (HIV, viral, tuberculosis, typhoid), immunosuppressive drugs, radiation, marrow failure (aplasia, leukemia, lymphoma), autoimmune (SLE), and congenital immunodeficiencies. Associated with impaired cell-mediated immunity and risk of opportunistic infection. Diagnosis: CBC, film, lymphocyte subsets (CD4/CD8/CD19), HIV testing, immunoglobulins. Management: treat underlying cause; prophylaxis against opportunistic infections (PCP, fungal) in severe deficiency (e.g., HIV); consider immunoglobulin replacement if humoral defect.

Lymphoma

– A malignancy of lymphocytes, divided into Hodgkin lymphoma (HL—Reed-Sternberg cells, cervical/supraclavicular nodes, B symptoms, younger adults) and non-Hodgkin lymphoma (NHL—heterogeneous, more common, aggressive

or indolent). NHL types: diffuse large B-cell (most common, aggressive), follicular (indolent), mantle cell, marginal zone, Burkitt, T-cell. Features: painless lymphadenopathy, B symptoms (fever, night sweats, weight loss), splenomegaly, cytopenias, extranodal disease. Diagnosis: lymph node biopsy (excisional), flow cytometry, staging (PET-CT, bone marrow). Management: HL—ABVD $\pm$ radiotherapy; NHL—R-CHOP for DLBCL, rituximab, observation/chemotherapy for indolent, targeted/immunotherapy (CAR-T). Prognosis varies widely.

Lymphoma (Hodgkin's and Non-Hodgkin's)

– See Hodgkin Lymphoma and Non-Hodgkin Lymphoma.

Mantle Cell Lymphoma

– An aggressive B-cell lymphoma characterized by t(11;14) translocation leading to cyclin D1 overexpression and CCND1-IGH fusion. Clinical: older males, widespread lymphadenopathy, splenomegaly, GI involvement (lymphomatous polyposis), bone marrow, peripheral blood (leukemic phase). Ki-67 index and MIPI (MCL International Prognostic Index) stratify risk. Treatment: young/fit: intensive chemoimmunotherapy (R-DHAP, R-HyperCVAD, Nordic MCL2/3) + autologous stem cell transplant. Older/unfit: less intensive regimens (R-CHOP, R-bendamustine, VR-CAP) plus rituximab maintenance. No cure; median survival 5-7 years.

Multiple Myeloma

– A plasma cell neoplasm characterized by clonal proliferation of malignant plasma cells in the bone marrow, producing monoclonal immunoglobulin (M-protein) and causing end-organ damage defined by the CRAB criteria: hypercalcemia (calcium greater than 11 mg/dL), renal insufficiency (creatinine greater than 2 mg/dL), anemia (hemoglobin less than 10 g/dL), and bone lesions (lytic lesions on imaging). The International Myeloma Working Group (IMWG) diagnostic criteria also include clonal bone marrow plasma cells $\geq 10\%$ or biopsy-proven bony or extramedullary plasmacytoma, and any one or more of the CRAB features or one or more biomarker of malignancy (clonal plasma cell proliferation $\geq 60\%$, involved:uninvolved serum free light chain ratio ≥ 100 , or >1 focal lesion on

MRI). Treatment: triplet regimens (VRd: bortezomib, lenalidomide, dexamethasone; or Dara-Rd for transplant-ineligible), followed by autologous stem cell transplant in eligible patients.

Myelodysplastic Syndrome

– MDS: a group of clonal stem cell disorders characterized by ineffective hematopoiesis, cytopenias, and risk of transformation to acute myeloid leukemia (AML). Features: anemia (most common), neutropenia, thrombocytopenia; dysplasia (abnormal morphology) in marrow and blood; cytogenetic abnormalities (del5q, trisomy 8, del7q). Subtypes by WHO classification (e.g., MDS with single lineage dysplasia, excess blasts). Diagnosis: CBC, blood film, bone marrow aspirate/biopsy with cytogenetics and molecular studies. Management: supportive (transfusions, growth factors), lenalidomide (del5q), hypomethylating agents (azacitidine, decitabine), and allogeneic stem cell transplant for eligible patients (only curative).

Myelodysplastic Syndromes

– A heterogeneous group of clonal hematopoietic stem cell disorders characterized by ineffective hematopoiesis, dysplastic morphology in one or more myeloid lineages, cytopenias, and risk of transformation to acute myeloid leukemia. MDS predominantly affects older adults (median age 70-75 years) and may be primary (de novo) or secondary (therapy-related from prior chemotherapy or radiation). Clinical presentation includes fatigue (anemia), infections (neutropenia), and bleeding (thrombocytopenia). IPSS-R (Revised International Prognostic Scoring System) stratifies risk based on cytopenias, blast percentage, and cytogenetics. Management: supportive care (transfusions, growth factors), lenalidomide for del(5q), luspatercept for ring sideroblasts, hypomethylating agents (azacitidine, decitabine), and allogeneic HSCT for high-risk disease.

Myelofibrosis

– A myeloproliferative neoplasm characterized by bone marrow fibrosis, extramedullary hematopoiesis, and JAK2, CALR, or MPL mutations. Presents with anemia, massive splenomegaly, constitutional symptoms (fever, night sweats, weight loss), and leukoerythroblastic blood smear. Diagnosis: bone marrow biopsy (fibrosis, megakaryocytic hyper-

plasia), JAK2 V617F mutation (50-60%), CALR (20-25%). Prognosis: dynamic IPSS. Treatment: JAK1/2 inhibitors (ruxolitinib, fedratinib), splenectomy for symptomatic splenomegaly, and allogeneic stem cell transplant as only curative option.

Neutropenia

– A reduced neutrophil count ($<1.5 \times 10^9/L$; severe <0.5), increasing risk of bacterial and fungal infection, especially febrile neutropenia. Causes: marrow suppression (chemotherapy, radiation), marrow infiltration (leukemia, aplasia), drugs (clozapine, methimazole, sulfonamides), autoimmune, infection (sepsis, viral), B12/folate deficiency, and congenital (Kostmann, cyclic). Features: often asymptomatic; fever in neutropenia is an emergency (neutropenic sepsis). Diagnosis: CBC, film, drug history; marrow exam if unexplained. Management: treat cause, stop culprit drug, G-CSF (filgrastim), infection precautions; febrile neutropenia: empiric broad-spectrum antibiotics, blood cultures.

Non-Hodgkin Lymphoma

– Hematologic malignancy of B or T/NK cells. B-cell NHL (85%) includes diffuse large B-cell lymphoma (DLBCL, most common aggressive), follicular lymphoma (most common indolent), mantle cell lymphoma, marginal zone lymphoma, and Burkitt lymphoma. T-cell NHL: peripheral T-cell lymphoma, anaplastic large cell lymphoma. Presents with painless lymphadenopathy, B symptoms (fever, night sweats, weight loss), and cytopenias. Diagnosis: excisional biopsy with flow cytometry, cytogenetics, FISH. Treatment: R-CHOP for DLBCL, rituximab-based therapy for follicular, and stem cell transplant for relapsed/refractory disease.

Pancytopenia

– Simultaneous reduction of red cells, white cells, and platelets, indicating bone marrow failure or infiltration. Causes: aplastic anemia (immune, drug/toxin, viral—parvovirus, hepatitis), marrow infiltration (leukemia, myeloma, lymphoma, metastases, myelofibrosis), B12/folate deficiency, megakaryoblastic states, chemotherapy/radiation, myelodysplastic syndrome, overwhelming sepsis, and hypersplenism. Features: anemia (fatigue, pallor), neutropenia (infections), thrombocytopenia (bleeding). Diagnosis: CBC with low all lines, reticulocytes, blood film, B12/folate, and bone marrow

aspirate/biopsy. Management: treat cause, supportive transfusions, growth factors, stem cell transplant for aplastic anemia; infection/bleeding prophylaxis.

Paroxysmal Nocturnal Hemoglobinuria

– A rare, acquired clonal disorder of hematopoietic stem cells characterized by complement-mediated intravascular hemolysis, thrombosis (particularly in unusual sites such as hepatic, portal, and cerebral veins), and bone marrow failure. The underlying defect is a somatic mutation in the PIGA gene, which encodes a subunit of the GPI-anchor synthesis enzyme complex, resulting in deficient expression of GPI-anchored proteins (CD55 and CD59) on the surface of blood cells. Diagnosis: flow cytometry showing deficient CD55/CD59 on red blood cells. Treatment: eculizumab or ravulizumab (anti-C5 monoclonal antibodies) for hemolysis and thrombosis; anticoagulation for thrombotic events; supportive care with folic acid, transfusion, and iron chelation for transfusion burden.

Partial Thromboplastin Time

– aPTT/PTT: a coagulation test measuring the intrinsic and common pathways (factors XII, XI, IX, VIII, X, V, II, fibrinogen), used to monitor unfractionated heparin and detect factor deficiencies. Prolonged aPTT: hemophilia A/B (VIII/IX), heparin, lupus anticoagulant, factor deficiency, DIC, von Willebrand disease (rare), vitamin K deficiency (less than PT). Mixing studies distinguish factor deficiency from inhibitor. Used with PT to localize coagulation defects (isolated aPTT prolongation = intrinsic pathway). Correction studies and specific factor assays aid diagnosis.

Pentad of TTP

– Classic clinical pentad of Thrombotic Thrombocytopenic Purpura: (1) Thrombocytopenia, (2) Microangiopathic Hemolytic Anemia (schistocytes), (3) Neurological symptoms, (4) Renal insufficiency, and (5) Fever. *See Thrombotic Thrombocytopenic Purpura (TTP).*

Pernicious Anemia

– A type of vitamin B12 deficiency anemia caused by autoimmune destruction of gastric parietal cells, leading to lack of intrinsic factor and impaired B12 absorption in the terminal ileum. More common in older adults, those with autoimmune disorders,

and pernicious anemia is associated with atrophic gastritis and increased gastric cancer risk. Presents with megaloblastic anemia (macrocytic RBCs, hypersegmented neutrophils), neuropathy (paresthesias, ataxia, cognitive impairment), and glossitis. Diagnosis: low B12, elevated methylmalonic acid and homocysteine, positive anti-intrinsic factor antibodies. Treatment: lifelong parenteral B12 (cyanocobalamin) replacement.

Platelet Count

– The number of platelets per unit volume of blood (normal 150,000–400,000/ μ L), part of the CBC. Reduced (thrombocytopenia): bleeding risk (severe $<20,000$, spontaneous $<10,000$)—ITP, TTP, HIT, DIC, marrow failure, drugs, sepsis. Elevated (thrombocytosis): reactive or myeloproliferative. Pseudothrombocytopenia (EDTA-induced clumping) is a false low on the analyzer. Platelet count guides transfusion thresholds, anticoagulation decisions, and chemotherapy monitoring. Verify abnormal values on the blood film; consider platelet function testing when count is normal but bleeding occurs.

Platelet Function Disorders

– Inherited: Glanzmann thrombasthenia (GPIIb/IIIa deficiency, absent platelet aggregation, mucocutaneous bleeding, recombinant FVIIa, platelet transfusions), Bernard-Soulier syndrome (GPIb/IX/V deficiency, giant platelets, thrombocytopenia, prolonged bleeding time, platelet transfusions), Storage pool deficiency (delta/dense granules, mild bleeding). Acquired: uremia (platelet dysfunction, desmopressin, dialysis), myeloproliferative neoplasms (acquired von Willebrand syndrome in ET/PV, aspirin), myelodysplasia. Diagnosis: bleeding time, PFA-100, platelet aggregation studies, flow cytometry for glycoprotein expression. Treatment: desmopressin for uraemia and mild type 1 VWD; platelet transfusions for Glanzmann and Bernard-Soulier; recombinant FVIIa for Glanzmann with anti-GPIIb/IIIa antibodies.

Platelets (Thrombocytes)

– Small, anucleate, disc-shaped cell fragments (2–4 μ m diameter) derived from megakaryocytes in the bone marrow, circulating at $150\text{--}400 \times 10^9/\text{L}$. Platelets are essential for primary hemostasis: they adhere to exposed subendothelial collagen via von Willebrand factor (GPIb receptor), become acti-

vated (shape change, degranulation—release ADP, serotonin, thromboxane A_2), and aggregate via fibrinogen bridges (GPIIb/IIIa receptor) to form a platelet plug. They also provide a phospholipid surface for coagulation factor assembly (tenase and prothrombinase complexes). Platelet lifespan: 7–10 days; old platelets are removed by the spleen. Thrombocytopenia ($<150 \times 10^9/L$) increases bleeding risk; thrombocytosis ($>450 \times 10^9/L$) is reactive (infection, inflammation, iron deficiency) or clonal (essential thrombocythaemia). Platelet function disorders: Glanzmann thrombasthenia (GPIIb/IIIa deficiency), Bernard–Soulier syndrome (GPIb deficiency), storage pool disease. Drugs affecting platelets: aspirin (irreversible COX-1 inhibition), clopidogrel (P2Y₁₂ receptor antagonist), NSAIDs, and GPIIb/IIIa inhibitors.

Polycythemia

– Elevated red blood cell mass/hematocrit. Primary: polycythemia vera (JAK2 V617F mutation, trilineage proliferation, low EPO, risk of thrombosis and myelofibrosis/leukemia). Secondary: hypoxia (COPD, high altitude, congenital heart disease, sleep apnea) with high EPO, or EPO-secreting tumors (renal cell, hepatoma). Relative (Gaisbock): dehydration/plasma loss with normal RBC mass. Features: ruddy complexion, pruritus (especially post-bath), headache, thrombosis, splenomegaly. Diagnosis: Hb/Hct, JAK2, EPO level, ABG, imaging. Management: phlebotomy (target Hct <45 percent), aspirin, cytoreduction (hydroxyurea) for high-risk PV; treat cause in secondary.

Polycythemia Vera

– A chronic myeloproliferative neoplasm characterized by increased red blood cell mass, often with increased white blood cell and platelet counts, driven by constitutive activation of the JAK-STAT signaling pathway. The JAK2 V617F mutation is present in approximately 95 percent of PV patients, with an additional 3 percent harboring JAK2 exon 12 mutations. Clinical presentation includes elevated hemoglobin and hematocrit (per WHO criteria: male hemoglobin greater than 16.5 g/dL or haematocrit greater than 49% in men, greater than 16.0 g/dL or haematocrit greater than 48% in women), thrombocytosis, leukocytosis, and splenomegaly in 70% of patients. Treatment: phlebotomy (target

Hct $<45\%$), low-dose aspirin for all patients, cytoreduction (hydroxyurea, interferon-alpha, ruxolitinib) for high-risk patients (age >60 , prior thrombosis). Risk of thrombosis, hemorrhage, and transformation to myelofibrosis or AML.

Primary Myelofibrosis

– A chronic myeloproliferative neoplasm characterized by bone marrow fibrosis (reticulin and/or collagen fibrosis), extramedullary hematopoiesis (primarily splenic and hepatic), and a leukoerythroblastic peripheral blood picture. It results from clonal proliferation of hematopoietic stem cells carrying JAK2 V617F (50-60 percent), CALR (25-30 percent), or MPL (3-5 percent) mutations, leading to cytokine release that stimulates fibroblast proliferation and collagen deposition of extracellular matrix proteins. Clinical presentation includes progressive anemia, massive splenomegaly with early satiety and abdominal discomfort, constitutional symptoms (fever, night sweats, weight loss, fatigue), and extramedullary hematopoiesis. Peripheral blood shows leukoerythroblastosis with teardrop cells. Treatment: ruxolitinib (JAK1/2 inhibitor) for symptomatic splenomegaly and constitutional symptoms; allogeneic HSCT is the only potentially curative option; supportive care with transfusions, erythropoietin, and targeted therapy for iron overload.

Protein C Deficiency

– An inherited (autosomal dominant) thrombophilia causing increased VTE risk. Protein C is a vitamin K-dependent natural anticoagulant that inactivates factors Va and VIIIa and stimulates fibrinolysis. Heterozygous: 6-10 fold increased VTE risk. Homozygous: severe neonatal purpura fulminans (widespread skin necrosis and thrombosis) requiring protein C replacement. Diagnosis: functional and antigenic protein C levels (low). Caution: levels also low in warfarin therapy, liver disease, DIC, and vitamin K deficiency. Management: anticoagulation for VTE; warfarin initiation requires heparin bridging to avoid warfarin-induced skin necrosis.

Protein S Deficiency

– An inherited (autosomal dominant) thrombophilia. Protein S is a vitamin K-dependent natural anticoagulant that acts as a cofactor for activated protein C in inactivating factors Va and VIIIa. Heterozy-

gous: 2-10 fold increased VTE risk. Homozygous: rare, purpura fulminans. Total, free, and functional protein S levels must be interpreted carefully as levels are affected by pregnancy, oral contraceptives, liver disease, DIC, and acute thrombosis. Diagnosis: confirmed low free protein S on repeat testing. Management: anticoagulation for VTE; lifelong anticoagulation for recurrent or severe thrombosis.

Prothrombin Time

– PT: a coagulation test measuring the extrinsic and common pathways (factors VII, X, V, II, fibrinogen), used to monitor warfarin therapy (reported as INR) and assess bleeding risk. Prolonged PT: warfarin/Vitamin K deficiency, liver disease, DIC, factor deficiencies (VII), and anticoagulant use. INR standardizes PT across laboratories for warfarin monitoring (target 2-3 for most indications). Testing requires citrate anticoagulated plasma and tissue factor reagent. Part of the coagulation profile with aPTT; isolated PT prolongation suggests extrinsic pathway defect or warfarin/liver disease.

Rhesus (Rh) Factor

– A system of blood group antigens (the Rh system) on the surface of red blood cells, the most important of which is the D antigen (RhD). Individuals are Rh-positive (RhD+) if the D antigen is present (85% of Caucasians, 92% of Africans, 99% of Asians) or Rh-negative (RhD-) if absent. The Rh factor is determined by the RHD gene on chromosome 1. Rh incompatibility occurs when an Rh-negative mother carries an Rh-positive fetus: fetal red cells entering the maternal circulation (fetomaternal hemorrhage—typically at delivery, but also during pregnancy, trauma, or abortion) stimulate maternal anti-D antibody production (IgG). In a subsequent Rh-positive pregnancy, maternal anti-D IgG crosses the placenta and causes hemolytic disease of the fetus and newborn (HDFN—erythroblastosis fetalis), leading to fetal anemia, hydrops fetalis, kernicterus, and neonatal jaundice. Prevention: prophylactic anti-D immunoglobulin (RhoGAM) is given to Rh-negative women at 28 weeks gestation and within 72 hours of delivery (or any sensitizing event—amniocentesis, miscarriage, abortion, ectopic pregnancy), which coats fetal Rh-positive red cells and prevents maternal immune sensitisation. Other Rh antigens: C, c, E, e (Kell, Duffy, Kidd,

and MNS are other clinically important blood group systems).

Rh Factor

– See Rhesus (Rh) Factor.

Schistocytes

– Fragmented, helmet-shaped, or triangular red blood cells produced by mechanical shearing as erythrocytes pass through obstructed or fibrin-laden microvessels. Diagnostic hallmark of Microangiopathic Hemolytic Anemia (MAHA), including Thrombotic Thrombocytopenic Purpura (TTP), Hemolytic Uremic Syndrome (HUS), and Disseminated Intravascular Coagulation (DIC). Also seen with mechanical prosthetic heart valves.

Sickle Cell Trait

– Heterozygous carrier state for the HbS mutation (HbAS), present in 8% of African Americans. Red cells contain both HbA and HbS (typically 30-40% HbS). Usually asymptomatic with normal hemoglobin and RBC indices. Complications (rare but recognized): painless hematuria (renal papillary necrosis), urinary concentrating defect, splenic infarction at high altitude, exercise-related sudden death (during extreme exertion), and hyposthenuria. Diagnosis: hemoglobin electrophoresis showing HbA and HbS. Genetic counseling. No treatment needed; avoid extreme dehydration and high-altitude exposure.

Spherocytes

– Small, dark, sphere-shaped red blood cells lacking central pallor. Formed when RBC membrane is lost without loss of volume, reducing the surface area-to-volume ratio. Causes: Hereditary Spherocytosis (ANK1/SPTA1 mutation, defect in spectrin/ankyrin) and Autoimmune Hemolytic Anemia (AIHA, warm IgG antibodies lead to splenic macrophage membrane biting). Diagnosed with Osmotic Fragility Test or EMA binding test.

Splenomegaly

– Enlargement of the spleen beyond its normal size (12 cm, weight 150–200 g). Splenomegaly can be detected by percussion (Castell sign—dullness in the lowest intercostal space on inspiration) and palpation (normal spleen is not palpable; a palpable spleen indicates at least 2–3 times enlargement). Causes: congestive (portal hypertension—cirrhosis, hepatic vein throm-

bosis/Budd–Chiari syndrome, splenic vein thrombosis, heart failure), infectious (EBV, CMV, malaria, leishmaniasis, schistosomiasis, tuberculosis, endocarditis, brucellosis, HIV), hematological (hemolytic anemias—hereditary spherocytosis, thalassemia, sickle cell disease; myeloproliferative neoplasms—myelofibrosis, polycythemia vera, CML; leukemia—CLL, ALL, AML; lymphoma—Hodgkin, non-Hodgkin), inflammatory/autoimmune (sarcoidosis, SLE, rheumatoid arthritis—Felty syndrome, Still disease), infiltrative (Gaucher disease, Niemann–Pick, amyloidosis, glycogen storage diseases), and neoplastic (primary splenic tumors—rare). Massive splenomegaly (spleen >20 cm, >1000 g): most commonly myelofibrosis, CML, malaria, kala-azar, Gaucher disease, and schistosomiasis. Complications: hypersplenism (pancytopenia from increased sequestration/destruction of blood cells), splenic infarction (pain, left upper quadrant), and splenic rupture (trauma). Diagnosis: ultrasound, CT, MRI; further workup directed at underlying cause. Treatment: directed at the underlying cause; splenectomy for symptomatic massive splenomegaly, hypersplenism with severe cytopenias, splenic abscess, or splenic rupture.

Stem Cell Transplantation

– Hematopoietic stem cell transplantation (HSCT) replaces diseased or ablated bone marrow with healthy donor or autologous stem cells. Autologous HSCT: patient's own stem cells collected after mobilization (G-CSF with or without plerixafor), providing hematopoietic rescue after high-dose chemotherapy without graft-versus-host disease risk; indications include relapsed lymphoma and multiple myeloma. Allogeneic HSCT: donor stem cells (HLA-matched sibling, haploidentical family member, or matched unrelated donor). Conditioning: myeloablative (high-dose chemo + TBI) or reduced-intensity (older, comorbidities). GVHD prophylaxis: calcineurin inhibitor plus methotrexate or mycophenolate. Complications: GVHD (acute: skin, liver, GI; chronic: skin, mouth, eyes, liver, lungs), infection (CMV, EBV, fungal), VOD/SOS (veno-occlusive disease), graft failure, and relapse.

T-Cell Lymphomas

– Peripheral T-cell lymphomas (PTCL) are a heterogeneous group of aggressive lymphomas includ-

ing PTCL-NOS (not otherwise specified, most common), angioimmunoblastic T-cell lymphoma (AITL, T-follicular helper origin, RHOA mutations, dysimmune features), anaplastic large cell lymphoma (ALCL, ALK+ vs ALK-), enteropathy-associated T-cell lymphoma (EATL, celiac association), hepatosplenic T-cell lymphoma (gamma-delta, isochromosome 7q), and cutaneous T-cell lymphomas (mycosis fungoides, Sezary syndrome (erythroderma, generalised lymphadenopathy, circulating Sezary cells). Diagnosis: excisional lymph node biopsy with histology, IHC, flow cytometry, cytogenetics, and FISH. Treatment: CHOP-like chemotherapy for aggressive subtypes; novel agents (brentuximab vedotin for ALCL; romidepsin/belinostat for relapsed PTCL); allogeneic HSCT for eligible patients.

thalassemia

– A group of inherited hemoglobin disorders caused by reduced or absent synthesis of one or more globin chains, leading to microcytic hypochromic anemia. Types: α -thalassemia (deletion of α -globin genes on chromosome 16; severity depends on number of deleted genes: 1 deletion—silent carrier, 2— α -thalassemia trait/minor, 3—hemoglobin H disease (HbH—moderate hemolytic anemia), 4—Hb Bart hydrops fetalis (lethal in utero)), β -thalassemia (point mutations in β -globin gene on chromosome 11; β -thalassemia minor/trait—mild anemia, β -thalassemia intermedia—moderate anemia requiring intermittent transfusions, β -thalassemia major (Cooley anemia)—severe anemia presenting at 6–24 months, requiring lifelong transfusions, leads to iron overload, growth retardation, hepatosplenomegaly, and skeletal changes (bossing, chipmunk facies, osteopenia)). Epidemiology: high prevalence in the Mediterranean, Middle East, South Asia, and Southeast Asia (malaria protection). Diagnosis: full blood count (microcytosis, hypochromia), hemoglobin electrophoresis (HbA₂ elevated in β -thalassemia trait, HbF elevated in β -thalassemia major, HbH in α -thalassemia intermedia), and genetic testing. Management: mild forms require no treatment, or folate supplementation. Transfusion-dependent patients: regular packed red cell transfusions (maintain Hb 9–10 g/dL), iron chelation therapy (deferasirox, desferrioxamine, or deferiprone) to prevent iron overload—the main cause of morbidity

(cardiac, hepatic, endocrine). Allogeneic hematopoietic stem cell transplantation is the only curative option (best outcomes in children <16 years without significant iron overload). Luspatercept (erythroid maturation agent) reduces transfusion burden in β -thalassemia. Gene therapy (betibeglogene autotemcel—Zynteglo) is approved for transfusion-dependent β -thalassemia.

Thrombectomy

– A surgical or interventional radiology procedure to remove a blood clot (thrombus) from a blood vessel, restoring blood flow. Types: (1) Endovascular thrombectomy (mechanical thrombectomy)—for acute ischemic stroke due to large vessel occlusion (LVO—internal carotid artery, middle cerebral artery M1 segment). Performed via femoral artery access, a stent retriever or aspiration catheter is deployed to remove the clot. Window: up to 6–24 hours from symptom onset (selected by perfusion imaging). Number needed to treat (NNT) of 3 for functional independence. (2) Surgical thrombectomy—open arteriotomy and clot removal, rarely used now (reserved for failed endovascular therapy, massive PE with hemodynamic instability, or peripheral arterial occlusion). (3) Venous thrombectomy—for extensive iliofemoral DVT (phlegmasia cerulea dolens) or superior vena cava syndrome. (4) Vacuum-assisted thrombectomy (AngioJet, Penumbra)—for peripheral arterial or venous thrombosis. Complications: vessel perforation, dissection, distal embolisation, hemorrhage (especially intracranial hemorrhage post-thrombectomy for stroke).

Thrombocytes

– See Platelets (Thrombocytes).

Thrombocytopenia

– A reduced platelet count (<150,000/ μ L), causing bleeding risk when severe (<10–20,000). Causes: decreased production (marrow failure, aplasia, leukemia, chemotherapy, B12/folate, alcohol, viral—HIV, HCV), increased destruction (immune—ITP, drug-induced, heparin-induced thrombocytopenia HIT, DIC, TTP), sequestration (splenomegaly), and dilution (massive transfusion). Features: petechiae, purpura, mucosal bleeding, ecchymoses; intracranial hemorrhage when severe. Diagnosis: CBC, blood film (pseudothrombocytopenia—clumping), marrow examination, specific tests

(HIT antibodies, ADAMTS13 for TTP). Management: treat cause; ITP—steroids, IVIG, thrombopoietin receptor agonists, splenectomy; platelet transfusion for severe bleeding/thrombocytopenia (avoid in TTP/HIT).

Thrombocytosis

– An elevated platelet count (>450,000/ μ L). Reactive (secondary): infection, inflammation, iron deficiency, malignancy, post-splenectomy, hemorrhage, exercise—usually mild, no thrombotic risk. Essential thrombocythemia (ET): a myeloproliferative neoplasm (JAK2, CALR, MPL mutations) causing marked thrombocytosis with thrombosis (arterial/venous) and bleeding risk; splenomegaly. Features often asymptomatic. Diagnosis: CBC, blood film, iron studies (exclude deficiency), JAK2/CALR, bone marrow in suspected ET. Management: reactive—treat cause; ET—aspirin, cytoreduction (hydroxyurea, anagrelide) for high-risk (age, thrombosis, extreme thrombocytosis), and cardiovascular risk control.

Thrombophilia

– A tendency to develop venous thromboembolism (VTE) due to inherited or acquired hypercoagulable states. Inherited: factor V Leiden, prothrombin G20210A mutation, antithrombin deficiency, protein C deficiency, protein S deficiency. Acquired: antiphospholipid syndrome (lupus anticoagulant, anticardiolipin antibodies, beta-2 glycoprotein I antibodies), cancer, pregnancy, oral contraceptives, and obesity. Presents with DVT and PE, often recurrent or at unusual sites. Management: anticoagulation (DOACs, warfarin, heparin), with duration depending on provoking factors and risk of recurrence.

Thrombophilia Testing

– Thrombophilia testing evaluates for inherited and acquired hypercoagulable states in patients with venous thromboembolism, recurrent pregnancy loss, or strong family history of VTE. Inherited thrombophilias include Factor V Leiden (most common, 5 percent of Caucasians, activated protein C resistance, detected by clot-based or genetic assay), prothrombin G20210A mutation (2 percent of Caucasians, elevated prothrombin levels), antithrombin deficiency (1 percent, most thrombogenic, measured by activity (functional assay), protein C deficiency (activity assay), protein S deficiency (free protein

S antigen, activity). Acquired thrombophilias: antiphospholipid syndrome (lupus anticoagulant, anticardiolipin, anti-beta-2 glycoprotein I), malignancy-associated thrombosis. Testing should be performed at least 3 months after a thrombotic event and after discontinuation of anticoagulation to avoid false-positive or false-negative results.

Thrombotic Thrombocytopenic Purpura

– A life-threatening thrombotic microangiopathy caused by severe deficiency of ADAMTS13 (a disintegrin and metalloproteinase with thrombospondin type 1 motif member 13), a von Willebrand factor-cleaving protease. ADAMTS13 deficiency (activity less than 10 percent) leads to accumulation of ultra-large von Willebrand factor multimers that cause spontaneous platelet adhesion and aggregation in the microcirculation, forming platelet-rich thrombi that consume platelets and coagulation factors, causing thrombocytopenia and microangiopathic hemolytic anemia (schistocytes on peripheral smear). Clinical: fever, thrombocytopenia, microangiopathic hemolytic anemia, renal impairment, neurologic symptoms (headache, confusion, seizure, stroke), and fever. Diagnosis: ADAMTS13 activity <10% and detectable anti-ADAMTS13 antibodies. Treatment: daily plasma exchange (PLEX) until platelet count normalizes and hemolysis resolves; corticosteroids for immune suppression; rituximab for refractory/relapsed TTP; caplacizumab (anti-vWF nanobody) for acute TTP.

Thrombotic Thrombocytopenic Purpura (TTP)

– A life-threatening microangiopathic hemolytic anemia caused by severe deficiency (< 10% activity) of ADAMTS13, a plasma metalloprotease that cleaves ultra-large von Willebrand factor (vWF) multimers. Acquired (autoantibody against ADAMTS13) or congenital (Upshaw-Schulman syndrome). Uncleaved vWF multimers cause widespread microvascular platelet thrombosis. Classic clinical pentad (FAT RN): Fever, Anemia (MAHA with schistocytes), Thrombocytopenia, Renal impairment, Neurological symptoms (confusion, seizures, stroke). Lab findings: severe thrombocytopenia, elevated LDH, indirect hyperbilirubinemia, schistocytes, normal PT/aPTT (distinguishes

TTP from DIC). Medical emergency: immediate therapeutic plasma exchange (plasmapheresis) and caplacizumab; platelets are strictly contraindicated.

Total Iron Binding Capacity

– TIBC: a measure of the maximum iron-binding capacity of transferrin in serum, reflecting total iron-transport capacity. Calculated from transferrin or measured directly. High TIBC: iron deficiency (with low serum iron, low ferritin, low saturation); low TIBC: iron overload (hemochromatosis, repeated transfusion), chronic inflammation, liver disease, and malnutrition. Transferrin saturation (iron/TIBC) <15 percent indicates iron deficiency; >50 percent iron overload. Part of the iron panel for evaluating anemia and iron status.

Transferrin

– An iron transport protein synthesized by the liver, carrying iron in plasma (2 iron-binding sites). In iron deficiency: transferrin is elevated with low ferritin, giving high TIBC and low transferrin saturation; in iron overload/inflammation/chronic disease: transferrin is low (acute phase). Transferrin saturation (serum iron/TIBC x 100) assesses iron status: <15 percent indicates deficiency, >45-50 percent overload (hemochromatosis). Measured in anemia evaluation with ferritin and iron. Transferrin is affected by liver disease, protein malnutrition, and estrogen/pregnancy.

Transfusion Medicine

– Blood components: PRBCs (leukoreduced, irradiated for at-risk), FFP (coagulation factors), platelets (apheresis pooled, leukoreduced), cryoprecipitate (fibrinogen, vWF, factor VIII, XIII). ABO/Rh compatibility. Transfusion thresholds: restrictive (Hb 7-8 g/dL) for most stable patients (TRICC, FOCUS, TRISS trials); liberal (Hb 9-10) for acute coronary syndrome, severe TBI, acute bleeding. Massive transfusion protocol (MTP): 1:1:1 (PRBC:FFP:platelets) or 1:1:2; TXA within 3h (CRASH-2). Adverse reactions: acute hemolytic (ABO incompatibility, fever, hypotension, DIC, renal failure), febrile non-hemolytic (most common, cytokines in stored blood), allergic (urticaria, anaphylaxis in IgA deficiency), transfusion-related acute lung injury (TRALI, bilateral pulmonary infiltrates, hypoxia), transfusion-associated circulatory overload (TACO, pulmonary edema from volume

overload), and transfusion-transmitted infections (HIV, HBV, HCV, West Nile virus, bacterial contamination).

Trouseau Sign of Malignancy

- Episodes of recurrent, migratory superficial thrombophlebitis in atypical locations, associated with occult mucin-secreting adenocarcinomas (pancreatic, gastric, lung cancer). *See Deep Vein Thrombosis (DVT).*

Vitamin B12 Deficiency

- Vitamin B12 (cobalamin) deficiency causes megaloblastic anemia and neurologic dysfunction through impaired DNA synthesis and abnormal fatty acid metabolism in myelin. Dietary sources include animal products (meat, fish, dairy), with daily requirement of 2-3 mcg. Absorption requires adequate gastric acid and pepsin to release B12 from food proteins, binding to intrinsic factor (IF) produced by gastric parietal cells, and absorption in the terminal ileum via the cubilin-amnionless receptor complex. Causes: pernicious anemia (autoimmune destruction of parietal cells, most common in adults), dietary deficiency (vegans, malnutrition, alcoholism), malabsorption (gastric bypass, Crohn disease, celiac disease, pancreatic insufficiency), terminal ileal disease or resection, and drugs (metformin, PPI). Lab: macrocytic anemia (MCV >100), hypersegmented neutrophils, low B12, elevated methylmalonic acid and homocysteine. Treatment: intramuscular cyanocobalamin 1000 mcg daily for one week, then weekly for one month, then monthly for life; high-dose oral B12 (1000-2000 mcg/day) may be adequate for dietary deficiency.

von Willebrand Disease

- The most common inherited bleeding disorder, caused by quantitative or qualitative deficiency of von Willebrand factor (VWF), a multimeric glycoprotein that mediates platelet adhesion to subendothelium and carries factor VIII. Type 1 (partial quantitative deficiency, 70-80%): mild mucocutaneous bleeding, easy bruising, menorrhagia. Type 2 (qualitative defects): 2A (loss of high-molecular-weight multimers, decreased platelet adhesion), 2B (increased affinity for platelet GPIb (thrombocytopenia), 2M (normal multimers, decreased platelet adhesion), 2N (decreased factor VIII binding, mimics hemophilia A). Type 3 (severe quantitative de-

ciency). Treatment: desmopressin (DDAVP) for mild type 1; von Willebrand factor-containing concentrates (Humate-P) for more severe bleeding or surgical prophylaxis; tranexamic acid for mucocutaneous bleeding; avoid aspirin and NSAIDs.

Waldenstrom Macroglobulinemia

- A rare B-cell lymphoplasmacytic lymphoma characterized by bone marrow infiltration by lymphoplasmacytic cells and production of monoclonal IgM paraprotein. It accounts for less than 2 percent of hematologic malignancies and typically affects older adults (median age 63-65 years). Clinical manifestations result from both marrow infiltration (anemia, cytopenias) and IgM-related effects: hyperviscosity syndrome (visual disturbances, neurologic symptoms, bleeding, and cryoglobulinemia). Diagnosis: serum protein electrophoresis (M-spike), immunofixation (IgM), bone marrow biopsy (lymphoplasmacytic infiltrate >10%). Treatment: symptomatic or progressive disease: rituximab alone or in combination with bendamustine, cyclophosphamide/dexamethasone, or bortezomib; plasmapheresis for hyperviscosity syndrome; ibrutinib for MYD88-mutated disease; venetoclax for relapsed/refractory.

Warfarin Management

- Warfarin (vitamin K antagonist) inhibits gamma-carboxylation of factors II, VII, IX, X, proteins C and S. Target INR: 2-3 (most indications), 2.5-3.5 (mechanical mitral valve, recurrent VTE on therapeutic INR). Initiation: 5 mg daily x2-3 days, then adjust per INR; genotype-guided (CYP2C9, VKORC1) algorithms. Interactions: numerous (antibiotics, amiodarone, antifungals, NSAIDs, herbal). Monitoring: INR frequency per stability. Bridging: therapeutic LMWH when INR subtherapeutic for high thrombotic risk. Management: VTE treatment with DOACs or LMWH bridging to warfarin. Long-term anticoagulation based on recurrence risk and bleeding risk. Regular INR monitoring, dietary consistency (vitamin K intake), and medication review to avoid interactions.

White Blood Cell Count

- WBC count: the total number of leukocytes per unit volume (normal $4.0-11.0 \times 10^9/L$), part of the CBC with differential (neutrophils, lymphocytes, monocytes, eosinophils, basophils).

Leukocytosis: infection (neutrophilia), inflammation, stress, steroids, leukemia (marked), corticosteroids. Leukopenia: viral infection, marrow failure, chemotherapy, sepsis. Interpretation by differential: neutrophilia (bacterial, stress), lymphocytosis (viral, CLL, pertussis), eosinophilia (allergy, parasites, drug reactions), monocytosis (TB, recovery, myelomonocytic leukemia), basophilia (myeloproliferative). Used for infection screening, monitoring therapy, and leukemia diagnosis.

White Cell

– Also known as leukocytes, the cells of the immune system that defend the body against infection and foreign substances. Produced in the bone marrow from hematopoietic stem cells. Types: neutrophils (50-70%, first responders to bacterial infection, phagocytosis), lymphocytes (20-40%, adaptive immunity — T-cells, B-cells, NK cells), monocytes (2-8%, differentiate into macrophages and dendritic cells), eosinophils (1-4%, allergic reactions, parasitic infections), and basophils (<1%, allergic responses, release histamine). Normal WBC count: 4,000-11,000/ μ L. Leukocytosis (elevated WBC): infection, inflammation, stress, leukemia. Leukopenia (low WBC): bone marrow suppression, infection, autoimmune disorders.

White Cell Count

– A laboratory measurement of the number of white blood cells (leukocytes) in a given volume of blood, part of the complete blood count (CBC). Normal range: 4,000-11,000 cells/ μ L ($4-11 \times 10^9$ /L). Differential white cell count measures the proportion of each leukocyte type: neutrophils, lymphocytes, monocytes, eosinophils, basophils. An elevated WBC (leukocytosis) suggests infection, inflammation, tissue damage, or hematologic malignancy. A decreased WBC (leukopenia) suggests bone marrow suppression from chemotherapy, infection (HIV, sepsis), autoimmune destruction, or drug toxicity. Marked leukocytosis ($>100,000/\mu$ L) is a defining feature of chronic leukemias (CLL, CML). Left shift: increased band neutrophils, indicating acute bacterial infection.

Chapter 16

Immunology

Allergen

– A substance capable of inducing an allergic (IgE-mediated) immune response in susceptible individuals. Allergens are typically proteins or glycoproteins with molecular weights between 10 and 70 kilodaltons, possessing structural features that promote IgE binding including protease resistance and the ability to crosslink IgE on mast cells. Major allergen families include profilins (pan-allergens in pollen, latex, fruits), lipid transfer proteins (LTPs, important in food allergy, particularly to peaches, apples, and nuts), and tropomyosins (shellfish allergens).

Allergic Reactions

– Hypersensitivity reactions mediated by IgE antibodies in response to otherwise harmless environmental substances (allergens). Type I immediate hypersensitivity reactions involve initial sensitization where dendritic cells present allergen to T helper 2 cells, stimulating B cell class switching to IgE production. IgE binds to high-affinity Fc-epsilon-RI receptors on mast cells and basophils, priming these cells. Upon re-exposure, allergen crosslinks surface-bound IgE, triggering degranulation and release of histamine, leukotrienes, and prostaglandins, causing vasodilation, bronchoconstriction, and increased vascular permeability.

Allergic Rhinitis (Hay Fever)

– Allergies occur when the immune system overreacts to harmless environmental substances such as pollen, dust mites, mold, or pet dander. Hay fever (allergic rhinitis) specifically involves nasal symptoms like sneezing, congestion, and itchy eyes triggered by airborne allergens. Management includes avoidance, antihistamines, nasal corticosteroids, and immunotherapy.

Anaphylactic Shock

– See Anaphylaxis.

Antigen-Presenting Cell (APC)

– Specialized immune cells that process protein antigens and display peptide fragments bound to Major Histocompatibility Complex (MHC) molecules on their surface for recognition by T-cell receptors. Professional APCs: dendritic cells (most potent for naive T cells), macrophages, and B cells. Express MHC Class II and co-stimulatory molecules (B7-1/CD80, B7-2/CD86).

Ataxia-Telangiectasia

– Autosomal recessive (ATM gene mutation, DNA damage response kinase). Progressive cerebellar ataxia (gait, truncal, speech), oculocutaneous telangiectasias (conjunctiva, ears, face, 3-6 years), sinopulmonary infections (IgA deficiency in 70%, IgG2 subclass deficiency), increased radiosensitivity, high malignancy risk (lymphoma, leukemia, 10-15%), endocrinopathies (diabetes, gonadal failure). Elevated AFP in 95%. Diagnosis: ATM sequencing, radiosensitivity assay. Treatment: IVIG for recurrent infections; avoid live vaccines and unnecessary radiation.

Atopy

– The genetic predisposition to develop immediate (IgE-mediated, type I) hypersensitivity reactions to common environmental allergens (pollen, dust mites, foods, pet dander). Atopic disorders include allergic rhinitis (hay fever), asthma, atopic dermatitis (eczema), and food allergy; they frequently coexist in the same individual and family. Pathophysiology: Th2-dominant responses with IL-4, IL-5, IL-13 driving IgE production and mast cell/eosinophil activation. Management: allergen avoidance, antihistamines, intranasal corticosteroids, and immunotherapy.

Autoimmune Diseases

- Autoimmune diseases occur when the immune system mistakenly attacks the body's own healthy tissues, producing chronic inflammation and organ damage. There are over 80 types, including rheumatoid arthritis, lupus, type 1 diabetes, multiple sclerosis, and Hashimoto's thyroiditis. Treatment typically focuses on suppressing immune activity with corticosteroids, immunomodulators, or biologics.

Autoimmune Polyendocrine Syndromes

- APS-1 (APECED, AIRE mutation): autosomal recessive, chronic mucocutaneous candidiasis, hypoparathyroidism, adrenal insufficiency (Addison's), plus type 1 diabetes, autoimmune thyroiditis, vitiligo, alopecia, pernicious anemia, hepatitis, asplenia. APS-2 (Schmidt syndrome): autoimmune adrenal insufficiency + autoimmune thyroid disease (Hashimoto's or Graves) + type 1 diabetes; associated with HLA-DR3/DR4. APS-3: autoimmune thyroid disease + type 1 diabetes (no adrenal). APS-4: other combinations of autoimmune endocrinopathies not fitting APS-1, 2, or 3.

Autoimmunity: Mechanisms

- Loss of tolerance: central (thymic negative selection defects, AIRE mutation → APS-1) and peripheral (Treg dysfunction, anergy failure, ignorance loss). Molecular mimicry: cross-reactivity between pathogen and self (rheumatic fever: Strep M protein + cardiac myosin; Guillain-Barre: *Campylobacter* + GM1 ganglioside; reactive arthritis). Epitope spreading: immune response expands to new epitopes on same or different antigens (intramolecular/intermolecular). Bystander activation: inflammation activates autoreactive T cells non-specifically in the local milieu (e.g., in type 1 diabetes, myocarditis).

Basophil

- A rare (<1 percent of leukocytes) granulocyte with large, basophilic granules containing histamine, heparin, and leukotrienes. Basophils bear high-affinity IgE receptors (Fc-epsilon-RI) and, like mast cells, release histamine and mediators during immediate hypersensitivity (allergic) reactions. They participate in defense against parasites and in allergic inflammation. Activation causes vasodilation, bronchoconstriction, and increased vascular permeability.

Elevated basophils occur in myeloproliferative disorders (CML).

B Cell (B Lymphocyte)

- A key cellular component of adaptive humoral immunity that matures in the bone marrow. Upon antigen recognition via B-cell receptor (BCR/surface IgM) and T-cell help (CD40/CD40L interaction), B cells proliferate and differentiate into antibody-secreting plasma cells and long-lived memory B cells. Undergo somatic hypermutation and class-switch recombination.

Chediak-Higashi Syndrome

- Autosomal recessive (LYST mutation, lysosomal trafficking regulator). Giant lysosomal granules in neutrophils, melanocytes, neurons. Partial oculocutaneous albinism, silvery hair, photophobia, nystagmus. Recurrent pyogenic infections (Staph, Strep), accelerated phase (HLH-like, 85%): fever, hepatosplenomegaly, pancytopenia, neurologic decline. Peripheral smear: giant azurophilic granules in neutrophils. Treatment: HSCT before accelerated phase; ascorbic acid improves chemotaxis.

Chemokine

- A family of small secreted cytokines that direct leukocyte migration (chemotaxis) to sites of infection, inflammation, and tissue repair. Classified by cysteine motif: CXC (e.g., IL-8/CXCL8, recruit neutrophils), CC (e.g., MCP-1/CCL2, attract monocytes), C, and CX3C. Chemokines bind G protein-coupled receptors (CCR, CXCR); critical for immune cell homing, development (CXCL12/CXCR4), and lymph node organization. Also co-receptors for HIV (CCR5, CXCR4). The chemokine system is a therapeutic target in inflammation and cancer.

Chronic Granulomatous Disease

- A primary immunodeficiency caused by defects in the NADPH oxidase complex in phagocytes (neutrophils, monocytes, macrophages), impairing the respiratory burst and killing of catalase-positive organisms. The most common form is X-linked (CYBB gene mutation, encoding gp91phox, accounting for 65-70 percent of cases); autosomal recessive forms involve mutations in NCF1 (p47phox, 30 percent), NCF2 (p67phox), NCF4 (p40phox), or CYBA (p22phox). The defective phagocyte respiratory burst leads to recurrent infections with catalase-positive organisms including *S. aureus*, *Ser-*

ratia marcescens, Burkholderia cepacia, Nocardia, and Aspergillus.

Chronic Mucocutaneous Candidiasis

– Persistent/recurrent Candida infections of skin, nails, mucosa (oral, esophageal, vaginal) without systemic dissemination. Autosomal dominant (STAT1 gain-of-function) or recessive (IL17F, IL17RA, ACT1, RORC). Associated with autoimmunity (hypothyroidism, AIHA, ITP, alopecia), endocrinopathies, Staph infections. STAT1 GOF: multi-organ autoimmunity, cerebral aneurysms. Treatment: azole antifungals (fluconazole, itraconazole), JAK inhibitors (ruxolitinib) for STAT1 GOF; IL-17 pathway defects respond to recombinant IL-17 therapy.

Common Variable Immunodeficiency

– The most common symptomatic primary immunodeficiency in adults, affecting approximately 1 in 25,000 individuals. It is characterized by hypogammaglobulinemia (low IgG with low IgA and/or IgM), impaired antibody response to vaccines, and increased susceptibility to infections. The pathogenesis is heterogeneous: approximately 50 percent of cases have identifiable genetic mutations (TNFSF13B/BAFF-R, TACI, MS4A1/CD20, IKZF1, CD19), while the remainder are idiopathic.

Complement C1q Deficiency

– Autosomal recessive (C1QA, C1QB, C1QC). C1q essential for classical pathway activation and immune complex clearance. 85-90% develop SLE-like disease (malar rash, photosensitivity, nephritis, anti-nuclear antibodies). Recurrent infections with encapsulated bacteria. Low CH50, low C1q, normal C3/C4. Treatment: SLE management (hydroxychloroquine, immunosuppressives); prophylactic antibiotics; IVIG for infections.

Complement C2/C4 Deficiency

– C2 deficiency: most common early complement deficiency (1:20,000 Caucasians). SLE-like disease (10-30%), recurrent sinopulmonary infections. C4 deficiency: similar, strong SLE association (C4A/C4B null alleles). Low CH50, low C2 or C4, normal C3. Treatment: SLE management, prophylactic antibiotics, IVIG for recurrent infections.

Complement Cascade

– The ordered activation of 30 serum and membrane proteins (complement) that opsonize pathogens, lyse microbes (membrane attack complex), and promote inflammation. Three pathways: classical (antigen-antibody complexes, C1), lectin (mannose-binding lectin on microbial sugars), and alternative (spontaneous C3 activation, amplified by microbial surfaces)—all converge on C3 convertase, then C5 convertase forming the C5b-9 MAC. Functions: opsonization (C3b), anaphylatoxins (C3a, C5a—mast cell degranulation, chemotaxis), and immune clearance. Regulated by inhibitors (factor H, CD55, CD59); deficiencies cause recurrent infection or autoimmune disease.

Complement Deficiencies

– Rare primary immunodeficiencies caused by genetic defects in complement pathway proteins, increasing susceptibility to specific infections and autoimmune diseases. Terminal complement deficiencies (C5-C9) impair membrane attack complex (MAC) formation, leading to recurrent Neisseria infections (meningococcal disease, gonococcemia) with a 10,000-fold increased risk compared to the general population. Vaccination against Neisseria meningitidis (quadrivalent ACWY and serogroup B vaccines), prophylactic antibiotics (penicillin), and prompt treatment of infections.

Complement System

– A cascade of over 30 plasma proteins produced by the liver that enhances antibody and phagocytic action. Activated by three pathways: Classical (antigen-antibody complexes, C1 q r s), Lectin (mannose-binding lectin), and Alternative (spontaneous C3 hydrolysis). All converge at C3 convertase, leading to opsonization (C3b), chemotaxis/anaphylatoxins (C3a, C5a), and cell lysis via the Membrane Attack Complex (MAC, C5b-9).

Cyclosporine

– A calcineurin inhibitor immunosuppressant that blocks T-cell activation by preventing NFAT-mediated cytokine (IL-2) transcription. Used to prevent organ transplant rejection, graft-versus-host disease, and in autoimmune conditions (psoriasis, rheumatoid arthritis, nephrotic syndrome, ulcerative colitis). Narrow therapeutic index with therapeutic drug monitoring. Adverse effects: nephrotoxicity (major), hypertension, hy-

perkalemia, tremor, hirsutism, gingival hyperplasia, and infection/malignancy risk. Metabolized by CYP3A4—many drug interactions. Tacrolimus is a related calcineurin inhibitor.

Cytokine Release Syndrome

– CRS: systemic inflammatory response from massive cytokine release (IL-6, IFN-gamma, TNF, IL-10) after T cell engaging therapies (CAR-T, bispecific antibodies, TGN1412). Grading (ASTCT): Grade 1 (fever), Grade 2 (hypoxia/hypotension responsive to O₂/fluids), Grade 3 (hypoxia/hypotension requiring O₂/vasopressors), Grade 4 (life-threatening). Management: tocilizumab (anti-IL-6R) first-line; corticosteroids for neurotoxicity (ICANS) or refractory CRS; anakinra for steroid-refractory; siltuximab (anti-IL-6) for refractory CRS.

Cytotoxic T Cell

– Also CD8⁺ T cells; the effector cells of cell-mediated immunity that kill virus-infected cells and tumor cells. Recognize antigenic peptides presented on MHC class I molecules via the T-cell receptor; co-stimulation by CD4⁺ helper cells and cytokines (IL-2) is needed for activation. Killing mechanisms: perforin/granzyme release (apoptosis), Fas-FasL, and TNF. Cytotoxic T cells are central to defense against intracellular pathogens and tumors, and in transplant rejection. Measured with CD4 counts in HIV monitoring (CD8 preserved).

Dendritic Cell

– The most potent professional antigen-presenting cell, capturing antigens in tissues and migrating to lymph nodes to present peptides on MHC molecules to T cells, initiating adaptive immunity. Immature dendritic cells sample the environment; maturation (danger signals, TLR ligands) upregulates MHC, co-stimulatory molecules (B7/CD80-86), and cytokines. Subtypes: conventional/classical (cDC1, cDC2) and plasmacytoid (pDC, major type I interferon producer). Dendritic cells link innate and adaptive immunity and are targets for cancer vaccines.

DiGeorge Syndrome

– 22q11.2 deletion syndrome (most common microdeletion syndrome, 1:4000). Thymic hypoplasia/aplasia → T-cell deficiency (variable, partial in 75%, complete in <1%), cardiac defects (conotruncal: TOF, truncus arteriosus, interrupted aortic arch), hypocalcemia (parathyroid hypoplasia), facial

features, palatal abnormalities, learning disabilities. Immunodeficiency: variable CD4⁺ T-cell lymphopenia, impaired vaccine responses, autoimmunity risk. Treatment: calcium/vitamin D for hypocalcemia; IVIG if antibody deficiency is present; thymus transplant for complete DiGeorge.

Eosinophil

– A granulocyte (1-4 percent of leukocytes) with bilobed nucleus and eosinophilic granules containing major basic protein, eosinophil cationic protein, and peroxidase. Roles: defense against parasitic (helminth) infections and modulation of allergic inflammation; contain histaminase and aryl sulfatase. Elevated eosinophils (eosinophilia) occur in allergy, asthma, drug reactions, parasites, and eosinophilic disorders (hypereosinophilic syndrome, EGPA). Activation releases toxic proteins causing tissue damage (asthma, endomyocardial fibrosis).

Factor H Deficiency

– Autosomal recessive (CFH mutation). Factor H regulates alternative pathway (cofactor for factor I, accelerates decay). Uncontrolled alternative pathway activation → C3 consumption → low C3, normal C4. Atypical HUS (aHUS): microangiopathic hemolytic anemia, thrombocytopenia, acute kidney injury. C3 glomerulopathy (C3GN/DDD): C3-dominant deposits on IF. Treatment: eculizumab (anti-C5) for aHUS and C3G; plasma exchange for acute aHUS.

Factor I Deficiency

– Autosomal recessive (CFI mutation). Factor I cleaves C3b/C4b (cofactor: factor H, MCP, C4BP). Uncontrolled complement → low C3, low C4, low factor H. Recurrent pyogenic infections, aHUS, C3 glomerulopathy, SLE-like disease. Treatment: eculizumab for aHUS/C3G; plasma infusion (contains factor I); IVIG.

Granuloma

– A distinctive pattern of chronic inflammation characterized by the aggregation of modified macrophages (epithelioid histiocytes), often with multinucleated giant cells (Langhans or foreign-body type), surrounded by lymphocytes. Granulomas form when macrophages cannot eliminate a persistent antigen or pathogen. Types: (1) Caseating (central necrosis): tuberculosis, fungal infections (histoplasmosis, coccidioidomycosis), syphilis. (2)

Non-caseating: sarcoidosis, Crohn's disease, berylliosis, foreign body (talc, suture, silicone), granulomatosis with polyangiitis (GPA). (3) Suppurative (with neutrophils): actinomycosis, cat-scratch disease. Diagnosis: tissue biopsy (histology), special stains (AFB for TB, GMS for fungi), culture, PCR for specific pathogens. Treatment: depends on etiology (anti-TB therapy, corticosteroids for sarcoidosis, surgical excision for foreign body).

Griscelli Syndrome

- Three types: Type 1 (MYO5A mutation): primary neurologic impairment, no immunodeficiency; Type 2 (RAB27A mutation): immunodeficiency + partial albinism, HLH risk; Type 3 (MLPH mutation): only partial albinism. Type 2: silvery hair, large melanosomes in melanocytes, defective cytotoxic granule release → HLH. Treatment: HSCT for type 2; supportive for types 1 and 3.

Helper T Cell

- Also CD4+ T cells; orchestrators of the adaptive immune response. Recognize antigens on MHC class II presented by antigen-presenting cells, then differentiate into subsets: Th1 (cell-mediated immunity—IFN- γ , activates macrophages, cytotoxic cells), Th2 (humoral/allergic—IL-4, IL-5, IL-13, drives IgE and eosinophils), Th17 (IL-17, neutrophil/mucosal immunity, autoimmunity), and Treg (regulatory, suppress responses). HIV infects and depletes CD4+ cells, causing AIDS. Helper T cells activate B cells, cytotoxic T cells, and macrophages.

Hemophagocytic Lymphohistiocytosis

- HLH: uncontrolled immune activation with cytokine storm (IFN- γ , IL-6, IL-10, TNF). Familial HLH (FHL): PRF1 (FHL2), UNC13D (FHL3), STX11 (FHL4), STXBP2 (FHL5), RAB27A (FHL6/Griscelli type 2). Secondary HLH: infections (EBV, CMV), malignancy (lymphoma), autoimmune (SJIA/MAS, SLE), immunodeficiency. HLH-2004 criteria: 5/8 (fever, splenomegaly, cytopenias ≥ 2 lineages, hypertriglyceridemia/hypofibrinogenemia, hemophagocytosis, low NK activity, ferritin >500 , sCD25 >2400). Treatment: dexamethasone and etoposide (HLH-2004 protocol); emapalumab (anti-IFN- γ) for refractory HLH; HSCT for familial HLH.

Hermansky-Pudlak Syndrome

- Autosomal recessive (10+ genes: HPS1-10, BLOC/AP-3 complexes). Oculocutaneous albinism, bleeding disorder (absent dense bodies in platelets → prolonged bleeding time), pulmonary fibrosis (HPS-1, HPS-4), granulomatous colitis, neutropenia. Diagnosis: electron microscopy of platelets (absent dense bodies), genetic testing. Treatment: pulmonary fibrosis management (pirfenidone, nintedanib), avoid NSAIDs, HSCT not standard.

HIV/AIDS Immunopathogenesis

- HIV-1 infects CD4+ T cells, macrophages, dendritic cells via gp120 binding to CD4 + CCR5 (R5-tropic, early) or CXCR4 (X4-tropic, late). Reverse transcription → integration → transcription/translation → budding. Acute retroviral syndrome (2-4 weeks): fever, lymphadenopathy, pharyngitis, rash, high viral load. Clinical latency (8-10 years): CD4 declines from 500-1500 to <200 . AIDS: CD4 <200 or AIDS-defining OIs (PJP <200 , toxoplasma encephalitis <100 , CMV retinitis <50 , MAC <50 , cryptococcal meningitis <50).

Hyper-IgM Syndromes

- A group of disorders characterized by normal or elevated IgM with low IgG, IgA, and IgE, due to defective class switch recombination (CSR) and somatic hypermutation (SHM). X-linked (CD40LG mutation, CD40 ligand deficiency, 70% of cases): T cells cannot provide CD40 signals to B cells; presents with recurrent pyogenic infections, Pneumocystis jirovecii pneumonia (PJP), cryptosporidiosis (sclerosing cholangitis), neutropenia, increased malignancy risk. Autosomal recessive: AID (activation-induced cytidine deaminase, AICDA), UNG (uracil N-glycosylase), or other CSR/SHM defects.

Hypersensitivity Reactions

- Inappropriate or excessive immune responses causing tissue damage or disease. Coombs and Gell classification: Type I (Immediate/IgE-mediated: anaphylaxis, asthma, urticaria); Type II (Cytotoxic/IgG or IgM against cell surface antigens: AIHA, Goodpasture, Graves); Type III (Immune Complex-mediated: SLE, serum sickness, post-streptococcal glomerulonephritis); Type IV (Delayed-type/T-cell-mediated: contact dermatitis, PPD test, graft rejection).

IgA

– Immunoglobulin A, the predominant antibody in mucosal secretions (saliva, tears, breast milk, gastrointestinal and respiratory tract). Exists mainly as a dimer linked by a J chain and secretory component, which protects it from proteolysis. Functions: neutralizes pathogens and toxins at mucosal surfaces (first-line defense), prevents microbial adherence, and transfers passive immunity to infants via breast milk. Serum IgA is a minor fraction. Deficiency is common and often asymptomatic; selective IgA deficiency is associated with recurrent respiratory/GI infections, celiac disease, and anaphylaxis to blood products.

IgD

– Immunoglobulin D, a membrane-bound antibody expressed on the surface of mature naive B cells (with IgM) serving as a B-cell receptor. Serum IgD is present in trace amounts and its secreted function is unclear. Its role in B-cell activation and signaling is an area of research. Deficiency is rare and usually asymptomatic; elevated serum IgD occurs in hyper-IgD syndrome (mevalonate kinase deficiency, periodic fevers).

IgE

– Immunoglobulin E, the antibody class mediating immediate (type I) hypersensitivity and defense against parasites. Binds high-affinity Fc-epsilon-RI receptors on mast cells and basophils; allergen cross-linking triggers degranulation and release of histamine and leukotrienes, causing allergic rhinitis, asthma, urticaria, and anaphylaxis. Present in trace serum amounts; elevated levels occur in atopy, allergic bronchopulmonary aspergillosis, parasitic infection, and hyper-IgE syndrome. Antihistamines, corticosteroids, and anti-IgE monoclonal antibody (omalizumab) are used therapeutically.

IgG

– Immunoglobulin G, the most abundant antibody class in serum (75-80 percent), produced during secondary immune responses. Functions: neutralization, opsonization, complement activation (classical pathway), and antibody-dependent cellular cytotoxicity. IgG is the only antibody that crosses the placenta, providing passive immunity to the fetus (also causing hemolytic disease of the newborn). Subclasses (IgG1-4) differ in complement fixation and Fc receptor binding. Used therapeutically as

IVIG and monoclonal antibodies.

IgM

– Immunoglobulin M, the largest antibody (pentamer), produced during the primary immune response (first antibody to appear). Functions: potent complement activation (classical pathway) and agglutination; expressed as a membrane-bound B-cell receptor on naive B cells. High IgM indicates recent/active infection; low IgM occurs in some immunodeficiencies (selective IgM deficiency). IgM persists in certain chronic infections (EBV). Hyper-IgM syndromes result from defects in class switching (CD40L).

Immune and Infectious Diseases

– A medical field encompassing disorders of the immune system and illnesses caused by pathogenic microorganisms. Immune system disorders include autoimmune diseases (e.g., lupus, rheumatoid arthritis), immunodeficiencies, and hypersensitivity reactions. Infectious diseases range from viral respiratory infections to bacterial, fungal, and parasitic illnesses, requiring prevention through vaccination and treatment with antimicrobial agents.

Immune Tolerance

– The state of unresponsiveness of the immune system to self-antigens and to specific foreign antigens, preventing autoimmunity while preserving responses to pathogens. Central tolerance: deletion of self-reactive lymphocytes in the thymus (T cells) and bone marrow (B cells). Peripheral tolerance: anergy, regulatory T cells, and immune privilege. Mechanisms are exploited in allergy immunotherapy and tolerance-inducing protocols for transplantation; failure causes autoimmune disease, allergy, and graft rejection.

Immunoglobulin (Antibody)

– Y-shaped glycoprotein produced by plasma cells that specifically binds antigens. Composed of two identical heavy chains and two identical light chains linked by disulfide bonds. Variable regions (F_{ab}) bind antigen; constant region (F_c) mediates effector functions (complement activation, F_c receptor binding). Five classes: IgG (most abundant, crosses placenta), IgA (mucosal immunity, dimer in secretions), IgM (pentamer, first produced in primary response), IgE (allergy, parasite defense), IgD (naive B cell receptor).

Immunoglobulin Replacement Therapy

– Indications: primary antibody deficiencies (XLA, CVID, hyper-IgM, specific antibody deficiency), secondary hypogammaglobulinemia (CLL, myeloma, post-rituximab, post-transplant) with recurrent infections. IVIG: 400-600 mg/kg every 3-4 weeks (trough IgG >700-800 mg/dL); SCIG: 100-200 mg/kg/week (more stable levels, fewer systemic reactions). Products: varying IgA content (low IgA for anti-IgA antibodies), sucrose-free (renal safety), glycine, stabilizing agents. Adverse: headache, aseptic meningitis, infusion reactions, thrombosis; anaphylaxis in IgA deficiency (use low-IgA products).

Immunological Memory

– The ability of the adaptive immune system to mount a faster, larger, and more effective response upon re-exposure to an antigen, conferred by long-lived memory B cells and memory T cells generated during the primary response. Memory B cells produce high-affinity antibodies rapidly (secondary response); memory T cells respond rapidly to infected cells. Basis of vaccination and naturally acquired immunity. Longevity varies; vaccines require boosters to maintain memory. Loss of memory underlies waning immunity and immunosenescence.

Immunosuppressive Drug

– A drug that suppresses immune responses, used for organ transplantation, graft-versus-host disease, and autoimmune/inflammatory diseases. Classes: calcineurin inhibitors (cyclosporine, tacrolimus), antiproliferatives (azathioprine, mycophenolate, methotrexate), corticosteroids, mTOR inhibitors (sirolimus), biologic agents (anti-TNF, anti-IL-2 receptor, rituximab), and newer small molecules. Adverse effects: infection (opportunistic), malignancy (lymphoma, skin cancer), nephrotoxicity, and bone marrow suppression. Regimens balance efficacy and toxicity.

Immunotherapy and Biologic Treatments

– Advanced therapies that harness or modify the immune system to treat diseases, particularly cancer, autoimmune disorders, and inflammatory conditions. Biologics are large-molecule drugs derived from living organisms that target specific

immune pathways, such as TNF inhibitors, monoclonal antibodies, and checkpoint inhibitors. These treatments offer precision targeting but require careful monitoring for immune-related adverse effects.

Inflammasomes

– Multiprotein complexes activating caspase-1 → cleavage of pro-IL-1β/pro-IL-18 → mature IL-1β/IL-18 + pyroptosis (gasdermin D pores). Canonical: NLRP3 (crystals, ATP, K⁺ efflux, ROS, lysosomal rupture), NLRC4 (flagellin, T3SS), AIM2 (cytosolic DNA), Pyrin (RhoA inactivation). Non-canonical: caspase-11 (human caspase-4/5) activated by cytosolic LPS → GSDMD cleavage → pyroptosis + NLRP3 activation. Inflammasomopathies: CAPS (NLRP3 GOF), FMF (MEFV/pyrin LOF → pyrin inflammasome overactivation), NLRC4 GOF (macrophage activation syndrome).

Inflammation

– The body's biological response to harmful stimuli such as pathogens, damaged cells, or irritants, characterized by redness, heat, swelling, pain, and loss of function. Acute inflammation is a protective process that eliminates the initial cause of injury and initiates tissue repair. Chronic inflammation, however, contributes to the pathogenesis of numerous diseases including atherosclerosis, diabetes, arthritis, and cancer.

Innate Immunity

– First line of defense against pathogens, present from birth. Rapid (minutes to hours), germline-encoded, lacks immunological memory. Components: physical/chemical barriers (skin, mucus, gastric acid), cellular components (neutrophils, macrophages, natural killer cells, dendritic cells), and soluble factors (complement, lysozyme, interferons). Recognizes Pathogen-Associated Molecular Patterns (PAMPs) via Pattern Recognition Receptors (PRRs).

Innate Lymphoid Cells

– ILCs: lymphoid lineage, no rearranged antigen receptors, mirror Th subsets. ILC1 (T-bet, IFN-γ): intracellular pathogens, IBD. ILC2 (GATA3, IL-5/13): helminths, allergy, asthma, tissue repair. ILC3 (ROR-γ, IL-17/22): extracellular bacteria/fungi, lymphoid organogenesis. LT_i cells (ILC3 subset): lymph node/Peyer's patch

development. NK cells (Eomes, perforin/granzyme): cytotoxic, missing-self recognition. ILCs in disease: ILC2 in asthma/CRSwNP (target: anti-IL-33, anti-TSLP, anti-IL-5); ILC3 in IBD and psoriasis; ILC1 in chronic inflammation.

Interferon Signaling

– Type I IFN (IFN-alpha/beta): all nucleated cells produce; receptor IFNAR (ubiquitous); JAK1/TYK2 → STAT1/2/IRF9 (ISGF3) → ISGs (hundreds: antiviral, antiproliferative, immunomodulatory). Type II IFN (IFN-gamma): T/NK cells; receptor IFNGR; JAK1/JAK2 → STAT1 → GAS elements. Type III IFN (IFN-lambda): mucosal epithelium; receptor IFNLR. IFN signatures: high in SLE (IFN-alpha), Aicardi-Goutieres (TREX1, RNASEH2, SAMHD1, ADAR1 mutations → cytosolic nucleic acid accumulation → IFN), SAVI (STING GOF), and COPA syndrome.

Interleukin

– A family of cytokines (interleukins) produced mainly by leukocytes that regulate immune cell growth, differentiation, activation, and communication. Examples: IL-1 and IL-6 (inflammation, fever), IL-2 (T-cell growth), IL-4/IL-13 (Th2, IgE), IL-5 (eosinophils), IL-10 (anti-inflammatory), IL-12 (Th1), IL-17 (Th17, autoimmunity), IL-23. Interleukins are therapeutic targets (anti-IL-6 tocilizumab, anti-IL-1 anakinra, anti-IL-17) and used therapeutically (IL-2, IL-7). Named numerically in discovery order.

Leukocyte Adhesion Deficiency

– LAD-I (ITGB2 mutation, CD18 deficiency): absent CD11/CD18 integrins → impaired neutrophil adhesion/transmigration → delayed umbilical cord separation (>30 days), recurrent soft tissue infections without pus formation (leukocytosis >20,000), poor wound healing, periodontitis. Severe: death by age 2 without HSCT. LAD-II (SLC35C1 mutation, GDP-fucose transporter): absent sialyl Lewis X → impaired rolling; intellectual disability (formerly mental retardation), short stature, Bombay blood group. LAD-III (FERMT3 mutation, kindlin-3): impaired integrin activation leading to a similar phenotype to LAD-I plus Glanzmann-like bleeding tendency.

Lymph

– A clear, watery fluid that circulates through the

lymphatic system, derived from interstitial fluid that has entered the lymphatic capillaries. Lymph composition: water, electrolytes, small amounts of protein (especially in liver and intestine), white blood cells (predominantly lymphocytes, 95%, the remainder are monocytes, macrophages, and occasional granulocytes), cellular debris, microorganisms, and absorbed dietary lipids (chylomicrons, giving lymph a milky appearance—chyle). Lymph is formed when hydrostatic and osmotic pressures across the capillary wall cause net filtration of fluid into the interstitial space. Approximately 2-4 L of lymph per day drains through the thoracic duct into the left subclavian vein. Lymph flow is propelled by: contraction of smooth muscle in the wall of collecting lymphatics (intrinsic contractility), compression by skeletal muscle contraction, respiratory motion, and pulsation from adjacent arteries. One-way valves prevent backflow. Lymph nodes filter lymph, removing pathogens and antigens, and serving as sites for immune surveillance and activation. The lymphatic system has crucial roles in: fluid homeostasis (returns excess interstitial fluid to the bloodstream), immune surveillance (lymphocytes recirculate through lymph nodes, detecting and responding to antigens), and fat absorption (intestinal lacteals absorb dietary lipids).

Lymphadenopathy

– Enlargement of lymph nodes (greater than 1 cm in diameter, or >1.5 cm for inguinal nodes). Lymphadenopathy can be localised (single or contiguous region) or generalised (three or more non-contiguous regions). Localised causes: infection (most common—pharyngitis/tonsillitis causing cervical adenopathy, wound infection causing axillary/inguinal adenopathy, TB causing supraclavicular/scalene adenopathy, cat-scratch disease causing axillary/epitrochlear adenopathy), malignancy (lymphoma, metastatic cancer, leukemia), autoimmune (sarcoidosis, SLE, rheumatoid arthritis). Generalised causes: infectious (EBV, CMV, HIV, TB, toxoplasmosis, brucellosis), malignant (lymphoma, CLL, ALL), autoimmune (SLE, sarcoidosis, Still disease), drug-induced (phenytoin, allopurinol), and storage diseases (Gaucher, Niemann-Pick). Diagnostic evaluation: history (duration, size, tenderness, fever, night sweats, weight loss, exposure, travel), physical exam

(location, size, consistency—hard/fixed suggests malignancy, soft/mobile suggests infection, matted suggests TB/sarcoidosis, fluctuant suggests abscess), and workup: full blood count, CRP/ESR, serology (EBV, CMV, HIV, toxoplasma), chest X-ray, ultrasound of nodes, and excisional biopsy (indications: node >2 cm, supraclavicular location, firm/fixed, no regression after 4-6 weeks, systemic symptoms, or abnormal CXR).

Lymphangioma

– A benign congenital malformation of the lymphatic system, composed of dilated lymphatic channels. Lymphangiomas are typically present at birth (90% diagnosed by age 2) and result from failure of the lymphatic system to develop normal connections with the venous system. Types: (1) Cystic hygroma: most common (50-60%), large multiloculated cysts, typically in the neck (posterior triangle) or axilla. Antenatal ultrasound may detect as a nuchal translucency (associated with Turner syndrome, Noonan syndrome, trisomy 21). (2) Cavernous lymphangioma: deep, involves neck, tongue, lip (macrodontia, macroglossia). (3) Lymphangioma circumscriptum: cutaneous vesicles on skin surface. Symptoms: soft, fluctuant, transilluminating mass, often painless. May enlarge rapidly with upper respiratory infection or trauma due to increased lymph production. Complications: infection (lymphangitis), intralesional bleeding, compression of airways, dysphagia, cosmetic deformity. Diagnosis: clinical, ultrasound (cystic, anechoic, septated), MRI (T2 hyperintense, fluid-fluid levels, no enhancement). Management: observation (30% may regress spontaneously, especially small ones), surgical excision (complete excision is curative, but recurrence risk of 10-40% if incomplete), sclerotherapy (OK-432, bleomycin, doxycycline, alcoholic solution of zein-Ethibloc, especially for cystic hygroma), sirolimus (mTOR inhibitor, for complex/refractory cases).

Lymphatic System

– The network of vessels, lymph nodes, and lymphoid organs (thymus, spleen, tonsils, Peyer patches) that returns interstitial fluid (lymph) to the blood, transports dietary fat, and serves as the site of immune surveillance and adaptive immunity. Lymph drains via afferent lymphatics through lymph nodes (antigen presentation, B/T cell activation) and via

efferent vessels to ducts emptying into the subclavian veins. Dysfunction causes lymphedema; lymph nodes are sites of metastasis and infection.

Lymphedema (Lymphoedema)

– Chronic swelling of a body part due to impaired lymphatic drainage, leading to accumulation of protein-rich interstitial fluid. Primary lymphedema: caused by congenital or hereditary lymphatic maldevelopment. Milroy disease (autosomal dominant, VEGFR3 mutation, congenital, present at birth, 2:1 female:male, lower limbs, non-pitting), Meige disease (lymphedema praecox, onset at puberty, 2:1 female:male, lower limbs up to knee, mild), and late-onset lymphedema (tarda, >35 years). Secondary lymphedema: more common, acquired damage to lymphatic vessels or nodes. Causes: cancer-related (axillary lymph node dissection for breast cancer—most common cause of upper limb lymphedema, pelvic node dissection for gynaecological/ urological cancers, melanoma), radiation therapy (lymphatic fibrosis), filariasis (*Wuchereria bancrofti*, *Brugia malayi*—most common cause worldwide, mosquito-borne nematode infection, tropical regions, causes massive leg and genital swelling, elephantiasis), trauma/surgery (lymph node excision), recurrent cellulitis, liposuction (may worsen), and venous disease (phlebolympoedema). Pathophysiology: lymphatic obstruction leads to accumulation of protein-rich fluid, which triggers chronic inflammation, adipose deposition, and fibrosis. Over time, the skin becomes thickened, hyperkeratotic, and papillomatous. Diagnosis: clinical (non-pitting edema Stemmer sign—inability to pinch the skin of the dorsum of the second toe, specific for lymphedema), lymphoscintigraphy (radionuclide imaging of lymphatic transport, gold standard), MRI (honeycomb pattern, dermal thickening, edema fluid), ICG fluorescence lymphangiography. Management: complex decongestive therapy (CDT, gold standard)—phase 1 (intensive, 2-4 weeks, manual lymphatic drainage MLD, compression bandaging, exercise, skincare) and phase 2 (maintenance, daytime compression garments, nighttime bandaging, self-MLD). Additional: pneumatic compression devices, laser therapy, liposuction (for non-pitting, fibrotic, late-stage lymphedema), surgical (lymphaticovenous anastomosis LVA, vascularised lymph node transfer VLNT,

Charles procedure for severe elephantiasis). Antibiotic prophylaxis (penicillin V, 250 mg BD) for recurrent cellulitis. Long-term management with patient education, weight control, and skincare.

Lymph Node / Gland

– Small, bean-shaped organs of the lymphatic system that filter lymph and serve as sites for immune cell activation. Lymph nodes are distributed throughout the body (approximately 500-600 in total) and are concentrated in regions: cervical, axillary, inguinal, mediastinal, mesenteric, para-aortic, and iliac chains. Structure: fibrous capsule, cortex (B-cell follicles—primary and secondary with germinal centers), paracortex (T-cell zone, high endothelial venules), and medulla (medullary cords with plasma cells and macrophages, medullary sinuses). The subcapsular sinus receives afferent lymphatic vessels. The hilum contains the efferent lymphatic vessel and blood vessels. Functions: filtration—macrophages in the sinuses phagocytose particulate matter and microorganisms; immune surveillance—antigens are presented to lymphocytes by dendritic cells, leading to B-cell and T-cell activation, antibody production, and generation of memory cells. Lymph nodes enlarge (lymphadenopathy) in response to infection, inflammation, or malignancy. Palpable lymph nodes in adults: >1 cm in most regions is considered abnormal, except inguinal nodes (1.5 cm). Sentinel lymph node: the first lymph node draining a tumor, biopsied to stage cancer spread (e.g., melanoma, breast cancer).

Lymphocyte

– A type of white blood cell (leukocyte) that is the primary cellular component of the adaptive immune system. Lymphocytes account for 20-40% of circulating white blood cells ($1.0-4.8 \times 10^9/L$). Three main types: (1) T lymphocytes (T cells): develop in the thymus, responsible for cell-mediated immunity. Subsets: CD4+ helper T cells (Th1, Th2, Th17, Tfh, Treg) orchestrate immune responses by secreting cytokines; CD8+ cytotoxic T cells kill virus-infected cells, tumor cells, and allograft cells. (2) B lymphocytes (B cells): develop in the bone marrow, responsible for humoral immunity. Upon activation, B cells differentiate into plasma cells (secrete antibodies—immunoglobulins IgG, IgA, IgM, IgE, IgD) and memory B cells (long-lived, rapid response

upon re-exposure). (3) Natural killer (NK) cells: part of the innate immune system, kill virus-infected cells and tumor cells without prior sensitisation (no antigen receptor rearrangement). Lymphocyte development: hematopoietic stem cells in bone marrow differentiate into common lymphoid progenitors. B cells mature in the bone marrow, T cells migrate to the thymus for maturation (positive selection for self-MHC recognition, negative selection against self-reactivity). After encountering antigen, lymphocytes undergo clonal expansion and differentiate into effector and memory cells. Lymphocyte recirculation: naive lymphocytes travel from blood to lymph nodes via high endothelial venules (HEVs), then to lymph, and back to blood. Lymphocyte disorders: lymphocytosis (viral infection, CLL), lymphopenia (HIV, chemotherapy, immunodeficiency), lymphoma (malignant proliferation of lymphocytes), and autoimmune diseases (dysregulated lymphocyte reactivity).

Lymphokine

– A cytokine produced by lymphocytes (a subset of cytokines; the term lymphokine is largely historical, now 'cytokine'). Examples: IL-2, IL-4, IFN-gamma (from T cells), and B-cell growth factors. Mediate lymphocyte communication, activation, and regulation of immune responses. The term parallels 'monokine' (monocyte products) and has been largely replaced by the broader 'cytokine' terminology in immunology.

Macrophage Activation Syndrome

– MAS is a form of secondary HLH complicating rheumatic diseases (SJIA, Kawasaki, SLE, AOSD). MAS in SJIA: cytopenias, hyperferritinemia, elevated LDH, elevated triglycerides, low fibrinogen, transaminitis. High mortality (20-50%). IL-1/IL-6 driven. Treatment: high-dose corticosteroids, anakinra (IL-1 blockade), tocilizumab (IL-6 blockade), cyclosporine A, etoposide for severe.

Major Histocompatibility Complex (MHC)

– A locus of highly polymorphic genes encoding cell-surface glycoproteins that present antigen peptides to T cells. Human Leukocyte Antigen (HLA) in humans. MHC Class I (HLA-A, B, C): expressed on all nucleated cells, presents endogenous antigens (viral/tumor) to CD8+ cytotoxic T cells. MHC Class

II (HLA-DR, DQ, DP): expressed on professional APCs, presents exogenous antigens to $CD4^+$ helper T cells.

Mannose-Binding Lectin Deficiency

– MBL2 polymorphisms (common, 10-30% heterozygotes, 1-5% homozygotes). MBL activates lectin pathway. Low MBL associated with increased infections in immunocompromised (chemotherapy, transplant), recurrent infections in children, autoimmune disease susceptibility. Diagnosis: serum MBL level, MBL2 genotyping. Treatment: usually asymptomatic; IVIG for recurrent infections in immunocompromised.

Mast Cell

– A tissue-resident immune cell with large granules containing histamine, heparin, tryptase, and cytokines; bears high-affinity IgE receptors (Fc-epsilon-RI). Mast cells are central to immediate (type I) hypersensitivity: allergen cross-links IgE, triggering degranulation and release of histamine/leukotrienes causing vasodilation, bronchoconstriction, edema, and pruritus (anaphylaxis, allergic rhinitis, urticaria). Also participate in parasite defense, wound healing, and tumor surveillance. Activated by IgE, complement (C3a/C5a), and neuropeptides.

Memory Cell

– Long-lived lymphocytes (memory B cells and memory T cells) that survive after an immune response and mount rapid, enhanced responses to re-exposure to the same antigen (immunological memory). Memory B cells, with high-affinity B-cell receptors, differentiate into plasma cells producing antibodies quickly; memory T cells (CD4 and CD8) respond rapidly to infected cells. Basis of vaccine efficacy and durable immunity. Localized to bone marrow, lymph nodes, and tissues.

Methotrexate

– An antimetabolite that inhibits dihydrofolate reductase and adenosine signaling; used as a disease-modifying antirheumatic drug (rheumatoid arthritis, psoriasis, psoriatic arthritis, IBD, vasculitis) and as chemotherapy (leukemia, lymphoma, choriocarcinoma). Weekly low-dose oral/SC for inflammatory disease; higher doses for cancer (with leucovorin rescue). Adverse effects: myelosuppression, hepatotoxicity, pulmonary toxicity, stomatitis, and terato-

genicity. Supplement folic acid; avoid in pregnancy, significant renal/hepatic disease, and with trimethoprim.

Monoclonal Antibody

– An antibody produced by a single cloned B-cell line, specific for one epitope, generated by hybridoma technology or recombinant methods (name suffix -mab). Used diagnostically and therapeutically: rituximab (anti-CD20 for lymphoma/autoimmunity), trastuzumab (HER2 breast cancer), infliximab/adalimumab (anti-TNF), checkpoint inhibitors (pembrolizumab, nivolumab), and SARS-CoV-2 and RSV antibodies. Humanization reduces immunogenicity. Adverse effects: infusion reactions, immunosuppression, and cytokine release syndrome.

Monocyte

– A circulating leukocyte (2-8 percent) that differentiates into macrophages and dendritic cells in tissues. Monocytes phagocytose pathogens, present antigens, and secrete cytokines (TNF, IL-1, IL-6); participate in innate immunity, inflammation, and tissue repair. Subsets differ in function (classical, nonclassical, intermediate). Monocytosis occurs in infection (TB, subacute bacterial endocarditis), inflammation, and myelomonocytic leukemia. Circulate 1-3 days before entering tissues as macrophages.

mRNA Vaccine

– A vaccine delivering messenger RNA encoding a pathogen antigen that host cells translate into protein, triggering an immune response. Approved for COVID-19 (Pfizer-BioNTech, Moderna) and RSV; under study for influenza, cancer, and other infections. Advantages: rapid design, no live pathogen, potent CD4/CD8 and humoral responses, and scalable manufacturing. mRNA is stabilized by nucleoside modification and delivered in lipid nanoparticles. Adverse effects: injection-site reactions, fever, fatigue; rare myocarditis (young males). Require cold-chain storage.

Natural Killer (NK) Cell

– A cytotoxic innate lymphoid cell that kills virus-infected and tumor cells without prior sensitization or MHC restriction. Recognition: activating receptors (NKG2D) and inhibitory receptors (KIR, NKG2A) for MHC class I—'missing self' (reduced MHC) triggers killing. Effector mechanisms: per-

forin/granzyme, TNF, IFN-gamma, and antibody-dependent cellular cytotoxicity (via CD16). NK cells also regulate adaptive immunity. Deficiencies cause severe herpesvirus infections (especially HSV, CMV); large granular lymphocytes on smear.

Neutrophil Extracellular Traps

– NETs: web-like structures of chromatin + granular proteins (MPO, NE, histone) released by neutrophils (NETosis: suicidal vs vital). Functions: trap/kill pathogens (bacteria, fungi, viruses); pathological in thrombosis (NETs provide scaffold for platelets, activate coagulation), autoimmunity (SLE: NETs expose LL-37/DNA → pDC activation → IFN-α; RA: citrullinated antigens in NETs → ACPA), cancer (NETs trap circulating tumor cells → metastasis), COVID-19 (immunothrombosis). DNase I degrades NETs; therapeutic DNase (dornase alfa) used in NET-related pathology.

Opsonization

– The process by which pathogens or particles are coated with opsonins (antibodies—IgG, complement—C3b, or acute-phase proteins) that enhance recognition and phagocytosis by phagocytes bearing corresponding receptors (Fc receptors, complement receptors). Opsonization promotes efficient uptake and killing of bacteria by neutrophils and macrophages. It is a key effector mechanism of antibody and complement function. Defects (deficiencies of C3, Fc receptors) predispose to pyogenic infections.

Pattern Recognition Receptors

– PRRs recognize PAMPs (pathogen) and DAMPs (damage). TLRs: TLR1/2 (lipoproteins), TLR2/6 (lipoteichoic acid), TLR3 (dsRNA), TLR4 (LPS, MD-2, CD14), TLR5 (flagellin), TLR7/8 (ssRNA), TLR9 (CpG DNA). Cytosolic: RIG-I/MDA5 (RNA), cGAS (DNA → cGAMP → STING → IFN), NOD1/2 (peptidoglycan). CLRs: Dectin-1 (beta-glucan), Mincle (mycobacterial TDM), DC-SIGN (mannose). NLRs: NOD1/2 (cytosolic bacteria), NLRP3 (inflammasome). Signaling: MyD88 (all TLRs except TLR3) → NF-κB/IRF; TRIF (TLR3/4) → IRF3/NF-κB activation.

Phagocytosis

– The process by which specialized cells (phagocytes) engulf and destroy foreign particles, microorganisms, and cellular debris. Professional phagocytes:

neutrophils (most abundant, first responders, short-lived), macrophages (tissue-resident—Kupffer cells in liver, alveolar macrophages in lung, microglia in brain, osteoclasts in bone), dendritic cells (antigen presentation to T cells), and eosinophils (parasite defence). Phagocytosis steps: (1) Chemotaxis—phagocytes migrate to the site of infection guided by chemoattractants (IL-8, C5a, bacterial peptides). (2) Recognition and opsonisation—pathogens are coated with opsonins (IgG antibodies, complement C3b, collectins) that bind phagocyte receptors (Fcγ receptors, complement receptors, mannose receptors). (3) Engulfment—the phagocyte extends pseudopods around the particle, forming a phagosome. (4) Phagosome-lysosome fusion—the phagosome fuses with lysosomes to form a phagolysosome; the pathogen is killed by reactive oxygen species (respiratory burst—NADPH oxidase produces superoxide), nitric oxide, antimicrobial peptides (defensins, cathelicidins), and hydrolytic enzymes (lysozyme, proteases). (5) Exocytosis—degraded material is expelled. Defects in phagocytosis cause recurrent infections: chronic granulomatous disease (NADPH oxidase deficiency—inability to produce reactive oxygen species), Chediak-Higashi syndrome (defective phagolysosome fusion), and leukocyte adhesion deficiency (impaired migration).

Plasma Cell

– The terminally differentiated antibody-secreting cell derived from activated B lymphocytes (after antigen stimulation, class switching, and affinity maturation in germinal centers). Plasma cells produce large amounts of a single antibody class (IgG, IgA, IgM, etc.) and reside mainly in the bone marrow and mucosa, providing sustained antibody production and immunity. Multiple myeloma is a malignancy of plasma cells producing monoclonal immunoglobulin. Plasma cells lack surface immunoglobulin and CD20.

Primary Immune Response

– The adaptive immune response to first exposure to an antigen, characterized by a slow onset (lag phase: days, during which antigen processing, clonal expansion, and differentiation occur), followed by rising antibody titers (predominantly IgM, then IgG), and generation of memory cells. The primary

response is smaller and slower than the secondary response; antibody levels then decline. Detection of IgM suggests recent infection.

Primary Immunodeficiency

– A group of genetically determined disorders of the immune system causing increased susceptibility to infection, autoimmunity, and malignancy. Examples: severe combined immunodeficiency (SCID, T-cell defect), X-linked agammaglobulinemia (B cells), common variable immunodeficiency (hypogammaglobulinemia), chronic granulomatous disease (phagocyte defect), complement deficiencies, and DiGeorge syndrome (thymic aplasia). Present early with recurrent, unusual, or severe infections. Newborn screening (TREC) detects SCID. Management: immunoglobulin, antibiotics, and stem cell transplant.

Properdin Deficiency

– X-linked recessive (CFP gene). Properdin stabilizes alternative pathway C3 convertase. Recurrent *Neisseria* infections (meningococcemia, gonococcemia). Low AH50, normal CH50, low properdin. Treatment: meningococcal vaccination (ACWY + B), prophylactic penicillin, IVIG for severe infections.

Regulatory T Cells

– Tregs (CD4+ CD25+ FOXP3+): essential for peripheral tolerance. Thymic (tTreg) vs peripheral (pTreg) origin. FOXP3: master transcription factor; mutations cause IPEX. Mechanisms: IL-2 consumption (CD25 high), CTLA-4 (transendocytosis of CD80/86), TGF-beta/IL-10 secretion, cAMP transfer, granzyme/perforin killing of APCs, metabolic disruption (CD39/CD73 -> adenosine). Treg defects: IPEX (FOXP3), autoimmune polyendocrinopathy. Therapeutic: low-dose IL-2 expands Tregs (trials in SLE, GVHD); Treg adoptive transfer (trials in GVHD, type 1 diabetes, transplant rejection).

Secondary Immune Response

– The rapid, enhanced immune response on re-exposure to an antigen, mediated by memory B cells and memory T cells generated during the primary response. Features: shorter lag phase, higher and faster antibody titers (predominantly high-affinity IgG), and more effective cell-mediated responses. The secondary response underlies vaccine booster efficacy and durable immunity. Contrast with the

primary response.

Secondary Immunodeficiencies

– Acquired immune defects from: HIV/AIDS (CD4+ T-cell depletion), malignancies (CLL: hypogammaglobulinemia; myeloma: hypogammaglobulinemia + impaired specific antibody; lymphoma), immunosuppressive medications (corticosteroids, chemotherapy, biologics: rituximab -> prolonged B-cell depletion and hypogammaglobulinemia; TNF inhibitors -> TB reactivation; alemtuzumab -> profound T-cell depletion), protein-losing states (nephrotic syndrome, enteropathy, burns), splenectomy (encapsulated bacteria risk, asplenia), and advanced age (immunosenescence).

Secondary Immunodeficiency

– An acquired (not genetic) impairment of the immune system due to an underlying cause: HIV/AIDS (CD4 depletion), malnutrition, malignancy (leukemia, lymphoma), chemotherapy/radiation, immunosuppressive drugs (corticosteroids, biologics), splenectomy, burns, and chronic disease (diabetes, renal failure). Presentation: opportunistic and recurrent infections. Management targets the cause (antiretrovirals for HIV, immunoglobulin, antibiotics, vaccination). Contrast with primary immunodeficiency.

Severe Combined Immunodeficiency

– Severe combined immunodeficiency (SCID) represents a group of genetic disorders characterized by profoundly defective T cell development and function, with variable B and NK cell involvement, resulting in severe susceptibility to life-threatening infections in infancy. It is the most serious primary immunodeficiency, with a combined incidence of approximately 1 in 50,000-100,000 live births. The classic form (X-linked SCID, accounting for approximately 45-50 percent of cases) is caused by mutations in the IL2RG gene (common gamma chain), resulting in absent T cells and NK cells with normal or elevated B cells (T-B+NK- SCID).

Tacrolimus

– A calcineurin inhibitor immunosuppressant (macrolide) that blocks T-cell activation (NFAT/IL-2 inhibition). Used for solid organ transplant rejection prophylaxis/treatment and graft-versus-host disease, and topically for atopic dermati-

tis. More potent than cyclosporine; narrow therapeutic index with therapeutic drug monitoring (trough levels). Adverse effects: nephrotoxicity, hypertension, hyperglycemia/diabetes, neurotoxicity (tremor, headache), hyperkalemia, and infection/malignancy risk. Metabolized by CYP3A4—numerous interactions (azole antifungals, macrolides, grapefruit).

T-Cells (T-Lymphocytes)

– A type of lymphocyte that matures in the thymus and is the central effector of cell-mediated immunity. T-cells express the T-cell receptor (TCR) on their surface, which recognises peptide antigens presented by major histocompatibility complex (MHC) molecules on antigen-presenting cells. T-cells are divided into subsets by function and surface markers: (1) CD4+ helper T cells (Th)—recognise MHC class II, orchestrate immune responses. Subsets: Th1 (IFN- γ , cell-mediated immunity against intracellular pathogens), Th2 (IL-4, IL-5, IL-13, humoral immunity, allergic responses), Th17 (IL-17, neutrophil recruitment, antifungal/extracellular bacterial immunity), Tfh (follicular helper T-cells—help B cells in germinal centers, antibody production), and Treg (regulatory T-cells, FOXP3+, suppress immune responses, maintain self-tolerance). (2) CD8+ cytotoxic T cells (CTL)—recognise MHC class I, kill virus-infected cells, tumor cells, and allograft cells via perforin/granzyme and Fas/FasL pathways. (3) $\gamma\delta$ T-cells—innate-like, recognise non-peptide antigens, bridge innate and adaptive immunity. T-cell development: bone marrow progenitor $\rightarrow$ thymus (positive selection in the cortex, negative selection in the medulla) $\rightarrow$ naive T-cell $\rightarrow$ circulation. Activation: requires TCR binding (signal 1) and co-stimulation (CD28–CD80/86, signal 2). Deficient T-cell function causes severe opportunistic infections (HIV/AIDS, severe combined immunodeficiency—SCID). CD4 count is the key marker of immune function in HIV (normal 500–1500 cells/ μ L; <200 defines AIDS).

T Cell (T Lymphocyte)

– Central cell of cell-mediated adaptive immunity, maturing in the thymus. Recognizes processed peptide-MHC complexes via T-cell receptor (TCR) along with CD3 complex. Subtypes: CD4+ Helper T cells (T_H1 , T_H2 , T_H17 , T_{reg}) secrete cytokines to

coordinate immune responses; CD8+ Cytotoxic T cells (CTLs) release perforin and granzymes to induce apoptosis in infected/malignant cells.

Th1/Th2/Th17/Tfh/Treg Balance

– CD4+ T helper subsets defined by master transcription factors and signature cytokines: Th1 (T-bet, IFN-gamma, IL-12, STAT4): intracellular pathogens, autoimmunity (RA, MS, type 1 diabetes). Th2 (GATA3, IL-4/5/13, IL-4/STAT6): helminths, allergy, asthma. Th17 (ROR-gammat, IL-17A/F, IL-21, IL-22, IL-6+TGF-beta/IL-23/STAT3): extracellular bacteria/fungi, autoimmunity (PSA, AS, MS, IBD). Tfh (Bcl-6, IL-21, CXCR5): germinal center help, antibody affinity maturation, memory B cells. Treg (FOXP3, TGF-beta, IL-10, IL-35): suppression, immune regulation, tolerance.

Titer

– A laboratory measure of the concentration of an antibody (or other substance) in serum, expressed as the highest dilution that still produces a detectable reaction (e.g., 1:128). Titers quantify antibody response to infection or vaccination (e.g., measles, rubella, hepatitis B surface antibody) and are used to assess immunity, guide vaccination, and monitor autoimmune markers (ANA, ASO). A rising titer (fourfold) indicates active/recent infection.

Toll-Like Receptor (TLR)

– A class of single-pass membrane-spanning pattern recognition receptors (PRRs) expressed on innate immune cells (macrophages, dendritic cells). Recognize evolutionary conserved microbial structures (PAMPs). Examples: TLR4 recognizes lipopolysaccharide (LPS) of Gram-negative bacteria; TLR2 recognizes peptidoglycan; TLR3 recognizes double-stranded viral RNA; TLR5 recognizes flagellin. Signaling activates NF- κ B to stimulate pro-inflammatory cytokine expression.

Trained Immunity

– Innate immune memory: epigenetic/metabolic reprogramming of monocytes/macrophages/NK cells after initial stimulus (BCG, beta-glucan, Candida, oxidized LDL) $\rightarrow$ enhanced response to secondary challenge (heterologous protection). Mechanisms: histone modifications (H3K4me3, H3K27ac), metabolic shifts (aerobic glycolysis, glutaminolysis, cholesterol synthesis), mTOR-HIF1alpha pathway.

BCG vaccination protects against unrelated infections (neonatal sepsis, respiratory infections). Relevance: sepsis-induced immunoparalysis (trained immunity reversal).

Transplant Immunology

– Hyperacute rejection: preformed anti-donor antibodies (ABO, HLA) → immediate graft failure (minutes-hours); prevented by crossmatch. Acute cellular rejection: recipient T cells recognize donor alloantigens (direct: donor APC → recipient T cell; indirect: recipient APC presents donor peptides); days-months; treated with steroids, T cell depletion (thymoglobulin, alemtuzumab). Acute antibody-mediated rejection: de novo DSA → C4d deposition, capillaritis, glomerulitis; treated with plasmapheresis, IVIG, rituximab, and bortezomib. Chronic rejection: interstitial fibrosis and tubular atrophy (IFTA) with DSA; poorly responsive to therapy.

Tumor Necrosis Factor (TNF)

– A proinflammatory cytokine (TNF- α) produced mainly by macrophages, acting on TNFR1/TNFR2 receptors. Functions: activation of endothelium and leukocytes, fever, cachexia, apoptosis, and coordination of inflammation and the acute-phase response. TNF is central to inflammatory diseases (rheumatoid arthritis, IBD, psoriasis, ankylosing spondylitis); anti-TNF biologics (infliximab, adalimumab, etanercept) are used therapeutically. Excess TNF contributes to septic shock and inflammatory organ damage.

Type I Hypersensitivity

– An immediate (anaphylactic) hypersensitivity reaction mediated by allergen-specific IgE bound to mast cells and basophils; re-exposure cross-links IgE, triggering degranulation and release of histamine and mediators within minutes. Manifestations: allergic rhinitis, asthma, urticaria, food allergy, and anaphylaxis. Testing: skin prick tests and specific IgE (RAST). Treatment: allergen avoidance, antihistamines, corticosteroids, epinephrine for anaphylaxis, and immunotherapy (desensitization).

Type II Hypersensitivity

– An antibody-mediated (cytotoxic) hypersensitivity reaction in which IgG or IgM binds to cell-surface or matrix antigens, causing cell destruction by complement activation (MAC), opsonization/phagocytosis,

or antibody-dependent cellular cytotoxicity. Examples: autoimmune hemolytic anemia, immune thrombocytopenia (ITP), hemolytic disease of the newborn (Rh incompatibility), transfusion reactions, Goodpasture syndrome, and myasthenia gravis. Diagnosis: direct antiglobulin (Coombs) test, specific autoantibodies.

Type III Hypersensitivity

– An immune complex-mediated hypersensitivity reaction in which circulating antigen-antibody complexes deposit in tissues and vessels, activating complement and attracting neutrophils, causing inflammation and tissue damage. Local forms: Arthus reaction, serum sickness. Systemic examples: systemic lupus erythematosus (glomerulonephritis, vasculitis), rheumatoid arthritis, polyarteritis nodosa, post-streptococcal glomerulonephritis. Deposition is favored by antigen excess, vascular filtration, and reduced clearance. Diagnosis: complement levels, immune complex assays, biopsy.

Type IV Hypersensitivity

– A delayed-type hypersensitivity (cell-mediated) reaction mediated by sensitized T cells (not antibody), occurring 24-72 hours after antigen exposure. CD4+ Th1 cells activate macrophages (tuberculin reaction, contact dermatitis, granuloma formation); CD8+ cytotoxic T cells cause cell destruction (contact dermatitis, transplant rejection, graft-versus-host disease). Examples: Mantoux TB test, poison ivy dermatitis, sarcoid granulomas, celiac disease. Testing: patch tests, tuberculin skin test. No role for IgE or complement.

Vaccine Immunology

– Live attenuated (MMR, varicella, rotavirus, yellow fever, oral typhoid, BCG, intranasal flu): replicate in host → strong humoral + cellular immunity; contraindicated in immunocompromised. Inactivated/killed (polio IPV, hepatitis A, rabies, injectable flu): safer, weaker immunity, need boosters. Subunit/recombinant (hepatitis B, HPV, pertussis acellular, MenB, RSV): specific antigens, safe, need adjuvants. Toxoid (diphtheria, tetanus): inactivated toxin. mRNA (COVID-19 Pfizer/Moderna): lipid nanoparticles, highly effective, rapid development, require cold chain storage.

Vaccines and Immunizations

– Biological preparations that stimulate the immune

system to develop protection against specific infectious diseases. By exposing the body to harmless components of a pathogen, vaccines enable the immune system to generate memory B and T cells that can mount a rapid response upon future exposure. Widespread immunization has dramatically reduced the burden of diseases such as polio, measles, influenza, and COVID-19, and remains one of the most cost-effective public health interventions for preventing morbidity and mortality.

Wiskott-Aldrich Syndrome

– X-linked recessive disorder (WAS gene mutation, encodes WASP protein, regulates actin polymerization in hematopoietic cells). Triad: microthrombocytopenia (small platelets, <70 fl), eczema, recurrent infections (encapsulated bacteria, viruses). Combined immunodeficiency with progressive T-cell lymphopenia. Increased risk of autoimmune disease (AIHA, ITP, vasculitis, IBD) and malignancy (lymphoma, 10-15%). Diagnosis: low WASP expression, WAS gene sequencing. Treatment: IVIG for infections, platelet transfusions for bleeding; splenectomy for refractory thrombocytopenia; HSCT as definitive cure.

X-Linked Agammaglobulinemia

– Caused by mutations in the BTK gene (Bruton tyrosine kinase), essential for B-cell development and maturation. Results in absent or very low mature B cells ($<1\%$ CD19+ cells), profoundly low all immunoglobulin isotypes, and absent antibody responses. Presents in male infants at 4-8 months (after maternal IgG wanes) with recurrent sinopulmonary infections (*S. pneumoniae*, *H. influenzae*, *M. catarrhalis*), enteroviral infections (chronic enteroviral meningoencephalitis), and lack of lymph nodes and tonsils. Diagnosis: low immunoglobulins, absent B cells, BTK sequencing. Treatment: life-long IVIG or SCIG replacement therapy; avoid live vaccines; gene therapy is experimental.

Chapter 17

Infectious Disease

Acute HIV Syndrome

– The acute retroviral syndrome occurring 2-6 weeks after primary HIV infection, corresponding to high-level viremia and immune activation. Presents with fever (most common), lymphadenopathy, pharyngitis, rash (maculopapular, trunk/face), myalgia, arthralgia, headache, nausea, diarrhea, and oral ulcers. High viral load, low CD4 count transiently. Highly infectious period. Diagnosis: HIV RNA (viral load) is positive; HIV antibody may be negative (window period). p24 antigen is detectable. Treatment: immediate ART regardless of CD4 count; pre-exposure prophylaxis for partners. Early diagnosis and treatment improves outcomes and reduces transmission.

AIDS

– Acquired immunodeficiency syndrome: the advanced stage of HIV infection, defined by CD4 count <200 cells/ μL or the presence of AIDS-defining illnesses. Opportunistic infections: Pneumocystis jirovecii pneumonia, candidiasis, toxoplasmosis, cryptococcal meningitis, CMV retinitis, tuberculosis, mycobacterium avium complex; malignancies: Kaposi sarcoma, non-Hodgkin lymphoma, cervical cancer; wasting, dementia. Management: antiretroviral therapy (immune reconstitution), prophylaxis for opportunistic infections (trimethoprim-sulfamethoxazole for PCP when CD4 <200), and treatment of active infections; monitor viral load/CD4. Prevention of progression with early ART dramatically improves prognosis.

Amoebiasis

– Infection caused by the protozoan parasite Entamoeba histolytica, transmitted via the fecal-oral route (contaminated food or water). Most infections are asymptomatic; symptomatic disease ranges from amoebic dysentery (bloody diarrhea, abdomi-

nal pain, tenesmus) to extra-intestinal disease, most commonly amoebic liver abscess (right upper quadrant pain, fever, weight loss). Diagnosis: microscopy of stool samples (identification of trophozoites containing ingested red blood cells), antigen detection, PCR, and serology for extra-intestinal disease. Treatment: tinidazole or metronidazole for invasive disease, followed by a luminal agent (paromomycin or diloxanide furoate) to eradicate cyst carriage. Prevention: safe water, hand hygiene, sanitation.

Anthrax

– A serious infectious disease caused by the gram-positive bacterium Bacillus anthracis, which forms highly resistant spores that can persist in the environment for decades, and it is primarily a zoonotic disease of herbivores (cattle, sheep, goats) that can be transmitted to humans through contact with infected animals or their products. In humans, anthrax occurs in three main forms depending on the route of exposure: cutaneous (most common, 95 percent, presenting as a painless pruritic papule that progresses to a vesicle and then to a characteristic black eschar, with surrounding edema), inhalational (the most lethal form, causing hemorrhagic mediastinitis and mediastinal widening on chest radiography, with a biphasic illness of initial nonspecific symptoms followed by sudden respiratory deterioration), and gastrointestinal (following ingestion of contaminated meat, causing abdominal pain, nausea, vomiting, and bloody diarrhea). Diagnosis is confirmed by culture, Gram stain, or PCR from blood, skin lesions, or tissue samples, and serology may be used retrospectively. Treatment involves high-dose IV antibiotics: ciprofloxacin or doxycycline in combination with one or two additional agents (clindamycin, rifampin, meropenem), and antitoxin (raxibacumab or obiltoxaximab) may be

considered for inhalational anthrax. Post-exposure prophylaxis consists of ciprofloxacin or doxycycline for 60 days combined with anthrax vaccine adsorbed (AVA, BioThrax).

Antibiotic

- A substance that kills or slows the growth of bacteria.

Antimicrobial

- A general term for antibiotics and other drugs that fight microscopic organisms in the body, such as bacteria, viruses, fungi, and parasites.

Antimicrobial Resistance Mechanisms

- Beta-lactamases: Ambler class A (TEM, SHV, CTX-M ESBLs, KPC carbapenemases), class B (metallo-beta-lactamases: NDM, VIM, IMP zinc-dependent, not inhibited by avibactam), class C (AmpC, chromosomal/inducible, hydrolyzes cephalosporins), class D (OXA carbapenemases).

Antimicrobial Stewardship

- Core elements (CDC): leadership commitment, accountability, drug expertise, action (prospective audit/feedback, preauthorization), tracking (DOT).

Antiseptic

- Substances used on wounds to prevent or treat infection; they kill or slow the growth of disease-causing organisms, such as bacteria, on the surface of the body.

Antiviral

- A class of drugs that inhibit viral replication, used to treat viral infections. Mechanisms: nucleoside/nucleotide analogs (acyclovir—HSV/VZV, ganciclovir—CMV, tenofovir/lamivudine—HIV/HBV, remdesivir—RNA viruses), protease inhibitors (HIV), neuraminidase inhibitors (oseltamivir, zanamivir—influenza), polymerase inhibitors, integrase inhibitors, entry/fusion inhibitors, and monoclonal antibodies. Used for herpesviruses, HIV (ART), hepatitis B/C, influenza, COVID-19, RSV (palivizumab prophylaxis), and CMV. Adverse effects: nephrotoxicity, myelosuppression, GI effects, and resistance with incomplete suppression. Aimed at reducing viral load, symptoms, transmission, and complications.

Arbovirus

- A virus transmitted by mosquitoes or other member

of the arthropod phylum.

Ascariasis

- Infection with *Ascaris lumbricoides*, the most common helminth infection worldwide (soil-transmitted). Lifecycle: ingestion of embryonated eggs → larvae hatch in small intestine → penetrate intestinal wall → migrate through liver and lungs (Loeffler syndrome: cough, eosinophilia, transient pulmonary infiltrates) → return to small intestine as adults. Most infections are asymptomatic. Heavy burden: intestinal obstruction (especially children), biliary obstruction, pancreatitis, malnutrition in children. Diagnosis: stool microscopy (characteristic eggs). Treatment: albendazole or mebendazole (single dose).

Aspergillosis

- A spectrum of diseases caused by the fungus *Aspergillus* (most commonly *A. fumigatus*). Allergic forms: allergic bronchopulmonary aspergillosis (ABPA, in asthma or cystic fibrosis – wheezing, eosinophilia, pulmonary infiltrates), allergic *Aspergillus* sinusitis. Saprophytic: aspergilloma (fungus ball in pre-existing lung cavity – haemoptysis). Invasive aspergillosis: occurs in immunocompromised patients (neutropenia, transplant, steroid therapy) – hyphal invasion of blood vessels causes tissue infarction, pneumonia, and dissemination to brain, heart, and kidneys (high mortality). Diagnosis: serum galactomannan, beta-D-glucan, CT chest (halo sign, air crescent sign), culture, biopsy. Treatment: voriconazole (first-line), amphotericin B, isavuconazole.

Athlete Foot

- Tinea pedis: dermatophyte infection (*Trichophyton rubrum*, *T. mentagrophytes*) of the feet, common in those who wear occlusive footwear or use communal showers. Forms: interdigital (scaly, fissured, macerated between toes—most common), moccasin (diffuse plantar scaling), vesicular. Features: itching, burning, cracking, odor; predisposes to bacterial cellulitis (portal of entry). Diagnosis: clinical; KOH preparation, culture. Management: topical antifungals (terbinafine, clotrimazole) for 2-4 weeks; oral terbinafine/itraconazole for resistant or extensive cases; hygiene (dry feet, clean socks, footwear rotation, avoid walking barefoot in public).

Bacillary Angiomatosis

– A vascular proliferative disease caused by *Bartonella henselae* or *B. quintana*, occurring in immunocompromised patients (HIV/AIDS, transplant). Presents with erythematous papules, nodules, or pedunculated lesions resembling Kaposi sarcoma or pyogenic granuloma. Can involve skin, liver (peliosis hepatis), spleen, bone, and lymph nodes. Fever, night sweats, and weight loss may accompany. Diagnosis: biopsy shows lobular proliferations of blood vessels with epithelioid endothelial cells and Warthin-Starry silver stain positive bacilli; PCR confirmation. Treatment: erythromycin or doxycycline for 3 months. Lesions resolve with treatment.

Bacteremia

– The presence of viable bacteria in the bloodstream, a serious condition that can be transient (after dental procedures, toothbrushing), intermittent (undrained abscess), or continuous (endovascular infection like endocarditis). Bacteremia triggers systemic inflammatory responses ranging from fever and leukocytosis to septic shock. Diagnosis requires positive blood cultures; treatment involves IV antibiotics targeting the identified organism and source control of the primary infection site.

Bacterial Infections

– Illnesses caused by pathogenic bacteria proliferating in the body, ranging from mild sore throats and ear infections to life-threatening sepsis and meningitis. They are diagnosed through cultures, PCR testing, or other microbiological methods. Treatment typically involves antibiotics, though rising antimicrobial resistance demands careful stewardship.

Bartonellosis

– A group of infections caused by *Bartonella* species. Cat scratch disease (*B. henselae*): regional lymphadenopathy after cat scratch/bite, fever, inoculation papule. Bacillary angiomatosis (*B. henselae*, *B. quintana*): vascular proliferative lesions in immunocompromised (HIV), red papules/nodules on skin, bone, and viscera. Oroya fever (*B. bacilliformis*, endemic in Peru): acute hemolytic anemia, fever, severe myalgia (Carrion disease). Verruga peruana: chronic cutaneous nodular stage. Trench fever (*B. quintana*): relapsing fever, bone pain, louse-borne. Diagnosis: culture, PCR, serology.

Treatment: azithromycin for CSD, doxycycline + rifampin for bacillary angiomatosis.

Bioterrorism Agents

– Category A: anthrax (*Bacillus anthracis*), smallpox (variola), botulism (*Clostridium botulinum*), plague (*Yersinia pestis*), tularemia (*Francisella tularensis*), viral hemorrhagic fevers (Ebola, Marburg, Lassa, Machupo). Anthrax: inhalational (mediastinal widening, hemorrhagic mediastinitis), cutaneous (eschar), GI. Treatment: ciprofloxacin/doxycycline x60d + vaccine (BioThrax). Smallpox: eradicated 1980, vaccine (ACAM2000, Jynneos), tecovirimat, brincidofovir. Botulism: descending flaccid paralysis, antitoxin (heptavalent). Plague: bubonic (lymphadenopathy/bubo), pneumonic (person-to-person), septicemic. Doxycycline/ciprofloxacin/gentamicin. Tularemia: ulceroglandular, oculoglandular, pneumonic, typhoidal. Streptomycin/gentamicin/doxycycline. VHF: supportive, specific antivirals where available. Public health response: isolation, contact tracing, prophylaxis, risk communication.

Blastomycosis

– A fungal infection caused by *Blastomyces dermatitidis*, endemic to the Ohio and Mississippi River valleys and Great Lakes region. Inhalation of conidia causes pulmonary infection. Pulmonary: acute pneumonia (often misdiagnosed as bacterial), chronic pneumonia with nodules and cavitation. Disseminated: skin (verrucous or ulcerative lesions, most common extrapulmonary site), bone (osteomyelitis), and GU (prostatitis, epididymitis). Diagnosis: sputum culture, histopathology (broad-based budding yeasts), serum antigen testing. Treatment: itraconazole for mild-moderate; amphotericin B for severe or CNS disease.

Borrelia

– A genus of spiral-shaped bacteria (spirochetes) transmitted by arthropod vectors, most notably ticks and lice. The major human pathogen is *Borrelia burgdorferi sensu lato*, the causative agent of Lyme disease, transmitted by Ixodes ticks. *Borrelia recurrentis* causes louse-borne relapsing fever, and *Borrelia duttonii* causes tick-borne relapsing fever. *Borrelia* species have a complex genome with multiple linear and circular plasmids. Diagnosis relies on serology (ELISA with Western blot con-

firmation), PCR, or direct microscopy. Treatment: doxycycline, amoxicillin, or ceftriaxone depending on disease stage.

Botulism

- A rare, potentially fatal neuroparalytic disease caused by botulinum toxin, a potent presynaptic neurotoxin produced by *Clostridium botulinum*, an anaerobic, spore-forming, gram-positive bacillus. Botulinum toxin blocks the release of acetylcholine at the neuromuscular junction by cleaving SNARE proteins (SNAP-25, VAMP/synaptobrevin, syntaxin), preventing vesicle fusion and causing flaccid paralysis. Four clinical forms exist: foodborne botulism (ingestion of preformed toxin in improperly canned or preserved foods, most commonly home-canned vegetables, honey, and fermented foods), infant botulism (the most common form in the United States, caused by intestinal colonization and in vivo toxin production after ingestion of *C. botulinum* spores, most commonly from honey), wound bo-

Brucellosis

- A zoonotic infectious disease caused by gram-negative coccobacilli of the genus *Brucella*, transmitted to humans through contact with infected animals (cattle, goats, pigs, sheep) or consumption of unpasteurized dairy products. *Brucella melitensis* (goats and sheep, most severe), *B. abortus* (cattle), *B. suis* (pigs), and *B. canis* (dogs) are the principal species. It is endemic in the Mediterranean basin, Middle East, Central Asia, Mexico, and South America. Clinical presentation is highly variable: acute brucellosis presents with undulant fever (fever that rises and falls in waves), sweats (often malodorous), arthralgia, fatigue, headache, and hepatosplenomegaly. Chronic brucellosis may persist for months to years with relapsing fever, chronic fatigue, depression, arthritic manifestations.

Candidiasis

- Fungal infection caused by *Candida* species, most commonly *C. albicans*. Mucocutaneous: oral thrush (white plaques on oral mucosa), esophagitis, vulvovaginitis (itching, discharge), and intertrigo. Invasive candidiasis: candidemia and deep organ infection, typically in immunocompromised or ICU patients. Diagnosis: culture, histopathology. Treatment: topical or oral azoles for mucocutaneous; echinocandins for invasive disease. Risk factors: an-

tibiotics, immunosuppression, diabetes, indwelling catheters.

Cardiac Device Infections

- CIED (pacemaker, ICD) infection: pocket infection (erythema, warmth, purulence, erosion), lead infection (bacteremia, endocarditis). Diagnosis: blood cultures, TEE (lead vegetations), pocket culture. Treatment: complete system removal (leads + generator) - CLASS I. Extraction: transvenous (laser, mechanical sheaths) vs surgical (thoracotomy). Antibiotics: pocket only - 10-14d; bacteremia/endocarditis 4-6w. Relapsing bacteremia if hardware retained. Bridge therapy: temporary transvenous pacing, wearable defibrillator (LifeVest). Reimplantation: contralateral side after clearance.

Cat Scratch Disease

- A regional lymphadenitis caused by *Bartonella henselae*, a gram-negative bacillus transmitted to humans through cat scratches, bites, or licks on broken skin, particularly from kittens (which carry higher bacterial loads). Clinical presentation: 1-2 weeks after exposure, a papule or pustule develops at the inoculation site, followed by regional lymphadenopathy (axillary, epitrochlear, cervical) that is tender and may suppurate (10-15 percent). Systemic symptoms include low-grade fever, fatigue, headache, anorexia. Atypical presentations: Parinaud oculoglandular syndrome (conjunctivitis + preauricular lymphadenopathy), encephalitis, neuroretinitis, osteomyelitis, hepatosplenic granulomas, endocarditis (culture-negative). Diagnosis: Warthin-Starry silver.

Cat-Scratch Fever

- An infectious disease caused by the bacterium *Bartonella henselae*, transmitted through a scratch, bite, or lick from an infected cat (typically kittens). After an incubation period of 3-14 days, a papule or pustule forms at the inoculation site, followed by painful regional lymphadenopathy (axillary, epitrochlear, cervical, or submandibular) within 1-3 weeks. Most cases are self-limited, resolving over 2-4 months. Atypical presentations: Parinaud oculoglandular syndrome (conjunctivitis with preauricular lymphadenopathy), hepatosplenic disease (fever, abdominal pain), neuroretinitis, and encephalopathy. Diagnosis: serology (IgG by IFA or ELISA), PCR of lymph node aspirate, or histology (Warthin-Starry

silver stain shows pleomorphic bacilli). Treatment: typically supportive; azithromycin for moderate-to-severe lymphadenopathy or immunocompromised patients.

Cell-mediated immunity

- A type of immune response mounted against viruses, certain types of parasites, and perhaps cancer cells.

Cellulitis

- A bacterial infection of the deep dermis and subcutaneous tissue, most commonly caused by *Streptococcus pyogenes* (Group A Strep) and *Staphylococcus aureus*. Presents with erythema, warmth, edema, and tenderness, with poorly defined margins. Often on the lower extremities. Risk factors: breaks in skin (trauma, ulcers, tinea pedis), lymphedema, venous insufficiency, and immunosuppression. Diagnosis: clinical; blood cultures if systemic signs. Treatment: antibiotics targeting Strep and Staph (cephalexin, dicloxacillin, clindamycin). Severe cases or facial involvement require IV antibiotics.

Chancroid

- A sexually transmitted infection caused by *Haemophilus ducreyi*, characterized by painful genital ulcers and tender inguinal lymphadenopathy (bubo). Ulcers are ragged, non-indurated, with purulent exudate and surrounding erythema. More common in men and in resource-limited settings. Associated with increased HIV transmission. Diagnosis: clinical (painful ulcer + tender lymphadenopathy), Gram stain (school of fish appearance), culture (chocolate agar with vancomycin). Treatment: azithromycin (single dose), ceftriaxone (single dose IM), ciprofloxacin, or erythromycin. Fluctuant buboes require aspiration.

Cholera

- An acute diarrheal illness caused by *Vibrio cholerae*, a gram-negative, comma-shaped, flagellated bacterium, serogroups O1 and O139, that produces cholera toxin, an enterotoxin that irreversibly activates adenylate cyclase in intestinal epithelial cells, causing massive secretion of isotonic fluid into the intestinal lumen. Transmission is fecal-oral through contaminated water and food, with humans as the only natural host. Seven pandemics have occurred since 1817, and cholera remains endemic in over 50

countries, particularly in regions with inadequate water and sanitation. The hallmark presentation is acute onset of profuse, painless, watery diarrhea described as rice-water stool (cloudy white fluid with flecks of mucus) that can exceed one liter per hour, leading to severe dehydration, metabolic acidosis, and hypovolemic shock within hours of onset. Vomiting may precede diarrhea. Clinical dehydration is classified as severe (two or more signs: delayed capillary refill, weak or absent radial pulse, sunken eyes, decreased skin turgor, altered consciousness) or some dehydration (less severe signs). Diagnosis is clinical; stool culture on thiosulfate-citrate-bile salts-sucrose (TCBS) agar grows yellow colonies, and rapid dipstick tests detect *V. cholerae* O1 and O139 antigen. Treatment is primarily fluid replacement: WHO low-osmolality oral rehydration solution (ORS: 75 mmol/L glucose, 75 mEq/L sodium) for some or no dehydration; aggressive IV Ringer's lactate for severe dehydration (100 mL/kg over 3 hours for adults, 100 mL/kg over 6 hours for children). Antibiotics reduce the duration and volume of diarrhea: azithromycin 1 gram orally as a single dose (preferred for all ages, including pregnant).

Clostridioides difficile Infection

- *Clostridioides difficile* infection (CDI): toxin-mediated colitis following antibiotic disruption of normal flora. Risk factors: antibiotics (clindamycin, fluoroquinolones, cephalosporins, penicillins), age >65, hospitalization, PPIs, immunosuppression, IBD. Clinical: watery diarrhea (3+ unformed stools/24h), abdominal pain, fever, leukocytosis. Severe: WBC >15k, creatinine >1.5x baseline. Fulminant: hypotension, ileus, toxic megacolon. Diagnosis: nucleic acid amplification test (NAAT, sensitive), glutamate dehydrogenase (GDH) + toxin EIA (specific), PCR. Treatment: non-severe: vancomycin 125 mg PO q6h x10d or fidaxomicin 200 mg PO q12h x10d. Severe: vancomycin 125 mg PO q6h (or 500 mg q6h) + metronidazole 500 mg IV q8h. Fulminant: vancomycin 500 mg PO/NG q6h + metronidazole 500 mg IV q8h + consider rectal vancomycin enema; surgery (subtotal colectomy) if refractory. Recurrence (20-30).

Clostridium Difficile

- *Clostridioides difficile* infection (CDI): a toxin-producing anaerobic gram-positive rod causing

antibiotic-associated diarrhea and pseudomembranous colitis, most commonly after broad-spectrum antibiotics (clindamycin, cephalosporins, fluoroquinolones). Features: watery diarrhea (often >3 stools/day), abdominal cramping, fever; severe: ileus, toxic megacolon, perforation. Diagnosis: GDH + toxin EIA or toxigenic PCR; consider when diarrhea in hospitalized/antibiotic-exposed patients. Management: stop culprit antibiotics, metronidazole (mild) or oral vancomycin/fidaxomicin (moderate-severe), and fecal microbiota transplant for recurrent; infection control (handwashing, contact precautions, environmental cleaning).

CMV

- See Cytomegalovirus Infection.

Coccidioidomycosis

- A fungal infection caused by *Coccidioides immitis* or *C. posadasii*, endemic to the southwestern US (San Joaquin Valley fever). Inhalation of arthroconidia causes primary pulmonary infection. Most cases are asymptomatic or mild (flu-like illness with cough, fever, erythema nodosum). Disseminated disease occurs in immunocompromised patients, affecting skin, bone/joints, and meninges. Diagnosis: serology (IgM, IgG), culture, and histopathology (spherules). Treatment: fluconazole or itraconazole; amphotericin B for severe disseminated disease.

Cold Sore

- Herpes labialis: recurrent herpes simplex virus type 1 (HSV-1) infection of the lips/around mouth, presenting as prodromal tingling, then grouped vesicles that crust and heal in 7-14 days. Triggered by stress, fever, sunlight, immunosuppression, illness. Recurrence due to reactivation of latent virus in the trigeminal ganglion. Diagnosis: clinical; PCR or culture if atypical. Management: topical antivirals (acyclovir cream) or oral antivirals (valacyclovir, famciclovir) initiated at prodrome reduce duration; sunscreen and trigger avoidance; severe/immunocompromised cases need systemic therapy. Transmission by contact with lesions.

Common Cold

- An acute, self-limited viral infection of the upper respiratory tract, one of the most frequent illnesses in humans, with adults experiencing 2-4 episodes annually and children 6-8 episodes. Over 200 viral serotypes cause the common cold, with rhinoviruses

(100 serotypes, most common, accounting for 30-50 percent of cases) as the leading cause, followed by coronaviruses (15-30 percent, including seasonal HCoV-OC43, -229E, -NL63, -HKU1), respiratory syncytial virus (RSV, 5-15 percent), parainfluenza virus (5-10 percent), adenovirus (5 percent), and enterovirus. Transmission occurs through direct contact, fomites, and respiratory droplets, with peak infectivity in the first 2-3 days of symptoms. The incubation period is 1-3 days. Pathophysiology: viral entry through the nasal epithelium triggers an innate immune response with release.

Communicable disease

- Any disease caused by bacteria, viruses, or other pathogens that is spread from person to person.

Community-Acquired Pneumonia

- CAP: acquired outside hospital. CURB-65 (confusion, uremia >7, respiratory rate ≥30, BP <90/60, age ≥65) and PSI/PORT score for severity/site of care. Outpatient: amoxicillin 1g TID, doxycycline 100 mg BID, or macrolide (if resistance <25).

COVID-19

- Coronavirus disease 2019 caused by SARS-CoV-2, first identified in December 2019. Ranges from asymptomatic to severe respiratory failure and death. Common symptoms: fever, cough, dyspnea, loss of taste/smell (anosmia), myalgia, and fatigue. Severe disease: pneumonia, ARDS, hyperinflammatory state, and thromboembolic complications. Diagnosis: RT-PCR, rapid antigen testing. Prevention: vaccination (mRNA, adenoviral vector). Treatment: supportive care, remdesivir, dexamethasone for severe disease, and anticoagulation.

Cryptococcosis

- A fungal infection caused by *Cryptococcus neoformans* or *C. gattii*, primarily affecting immunocompromised patients (HIV/AIDS, organ transplant, hematologic malignancy). Pulmonary cryptococcosis: cough, dyspnea, pulmonary nodules. Meningoencephalitis: fever, headache, altered mental status, and elevated intracranial pressure. Diagnosis: CSF India ink stain, cryptococcal antigen (CrAg), culture. Treatment: amphotericin B + flucytosine for induction, fluconazole for maintenance. Elevated ICP requires therapeutic lumbar punctures.

Cryptosporidiosis

- A diarrhoeal disease caused by the protozoan para-

site *Cryptosporidium parvum* (zoonotic) or *C. hominis* (anthroponotic), transmitted via contaminated water (chlorine-resistant oocysts), food, or direct contact. Presents with watery diarrhea, abdominal cramps, nausea, and low-grade fever, lasting 1-2 weeks. In immunocompromised patients (especially HIV with low CD4), it causes chronic, profuse, life-threatening diarrhea and wasting. Diagnosis: modified acid-fast stain of stool (oocysts appear red), antigen detection, PCR. Treatment: supportive (rehydration, electrolyte replacement). Nitazoxanide is effective in immunocompetent patients.

Cystitis

– Inflammation of the urinary bladder, typically from bacterial infection, one of the most common bacterial infections in women. Uncomplicated cystitis occurs in otherwise healthy, non-pregnant women with normal urinary tract anatomy; complicated cystitis occurs in men, pregnant women, children, patients with urinary tract abnormalities, indwelling catheters, immunosuppression, or recent instrumentation. The most common causative organism is *Escherichia coli* (75-95 percent of uncomplicated cases), followed by *Staphylococcus saprophyticus* (5-15 percent, particularly in young sexually active women), *Klebsiella pneumoniae*, and *Proteus mirabilis*. Clinical presentation includes urinary frequency, urgency, dysuria (painful urination), suprapubic pain, and occasionally hematuria. Fever and flank pain suggest upper tract involvement (pyelonephritis). Diagnosis: urinalysis shows pyuria (leukocyte esterase positive, greater than 5 WBCs per high-power field), nitrite positivity (gram-negative bacteria, not *S. saprophyticus* or enterococci), and bacteriuria. Urine culture (greater than 10³ CFU/mL of a single uropathogen for symptomatic women) confirms the diagnosis and provides antibiotic sensitivity. Treatment: uncomplicated cystitis in women is treated with a short course (3 days) of nitrofurantoin (100 mg twice daily), trimethoprim-sulfamethoxazole (160/800 mg twice daily, if local resistance less than 20 percent), or fosfomycin (3 gram single dose). Beta-lactams (cephalexin, amoxicillin-clavulanate) are less effective and require longer duration (5-7 days). Complicated cystitis requires 7-14 days of culture-directed antibiotics. Men with cystitis require longer treatment (7-14 days) and evaluation

for underlying prostatitis or obstruction. Recurrent cystitis (3 or more episodes per year) may be managed with prophylactic antibiotics (postcoital or continuous daily), behavioral modifications (hydration, postcoital voiding), and vaginal estrogen.

Cytomegalovirus Infection

– A widespread herpesvirus infection. Primary infection in immunocompetent individuals is usually asymptomatic or causes mononucleosis-like syndrome. Congenital CMV: most common congenital infection, causes sensorineural hearing loss, microcephaly, and developmental delay. In immunocompromised (HIV/AIDS, transplant): retinitis, colitis, esophagitis, pneumonitis, and encephalitis. Diagnosis: CMV PCR, pp65 antigen, serology. Treatment: ganciclovir, valganciclovir, foscarnet for resistant cases. Prevention: valganciclovir prophylaxis in high-risk transplant recipients.

Dengue fever

– An acute mosquito-borne viral illness caused by dengue virus (DENV-1, -2, -3, -4), a flavivirus transmitted primarily by *Aedes aegypti* mosquitoes. Dengue is the most rapidly spreading mosquito-borne viral disease worldwide, with an estimated 390 million infections annually and 100 million symptomatic cases, endemic in over 100 countries, particularly in Southeast Asia, the Western Pacific, the Americas, and Africa. The clinical course has three phases: febrile phase (abrupt onset of high fever lasting 2-7 days, severe headache, retro-orbital pain, myalgia, arthralgia, nausea, vomiting, and a characteristic maculopapular rash with islands of sparing); critical phase (occurs around defervescence at days 3-7, lasting 24-48 hours, marked by increased capillary permeability, plasma leakage, and risk of progression to dengue hemorrhagic fever and dengue shock syndrome, characterized by rising hematocrit with falling platelets, serous effusions, and hypoproteinemia); and recovery phase (reabsorption of extravasated fluid, diuresis, and clinical improvement). The World Health Organization classification categorizes severity as dengue without warning signs, dengue with warning signs (abdominal pain, persistent vomiting, fluid accumulation, mucosal bleeding, lethargy, liver enlargement greater than 2 cm, rising hematocrit with rapid platelet drop), and severe dengue (severe plasma leakage leading to shock,

severe bleeding, or severe organ involvement). Laboratory findings include leukopenia, thrombocytopenia, elevated liver enzymes, and prolonged aPTT. Diagnosis is confirmed by NS1 antigen detection (positive in the first 5 days), RT-PCR (days 1-5), or serology (IgM positive after days 5-7, IgG rises after 14 days). Treatment is supportive: fever control with acetaminophen (avoid NSAIDs and aspirin due to bleeding risk), aggressive IV fluid resuscitation for severe dengue with plasma leakage (crystalloids, colloids for hypotensive shock), blood transfusion for significant hemorrhage, and close monitoring of vital signs, hematocrit, and platelet counts during the critical phase. No specific an334.

Diphtheria

– An acute, toxin-mediated infectious disease caused by *Corynebacterium diphtheriae*, a gram-positive aerobic bacillus that produces a potent exotoxin that inhibits protein synthesis via ADP-ribosylation of elongation factor 2, causing local tissue necrosis and systemic toxicity. The bacteria are transmitted through respiratory droplets or direct contact with cutaneous lesions. The classic clinical presentation is respiratory diphtheria: after a 2-5 day incubation period, the patient develops low-grade fever, sore throat, malaise, and a characteristic grayish-white pseudomembrane that forms on the tonsils, pharynx, or larynx composed of fibrin, necrotic epithelial cells, and inflammatory cells. The membrane is firmly adherent, bleeds upon attempted removal, and may extend to obstruct the airway causing stridor, respiratory distress, and asphyxiation. Cervical lymphadenopathy and severe neck edema produce the classic bull neck appearance. Systemic effects of the toxin include myocarditis (occurring in 10-25 percent of cases, presenting with ECG changes, arrhythmias, and heart failure typically 1-2 weeks after onset) and neurologic involvement (palatal paralysis, cranial neuropathies, and peripheral neuritis developing weeks later). Cutaneous diphtheria presents as non-healing ulcers with a gray membrane, more common in tropical settings and individuals with poor hygiene. Diagnosis is clinical confirmed by culture on tellurite or Loeffler medium and the Elek test for toxigenicity. Treatment: equine diphtheria antitoxin (DAT) is the mainstay, neutralizing unbound toxin; it must be given early, intravenously

for respiratory cases, with monitoring for serum sickness. Antibiotics eradicate the bacteria and stop toxin production: penicillin G (procaine or IV) or erythromycin for 14 days. Close contacts require throat cultures, prophylaxis with penicillin or erythromycin, and booster immunization. Prevention is through routine childhood immunization with the DTaP vaccine, with boosters (Td or Tdap) every 10.

Donovanosis

– Also known as granuloma inguinale, a chronic, progressive, ulcerative genital infection caused by the intracellular gram-negative bacterium *Klebsiella granulomatis* (formerly *Calymmatobacterium granulomatis*). The disease is rare in developed countries but endemic in tropical and subtropical regions, including Papua New Guinea, parts of India, southern Africa, the Caribbean, and South America. Transmission occurs through direct sexual contact with an active ulcer, and the incubation period ranges from 1 week to 3 months after exposure. Clinical presentation begins as a painless, erythematous papule or nodule in the genital region (glans penis, prepuce, labia, vaginal mucosa, cervix, or perianal area) that progressively ulcerates into a painless, beefy-red, friable, granulating ulcer with rolled edges that bleeds easily on contact without significant lymphadenopathy. The ulcers are highly vascular and may have a characteristic beefy red appearance. Without treatment, the ulcer spreads slowly and may cause extensive destruction of genital tissue, fibrosis, lymphedema, and elephantiasis (pseudo-elephantiasis from lymphatic obstruction). Extragenital involvement may occur through autoinoculation to the mouth, lips, and anus. Diagnosis is clinical and confirmed by demonstrating.

Dysentery

– Inflammation of the colon causing frequent, small-volume, bloody, mucoid stools with abdominal cramps, tenesmus, and fever. Two main types: amoebic dysentery (caused by *Entamoeba histolytica*) and bacillary dysentery (caused by *Shigella* species). Bacillary dysentery is more common and typically more severe, with higher fever and systemic symptoms. Diagnosis: stool microscopy, culture, PCR. Treatment: rehydration (oral or intravenous), antibiotics for moderate-severe bacillary dysentery

(ciprofloxacin, azithromycin, or ceftriaxone – guided by sensitivity), tinidazole/metronidazole for amoebic dysentery. Complications: intestinal perforation, toxic megacolon, hemolytic uraemic syndrome (Shigella dysenteriae type 1).

Ebola

– Ebola virus disease (EVD): a severe, often fatal viral hemorrhagic fever caused by Ebola virus (Filoviridae, RNA), transmitted by direct contact with blood/body fluids of infected humans/animals. Incubation 2-21 days. Features: sudden fever, severe headache, myalgia, vomiting, diarrhea, then hemorrhagic manifestations (petechiae, bleeding), multi-organ failure, shock; high case fatality (25-90 percent). Diagnosis: RT-PCR, antigen tests; biocontainment required. Management: supportive (fluids, electrolytes), experimental therapies (monoclonal antibodies—REGEN-EB, remdesivir); infection control (isolation, PPE) is critical; ring vaccination (rVSV-ZEBOV) effective. Endemic to Central/West Africa.

Ebola Virus Disease

– A severe, often fatal hemorrhagic fever caused by the Ebola virus (Filoviridae family). Transmitted through direct contact with blood or body fluids of infected humans or animals. Incubation 2-21 days. Presents with acute onset of fever, myalgia, headache, followed by vomiting, diarrhea, and hemorrhagic manifestations (petechiae, ecchymosis, bleeding). High case fatality rate. Diagnosis: RT-PCR. Treatment: supportive care, monoclonal antibodies. Outbreak control: isolation, contact tracing, safe burials.

E Coli Infection

– Infections caused by Escherichia coli, a gram-negative enteric bacillus. Causes: UTI (most common—cystitis, pyelonephritis), diarrhea (enterotoxigenic ETEC—traveler's diarrhea; enteropathogenic; enterohemorrhagic EHEC O157:H7—bloody diarrhea, HUS; enteroinvasive), neonatal meningitis, sepsis, and intra-abdominal infections. Diagnosis: culture (urine, stool, blood), toxin testing (EHEC). Management: UTI—antibiotics guided by sensitivity; EHEC—avoid antibiotics (increase HUS risk), supportive care; sepsis—empiric broad-spectrum (third-generation cephalosporin, aminoglycoside). Multidrug-resistant (ESBL, carbapenem-resistant)

strains complicate therapy; strict hygiene.

Ehrlichiosis

– A tick-borne bacterial infection caused by Ehrlichia chaffeensis (human monocytic ehrlichiosis) and E. ewingii (granulocytic). Endemic in the southeastern and south-central US. Presents with fever, headache, myalgia, malaise, and thrombocytopenia/leukopenia. Rash less common than RMSF. Diagnosis: clinical suspicion in tick-endemic area, PCR of blood, serology (IFA), intracytoplasmic morulae on peripheral smear. Treatment: doxycycline (first-line). Untreated can be severe with respiratory failure, meningoencephalitis, and DIC.

Elephantiasis

– Massive enlargement of a body part, typically a limb or the scrotum, caused by chronic lymphedema from obstruction of lymphatic vessels. The most common cause worldwide is lymphatic filariasis, a mosquito-borne parasitic infection by Wuchereria bancrofti, Brugia malayi, or Brugia timori. Adult filarial worms inhabit the lymphatic vessels, causing inflammation, dilation, and eventual fibrosis and obstruction of lymph flow. Recurrent secondary bacterial infections (cellulitis, lymphangitis) worsen the edema. The affected limb becomes grossly swollen with thickened, hyperkeratotic, verrucous skin. Other causes: non-filarial elephantiasis (podoconiosis) from chronic exposure to irritant volcanic soil in barefoot agricultural workers, post-surgical lymphedema (axillary node dissection, inguinal node dissection), and congenital lymphatic malformations. Treatment: elevation, compression, meticulous skin hygiene, antibiotics for superinfection, and surgical debulking in severe cases.

Endemic

– Continually present among people in a geographic region.

Endocarditis Prophylaxis

– Infective endocarditis prophylaxis with antibiotics is recommended for patients at highest risk of adverse outcomes from endocarditis who are undergoing dental procedures that involve manipulation of gingival tissue, the periapical region of teeth, or perforation of the oral mucosa. The American Heart.

Epstein-Barr Virus

– EBV (human herpesvirus 4): ubiquitous virus

causing infectious mononucleosis, transmitted via saliva ('kissing disease'). Features: fever, tonsillopharyngitis, cervical lymphadenopathy, fatigue, splenomegaly; atypical lymphocytosis; complications: splenic rupture (avoid contact sport), hepatitis, hemolytic anemia, airway obstruction; association with malignancies: Burkitt lymphoma, nasopharyngeal carcinoma, Hodgkin lymphoma, post-transplant lymphoproliferative disease; chronic active EBV, hairy leukoplakia in HIV. Diagnosis: heterophile (Monospot) antibody, EBV serology (VCA IgM/IgG, EBNA), PCR. Management: supportive; antivirals not effective; avoid contact sports 4-6 weeks.

Febrile

- Feverish; having a high body temperature.

Flu

- Influenza: a highly contagious acute respiratory illness caused by influenza A and B viruses (orthomyxovirus, RNA, frequent antigenic drift/shift). Features: sudden fever, myalgia, headache, cough, sore throat, malaise; complications: pneumonia (viral or bacterial—*S. aureus*, *S. pneumoniae*), exacerbation of COPD/asthma, myocarditis, encephalitis; high risk: elderly, young, pregnancy, chronic disease, immunocompromised. Diagnosis: clinical; rapid antigen/RT-PCR. Management: supportive; antivirals (oseltamivir, zanamivir) within 48 h for high-risk/severe; annual vaccination (inactivated/live attenuated); infection control (cough etiquette, isolation). Pandemic potential via antigenic shift.

Fungal Infections

- Candidiasis: mucosal (thrush, esophagitis, vulvovaginal) - fluconazole; invasive (candidemia, intraabdominal, UTI) - echinocandin (caspofungin, micafungin, anidulafungin) first-line, step-down to fluconazole if susceptible. Aspergillosis: allergic bronchopulmonary (ABPA, asthma/CF, corticosteroids + itraconazole), chronic pulmonary (CPA, cavitary), invasive (IA, neutropenia, transplant, steroids) voriconazole first-line, isavuconazole alternative. Mucormycosis: rhinocerebral (DKA, neutropenia), pulmonary, cutaneous. Amphotericin B lipid formulation (liposomal 5 mg/kg) + surgical debridement; posaconazole/isavuconazole step-down. Cryptococcosis: meningoencephalitis (HIV CD4 <100), pulmonary. Induction: amphotericin

B + flucytosine x2w, consolidation: fluconazole x8w, maintenance: fluconazole x1yr. Endemic mycoses: Histoplasma (Ohio/Mississippi valleys), Coccidioides (Southwest US, Valley fever), Blastomyces (Great Lakes, Southeast), Paracoccidioides (Latin America). Treatment: mild-moderate - itraconazole; severe - amphotericin B then itraconazole. Pneumocystis jirovecii pneumonia (PJP): HIV CD4 <200, immunosuppressed. TMP-SMX (first-line), alternatives: dapsone+TMP, atovaquone, clindamycin+primaquine, pentamidine. Prophylaxis: TMP-SMX if CD4 <200.

Genital Herpes

- Herpes simplex virus infection of the genital region (HSV-2 most commonly; HSV-1 increasingly), transmitted sexually, causing painful grouped vesicles/ulcers, urethritis, dysuria, and lymphadenopathy; primary infection may cause fever and systemic symptoms. Recurrent episodes are shorter and milder. Complications: aseptic meningitis, neonatal herpes (serious—transmission during delivery, prevention by suppressive therapy/cesarean), increased HIV risk. Diagnosis: PCR (preferred) or viral culture of lesions; type-specific serology. Management: antivirals (acyclovir, valacyclovir, famciclovir) for primary, episodic, or suppressive therapy (reduces recurrences and transmission); safe sex counseling; cesarean if active lesions at delivery.

Genital Warts

- Condyloma acuminata: benign epithelial proliferations caused by low-risk human papillomavirus (types 6, 11), transmitted sexually; pink or flesh-colored papules that may be flat, papular, or pedunculated, occurring on the genitalia, perianal region, and perineum. Usually asymptomatic but may cause itching, bleeding, or psychological distress. Diagnosis: clinical; biopsy if atypical. Management: patient-applied (podophyllotoxin, imiquimod, sinecatechins) or provider-administered (cryotherapy, TCA, electrocautery, laser, excision) treatments; recurrence is common; spontaneous regression possible. HPV vaccination prevents infection; treat sexual partners and screen for other STIs.

Genital Warts (Condylomata Acuminata)

- Anogenital warts caused by human papillomavirus (HPV), most commonly types 6 and 11 (low-risk,

>90% of genital warts, not associated with malignancy). Transmission: direct skin-to-skin contact during vaginal, anal, or oral sex; highly infectious (65% transmission rate per sexual encounter). Incubation period: 2 weeks to 8 months (average 3 months). Clinical presentation: flesh-coloured, pink, or hyperpigmented papules or plaques on the genital, perianal, or oral mucosa. Morphologies: exophytic/cauliflower-like (condylomata acuminata), flat papules (smooth, slightly raised, more common on the cervix or penile shaft), keratotic (thick, wart-like, on dry skin of penile shaft or scrotum). Sites: males (foreskin, frenulum, glans, corona, shaft, scrotum, perianal), females (vulva, vaginal introitus, labia, perineum, perianal, cervix). Subclinical infection: detected only by HPV DNA testing or colposcopy. Natural history: 30% regress spontaneously within 4 months, 70% within 2 years. Malignant potential: HPV 6 and 11 rarely cause malignant transformation; HPV 16 and 18 (high-risk types) cause cervical, anal, and oropharyngeal cancer. Diagnosis: clinical (visual inspection, colposcopy, anoscopy). Biopsy if atypical, pigmented, ulcerated, or treatment-resistant. Treatment: patient-applied (imiquimod 5% cream, podophyllotoxin 0.5% solution/gel, sinecatechins 15% ointment); provider-administered (cryotherapy, trichloroacetic acid 80-90%, surgical excision, electrosurgery, laser ablation). No single treatment is universally effective; recurrence rates are 20-50% regardless of modality. Prevention: HPV vaccine (quadrivalent Gardasil targets HPV 6, 11, 16, 18; nonavalent Gardasil 9 targets 9 types) prevents >90% of genital warts when given before sexual debut.

German Measles (Rubella)

– See Rubella.

Giardiasis

– Infection of the small intestine caused by the protozoan parasite *Giardia intestinalis* (*G. lamblia*), transmitted via contaminated water (including untreated surface water), food, or person-to-person spread. Many infections are asymptomatic. Symptomatic disease presents 1-2 weeks after exposure with watery, foul-smelling diarrhea, bloating, flatulence, abdominal cramps, nausea, and steatorrhea. Chronic infection can cause malabsorption, weight

loss, and failure to thrive in children. Diagnosis: stool microscopy (trophozoites or cysts), antigen detection (ELISA), PCR. Treatment: tinidazole (single dose) or metronidazole (5-7 days). Prevention: water filtration or boiling, hand hygiene.

Glandular Fever (Infectious Mononucleosis)

– See Mononucleosis.

Gonorrhea

– A sexually transmitted infection caused by the Gram-negative diplococcus *Neisseria gonorrhoeae*. Epidemiology: second most common bacterial STI (after Chlamydia), highest incidence in 15-24 year olds. Clinical features: (1) Men: acute urethritis (purulent discharge, dysuria, 2-7 day incubation); (2) Women: often asymptomatic (50-70%), may present with cervicitis (mucopurulent discharge, intermenstrual bleeding, dyspareunia), urethritis, PID (salpingitis, tubo-ovarian abscess); (3) Extra-genital: pharyngeal (oropharyngeal swab—often asymptomatic), rectal (proctitis, discharge, tenesmus); (4) Disseminated: arthritis-dermatitis syndrome (tenosynovitis, migratory polyarthritis, pustular rash), perihepatitis (Fitz-Hugh-Curtis syndrome), meningitis, endocarditis (rare). Neonates: ophthalmia neonatorum (purulent conjunctivitis, can cause blindness without prophylaxis). Diagnosis: nucleic acid amplification test (NAAT) on urine or swab, culture for antibiotic sensitivity. Complications: PID, ectopic pregnancy, infertility (tubal scarring), epididymitis. Treatment: ceftriaxone 500 mg IM (single dose) plus azithromycin 1 g orally (single dose). Antimicrobial resistance: resistance to penicillin, tetracyclines, fluoroquinolones now widespread. Requires partner notification and treatment.

Grippe (see Influenza)

– An older term for influenza. See Influenza.

Group A Strep

– Group A *Streptococcus* (*Streptococcus pyogenes*), a gram-positive coccus in chains, beta-hemolytic. Infections: pharyngitis/tonsillitis, impetigo, erysipelas, cellulitis, scarlet fever, necrotizing fasciitis, streptococcal toxic shock syndrome, pneumonia, and puerperal sepsis. Complications: acute rheumatic fever (carditis, arthritis, chorea—post-pharyngitis) and post-streptococcal

glomerulonephritis (post-skin/pharynx). Diagnosis: rapid antigen test/throat culture (pharyngitis), culture. Management: penicillin (or amoxicillin) is first-line for pharyngitis—prevents rheumatic fever; surgical debridement for necrotizing fasciitis; penicillin for invasive disease with clindamycin; treatment of close contacts for severe disease.

Hansen's Disease (Leprosy)

– A chronic infectious disease caused by *Mycobacterium leprae*, an acid-fast, obligate intracellular bacillus. Transmission: respiratory droplets (prolonged close contact). Incubation: 2-10 years (average 5). Epidemiology: 200,000 new cases per year globally (mostly India, Brazil, Indonesia). Pathophysiology: *M. leprae* has a predilection for skin and Schwann cells of peripheral nerves; the clinical spectrum depends on host cell-mediated immunity. Ridley-Jopling classification: (1) Tuberculoid leprosy (TT): strong cell-mediated immunity, few well-defined anesthetic skin lesions (hypopigmented macules with raised edges), thickened nerves, few bacilli. (2) Lepromatous leprosy (LL): poor cell-mediated immunity, numerous symmetric skin lesions (nodules, plaques, diffuse infiltration), extensive nerve involvement (symmetrical, stocking-glove anesthesia), many bacilli (positive slit-skin smear). (3) Borderline forms (BT, BB, BL): unstable, may shift towards TT or LL. Reactions: type 1 (reversal reaction, cell-mediated, worsening skin and nerve lesions), type 2 (erythema nodosum leprosum, immune complex-mediated, fever, painful nodules, neuritis, iritis). Complications: peripheral neuropathy (anesthesia leading to unrecognised injuries, neuropathic ulcers, Charcot joints), claw hand, foot drop, lagophthalmos (facial nerve), nasal deformity, blindness. Diagnosis: clinical (anesthetic skin lesions, thickened nerves), slit-skin smear for acid-fast bacilli, skin or nerve biopsy. Treatment: multidrug therapy (MDT): dapsone + rifampicin +/- clozimine, duration 6-12 months for paucibacillary, 12-24 months for multibacillary. Free MDT from WHO.

Hantavirus

– A genus of enveloped negative-sense RNA viruses of the Bunyaviridae family, transmitted to humans primarily through inhalation of aerosolized excreta.

Healthcare-Associated Pneumonia

– HCAP concept retired (2016 IDSA/ATS); risk factors for MDR now assessed individually. Risk fac-.

Hepatitis

– Inflammation of the liver caused by hepatotropic viruses. See Hepatitis (Viral Hepatitis) for complete definition.

Hepatitis A

– An acute viral infection of the liver caused by hepatitis A virus (HAV), transmitted via fecal-oral route (contaminated food or water). Incubation 15-50 days. Presents with fever, malaise, nausea, jaundice, and elevated transaminases. Self-limited; does not cause chronic infection. Fulminant hepatitis is rare. Diagnosis: IgM anti-HAV. Prevention: HAV vaccine (recommended for travelers, children) and hygiene. Treatment: supportive care.

Hepatitis A, B, C, D, E

– The five hepatotropic viruses that cause inflammation of the liver. See individual entries: Hepatitis A, Hepatitis B, Hepatitis C, Hepatitis D, Hepatitis E.

Hepatitis B

– A viral infection caused by hepatitis B virus (HBV), transmitted via blood, sexual contact, and perinatally. Can cause acute (self-limited or fulminant) and chronic infection (defined by HBsAg positivity >6 months). Chronic HBV leads to cirrhosis and hepatocellular carcinoma. Diagnosis: HBsAg, anti-HBs, HBeAg, HBV DNA, and liver function tests. Treatment: tenofovir, entecavir, or peg-interferon for chronic infection. Prevention: HBV vaccine (universal infant immunization).

Hepatitis C

– A viral infection caused by hepatitis C virus (HCV), primarily transmitted through blood exposure (IV drug use, blood transfusion before 1992). Acute infection is often asymptomatic; 50-80% progress to chronic hepatitis. Chronic HCV can lead to cirrhosis and hepatocellular carcinoma over decades. Diagnosis: anti-HCV antibody, HCV RNA. Treatment: direct-acting antivirals (DAAs) achieve cure rates >95%. No vaccine available. Screening recommended for at-risk populations.

Hepatitis (Viral Hepatitis)

– Inflammation of the liver caused by hepatotropic viruses. Hepatitis A (HAV): fecal-oral, acute self-

limited, no chronic carrier state; vaccine-preventable. Hepatitis B (HBV): blood/sexual/perinatal transmission; acute and chronic infection; leading cause of cirrhosis and HCC. Hepatitis C (HCV): blood-borne; chronic in 50-80%, leading cause of liver transplantation. Hepatitis D (HDV): requires HBV co-infection. Hepatitis E (HEV): fecal-oral, self-limited but severe in pregnancy. Diagnosis: viral serology and PCR. Treatment: supportive for HAV/HEV; antivirals for HBV (tenofovir, entecavir) and HCV (DAAs).

Hepatitis Viruses

– Hepatitis A: fecal-oral, acute self-limited, vaccine (inactivated). Hepatitis B: blood/sexual/perinatal. Acute: HBsAg, IgM anti-HBc. Chronic: HBsAg >6 months, HBV DNA, HBeAg. Treatment: entecavir, tenofovir (TAF/TDF) - suppress DNA, prevent cirrhosis/HCC. HDV: requires HBV, pegylated interferon. Hepatitis C: blood-borne. Acute: HCV RNA. Chronic: genotype (1-6), fibrosis (F0-F4, elastography/biopsy). DAA: pangenotypic (glecaprevir/pibrentasvir 8w, sofosbuvir/velpatasvir 12w, sofosbuvir/velpatasvir/voxilaprevir for retreatment). SVR12 = cure. Hepatitis E: fecal-oral (genotype 1/2), zoonotic (3/4, pork), severe in pregnancy. Hepatitis G/GBV-C: non-pathogenic.

Herpes

– A common viral infection caused by herpes simplex virus (HSV, types 1 and 2) and varicella-zoster virus (VZV, herpes zoster/shingles). See Herpes Simplex and Herpes Zoster.

Herpes Simplex

– A viral infection caused by herpes simplex virus type 1 (HSV-1, primarily orolabial) and type 2 (HSV-2, primarily genital). Primary infection followed by lifelong latency in sensory ganglia with periodic reactivation. Oral herpes: cold sores/fever blisters. Genital herpes: painful vesicular lesions, recurrent outbreaks. Complications: herpes keratitis, encephalitis, and neonatal herpes. Treatment: acyclovir, valacyclovir, famciclovir for acute episodes and suppressive therapy.

Herpes Simplex (Cold Sores / Genital Herpes)

– A viral infection caused by herpes simplex virus type 1 (HSV-1, typically orofacial, though increasingly anogenital) and type 2 (HSV-2, predominantly anogenital). HSV is a double-stranded DNA virus

of the Herpesviridae family with latency in sensory ganglia and periodic reactivation. Primary infection: often asymptomatic; when symptomatic, causes painful vesicular lesions on an erythematous base. Orofacial herpes (cold sores): HSV-1, vesicular lesions on the vermilion border of the lips (herpes labialis), triggered by sun exposure, fever, stress, immunosuppression. Genital herpes: HSV-2 (80%) and HSV-1 (20%), painful genital/perianal vesicles that ulcerate and crust over; primary episode lasts 2-4 weeks; recurrent episodes are milder (viral shedding for 3-5 days). Other manifestations: herpetic whitlow (finger), herpes gladiatorum (skin-to-skin contact sports), herpes keratitis (corneal infection, leading cause of infectious blindness in developed countries), eczema herpeticum (Kaposi varicelliform eruption in atopic dermatitis), herpes encephalitis (temporal lobe, most common cause of sporadic viral encephalitis in adults). Neonatal herpes: transmitted during vaginal delivery if active genital lesions, severe with high mortality. Diagnosis: clinical, viral PCR (golden standard), Tzanck smear (multinucleated giant cells). Treatment: acyclovir, valacyclovir, famciclovir. Antiviral therapy can reduce duration and severity of primary and recurrent episodes. Suppressive therapy (daily valacyclovir 500 mg) reduces recurrences by 70-80% and reduces transmission risk. No cure exists.

Herpes Zoster (Shingles)

– A painful, vesicular rash caused by reactivation of latent varicella-zoster virus (VZV, human herpesvirus 3) in the dorsal root ganglia. VZV causes varicella (chickenpox) as a primary infection, then remains latent in sensory ganglia; reactivation occurs when cell-mediated immunity declines (age >50, immunosuppression, HIV, malignancy, chemotherapy, radiotherapy, stress). Incidence: 1 in 3 people develop shingles in their lifetime; incidence rises sharply after age 50. Prodrome: 2-3 days of burning, stabbing pain, paraesthesia in a dermatomal distribution before the rash appears. Rash: unilateral, vesicular, dermatomal (thoracic most common 50%, trigeminal-V1 ophthalmic branch 15%), clusters of clear vesicles on erythematous base, pustules, crusting over 7-10 days, typically resolves within 2-4 weeks. Complications: Postherpetic neuralgia (PHN, most common, 10-20% of patients, defined as

pain persisting >90 days after rash onset, incidence increases with age; treatment: gabapentin, pregabalin, tricyclic antidepressants, lidocaine patch, capsaicin cream), herpes zoster ophthalmicus (Hutchinson sign: rash on tip of nose indicates nasociliary nerve involvement, increased risk of keratitis, uveitis, glaucoma, blindness; needs urgent ophthalmology referral), Ramsay Hunt syndrome (VZV in geniculate ganglion: ear pain, vesicles in auditory canal and pinna, facial palsy, tinnitus, hearing loss), disseminated zoster (visceral involvement in severely immunocompromised patients), motor neuropathy (rare, segmental weakness). Diagnosis: clinical, PCR or DFA of vesicle fluid. Treatment: antiviral therapy (acyclovir 800 mg 5x/day, valacyclovir 1 g TID, famciclovir 500 mg TID for 7 days) best within 72 hours of rash onset, reduces acute pain and PHN risk; analgesics (NSAIDs, opioids, gabapentinoids). Prevention: recombinant zoster vaccine (Shingrix, adjuvanted subunit glycoprotein E vaccine, 97% efficacy in adults >50, 2 doses 2-6 months apart, recommended for all immunocompetent adults >50).

Histoplasmosis

– A systemic fungal infection caused by *Histoplasma capsulatum*, a dimorphic fungus found in nitrogen-rich soil enriched with bat or bird guano, most commonly in the Ohio and Mississippi River valleys of the United States, Central and South America, and parts of Africa and Asia. The organism exists as a mold in the environment (producing infectious microconidia that are aerosolized when soil is disturbed) and converts to a yeast form at body temperature (37 degrees C). Infection occurs through inhalation of conidia, which reach the alveoli and are ingested by alveolar macrophages, where they convert to yeasts and multiply intracellularly. Most immunocompetent individuals (90 percent) develop asymptomatic or self-limited, mild influenza-like illness. The remaining 10 percent develop progressive forms depending on the intensity of exposure and host immune status. Acute pulmonary histo-

HIV

– Human immunodeficiency virus: a retrovirus (HIV-1, HIV-2) causing progressive CD4+ T-cell depletion and AIDS if untreated. Transmitted via sexual contact, blood/blood products, mother-to-child. Natural history: acute seroconversion illness (fever, rash,

lymphadenopathy), asymptomatic phase, symptomatic phase (opportunistic infections), AIDS (CD4 <200 or AIDS-defining illness). Diagnosis: HIV antibody/antigen test (4th generation), confirmatory viral load; seroconversion window. Management: ART (combination antiretroviral therapy) suppresses viral load, restores immunity, prevents transmission (U=U); pre-exposure (PrEP) and post-exposure (PEP) prophylaxis; monitor CD4 and viral load; treat/prophylax opportunistic infections.

HIV/AIDS

– HIV-1/2: retrovirus, CD4+ T cell depletion. Transmission: sexual, blood, perinatal, breast milk. Acute retroviral syndrome: fever, lymphadenopathy, pharyngitis, rash, high viral load. Clinical latency: CD4 decline over years. AIDS: CD4 <200 or AIDS-defining illness (PJP, toxo, CMV, MAC, crypto, KS, lymphoma, TB). ART: 3+ drugs from 2 classes (2 NRTI + INSTI/NNRTI/PI). Preferred: bictegravir/TAF/FTC, dolutegravir/abacavir/lamivudine (HLA-B*5701 negative), dolutegravir + TAF/FTC. Monitoring: viral load (target <50 copies/mL), CD4, resistance if failure. OI prophylaxis: PJP (TMP/SMX if CD4<200), Toxo (if CD4<100), MAC (azithromycin if CD4<50), fungal (fluconazole if high risk). IRIS: paradoxical worsening after ART initiation. PrEP: TDF/FTC or TAF/FTC daily, cabotegravir LA bimonthly. PEP: 3-drug regimen within 72h x28d.

HIV (Human Immunodeficiency Virus)

– A retrovirus (family Retroviridae, genus Lentivirus) that causes acquired immunodeficiency syndrome (AIDS) by infecting and destroying CD4+ T lymphocytes (helper T cells). Two types: HIV-1 (pandemic, most common worldwide) and HIV-2 (less virulent, West Africa). HIV is an enveloped RNA virus; its genome encodes structural proteins (Gag, Env), enzymes (Pol=reverse transcriptase, integrase, protease), and regulatory proteins (Tat, Rev, Nef, Vif, Vpr, Vpu). Transmission: sexual contact (most common worldwide), blood-borne (IV drug use, blood transfusion), mother-to-child (vertical, during pregnancy, labour, or breastfeeding). Pathophysiology: HIV enters CD4+ cells via binding of gp120 to CD4 receptor and co-receptors (CCR5 or CXCR4); re-

verse transcriptase converts RNA to DNA; integrase incorporates viral DNA into host genome; protease cleaves viral polyproteins for assembly. Without treatment: acute HIV syndrome (2-4 weeks after infection: fever, rash, lymphadenopathy, pharyngitis, myalgia), clinical latency (8-12 years, viral replication continues, CD4 declines), AIDS (CD4 <200 cells/microL, opportunistic infections—PCP, cerebral toxoplasmosis, CMV retinitis, MAC, cryptococcal meningitis, and AIDS-defining cancers—Kaposi sarcoma, non-Hodgkin lymphoma, cervical cancer). Diagnosis: 4th generation antigen/antibody combo test (detects p24 antigen and HIV antibodies), confirm with Western blot or HIV RNA PCR. Management: antiretroviral therapy (ART) for life—combination therapy with 2 NRTIs (tenofovir disoproxil fumarate/emtricitabine) plus a third agent (integrase inhibitor—dolutegravir, bictegravir; NNRTI; or boosted PI). ART reduces viral load to undetectable (<20 copies/mL), restores immune function, prevents AIDS progression, and eliminates sexual transmission risk (U=U—undetectable equals untransmittable). Pre-exposure prophylaxis (PrEP: tenofovir/emtricitabine daily or on-demand for HIV-negative individuals at high risk). Post-exposure prophylaxis (PEP: 28 days of ART, started within 72 hours of exposure). Prevention: condoms, needle exchange, circumcision (reduces female-to-male transmission by 60%), prevention of mother-to-child transmission (ART during pregnancy + formula feeding). Global: 39 million people living with HIV; 1.3 million new infections/year; 630,000 deaths/year.

Hookworm

– Intestinal nematode infection by *Ancylostoma duodenale* or *Necator americanus*, acquired by skin penetration of filariform larvae (walking barefoot on contaminated soil). Larvae migrate through lungs, adults attach to small intestine mucosa and suck blood, causing iron-deficiency anemia, protein loss, and malnutrition; ground itch (entry site). Diagnosis: stool microscopy for eggs. Management: albendazole or mebendazole; iron supplementation for anemia; prevention: footwear, sanitation, and mass drug administration programs. Chronic infection in children impairs growth and cognitive development.

Host

– A person or other living organism that can be infected by a virus or other pathogen under natural.

HPV

– Human papillomavirus: a DNA virus with >100 types causing epithelial infections. Low-risk types (6, 11) cause genital warts (condyloma acuminata) and laryngeal papillomas; high-risk types (16, 18—70 percent of cervical cancer; 31, 33, 45, etc.) cause cervical, anal, penile, vulvar, vaginal, oropharyngeal cancers and precancerous lesions. Transmission: sexual and skin contact; most infections clear spontaneously. Screening: cervical cytology (Pap) ± HPV DNA testing. Prevention: HPV vaccine (9-valent, 9-45 years—prevents warts and high-risk types). Management: treatment of warts (topical, cryotherapy, excision), treatment of CIN/precancer (LEEP, conization), and surveillance of cervical abnormalities.

Hydrophobia

– See Rabies.

Immunization

– Routine childhood (CDC schedule): HepB, RV, DTaP, Hib, PCV, IPV, Influenza, MMR, VAR, HepA, HPV, MenACWY, MenB, COVID19. Adult: Tdap/Td q10y, influenza annually, zoster (RZV 2-dose), pneumococcal (PCV20 or PCV15+PPSV23), HPV (through 26, shared decision 27-45), HepA/B, MenACWY/MenB (riskbased), COVID-19. Pregnancy: Tdap 27-36w, influenza, COVID-19, RSV (32-36w). Contraindications: anaphylaxis to component, live vaccines in immunocompromised/pregnancy (MMR, VAR, LAIV, yellow fever, oral typhoid). Precautions: moderate/severe illness, GBS <6w post-vaccine. Vaccine safety: VAERS, VSD, CISA. Hesitancy: communication (presumptive recommendation, motivational interviewing).

Incubation period

– The time between when a person is exposed to an infection and when symptoms appear.

Infection

– The growth of harmful organisms that can cause disease, such as bacteria, in the body.

Infections in Pregnancy

– Listeriosis: *Listeria monocytogenes* (deli meats, soft cheese), meningoencephalitis, fetal loss, neonatal sepsis. Ampicillin + gentamicin. GBS: vaginal colonization 20-30.

Infective Endocarditis

- Infection of the endocardial surface of the heart, most commonly involving valves (native or prosthetic). Etiology: *Staphylococcus aureus* (most common overall, 30).

Intravascular Catheter Infections

- CLABSI: central line-associated bloodstream infection. Diagnosis: quantitative blood cultures (catheter vs peripheral >5:1), differential time to positivity (>2h), catheter tip culture (>15 CFU). Catheter-related BSIs: coagulase-negative staphylococci (most common), *S. aureus*, enterococci, gram-negatives, *Candida*. Management: remove catheter if *S. aureus*, *Pseudomonas*, *Candida*, mycobacteria, tunnel infection, port abscess, severe sepsis, persistent bacteremia >72h. Exchange over guidewire if no signs of exit site/tunnel infection and non-severe pathogens (CoNS, *Bacillus*, *Corynebacterium*). Antibiotics: CoNS 5-7d, *S. aureus* 2w (4-6w if endocarditis), gram-negative 7-14d, *Candida* 14d post-clearance. Lock therapy: antibiotic/ethanol/heparin locks for salvage. Prevention: maximal sterile barrier, chlorhexidine prep, daily necessity review, chlorhexidine dressings.

Keshan disease

- Heart disease caused by a lack of selenium, an element that the body needs to function properly.

Koplik Spots

- Pathognomonic enanthem of Measles (Rubeola virus infection). Consists of small, 1-2 mm, bluish-white spots on an erythematous background located on the buccal mucosa opposite the lower molars ("grains of salt on a red background"). Appear 1-2 days prior to the onset of the maculopapular rash and disappear 1-2 days after rash onset. Accompanied by the classic 3 Cs: Cough, Coryza, and Conjunctivitis.

Lassa Fever

- An acute viral hemorrhagic illness caused by Lassa virus, an arenavirus, endemic in West Africa (Nigeria, Sierra Leone, Guinea, Liberia). Transmission: exposure to excreta (urine, feces) of the multimammate rat (*Mastomys natalensis*), the natural reservoir. Incubation: 6-21 days. Clinical features: 80% of infections are asymptomatic or mild. Symptomatic illness: gradual onset of fever, malaise, headache, sore throat, myalgia, retrosternal pain,

cough, and gastrointestinal symptoms (vomiting, diarrhea). Severe disease (20%): hemorrhage (gingival, nasal, gastrointestinal, vaginal), facial/neck edema, pleural effusion, hypotension/shock, encephalopathy, seizures, multi-organ failure, and sensorineural hearing loss (a unique complication, occurring in 25-30% of survivors, may be permanent). Case fatality rate: 1-2% overall, 15-20% in hospitalised patients, >50% in third trimester of pregnancy (high maternal and fetal mortality). Diagnosis: RT-PCR (most sensitive, first week), Lassa virus-specific IgM/IgG (seroconversion by week 3), virus isolation (BSL-4). Treatment: ribavirin (IV or oral, most effective if given early, within 6 days of onset). Supportive care: fluid resuscitation, blood products, oxygen, vasopressors. Prevention: rodent control, safe food storage, avoidance of rodent contact. No licensed vaccine. Outbreak management: strict infection control (contact and droplet precautions), case surveillance, contact tracing.

Legionnaires' Disease

- A severe form of pneumonia caused by *Legionella pneumophila*, a Gram-negative aerobic bacillus that is found naturally in freshwater environments (lakes, streams) and artificially in water systems (air conditioning cooling towers, hot tubs, decorative fountains, plumbing systems, showers, humidifiers). First identified after an outbreak at the 1976 American Legion convention in Philadelphia. Transmission: inhalation of aerosolised contaminated water (not person-to-person). Incubation: 2-14 days. Risk factors: age >50, smoking, chronic lung disease, immunocompromised (especially organ transplant recipients), diabetes, and male sex. Clinical features: atypical pneumonia- fever (>39 C), cough (initially non-productive), myalgia, headache, confusion, diarrhea, relative bradycardia, and hyponatraemia. Pontiac fever: a milder, self-limiting flu-like illness without pneumonia caused by the same bacterium. Diagnosis: urinary antigen test (detects *L. pneumophila* serogroup 1, 70-90% sensitive), sputum culture (requires selective media, BCYE agar), PCR on respiratory samples, direct fluorescent antibody (DFA) staining. Treatment: macrolides (azithromycin 500 mg daily, 7-14 days) or fluoroquinolones (levofloxacin 750 mg daily, 7-14 days) as first-line. Doxycycline is an alternative. Se-

vere cases require IV therapy. Complications: respiratory failure, septic shock, empyema, lung abscess, acute kidney injury, pericarditis. Mortality: 10–15% (higher in immunocompromised). Reportable disease in most jurisdictions.

Leishmaniasis

– A parasitic disease caused by protozoa of the genus *Leishmania*, transmitted by the bite of infected female phlebotomine sandflies. Visceral leishmaniasis (kala-azar): caused by *L. donovani*/*L. infantum* – fever, hepatosplenomegaly, pancytopenia, weight loss, hypergammaglobulinaemia; fatal if untreated. Cutaneous leishmaniasis: skin ulcers at bite sites that heal slowly with scarring (*L. major*, *L. tropica*, *L. mexicana*). Mucocutaneous leishmaniasis: destructive lesions of the nasopharynx (*L. braziliensis*). Diagnosis: microscopy of tissue smears (amastigotes in macrophages), culture, PCR. Treatment: liposomal amphotericin B (visceral), miltefosine, sodium stibogluconate.

Leprosy

– A chronic bacterial infection caused by *Mycobacterium leprae*, affecting skin and peripheral nerves. Transmission via nasal droplets. Spectrum of disease determined by immune response: tuberculoid (paucibacillary): one or few hypopigmented, anesthetic skin lesions, thickened nerves. Lepromatous (multibacillary): numerous symmetric nodules, plaques, and nerve involvement with sensory loss and deformities (leonine facies, claw hand, foot drop). Diagnosis: skin biopsy with acid-fast bacilli. Treatment: multi-drug therapy (dapsone + rifampin for paucibacillary; add clofazimine for multibacillary) for 6–12 months. Reactions require corticosteroids.

Leprosy (Hansen's Disease)

– See Hansen's Disease (Leprosy).

Leptospirosis

– A zoonotic bacterial infection caused by spirochaetes of the genus *Leptospira*, transmitted through contact with water or soil contaminated with the urine of infected animals (rodents, cattle, dogs). Incubation period 5–14 days. Mild form: fever, headache, myalgia (especially calves), conjunctival suffusion. Severe form (Weil disease): jaundice, renal failure, hemorrhage, myocarditis, and pulmonary hemorrhage with respiratory failure. Diagnosis: culture (blood/urine), PCR, serology

(microscopic agglutination test). Treatment: doxycycline or penicillin for mild disease; intravenous penicillin or ceftriaxone for severe disease. Prevention: avoiding contaminated water, rodent control, doxycycline prophylaxis for high-risk exposure.

Lice

– Pediculosis: infestation by blood-sucking lice—head lice (*Pediculus humanus capitis*, common in children, scalp), body lice (*Pediculus humanus corporis*, clothing/seams, associated with poor hygiene and epidemic typhus transmission), and pubic/crab lice (*Phthirus pubis*, sexually transmitted). Features: pruritus (worse at night), visible nits (eggs) attached to hair shafts, excoriations; body lice with rash. Diagnosis: visual inspection, finding live lice/nits. Management: pediculicides (permethrin, malathion, benzyl alcohol, ivermectin), nit combing, laundering clothing/bedding, treating contacts; body lice—hygiene and laundering; treat with oral ivermectin for extensive.

Listeriosis

– A bacterial infection caused by *Listeria monocytogenes*, transmitted through contaminated food (deli meats, soft cheeses, unpasteurized dairy, produce). Risk groups: pregnant women (fever, flu-like illness), neonates (sepsis, meningitis), immunocompromised, and elderly. Manifestations: febrile gastroenteritis in immunocompetent; bacteremia and meningitis in at-risk. Neonatal: early-onset (sepsis, granulomatosis infantiseptica) and late-onset (meningitis) listeriosis. Diagnosis: blood and CSF culture. Treatment: ampicillin + gentamicin (synergistic); TMP-SMX for PCN-allergic.

Lockjaw (Tetanus)

– See Tetanus.

Lupus Vulgaris

– A chronic, progressive form of cutaneous tuberculosis (TB of the skin) caused by *Mycobacterium tuberculosis*. Once common in Europe, now rare in developed countries but still seen in developing regions. Presents as red-brown, gelatinous plaques (apple-jelly nodules on diascopy) typically on the face (nose, cheeks), which slowly enlarge and ulcerate over years without treatment. Can cause extensive tissue destruction and disfigurement. Diagnosis: skin biopsy (epithelioid granulomas with caseous necrosis), acid-fast stain, mycobacterial cul-

ture, PCR. Treatment: standard anti-TB therapy (isoniazid, rifampicin, ethambutol, pyrazinamide for 2 months, then isoniazid + rifampicin for 4 months).

Lyme Disease

– A tick-borne infection caused by *Borrelia burgdorferi* (*Ixodes scapularis*, deer tick), endemic to the northeastern and upper midwestern US. Early localized: erythema migrans (bullseye rash, >5cm) at tick bite site, fatigue, fever, myalgia. Early disseminated: multiple EM lesions, cranial nerve VII palsy (facial nerve), meningitis, carditis (AV block). Late: arthritis (monoarticular, knee), acrodermatitis chronica atrophicans, encephalopathy. Diagnosis: clinical (EM rash is diagnostic), two-tier serology (ELISA + Western blot). Treatment: doxycycline for early; ceftriaxone IV for neurologic or cardiac involvement. Prevention: tick avoidance, prophylactic doxycycline after high-risk tick bite.

Lymphangitis

– Inflammation of the lymphatic channels, most commonly due to acute bacterial infection spreading from a peripheral wound or cellulitis. The most common causative organism is group A *Streptococcus pyogenes* (90%), followed by *Staphylococcus aureus*. Lymphangitis is a sign that infection is spreading and requires urgent medical attention. Clinical features: visible red, warm, tender linear streaks (lymphangitic streaking) extending proximally from the infected wound towards the draining lymph nodes (e.g., from the hand to the axilla, from the foot to the groin). Associated with: cellulitis, ascending lymphadenitis, fever, chills, malaise, and leukocytosis. The draining lymph nodes may be enlarged and tender (lymphadenitis). Diagnosis: clinical (pathognomonic appearance). Blood cultures may be positive. Complications: sepsis, bacteraemia, necrotising fasciitis (if anaerobes or mixed infection), and abscess formation. Treatment: antibiotics active against *Streptococcus* and *Staphylococcus* (e.g., cephalexin, clindamycin, flucloxacillin, or IV ceftriaxone/vancomycin for severe cases), elevation of the affected limb, warm compresses, analgesics. Surgical drainage if abscess forms. Prevention: prompt wound cleaning and antisepsis.

Malaria

– A life-threatening mosquito-borne disease caused

by *Plasmodium* parasites (*P. falciparum*, *P. vivax*, *P. ovale*, *P. malariae*, *P. knowlesi*), transmitted by *Anopheles* mosquitoes. Presents with cyclical fevers, chills, headache, myalgia, and anemia. Severe *P. falciparum* malaria: cerebral malaria, severe anemia, respiratory distress, and multi-organ failure. Diagnosis: blood smear (thick and thin), rapid diagnostic test. Treatment: artemisinin-based combination therapy (ACT); severe malaria requires IV artesunate. Prevention: insecticide-treated nets, chemoprophylaxis.

Meningococcal Disease

– A bacterial infection caused by *Neisseria meningitidis* (serogroups A, B, C, W, Y), transmitted via respiratory droplets. Meningococcemia: sudden onset fever, petechial/purpuric rash, hypotension, and DIC. Meningococcal meningitis: fever, nuchal rigidity, headache, photophobia. Waterhouse-Friderichsen syndrome: fulminant meningococcemia with bilateral adrenal hemorrhage and septic shock. Diagnosis: blood and CSF culture, Gram stain, PCR. Treatment: IV ceftriaxone urgently; droplet precautions. Chemoprophylaxis for close contacts (rifampin, ciprofloxacin, ceftriaxone). Vaccination: MenACWY and MenB vaccines are available.

Mononucleosis

– An acute viral syndrome caused by Epstein-Barr virus (EBV), primarily affecting adolescents and young adults. Classic triad: fever, pharyngitis/exudative tonsillitis, and cervical lymphadenopathy. Associated with splenomegaly, fatigue, and atypical lymphocytosis. Diagnosis: positive heterophile antibody (Monospot) and EBV serology. Self-limited, supportive care. Avoid contact sports for 3-4 weeks due to splenic rupture risk.

Neonatal Infections

– Early-onset sepsis (EOS, <72h): GBS, *E. coli*, *Listeria*. Risk factors: maternal GBS+, chorioamnionitis, PROM >18h. Kaiser sepsis calculator for management. Late-onset sepsis (LOS, >72h): CoNS, *S. aureus*, gram-negatives, *Candida*. NEC: prematurity, formula feeding, ischemic gut. Pneumatosis intestinalis, portal venous gas. Treatment: NPO, antibiotics (ampicillin + gentamicin/clindamycin + metronidazole), surgery for perforation. HSV: SEM (skin/eye/mouth), CNS, disseminated. Acyclovir 20mg/kg q8h IV x14d (CNS/disseminated)

Nocardiosis

– A bacterial infection caused by *Nocardia* species (*N. asteroides*, *N. brasiliensis*), found in soil. Most common in immunocompromised patients (transplant, HIV, chronic steroid use). Pulmonary nocardiosis (most common): cough, fever, necrotizing pneumonia, cavitary lesions. Disseminated: brain abscesses (most common site), skin and soft tissue abscesses, bacteremia. Cutaneous nocardiosis: cellulitis, abscess, mycetoma after trauma in immunocompetent. Diagnosis: modified acid-fast stain (partially acid-fast), culture (aerobic, grows slowly). Treatment: TMP-SMX (first-line); alternatives: carbapenems, linezolid, amikacin for severe or resistant cases. Prolonged therapy (6-12 months).

Non-Tuberculous Mycobacteria

– NTM: environmental mycobacteria (*M. avium* complex - MAC, *M. kansasii*, *M. abscessus*). Pulmonary NTM: ATS/IDSA criteria (clinical + radiographic + microbiologic: 2+ sputum or 1 BAL + nodules/cavities/bronchiectasis on CT). MAC: nodular bronchiectatic (middle-aged women, "Lady Windermere syndrome") or fibrocavitary (older men, COPD). Treatment: MAC macrolide (azithromycin/clarithromycin) + ethambutol + rifampin x12 months after culture conversion. *M. kansasii* - INH + RIF + EMB x12m post-conversion. *M. abscessus* - macrolide + IV amikacin + imipenem/cefoxitin + oral (clarithromycin) - difficult, often requires surgery. Disseminated MAC: AIDS (CD4 <50), MAC bacteremia, fever, weight loss, anemia. Treatment: clarithromycin/azithromycin + ethambutol + rifabutin; prophylaxis if CD4 <50 (azithromycin 1200mg weekly).

Onchocerciasis

– Also known as river blindness, a parasitic disease caused by the filarial nematode *Onchocerca volvulus*, transmitted by repeated bites of infected blackflies (*Simulium* species) breeding near fast-flowing rivers. Adult worms form subcutaneous nodules (onchocercomata). Microfilariae migrate through skin and eyes, causing intense pruritus, dermatitis, depigmentation (leopard skin), lichenification, and, most importantly, ocular damage leading to blindness (keratitis, iridocyclitis, chorioretinitis, optic atrophy). Diagnosis: skin snip biopsy (microfilariae),

slit-lamp examination of the cornea, PCR. Treatment: ivermectin (annual or semi-annual mass drug administration, kills microfilariae but not adults). No safe, effective macrofilaricide exists.

Opportunistic Infection

– An infection caused by organisms that ordinarily do not cause disease in immunocompetent hosts but cause significant illness when host defences are impaired. Common causative organisms: *Pneumocystis jirovecii* (PCP pneumonia in HIV with CD4 <200/ μ L), *Toxoplasma gondii* (cerebral toxoplasmosis—HIV CD4 <100/ μ L), CMV (retinitis, colitis—HIV CD4 <50/ μ L, post-transplant), *Mycobacterium avium* complex (disseminated—HIV CD4 <50/ μ L), *Cryptococcus neoformans* (meningitis—HIV CD4 <100/ μ L), *Aspergillus fumigatus* (invasive aspergillosis—neutropenia, post-transplant), and *Candida* species (mucocutaneous and invasive—HIV, ICU, neutropenia). Prophylaxis is given based on CD4 thresholds in HIV (cotrimoxazole for PCP/*Toxoplasma*, azithromycin for MAC, fluconazole for *Cryptococcus* in endemic areas). Immune reconstitution inflammatory syndrome (IRIS) can occur when antiretroviral therapy is started in severely immunocompromised HIV patients.

Orchitis

– Inflammation of the testis, often associated with epididymitis (epididymo-orchitis). Causes: infectious—viral (mumps—most common cause of viral orchitis in postpubertal males, typically 4–6 days after parotitis, bilateral in 30%), bacterial (*Escherichia coli*, *Pseudomonas*, sexually transmitted—*Chlamydia trachomatis*, *Neisseria gonorrhoeae*—typically ascending from urethra/epididymis), Coxsackie virus, and rarely tuberculosis. Non-infectious: trauma, autoimmune, and idiopathic. Presentation: acute scrotal pain and swelling, erythema, fever, and nausea. Diagnosis: clinical plus urine dipstick, urine culture, and Doppler ultrasound (increased testicular blood flow distinguishes orchitis from testicular torsion—torsion shows decreased flow). Treatment: antibiotics (ceftriaxone 500 mg IM single dose plus doxycycline 100 mg BD for 14 days for STI; levofloxacin for enteric organisms), NSAIDs, scrotal elevation, and cold packs; mumps orchitis is supportive (analgesia, steroids for severe inflammation).

Complications: abscess, testicular infarction, atrophy, and infertility.

Orf

– A zoonotic viral skin infection caused by the parapoxvirus, transmitted to humans from infected sheep and goats (direct contact with lesions, fomites—virus survives in scabs for months). Orf is an occupational disease of farmers, butchers, and veterinarians. Incubation: 3–7 days. Lesions typically appear on the hands, fingers, or forearms: a single papule at the inoculation site progresses through stages—macule, target (bullseye) lesion, nodule (exudative, weeping), regenerative (dry crust), papillomatous, and regression (resolves over 4–6 weeks without scarring). Lesions may be large (up to 3–5 cm), tender, and occasionally complicated by secondary bacterial infection, lymphangitis, or erythema multiforme. Diagnosis is clinical; electron microscopy of vesicle fluid shows characteristic ovoid virions. Treatment: supportive (hygiene, dressings), no specific antiviral; lesions heal spontaneously. Prevention: gloves during handling of animals with orf lesions, quarantine of infected animals.

Osteomyelitis

– An infection of bone and bone marrow, most commonly caused by bacterial pathogens, with *Staphylococcus aureus* responsible for the majority of cases. It is classified by etiology (hematogenous, contiguous focus, or direct inoculation), duration (acute less than 2 weeks, subacute 2 weeks to 3 months, chronic greater than 3 months), and route. Hematogenous osteomyelitis typically affects the metaphysis of long bones in children (most commonly the femur, tibia, and humerus) and the vertebral bodies in adults (vertebral osteomyelitis).

Outbreak

– Synonymous with epidemic. Sometimes used to refer to a local epidemic as compared to a larger, general epidemic.

Pandemic

– A disease outbreak affecting large populations or a whole region, country, or continent.

Parasite

– An organism that lives on or within a host organism, deriving nutrients at the host's expense. Medical parasites are classified into three main groups: (1) Protozoa—single-celled organisms (Plas-

modium—malaria, *Toxoplasma*—toxoplasmosis, *Giardia*—giardiasis, *Entamoeba histolytica*—amoebic dysentery, *Leishmania*—leishmaniasis, *Trypanosoma*—African sleeping sickness, Chagas disease). (2) Helminths—multicellular worms (nematodes/roundworms—*Ascaris*, hookworm, filariae; cestodes/tapeworms—*Taenia solium*, *Echinococcus*; trematodes/flukes—*Schistosoma*, liver flukes). (3) Ectoparasites—arthropods that infest the skin (scabies mites, lice, fleas, ticks, bed bugs). Parasitic infections disproportionately affect tropical and subtropical regions, causing significant morbidity and mortality (malaria alone causes >600,000 deaths annually). Transmission: vector-borne (mosquitoes, sandflies, ticks), fecal-oral (contaminated water/food), skin penetration (hookworm, *Schistosoma*), and vertical (*Toxoplasma*, malaria). Diagnosis: microscopy (blood films, stool examination, tissue biopsy), serology, antigen detection, and PCR. Treatment: antiparasitic drugs (antimalarials, antihelminthics—albendazole, praziquantel, ivermectin, metronidazole). Prevention: vector control, sanitation, hygiene, and health education.

Parasitic Infections

– Malaria: *Plasmodium* (*falciparum*, *vivax*, *ovale*, *malariae*, *knowlesi*). *Falciparum*: cerebral malaria, severe anemia, ARDS, AKI, hypoglycemia. Diagnosis: thick/thin smear, RDT (HRP2, pLDH),.

Pathogen

– A tiny organism such as a virus, bacterium, or parasite that can invade the body and produce disease.

Pediculus humanus capitis

– A blood-sucking parasite commonly known as the louse (plural, lice) that can cause an itchy scalp; infestations are highly contagious and especially common in school-age children.

Pinworm

– Infection with *Enterobius vermicularis*, the most common helminth infection in developed countries, primarily in school-age children. Lifecycle: ingestion of eggs → larvae hatch in small intestine → adults colonize the cecum/appendix; female migrates to perianal area at night to deposit eggs. Presents with intense perianal itching (especially at night), restless sleep, and secondary bacterial infection from scratching. Diagnosis: scotch tape test (adhesive

tape applied to perianal area in the morning, examined microscopically for eggs). Treatment: albendazole or mebendazole (single dose, repeated after 2 weeks). Treat all household contacts.

Plague

– A bacterial infection caused by *Yersinia pestis*, transmitted by fleas from rodents. Three forms: bubonic (most common, 80-90%): painful, swollen lymph nodes (buboes) after flea bite, fever, chills. Septicemic: bacteremia without bubo, endotoxic shock, DIC, purpura. Pneumonic: primary (inhalation) or secondary (from bubonic spread); fulminant pneumonia with bloody sputum; highly contagious via respiratory droplets. Untreated bubonic mortality 50-60%; pneumonic nearly 100% untreated. Diagnosis: culture, PCR, Gram stain of bubo aspirate. Treatment: streptomycin, gentamicin, doxycycline, or fluoroquinolones. Isolation for pneumonic plague.

Polio

– Abbreviation for poliomyelitis, an acute viral infection caused by poliovirus, an enterovirus of the Picornaviridae family transmitted via the fecal-oral route, primarily affecting children under 5 years of age. The virus replicates in the oropharynx and intestinal mucosa, then invades regional lymph nodes and the bloodstream; in a small proportion of cases (less than 1 percent), it invades the central nervous system and destroys motor neurons in the anterior horn of the spinal cord and brainstem. Most infections (approximately 95 percent) are asymptomatic or cause only mild nonspecific illness (abortive polio), while non-paralytic polio presents with fever, headache, vomiting, and meningismus. Paralytic polio presents with asymmetric acute flaccid paralysis, most commonly affecting the lower extremities, with loss of deep tendon reflexes but preserved sensation; bulbar polio affects the cranial nerves and respiratory center, potentially causing respiratory failure and death. There is no specific antiviral treatment; management is supportive, including physical therapy and respiratory support. Prevention is highly effective through vaccination with inactivated polio vaccine (IPV, Salk vaccine, injected) or oral polio vaccine (OPV, Sabin vaccine, oral). Global polio eradication efforts have reduced cases by over 99 percent since 1988, with wild poliovirus remaining endemic only in Afghanistan and Pakistan.

Poliomyelitis

– An acute viral infection caused by poliovirus (enterovirus), transmitted fecal-orally. Most infections are asymptomatic (95%). Non-paralytic polio: fever, headache, vomiting, and meningismus. Paralytic polio: asymmetric acute flaccid paralysis due to destruction of anterior horn cells; most commonly affects lower extremities. Respiratory paralysis can be fatal. Post-polio syndrome: progressive muscle weakness decades after initial infection. Diagnosis: stool and throat culture, CSF PCR. No antiviral treatment; supportive care. Prevention: IPV (inactivated polio vaccine). Global eradication is near-complete.

Prophylaxis

– Steps taken to prevent a particular disease or condition, such as taking nitroglycerin to prevent angina.

Prostatitis

– An inflammation of the prostate gland, sometimes caused by a bacterial infection, which may result in painful or difficult urination.

Psittacosis

– A zoonotic infection caused by *Chlamydia psittaci*, transmitted from infected birds (parrots, pigeons, poultry) via inhalation of dried bird droppings/secretions. Features: abrupt fever, headache, myalgia, dry cough, atypical pneumonia; complications: hepatitis, myocarditis, meningitis. Diagnosis: exposure history, serology (complement fixation, MIF), PCR. Management: doxycycline (or tetracycline) for 10-14 days; azithromycin alternative; reportable disease. Prevention: precautions with birds, treatment of infected birds.

Pus

– A thick, yellow or green liquid that is composed of dead cells and bacteria, most often found at the site of a bacterial infection.

Pyrexia

– Body temperature $>38^{\circ}\text{C}$ (100.4°F), also known as fever. A regulated rise in body temperature mediated by pyrogens (exogenous: microbial products, endotoxins; endogenous: IL-1, IL-6, TNF, prostaglandin E_2) acting on the hypothalamic thermoregulatory center. Pyrexia is a protective host response (enhances immune function, inhibits pathogen growth), not a disease itself. Fever of unknown origin (FUO): temperature $>38.3^{\circ}\text{C}$ for

>3 weeks without diagnosis despite 3 outpatient visits or 3 inpatient days. Patterns: continuous (typhoid, UTI), intermittent (malaria, sepsis, abscess), relapsing (borreliosis, lymphoma), and Pel-Ebstein (Hodgkin lymphoma). Management: treat underlying cause; antipyretics (paracetamol, NSAIDs) for patient comfort. Fever itself does not require treatment unless >40°C or in vulnerable patients (young children, pregnancy, cardiac disease).

Q Fever

– A zoonotic disease caused by *Coxiella burnetii*, an obligate intracellular Gram-negative bacterium. Q fever is transmitted to humans primarily by inhalation of contaminated aerosols from infected livestock (cattle, sheep, goats) and their products (placenta, birth fluids, urine, feces, milk). Incubation: 2–3 weeks. Acute Q fever: high fever (up to 40°C, may last 1–3 weeks), severe headache, myalgia, arthralgia, fatigue, and atypical pneumonia (cough, chest pain, abnormal chest X-ray). Hepatitis (granulomatous—doughnut granulomas on liver biopsy) is common. Chronic Q fever (<5% of cases): endocarditis (culture-negative, affecting prosthetic and native valves), vascular graft infection, and osteomyelitis. Diagnosis: serology (phase II IgG and IgM—antibodies rise 2–4 weeks after infection; phase I IgG $\geq 1:800$ suggests chronic infection), PCR on blood or tissue during acute illness. Treatment: acute—doxycycline 100 mg BD for 14 days (first-line, shortens fever duration). Chronic—doxycycline plus hydroxychloroquine for ≥ 18 months. Prevention: pasteurisation of milk, biosecurity measures on farms, and veterinary vaccination (phase I vaccine—Coxevac). Q fever is a notifiable disease in many countries. The Netherlands experienced the largest outbreak (2007–2010, >4,000 cases) linked to intensive goat farming.

Quarantine

– A period of time in which a sick person is kept away from others to prevent the spread of disease.

Relapsing Fever

– An acute febrile illness caused by *Borrelia* species, characterized by recurrent episodes of fever separated by afebrile intervals. Two forms: (1) Louse-borne relapsing fever (*Borrelia recurrentis*)—transmitted by the human body louse (*Pediculus humanus corporis*), associated with overcrowd-

ing, poverty, and refugee settings; epidemic potential. (2) Tick-borne relapsing fever (*Borrelia duttonii*, *B. hermsii*, *B. parkeri*)—transmitted by soft ticks (*Ornithodoros*), endemic in Africa, North America, and the Middle East; tends to have more relapses. Pathophysiology: *Borrelia* spirochetes multiply in the blood and cause high fever; the immune system clears the organisms by antibody production, but antigenic variation (variable major proteins—Vmp) allows a new variant to emerge and cause a relapse. Clinical: sudden onset of high fever (39–40°C), rigors, severe headache, myalgia, arthralgia, photophobia, and hepatosplenomegaly. The initial febrile episode lasts 3–6 days, followed by an afebrile period of 7–9 days, then 1–3 relapses (tick-borne) or a single relapse (louse-borne). A petechial rash may be present. Diagnosis: dark-field microscopy of blood smears (spirochetes visible during febrile episodes); PCR. Treatment: doxycycline 100 mg BD for 7–10 days (or tetracycline, erythromycin). Jarisch–Herxheimer reaction (fever, rigors, hypotension) occurs within 2–4 hours of starting antibiotics in 50–90% of patients (especially louse-borne)—pre-treated with IV fluids and antipyretics; severe cases may require hydrocortisone.

River Blindness

– See Onchocerciasis.

Roundworm

– Ascariasis: infection by *Ascaris lumbricoides*, the most common human soil-transmitted helminth, acquired by ingesting eggs from contaminated food/soil. Life cycle: larvae migrate through lungs (pneumonitis, Loeffler syndrome) → adult worms in small intestine (malnutrition, obstruction, biliary colic, intestinal obstruction in heavy infection); worms passed in stool. Diagnosis: stool microscopy (eggs), adult worms. Management: albendazole or mebendazole (single dose); prevention: hygiene, sanitation, and treatment of infected. Distinguish from other roundworms (hookworm, *Strongyloides*, *Trichuris*).

Salmonella

– A genus of Gram-negative, facultatively anaerobic, rod-shaped bacteria in the Enterobacteriaceae family, a major cause of foodborne illness worldwide. Classification: *Salmonella enterica* subsp. *enterica* serovars (>2,500 serovars).

Clinically important serovars: *S. Typhi* and *S. Paratyphi* A, B, C (cause enteric fever—typhoid and paratyphoid fever—systemic illness, humans are the only reservoir, transmitted by fecal–oral route through contaminated food/water), and non-typhoidal *Salmonella* (NTS): *S. Enteritidis* and *S. Typhimurium* (most common—cause self-limited gastroenteritis, transmitted from animals—poultry, eggs, meat, reptiles). Pathogenesis: bacteria invade intestinal epithelial cells (via type III secretion system), survive within macrophages, and cause inflammation. Clinical: NTS gastroenteritis—nausea, vomiting, non-bloody diarrhea (may become bloody), abdominal cramps, fever (self-limiting, 4–7 days). Enteric fever (typhoid)—incubation 7–14 days, prolonged high fever (stepwise rise), headache, malaise, rose spots on trunk, relative bradycardia, hepatosplenomegaly, constipation initially then diarrhea. Complications of typhoid: intestinal perforation and hemorrhage (most feared). Chronic carriers: *S. Typhi* persists in the gallbladder (gallstones) and is shed in stool (Typhoid Mary). Diagnosis: stool culture (gastroenteritis), blood culture (enteric fever—most sensitive in first week), bone marrow culture (gold standard), and Widal test (serology, limited utility). Treatment: NTS gastroenteritis—supportive care (antibiotics not recommended for mild cases; prolongs carriage); severe or immunocompromised—ceftriaxone or azithromycin. Enteric fever—ceftriaxone 2 g IV daily for 10–14 days, azithromycin, or ciprofloxacin (if sensitive). Multidrug-resistant (MDR) and extensively drug-resistant (XDR) *S. Typhi* are emerging (azithromycin and carbapenems for XDR). Prevention: hand hygiene, safe food/water, typhoid vaccines (Vi polysaccharide injectable, Ty21a oral live attenuated).

Scabies

– A contagious skin infestation caused by the mite *Sarcoptes scabiei* var. *hominis*, transmitted by prolonged skin-to-skin contact. The female mite burrows into the stratum corneum, laying eggs, causing intense pruritus (worse at night) and a papular erythematous rash. Typical distribution: interdigital finger webs, wrists, elbows, axillae, waist, genitalia (spares the face in adults). Burrows appear as greyish, serpiginous lines. Crusted (Norwegian) scabies

occurs in immunocompromised patients. Diagnosis: clinical, confirmed by microscopy of scrapings from burrows (mite, eggs, feces). Treatment: permethrin 5% cream (two applications, 1 week apart) or oral ivermectin. Treat all close contacts.

Sepsis

– The destruction or infection of tissues by disease-causing organisms, usually accompanied by a fever.

Sepsis Syndrome

– The spectrum of the host's dysregulated response to infection: sepsis (infection + organ dysfunction, SOFA increase ≥ 2), septic shock (sepsis + hypotension requiring vasopressors with lactate >2 mmol/L despite adequate fluid), and severe organ dysfunction/multi-organ failure. Features: fever/hypothermia, tachycardia, tachypnea, hypotension, altered mental status, raised lactate, elevated inflammatory markers. Management (Surviving Sepsis): early recognition, cultures before antibiotics, broad-spectrum antibiotics within 1 hour, IV fluids (30 mL/kg), vasopressors (norepinephrine), source control, and lactate-guided resuscitation; monitor organ function in ICU. High mortality.

Septicaemia

– See Sepsis.

Septicemia

– A condition in which disease-causing organisms have spread to the bloodstream from an infection elsewhere in the body. Also known as blood poisoning.

Sexually Transmitted Infections (STIs)

– Sexually transmitted infections are infections passed from one person to another through sexual contact, including vaginal, anal, and oral sex. Common STIs include chlamydia, gonorrhea, syphilis, herpes simplex virus, human papillomavirus, and HIV. Many STIs can be asymptomatic, making regular screening essential for sexually active individuals; treatment varies by infection, with bacterial STIs being curable with antibiotics, while viral STIs are managed with antiviral medications to reduce symptoms and transmission risk.

Shingles

– Herpes zoster: reactivation of varicella-zoster virus (VZV) from dorsal root ganglia, causing a painful, unilateral vesicular rash in a dermatomal distribu-

tion ('belt-like'), often preceded by burning pain. Risk increases with age and immunosuppression. Complications: postherpetic neuralgia (persistent pain), ophthalmic zoster (eye involvement—Ramsay Hunt syndrome with facial palsy if geniculate), disseminated disease, bacterial superinfection. Diagnosis: clinical; PCR/DFA of lesions. Management: antivirals (acyclovir, valacyclovir, famciclovir) within 72 h reduce duration and neuralgia; analgesics including gabapentin/amitriptyline; zoster vaccine (Shingrix) for prevention. Contagious to VZV-naïve contacts (causes chickenpox).

Smallpox

– A highly contagious and deadly disease caused by variola virus, eradicated globally by 1980 through vaccination. Characterized by febrile prodrome followed by vesicular/pustular rash (centrifugal distribution, all lesions at same stage). Last known natural case: 1977. Bioterrorism concern due to stored virus in WHO-approved laboratories. Diagnosis: PCR, electron microscopy. No proven treatment; supportive care. Vaccination within 3-4 days of exposure can prevent disease.

Staph Infection

– Infections caused by *Staphylococcus aureus* (and coagulase-negative staphylococci), a gram-positive coccus in clusters. Skin/soft tissue (boils, cellulitis, abscess, impetigo), bacteremia, infective endocarditis, osteomyelitis, septic arthritis, pneumonia (post-influenza), toxic shock syndrome (TSST superantigen), food poisoning (enterotoxin), and device infections. MRSA (methicillin-resistant) is a major concern—community and hospital associated. Diagnosis: culture and sensitivity. Management: incision and drainage of abscesses, antibiotics (flucloxacillin/cefazolin for MSSA; vancomycin/daptomycin/linezolid for MRSA), treat endocarditis with prolonged therapy and source control; decolonization strategies.

Staphylococcal Infection

– Infections caused by *Staphylococcus aureus* and other staphylococci. Manifestations range from superficial skin infections (folliculitis, furuncles, carbuncles, impetigo) to deep-seated infections (osteomyelitis, septic arthritis, endocarditis, pneumonia, bacteremia, sepsis). Methicillin-resistant *S. aureus* (MRSA) is a major healthcare and community-

associated pathogen. Treatment: beta-lactams for MSSA, vancomycin for MRSA; incision and drainage for abscesses.

Streptococcal Infection

– Infections caused by *Streptococcus pyogenes* (Group A Strep, GAS). Common presentations: pharyngitis (strep throat), scarlet fever (pharyngitis with erythematous rash), impetigo, cellulitis, and necrotizing fasciitis. Immune-mediated complications: acute rheumatic fever (can cause rheumatic heart disease) and post-streptococcal glomerulonephritis. Diagnosis: rapid antigen test, throat culture. Treatment: penicillin or amoxicillin. Prevention of rheumatic fever requires adequate treatment of GAS pharyngitis.

Strongyloidiasis

– Infection with *Strongyloides stercoralis*, a unique helminth capable of autoinfection. Most infections asymptomatic or mild (abdominal pain, diarrhea, urticaria). Larvae migration causes larva currens (rapidly migrating serpiginous rash, perianal). Hyperinfection syndrome: life-threatening in immunocompromised (HIV/HTLV-1, corticosteroids, transplant), leading to massive larval dissemination with Gram-negative bacteremia, meningitis, and respiratory failure. Diagnosis: stool microscopy (Baermann technique, agar plate culture), serology. Treatment: ivermectin (first-line); albendazole as alternative. Screening and treatment before immunosuppression is critical.

Swine Flu

– See Influenza.

Systemic Inflammatory Response Syndrome

– SIRS: a systemic inflammatory response defined by two or more of: temperature $>38^{\circ}\text{C}$ or $<36^{\circ}\text{C}$, heart rate >90 , respiratory rate >20 or $\text{PaCO}_2 <32$ mmHg, WBC $>12,000$ or $<4,000$ or >10 percent bands. May result from infection (sepsis), trauma, burns, pancreatitis, surgery, or other insults. Historically used to define sepsis; now largely superseded by sepsis-3 criteria (SOFA, qSOFA) which emphasize organ dysfunction. SIRS criteria are sensitive but nonspecific; still used in pediatric definitions and bedside screening. Management: identify and treat the trigger, support organ function.

Taeniasis (Tapeworm Infection)

– Intestinal infection caused by adult tapeworms of the genus *Taenia* (cestodes). Two important species: *Taenia solium* (pork tapeworm) and *Taenia saginata* (beef tapeworm). Transmission: ingestion of undercooked meat containing cysticerci (larval cysts). Adult tapeworms attach to the small intestinal wall via scolex (armed with hooks in *T. solium*, suckers only in *T. saginata*) and produce proglottids (segments) containing eggs. Clinical: often asymptomatic; may cause mild abdominal discomfort, nausea, weight loss, increased appetite, and passage of proglottids in stool. Diagnosis: stool microscopy (eggs, proglottids—*T. solium* eggs are indistinguishable from *T. saginata*; species identified by uterine branching in gravid proglottids), perianal tape test. Treatment: praziquantel (5–10 mg/kg single dose) or niclosamide. Complications: *T. solium* can cause neurocysticercosis (ingestion of eggs from autoinfection or contaminated food/water)—larval cysts in the brain cause seizures, hydrocephalus, and focal neurological deficits. Prevention: thorough cooking of meat, improved sanitation, and meat inspection.

Tapeworm

– Cestode infection: segmented flatworms (tapeworms) transmitted by ingestion of larvae (pork—*Taenia solium*; beef—*Taenia saginata*; fish—*Diphyllobothrium latum*, causing B12 deficiency) or eggs (*Echinococcus*—hydatid cysts; *Hymenolepis*). Intestinal tapeworm: abdominal discomfort, passage of proglottids in stool; *T. solium* eggs cause cysticercosis (neurocysticercosis—seizures, intracranial cysts). Diagnosis: stool ova/parasite examination (proglottids, eggs), serology, imaging for cysticercosis/hydatid. Management: praziquantel (or niclosamide) for intestinal forms; albendazole ± surgery for cysticercosis and hydatid; prevention: thorough cooking of meat/fish, sanitation.

Tapeworm Infection

– See Taeniasis (Tapeworm Infection).

Tetanus

– An acute neurological disease caused by tetanospasmin toxin from *Clostridium tetani*, introduced through wounds. Characterized by generalized rigidity and painful muscle spasms (trismus/lockjaw, risus sardonicus, opisthotonos). Autonomic instability can occur in severe cases. Diagnosis: clinical.

cal. Treatment: human tetanus immune globulin (HTIG), wound debridement, metronidazole, and supportive care (benzodiazepines, ICU). Prevention: Tdap/Td vaccination at recommended intervals.

Threadworm (Enterobiasis)

– A common intestinal parasitic infection caused by *Enterobius vermicularis* (pinworm). Prevalence: most common helminth infection in developed countries, primarily affecting children aged 5–10 years. Transmission: fecal–oral (ingestion of eggs from contaminated hands, food, bedding, or fomites). Eggs are deposited in the perianal region by the female worm at night, causing intense perianal itching (pruritus ani), especially at night. Scratching contaminates fingers and nails, perpetuating the cycle. Diagnosis: perianal tape test (apply transparent adhesive tape to the perianal area in the morning before bathing, examined under microscope for eggs). Stool microscopy has low sensitivity. Treatment: mebendazole 100 mg single dose (or albendazole 400 mg single dose), repeated after 2 weeks (to kill newly hatched worms). All household members should be treated simultaneously. Good hand hygiene, short nails, frequent washing of bedding and pyjamas, and avoidance of scratching. Reinfection is common. Complications: vulvovaginitis (in girls), occasional appendicitis (worm in the appendix).

Tinea

– Dermatophytosis: superficial fungal infection of keratinized tissue (skin, hair, nails) by dermatophytes (*Trichophyton*, *Microsporum*, *Epidermophyton*). Types by site: tinea corporis (body—ringworm), tinea pedis (athlete's foot), tinea cruris (jock itch), tinea capitis (scalp—most common in children), tinea unguium/onychomycosis (nails), tinea manuum, tinea faciei. Features: annular erythematous scaly plaque with central clearing and active border. Diagnosis: clinical, KOH preparation, culture, or PCR. Management: topical antifungals (terbinafine, clotrimazole, miconazole) for most; oral terbinafine/griseofulvin for tinea capitis and nail infection; hygiene measures to prevent spread.

Toxic Shock Syndrome

– An acute, life-threatening illness caused by bacterial exotoxins. Staphylococcal TSS: associated with tampon use, surgical wounds, and nasal packing; presents with fever, hypotension, diffuse rash,

and multi-organ involvement. Streptococcal TSS: associated with invasive GAS infections. Diagnosis: CDC case definition. Treatment: source control, IV fluids, vasopressors, and antibiotics (clindamycin + a beta-lactam for Strep; vancomycin for MRSA). IVIG may be beneficial.

Toxocariasis

– Infection by dog roundworm (*Toxocara canis*) or cat (*T. cati*), acquired by ingesting infective eggs from soil contaminated by animal feces (pica in children a risk). Larvae do not mature in humans but migrate (visceral larva migrans—fever, hepatomegaly, eosinophilia, pulmonary symptoms) or cause ocular larva migrans (granuloma in the eye, vision loss, strabismus). Diagnosis: clinical, eosinophilia, ELISA serology (*Toxocara* antibodies); eye examination. Management: albendazole or mebendazole ± corticosteroids (ocular/visceral severe); prevention: deworm pets, hygiene, prevent pica.

Toxoid vaccines

– Vaccines that protect against harmful bacterial toxins. These vaccines contain toxins that have been detoxified and rendered inactive.

Toxoplasmosis

– Infection caused by the intracellular protozoan *Toxoplasma gondii*. Definitive host: cats (shed oocysts in feces). Humans are intermediate hosts, infected via ingestion of undercooked meat (containing tissue cysts), cat feces, or transplacentally. Immunocompetent: usually asymptomatic or mild flu-like illness with lymphadenopathy. Immuno-compromised (HIV, transplant): toxoplasma encephalitis (brain abscesses, headache, confusion, seizures, focal neurology), myocarditis, pneumonitis. Congenital toxoplasmosis: infection in pregnancy can cause chorioretinitis, intracranial calcifications, hydrocephalus, and developmental delay. Diagnosis: serology (IgM, IgG, PCR), imaging (CT/MRI). Treatment: pyrimethamine + sulfadiazine + folinic acid.

Trachoma

– A chronic keratoconjunctivitis caused by *Chlamydia trachomatis* (serovars A-C), the leading infectious cause of blindness worldwide. Repeated infection causes conjunctival scarring, trichiasis (in-turned eyelashes), corneal abrasion, opacification, and blindness. Transmission: direct contact, flies,

fomites. Active trachoma: follicular conjunctivitis, papillary hypertrophy. Cicatricial trachoma: scarring, entropion, trichiasis. Diagnosis: clinical WHO grading system. Treatment: SAFE strategy (Surgery for trichiasis, Antibiotics: azithromycin mass drug administration, Facial cleanliness, Environmental improvement). Global elimination program is ongoing.

Travel Medicine

– Pre-travel consultation: vaccines (routine, hepatitis A/B, typhoid, yellow fever, meningococcal, rabies pre-exposure, Japanese encephalitis, cholera), malaria prophylaxis (atovaquone-proguanil daily, doxycycline daily, mefloquine weekly, tafenoquine).

Trichinosis

– A parasitic infection caused by *Trichinella spiralis*, acquired by eating undercooked pork or wild game (bear, boar) containing encysted larvae. Larvae are released in the intestine (enteric phase: diarrhea, abdominal pain), then migrate to skeletal muscle (parenteral phase: myositis, periorbital edema, fever, eosinophilia). Classic presentation: periorbital edema + myalgia + eosinophilia after eating undercooked meat. Diagnosis: serology (ELISA, Western blot), muscle biopsy. Treatment: albendazole or mebendazole (enteric phase); corticosteroids for severe myositis.

Trichomonas

– A protozoan parasite, *Trichomonas vaginalis*, causing trichomoniasis—the most common non-viral sexually transmitted infection worldwide (156 million cases annually). *T. vaginalis* is a flagellated, motile protozoan that infects the urogenital tract. Transmission: sexual intercourse. Incubation: 4–28 days. Clinical: women—vaginal discharge (frothy, yellow-green, malodorous), vulvovaginal itching, dysuria, dyspareunia, punctate cervical haemorrhages ('strawberry cervix' on colposcopy). Men—often asymptomatic (70%), may cause urethritis (thin, white discharge), balanitis, prostatitis. Complications: preterm birth, low birth weight, and increased HIV acquisition/transmission. Diagnosis: wet mount microscopy (motile trichomonads, sensitivity 60–70%), culture, nucleic acid amplification test (NAAT—gold standard, sensitivity >95%). Treatment: metronidazole 2 g PO single dose (or tinidazole). Treat sexual partners. Metronidazole

resistance occurs in 5–10% (treat with higher dose or tinidazole). Avoid alcohol during and for 24 hours after treatment (disulfiram-like reaction).

Trichomoniasis

– A sexually transmitted infection caused by the protozoan *Trichomonas vaginalis*. Often asymptomatic in men; women present with vaginal discharge (frothy, yellow-green, malodorous), itching, dysuria, and inflammation. Associated with preterm birth and increased HIV acquisition risk. Diagnosis: wet mount microscopy, culture, NAAT. Treatment: metronidazole or tinidazole (single dose) for patient and partner(s).

Trypanosomiasis

– Two forms: African trypanosomiasis (sleeping sickness, transmitted by tsetse fly, caused by *Trypanosoma brucei gambiense* – chronic West African form, or *T. b. rhodesiense* – acute East African form) and American trypanosomiasis (Chagas disease, transmitted by triatomine bugs, caused by *Trypanosoma cruzi*). Clinical features: African – chancre at bite site, fever, lymphadenopathy (Winterbottom sign), headache, followed by meningoencephalitis (sleep disturbance, neurological deterioration, coma). Chagas disease: acute phase (fever, Romana sign – unilateral periorbital edema), chronic phase (cardiomyopathy, megaoesophagus, megacolon decades later). Diagnosis: microscopy of blood/CSF, serology, PCR. Treatment: African – pentamidine/suramin (early), melarsoprol/eflornithine (late). Chagas – benznidazole, nifurtimox.

Tuberculosis

– TB: *Mycobacterium tuberculosis*, airborne transmission. Primary TB: Ghon focus + hilar lymphadenopathy (Ghon complex). Reactivation TB: apical/posterior upper lobe cavitory lesions. Clinical: cough >2 weeks, fever, night sweats, weight loss, hemoptysis. Diagnosis: AFB smear (3 sputums, sensitivity 50–60).

Tuberculosis (TB)

– A chronic infection caused by *Mycobacterium tuberculosis*, transmitted by airborne droplets; pulmonary TB is most common, extrapulmonary forms occur (lymph node, pleural, meningeal, miliary, skeletal, renal). Features: chronic cough (>3 weeks), hemoptysis, fever, night sweats, weight

loss; Ghon complex, apical cavitation on imaging. Diagnosis: sputum smear/culture, nucleic acid amplification (GeneXpert), IGRA/TST (latent), CXR. Treatment: RIPE (rifampicin, isoniazid, pyrazinamide, ethambutol) 2 months + rifampicin/isoniazid 4 months (6-month total); MDR/XDR requires second-line agents. Latent TB: isoniazid or rifampicin prophylaxis. Directly observed therapy and infection control are key.

Tularemia

– A zoonotic bacterial infection caused by *Francisella tularensis*, transmitted through tick bites, handling infected animals (rabbits, rodents), contaminated water, or aerosolization. Ulceroglandular (most common): ulcer at inoculation site + tender lymphadenopathy. Other forms: glandular (lymphadenopathy only), oculoglandular (conjunctivitis + preauricular adenopathy), oropharyngeal (pharyngitis), typhoidal (fever without localizing signs), pneumonic (cough, chest pain). Diagnosis: serology, PCR, culture (biohazard). Treatment: streptomycin, gentamicin, doxycycline, or ciprofloxacin.

Typhus

– A group of acute febrile illnesses caused by *Rickettsia* species, transmitted by arthropod vectors. Three main forms: (1) Epidemic (louse-borne) typhus—*Rickettsia prowazekii*, transmitted by the human body louse (*Pediculus humanus corporis*). Associated with overcrowding, poverty, cold climate, and refugees ('war typhus'). Incubation 10–14 days. Clinical: sudden high fever, severe headache, myalgia, prostration, a macular rash starting in the axillae and spreading to the trunk (spares face, palms, soles), and meningismus. Mortality 10–60% without treatment (highest in older, malnourished patients). Brill-Zinsser disease: reactivation of latent *R. prowazekii* years after primary infection, milder. (2) Endemic (murine/flea-borne) typhus—*Rickettsia typhi*, transmitted by rat fleas (*Xenopsylla cheopis*). Milder than epidemic typhus; rash is maculopapular, centripetal. (3) Scrub typhus (*tsutsugamushi* disease)—*Orientia tsutsugamushi* (formerly *Rickettsia tsutsugamushi*), transmitted by chigger mites (*Leptotrombidium*). Endemic in the Asia-Pacific region ('tsutsugamushi triangle'). An eschar (tache noire) at the bite site is characteristic. Diagnosis: serology (IFA—gold standard; Weil-Felix test is ob-

solete), PCR on blood or eschar biopsy. Treatment: doxycycline 100 mg BD for 7–14 days (first-line). Azithromycin and chloramphenicol are alternatives (pregnancy, doxycycline allergy). Prevention: louse control (epidemic typhus—delousing with insecticides, improved hygiene), flea control (endemic typhus—rodent control), mite avoidance (scrub typhus—insect repellent DEET, protective clothing). No vaccine is currently available for typhus.

Undulant Fever

– See Brucellosis.

Urinary Tract Infection

– Infection of the urinary tract, classified as lower (cystitis, urethritis) or upper (pyelonephritis). Most common pathogen: *Escherichia coli* (80%). Cystitis: dysuria, urinary frequency, urgency, suprapubic pain. Pyelonephritis: fever, flank pain, nausea/vomiting, costovertebral angle tenderness. Complicated UTI: structural/functional abnormality, catheter, pregnancy, male sex, immunocompromised. Diagnosis: urinalysis with nitrites and leukocyte esterase, urine culture. Treatment: TMP-SMX, nitrofurantoin, fosfomycin for uncomplicated; fluoroquinolones or cephalosporins for complicated/pyelonephritis.

Urinary Tract Infections

– UTI: significant bacteriuria ($>10^5$ CFU/mL) with symptoms. Uncomplicated cystitis: women, dysuria, frequency, urgency, suprapubic pain. Nitrite/leukocyte esterase dipstick. Pathogens: *E. coli* (75–90).

Urinary Tract Infections (UTIs)

– Urinary tract infections are bacterial infections affecting any part of the urinary system, including the urethra, bladder, ureters, and kidneys. They are much more common in women due to the shorter urethra, and typical symptoms include urinary urgency, frequency, dysuria, and suprapubic pain, while upper tract infections may cause flank pain, fever, and systemic illness. Diagnosis is confirmed by urinalysis and culture, and treatment involves antibiotic therapy tailored to the causative organism, with a emphasis on adequate hydration and preventive measures.

UTI

– See Urinary Tract Infection.

Varicella

– Varicella-zoster virus (VZV) infection: primary infection causes chickenpox, characterized by a generalized vesicular rash (macules → papules → vesicles → crusts, 'dew drops on a rose petal'), fever, and malaise; highly contagious. Complications: bacterial superinfection (impetigo, cellulitis), pneumonia (adults, immunocompromised), encephalitis, Reye syndrome (with aspirin), congenital varicella syndrome (pregnancy), and neonatal varicella. Diagnosis: clinical; PCR of vesicle fluid. Management: supportive; acyclovir for adolescents/adults, immunocompromised, and severe disease; varicella vaccine prevents disease; varicella-zoster immunoglobulin (VZIG) for post-exposure prophylaxis in high-risk. Reactivation causes herpes zoster (shingles).

Variola

– See Smallpox.

Venereal Diseases

– See Sexually Transmitted Infections (STIs).

Viral Infections

– Illnesses caused by viruses, which are intracellular pathogens that hijack host cellular machinery to replicate. They range from self-limited conditions such as the common cold and gastroenteritis to serious diseases including influenza, hepatitis, HIV, and COVID-19. Treatment is primarily supportive for most viral infections, though antiviral medications are available for specific viruses, and vaccination remains the most effective strategy for preventing many viral diseases.

Weil's Disease

– See Leptospirosis.

West Nile Virus

– A mosquito-borne flavivirus, endemic in the US, Africa, Europe, and Asia. Most infections (80%) are asymptomatic. West Nile fever (20%): fever, headache, myalgia, arthralgia, rash. Neuroinvasive disease ($<1\%$): meningitis, encephalitis, acute flaccid paralysis (anterior horn cell involvement). Risk factors for severe disease: age >50 , immunosuppression, diabetes, hypertension. Diagnosis: serum/CSF WNV IgM, RT-PCR. No specific antiviral; supportive care. Prevention: mosquito avoidance and vector control.

Whipworm (Trichuriasis)

– Intestinal infection caused by the soil-transmitted helminth *Trichuris trichiura* (whipworm), endemic

in tropical and subtropical regions with poor sanitation. Humans acquire infection by ingesting embryonated eggs from contaminated soil, food, or water. Larvae hatch in the small intestine and migrate to the large intestine (caecum and colon), where adult worms (3-5 cm) embed their anterior ends into the mucosa. Light infections are often asymptomatic. Heavy infections cause abdominal pain, diarrhea (sometimes bloody), tenesmus, rectal prolapse (especially in children with massive worm burden), anemia (iron-deficiency from chronic blood loss), and growth retardation. Whipworm potentiates the severity of other infections (malaria, bacterial dysentery). Diagnosis: microscopic identification of characteristic bipolar-plugged eggs in stool (Kato-Katz technique, sedimentation). Treatment: albendazole (400 mg daily for 3 days) or mebendazole (100 mg twice daily for 3 days); ivermectin is less effective alone but synergistic in combination. Mass drug administration (MDA) with albendazole targets whipworm in deworming programmes. Prevention: improved sanitation, hand washing, and avoiding soil-contaminated food.

Yaws (Frambesia)

– A chronic, non-venereal treponematoses caused by *Treponema pallidum* subspecies *pertenue*, closely related to the syphilis spirochete (*T. pallidum pallidum*). Yaws is endemic in warm, humid tropical regions of Africa, Southeast Asia, and the Pacific Islands, affecting primarily children aged 2-15 years living in rural, resource-limited areas. Transmission: direct skin-to-skin contact with an infectious lesion (abrasion, cut, or insect bite), not sexually transmitted and not vertically transmitted. Yaws is classified into stages based on clinical progression: primary yaws (mother yaw): a single, painless, papillomatous papule at the inoculation site (typically on the lower extremities, buttocks, or face) that enlarges into a raspberry-like lesion (frambesia, from French framboise = raspberry) with a characteristic yellow crust; heals spontaneously over 3-6 months, leaving a hypopigmented scar. Secondary yaws (disseminated): occurs weeks to months after the primary lesion, consisting of multiple, painless, papillomatous or ulcerated lesions (daughter yaws) on the trunk, extremities, perioral and perianal areas; hyperkeratosis of the palms and soles (crab

yaws or dry yaws — painful, fissured hyperkeratotic plaques causing a crab-like gait), periostitis, and lymphadenopathy. Late/latent yaws: occurs in 10% of untreated individuals, after 5-10 years of latency, causing destructive gummatous lesions of the skin and bones (gondou/bossed nose — hypertrophic periostitis of the maxilla), palatal and nasopharyngeal destruction (gangosa/rhinopharyngitis mutilans — destructive ulceration of the nose, palate, and pharynx), and juxta-articular nodules. Diagnosis: dark-field microscopy of serous exudate from early lesions shows motile spirochetes; serology (VDRL, RPR, TPHA, FTA-ABS — identical to syphilis, cannot distinguish between *T. pallidum* subspecies). Treatment: single-dose intramuscular benzathine penicillin G (1.2 million units for adults, 0.6 million units for children <10 years) is highly effective (>95% cure rate). Alternative: oral azithromycin (single 30 mg/kg dose, maximum 2 g) — azithromycin-based mass drug administration (MDA) is the cornerstone of the WHO yaws eradication campaign. Prevention: MDA, improved hygiene, and contact tracing.

Yellow Fever

– A mosquito-borne viral hemorrhagic fever caused by yellow fever virus (Flavivirus), endemic in tropical Africa and South America. Incubation 3-6 days. Presents with fever, myalgia, headache, and vomiting. A proportion of patients progress to toxic phase with jaundice, hemorrhagic fever, and multi-organ failure (hepatorenal). Case fatality rate 20-60% in severe cases. Diagnosis: RT-PCR, serology. No specific antiviral treatment; supportive care. Prevention: live-attenuated yellow fever vaccine (highly effective, required for travel to endemic areas).

Yersinia Enterocolitica

– A gram-negative coccobacillus of the family Enterobacteriaceae, a common cause of enterocolitis and mesenteric lymphadenitis, especially in children and young adults in temperate climates. Transmission: ingestion of contaminated food (undercooked pork — the most common source, unpasteurised milk, contaminated water), direct contact with infected animals (pigs are the primary reservoir), and person-to-person spread (rare). Pathogenicity: *Y. enterocolitica* carries a 70-kb virulence plasmid (pYV) encoding a type III secretion system (T3SS, injectisome) that injects Yersinia outer pro-

teins (Yops) into host cells, disrupting actin cytoskeleton, inhibiting phagocytosis, and triggering apoptosis of macrophages. Clinical: acute enterocolitis (watery or bloody diarrhea, fever, abdominal pain, vomiting, most common in young children, self-limited over 5-14 days), pseudoappendicitis syndrome (mesenteric lymphadenitis and terminal ileitis mimicking acute appendicitis — fever, right lower quadrant pain, leukocytosis, common in older children and adolescents), and post-infectious complications (reactive arthritis, erythema nodosum, and uveitis, associated with HLA-B27). Diagnosis: stool culture (requires selective media — cefsulodin-irgasan-novobiocin/CIN agar), serology (antibodies to *Yersinia* antigens). Treatment: self-limited in immunocompetent patients; supportive care (rehydration) is the mainstay. Antibiotics are indicated for severe, prolonged, or invasive infections and immunocompromised patients: doxycycline + aminoglycoside, TMP-SMX, fluoroquinolones (ciprofloxacin), or third-generation cephalosporins (ceftriaxone). *Y. enterocolitica* produces beta-lactamase and is resistant to ampicillin, amoxicillin, and first-generation cephalosporins.

Zika

– Zika virus: a mosquito-borne (*Aedes*) flavivirus, also sexually transmitted. Usually asymptomatic or mild (fever, rash, conjunctivitis, arthralgia). Major concern: congenital Zika syndrome if acquired in pregnancy—microcephaly, brain abnormalities, eye defects; also Guillain-Barré syndrome. Diagnosis: RT-PCR (acute), IgM serology (cross-reacts with dengue); travel history. Management: supportive (no specific antiviral); prevention: mosquito avoidance, condoms, and travel advice for pregnant women; no vaccine widely available. Surveillance and vector control are central.

Zoonoses

– Infectious diseases that are naturally transmitted between vertebrate animals and humans. Zoonotic infections account for approximately 60% of all human infectious diseases and 75% of emerging infectious diseases (including HIV, SARS, MERS, Ebola, Nipah, and COVID-19). Classification by transmission route: direct zoonoses (transmission by direct contact — rabies from animal bites, anthrax from handling infected animal products), vector-

borne zoonoses (transmitted by arthropod vectors — Lyme disease/*Borrelia* from ticks, West Nile fever from mosquitoes, plague/*Yersinia pestis* from fleas), food-borne zoonoses (ingestion of contaminated animal products — salmonellosis from eggs/poultry, campylobacteriosis from undercooked poultry, brucellosis from unpasteurised dairy, toxoplasmosis from undercooked meat), and water-borne zoonoses (leptospirosis from water contaminated with rodent urine). Reservoir hosts: mammals (rodents — hantavirus, plague, leptospirosis; bats — rabies, Nipah, Hendra, Ebola, Marburg, SARS, MERS; primates — HIV, yellow fever, monkeypox; pigs — influenza, Nipah, Japanese encephalitis), birds (avian influenza, West Nile virus, psittacosis), and arthropods (ticks, mosquitoes, fleas). One Health approach: integrates human health, animal health, and environmental health for surveillance, prevention, and control of zoonotic infections. Prevention: animal vaccination (rabies in dogs, brucellosis in cattle), vector control (mosquito nets, insect repellents, insecticide spraying, environmental management), food safety (pasteurisation, thorough cooking), personal protective equipment (for veterinarians, slaughterhouse workers, laboratory personnel), and surveillance of both animal and human populations for early detection of emerging zoonoses., endemic in tropical and subtropical regions with poor sanitation. Humans acquire infection by ingesting embryonated eggs from contaminated soil, food, or water. Larvae hatch in the small intestine and migrate to the large intestine (caecum and colon), where adult worms (3-5 cm) embed their anterior ends into the mucosa. Light infections are often asymptomatic. Heavy infections cause abdominal pain, diarrhea (sometimes bloody), tenesmus, rectal prolapse (especially in children with massive worm burden), anemia (iron-deficiency from chronic blood loss), and growth retardation. Whipworm potentiates the severity of other infections (malaria, bacterial dysentery). Diagnosis: microscopic identification of characteristic bipolar-plugged eggs in stool (Kato-Katz technique, sedimentation). Treatment: albendazole (400 mg daily for 3 days) or mebendazole (100 mg twice daily for 3 days); ivermectin is less effective alone but synergistic in combination. Mass drug administration (MDA) with albendazole targets whipworm in deworming programmes. Prevention: improved sanita-

tion, hand washing, and avoiding soil-contaminated food.

Chapter 18

Medical Implants

Artificial Ventricle (Total Artificial Heart)

– A pulsatile, pneumatically or electrically driven biventricular replacement that removes the native ventricles. The SynCardia temporary Total Artificial Heart (TAH-t) is FDA-approved as a bridge to cardiac transplantation. The Carmat TAH is a bioprosthetic option available in Europe. Indications: severe biventricular failure, massive myocardial infarction, and end-stage heart disease when a donor heart is unavailable. Implantation involves full median sternotomy, cardiopulmonary bypass, and excision of the native ventricles. Pneumatic drivers (Big Blue, Companion 2) power the system externally. Complications: stroke, bleeding, infection (mediastinitis, driveline site), hemolysis, and device malfunction. Longest survival: >4 years as bridge to transplant.

BAC (Bone Anchored Cochlear) – See Bone-Anchored Hearing Aid (BAHA)

– An auditory implant that uses a titanium screw implanted in the temporal bone behind the ear with a sound processor attached. The implant bypasses the outer and middle ear by conducting sound through bone directly to the cochlea. Widely known as BAHA (Bone-Anchored Hearing Aid). The modern term is BCI (Bone Conduction Implant).

BAHA (Bone-Anchored Hearing Aid)

– A surgically implantable bone conduction hearing system. Components: a titanium abutment (fixture) placed in the mastoid bone, and an external sound processor that clips onto the abutment. The fixture osseointegrates with bone (takes 3-12 weeks). Indications: conductive hearing loss (chronic otitis

media, aural atresia, otosclerosis), mixed hearing loss, and single-sided deafness (SSD). Contraindications: poor bone quality, uncontrolled diabetes, prior radiation to the temporal bone, and age <5 years. The Cochlear Baha system and Oticon Medical Ponto are the major brands. Complications: skin infection (peri-abutment dermatitis, most common), fixture failure (loss of osseointegration), and soft tissue overgrowth. Implant survival: >95% at 5 years.

Biodegradable Stent (Bioresorbable Stent)

– A coronary stent made of a bioabsorbable material (poly-L-lactic acid, magnesium alloy) that gradually dissolves over 2-3 years, theoretically restoring vascular vasomotion and avoiding the long-term risks of permanent metallic stents (e.g., late stent thrombosis, neoatherosclerosis). The Absorb BVS (Abbott) was the first FDA-approved bioresorbable stent but was withdrawn due to higher target lesion failure and scaffold thrombosis rates compared to drug-eluting stents. Second-generation scaffolds (e.g., Magmaris magnesium stent, Fantom sirolimus-eluting scaffold) aim to improve outcomes. Complications: scaffold thrombosis (higher than DES, especially in small vessels), malapposition, and fracture. Current use: selective, in clinical trials or specific anatomical settings.

Bone Graft (Implantable)

– Natural or synthetic bone material implanted to promote bone healing, fill defects, or achieve spinal fusion. Types: autograft (from the patient — iliac crest, fibula, rib, distal radius — the gold standard for osteogenesis, osteoconduction, and osteoinduction), allograft (cadaveric — cortical strut, cancellous chips, demineralized bone matrix DBM),

synthetic (calcium phosphate hydroxyapatite, tricalcium phosphate, bioactive glass, calcium sulfate), and growth factor-enhanced (BMP-2 on an absorbable collagen sponge, e.g., Infuse Bone Graft). Formulations: putty, paste, granules, sheets, and structural blocks. Autograft limitations: donor site morbidity (pain, infection, hematoma, fracture) and limited quantity. Allograft risks: infection (very low with modern processing), and fracture. DBM: osteoinductive but inconsistent quality. BMP-2: potent but associated with ectopic bone formation, radiculitis, and cancer risk.

Bone Plate and Screws—(Implantable Fracture Fixation)

– Metal plates and screws used to stabilize bone fractures or osteotomies. Materials: stainless steel (strong, cheap, corrodes), titanium (biocompatible, MRI-safe, elastic modulus closer to bone), and bioabsorbable (PLLA, PGA — for children, no removal needed). Locking vs. non-locking screws: locking screws thread into the plate, creating a fixed-angle construct (like an external fixator internally), ideal for osteoporotic bone. Compression plating: dynamic compression plate (DCP) and limited-contact DCP (LC-DCP) for anatomic reduction and axial compression. Neutralization plate: protects lag screws from rotational forces. Buttress plate: supports a metaphyseal fragment (e.g., tibial plateau). Bridge plate: spans a comminuted fracture zone without direct reduction. Anatomical plates: pre-contoured for specific bones (distal radius, proximal humerus, acetabulum, calcaneus). The AO/ASIF principles guide fixation: anatomic reduction (articular), stable fixation, preservation of blood supply, and early mobilization. Complications: nonunion/malunion, infection (hardware removal if chronic), screw breakage, plate loosening, stress shielding (bone resorption under rigid plates), and refracture after removal.

Breast Implant (Prosthesis)

– A silicone- or saline-filled device placed in the subglandular or submuscular plane for breast augmentation (cosmetic) or reconstruction (post-mastectomy). Silicone gel implants: cohesive gel ("gummy bear") that retains shape even if the shell ruptures. Saline implants: filled intraoperatively, less natural feel. Surface types: smooth (less friction, higher cap-

sular contracture) and textured (lower capsular contracture, but associated with BIA-ALCL — breast implant-associated anaplastic large cell lymphoma). Shape: round (most common) and anatomical (teardrop, requires textured surface to prevent rotation). FDA-approved manufacturers: Allergan (Natrelle), Mentor (MemoryGel, MemoryShape), Sientra, and Motiva (ergonomix). Implant placement: subglandular (on top of pectoralis, more animation deformity), subpectoral (dual plane, partial under muscle), and prepectoral (on top of muscle, for reconstruction). Complications: capsular contracture (most common, Baker grade I-IV), rupture (silent in silicone gel, MRI recommended at 5-6 years post-op then q2-3 years), implant malposition, rippling, infection, hematoma, and BIA-ALCL (textured implants, 1:3,000 to 1:30,000). Implant life: 10-20 years (not lifetime devices).

Cochlear Implant

– An electronic medical device that bypasses damaged hair cells in the cochlea and directly stimulates the auditory nerve. Components: internal (receiver-stimulator placed in a bony well behind the ear, electrode array inserted into the scala tympani of the cochlea) and external (microphone, speech processor worn behind the ear or body-worn, and transmitter coil held in place by a magnet). Indications: severe-to-profound bilateral sensorineural hearing loss with insufficient benefit from hearing aids (aided word recognition <50-60% in the best-aided condition). Adult candidacy: post-lingual onset. Pediatric candidacy: FDA-approved down to 9 months of age; earlier implantation improves language outcomes. Major brands: Cochlear (Nucleus series), Advanced Bionics (HiRes Ultra, Naída CI), and MED-EL (SYNCHRONY, RONDO). Speech processors replaceable/upgradable externally. Surgery: mastoidectomy, facial recess approach, cochleostomy or round window insertion, NRT/telemetry to confirm placement. Complications: facial nerve injury (rare, <1%), meningitis (pneumococcal vaccination required pre-op), flap infection, electrode migration, device failure (1-3%), and vestibular symptoms (vertigo). Outcomes: most achieve open-set speech understanding; factors are age at implantation, duration of deafness, and adherence to aural rehabilitation.

Continuous Glucose Monitor (CGM Implant)

– A subcutaneous sensor that measures interstitial glucose levels every 5-15 minutes. The Dexcom G7 and G6 (FDA-approved for non-adjunctive use, i.e., can dose insulin without fingersticks), Abbott FreeStyle Libre (flash glucose monitoring, reader on demand with 8-hour continuous data), and Medtronic Guardian (integrated with insulin pumps). Inserted subcutaneously in the abdomen (or arm for Libre) and worn for 7-14 days. Fully implantable CGM (Eversense, Senseonics) with a subcutaneous fluorescence-based sensor lasting 90-180 days; requires surgical insertion in an office procedure. MARD (mean absolute relative difference): <10%. Alarms: hypo/hyperglycemia, rate of change, and predictive alerts. Benefits: reduced HbA1c, less hypoglycemia, improved time-in-range (TIR, 70-180 mg/dL), and integration with automated insulin delivery (AID) systems. Limit: lag behind blood glucose (5-10 minutes interstitial delay).

Coronary Stent

– A metallic mesh tube deployed in a coronary artery to treat atherosclerotic narrowing. Bare metal stent (BMS): first generation, high restenosis rate (20-40%) due to neointimal hyperplasia. Drug-eluting stent (DES): releases an antiproliferative drug (sirolimus, paclitaxel, everolimus, zotarolimus) from a polymer coating to inhibit restenosis. Second-generation DES (everolimus: Xience, Promus; zotarolimus: Resolute): thinner struts, biocompatible polymers, 5-10% restenosis, and lower late stent thrombosis (LST) than first-generation (Cypher, Taxus). Third-generation: bioabsorbable polymer (Orsiro, Synergy) or polymer-free (BioFreedom) to reduce inflammation. Ultra-thin strut DES (<65 μm): improved deliverability. Cobalt-chromium and platinum-chromium alloys provide radial strength with thinner struts. Current standard: DES is used in >95% of PCI. Dual antiplatelet therapy (DAPT: aspirin + P2Y12 inhibitor) is required after deployment to prevent in-stent thrombosis, typically for 3-6 months (new-generation DES) to 12 months (high-risk ACS), then aspirin lifelong. In-stent restenosis (ISR): treated with drug-coated balloon (SeQuent Please, Lutonix) or another DES.

Very late stent thrombosis (>1 year): rare with modern DES (0.2-0.5%/year).

Deep Brain Stimulator (DBS)

– A neurostimulator that delivers electrical pulses to targeted deep brain structures via implanted electrodes. Components: intracranial leads (quadripolar electrodes) placed stereotactically, extension cables tunneled subcutaneously, and an implantable pulse generator (IPG, "battery") placed in the infraclavicular or abdominal subcutaneous pocket. Targets: subthalamic nucleus (STN — for Parkinson's disease, most common), globus pallidus internus (GPi — for Parkinson's and dystonia), ventral intermediate nucleus (VIM — for essential tremor), and anterior nucleus of the thalamus (ANT — for epilepsy). The Medtronic Percept PC (with sensing capability, BrainSense), Abbott Infinity (directional leads), and Boston Scientific Vercise (multiple independent current control) are current IPG platforms. DBS is MRI-conditional (specific conditions). Stimulation parameters: amplitude (voltage), pulse width (60-90 μs), frequency (130-180 Hz for Parkinson's), and active electrode configuration. Indications: Parkinson's disease (motor fluctuations, dyskinesias, tremor refractory to medication), essential tremor, dystonia (primary generalized), obsessive-compulsive disorder (OCD, under HDE), and epilepsy. Surgery: frame-based (CRW, Leksell) or frameless (NextFrame, StealthStation) stereotaxy, microelectrode recording (MER) for physiological mapping, intraoperative test stimulation for symptom improvement and side effect assessment. Complications: hemorrhage (1-2%, intraparenchymal or along the lead tract), infection (2-5%, often IPG pocket), lead fracture/migration, hardware erosion, stimulation-induced side effects (paresthesias, dysarthria, mood changes), and IPG battery depletion (replaced every 2-5 years, rechargeable IPGs are emerging).

Dental Implant (Endosseous)

– A titanium or titanium-alloy screw-shaped post that osseointegrates with the alveolar bone to support a crown, bridge, or denture. Materials: commercially pure titanium (Grade 4, rough surface for osseointegration) and zirconia (esthetic, metal-free, but less evidence for posterior teeth). Two-stage: implant placed, submerged under gingiva

for 3-6 months of osseointegration, then uncovered and loaded. Single-stage: transgingival healing abutment placed at the time of implant insertion, avoiding a second surgery. Immediate loading: crown placed within 48 hours (for anterior teeth, ideal bone quality). Delayed loading: standard after 3-6 months. The Branemark protocol (1965) established the principles: atraumatic extraction, sterile surgical technique, and uninterrupted healing. Brands: Straumann (SLA, Roxolid), Nobel Biocare (Replace, Brånemark), Zimmer (Tapered Screw-Vent), Dentsply (Astra Tech, OsseoSpeed), and BioHorizons. Surface modifications: SLA (sandblasted + acid-etched), TiUnite (oxidized), and SLActive (hydrophilic, faster osseointegration). Contraindications: uncontrolled diabetes, bisphosphonate therapy (MRONJ risk), heavy smoking, and history of head/neck radiation. Complications: peri-implantitis (inflammation and bone loss, 20-30% of patients), implant failure (early: failed osseointegration, 1-5%; late: due to overloading or infection), nerve injury (inferior alveolar nerve, mental nerve), sinus perforation (maxillary sinus), and esthetic problems (gum recession visible metal margin). 10-year survival: >95% in well-selected patients.

Glaucoma Drainage Device (Tube Shunt)

– An implant for reducing intraocular pressure (IOP) in glaucoma by draining aqueous humor from the anterior chamber to an equatorial bleb. Components: a silicone tube (placed in the anterior chamber through a scleral track) connected to an end plate (positioned under the rectus muscles on the scleral surface). The Ahmed valve (New World Medical) has a flow restrictor (venturi-based or silicone membrane) that limits hypotony immediately post-op. The Baerveldt implant (Johnson & Johnson) has no valve; flow is restricted by a ligation suture or dissolvable Vicryl tie for a 4-6 week delay. The Molteno implant (single- or double-plate) is the original. Indications: neovascular glaucoma, uveitic glaucoma, post-penetrating keratoplasty glaucoma, prior failed trabeculectomy, congenital glaucoma, and high-risk glaucoma. Contraindications: corneal endothelial disease (tube can cause corneal decompensation) and active infection. Surgery: super-

otemporal quadrant, peritomy, quadrant dissection, tube trimmed bevel-up, scleral patch graft (donor sclera, pericardium, or cornea) over the tube entry site, and conjunctival closure. Complications: hypotony (especially Baerveldt without ligation), tube erosion (conjunctival breakdown), corneal edema, tube obstruction (iris, fibrin, vitreous), choroidal effusion, endophthalmitis, and diplopia from the plate interfering with extraocular muscles. Tube shunt survival: >80% at 2 years, decreasing to about 50% at 5 years.

Implantable Cardioverter-Defibrillator (ICD)

– An electronic device that monitors heart rhythm and delivers therapy (antitachycardia pacing ATP, cardioversion, or defibrillation) for ventricular arrhythmias. Components: pulse generator (placed in the left infraclavicular subcutaneous pocket) and one or more leads (transvenous: single-coil or dual-coil, placed in the RV apex or septum; or entirely subcutaneous S-ICD). Indications (primary prevention): ischemic cardiomyopathy ($EF \leq 35\%$ >40 days post-MI), non-ischemic cardiomyopathy ($EF \leq 35\%$, on GDMT for ≥ 3 months), and certain channelopathies (long QT, Brugada, HCM, ARVC). Secondary prevention: survivors of SCD due to VF/VT. Transvenous ICD: pectoral implant, 1-3 leads (RA, RV, LV for CRT-D). Subcutaneous ICD (S-ICD, Boston Scientific Emblem): no intravascular leads, left parasternal electrode and left lateral pocket, for patients without need for pacing/bradycardia pacing. Leadless ICD: entirely within the RV (currently only a pacemaker is available commercially leadless). Shock: up to 41 J delivered biphasic waveform. Defibrillation threshold (DFT): <10 J difference from maximum output is acceptable. Programming: optimizing VT detection zones (monitor, ATP, shock), S-ICD with SMART Pass algorithm reduces inappropriate shocks. Complications: infection (pocket, endocarditis, highest with system revision), lead failure (fracture, insulation break), inappropriate shocks (SVT, AF, lead noise, T-wave oversensing), pneumothorax/hemothorax (transvenous), and device erosion. Device generators last 5-10 years (transvenous), longer with S-ICD (no pacing drain). Remote monitoring is standard (CareLink, Merlin,

Latitude) and reduces clinic visits and improves survival.

Implantable Loop Recorder (ILR)

– A subcutaneous cardiac monitoring device that continuously records a single-lead ECG for up to 3 years. The size of a thumb drive, inserted in the left parasternal area (4th intercostal space) in a 1-cm pocket under local anesthesia. The Medtronic LINQ II (micra-like, injectable), Abbott Confirm Rx (Bluetooth-enabled, smartphone-based transmission), and Biotronik BioMonitor 3 are current models. Autotriggered recordings: asystole (>3 sec), bradycardia, tachycardia, and AF detection (P-wave analysis, AF burden%). Patient-activated recordings: for symptoms (palpitations, syncope, presyncope, chest pain). Indications: syncope of unclear etiology (after negative workup — most common indication), cryptogenic stroke (to detect occult AF, 20-30% detection rate), and AF management (AF burden monitoring after ablation or cardioversion). Ill at TIA/CVA workup: monitor 3 years, detects AF in up to 20-30% of patients. Battery life: 2-3 years. The device is explained at the end of monitoring or battery depletion. Complications: infection (1-3%), pocket hematoma, device migration, and discomfort.

Insulin Pump (CSII – Continuous Subcutaneous Insulin Infusion)

– A battery-powered device that delivers rapid-acting insulin (analog) subcutaneously through a cannula, providing a continuous basal rate and patient-activated boluses. Types: tethered pump (Medtronic MiniMed 780G, Tandem t:slim X2 — with touchscreen, tubed, Control-IQ/Advanced Hybrid Closed Loop), patch pump (Omnipod DASH/Omnipod 5 — tubeless, fully disposable, worn for 3 days, controlled via a PDM or smartphone), and the Ypsomed mylife YpsoPump (tubed, color touchscreen). Hybrid closed-loop (HCL, automated insulin delivery AID): integrates CGM data to automatically adjust basal insulin; the Medtronic 780G (SmartGuard, targets BG 100-120 mg/dL) and Tandem Control-IQ (target 112.5-160 mg/dL) are FDA-approved. The Omnipod 5 closed-loop is the first tubeless HCL. Indications: type 1 diabetes (all patients considered), poorly controlled type 2 diabetes, frequent/severe hypoglycemia, dawn phe-

nomenon, and gastroparesis. Cannula: inserted subcutaneously (abdomen, arm, hip, thigh) with an automatic inserter, changed every 2-3 days. Insulin: only rapid-acting (Humalog, Novolog, Fiasp, Lyumjev). Reservoirs: 180-300 units. Contraindications: unwillingness/unable to manage the system, untreated eating disorder, and severe visual impairment without caregiver support. Complications: infusion set failure (kinked cannula, dislodgment, occlusion, bleeding) leading to DKA within 4-6 hours (no long-acting insulin on board), lipohypertrophy, infection at the insertion site, and pump malfunction.

Intraocular Lens (IOL)

– An artificial lens implanted in the eye after cataract extraction (phacoemulsification). One-piece acrylic (monofocal, aspheric, with blue-blocking chromophore) is the standard of care placed in the capsular bag. Monofocal IOL: single focal point (set for distance), requires reading glasses. Multifocal IOL: diffractive rings on the surface divide light into multiple focal points (distance, near, intermediate), reduces spectacle dependence (e.g., Alcon Restor, Johnson & Johnson Tecnis Symfony). Depth-of-focus (EDOF) IOL: extends the focal range with less dysphotopsia than multifocal (e.g., Tecnis Symfony, Alcon Vivity). Toric IOL: corrects pre-existing corneal astigmatism (≥ 0.75 D); requires careful alignment (axis marking). Accommodating IOL: changes shape with ciliary muscle contraction (e.g., Crystalens, no longer commonly used). Light-adjustable lens (LAL, RxSight): can be adjusted postoperatively with UV light to fine-tune refractive outcome. Blue-blocking IOLs: filter UV and blue light (theoretical protection against macular degeneration, though controversial). Biometry: optical (IOLMaster, Lenstar) measures axial length, K-readings, and ACD; formulas (SRK/T, Holladay 2, Barrett Universal II, Hill-RBF) calculate IOL power. Target refraction: 0.0 D (plano) for distance, -0.25 D to -0.50 D for most patients. Contraindications: zonular weakness (pseudoexfoliation, trauma), capsular tear, and uveitis (active). Complications: posterior capsule opacification (PCO, 20-40% at 5 years, treated with YAG capsulotomy), IOL dislocation/decentration, cystoid macular edema (Irvine-Gass syndrome), dys-

photopsia (positive: arc-like light streaks; negative: temporal shadow), and refractive error. Phakic IOL (ICL, implantable collamer lens): placed in the sulcus (EVO ICL by STAAR Surgical) in front of the natural lens for high myopia correction, without removing the natural lens.

Intrathecal Pump (Baclofen Pump)

– An implantable pump that delivers baclofen directly into the intrathecal space for the treatment of severe spasticity. The Medtronic SynchroMed II is the only FDA-approved implantable pump for intrathecal baclofen (ITB). A catheter is tunneled subcutaneously from the pump (placed in the lower abdominal wall) to the lumbar spine and threaded into the intrathecal space (typically at L2-L3). The pump reservoir (20 mL or 40 mL) is refilled percutaneously every 1-3 months through the central fill port. Indications: severe spasticity refractory to oral therapy (max dose of oral baclofen: 80 mg/day) due to multiple sclerosis, spinal cord injury (most common indication), cerebral palsy, traumatic brain injury, and stroke. Efficacy: reduces spasticity (Ashworth score decrease of 1-2 points) and improves function/pain. Screening test: 50-100 µg intrathecal bolus to assess response before implantation. Baclofen concentration: 500-2000 µg/mL. Flow rate: adjustable (continuous infusion, simple or complex dosing). Contraindications: active infection, small body habitus, and coagulopathy. Complications: pump pocket infection (most common, 5-10%), catheter kink/occlusion/dislodgement, pump malfunction, baclofen overdose (respiratory depression, hypotonia, sedation — treat with physostigmine), baclofen withdrawal (severe rebound spasticity, fever, confusion, rhabdomyolysis — treat with oral baclofen/benzodiazepines), and CSF leak. Catheter-related failures account for 50% of ITB system revisions.

Intrauterine Device (IUD)

– A small T-shaped device inserted into the uterine cavity for long-acting reversible contraception (LARC). Hormonal IUD (levonorgestrel-releasing): Mirena (52 mg, approved 8 years), Kyleena (19.5 mg, 5 years), Skyla (13.5 mg, 3 years). Copper IUD (non-hormonal): Paragard (T380A, approved 10-12 years, contains copper wire on arms and stem). Mechanism: hormonal IUD thickens cer-

vical mucus, suppresses endometrial proliferation, and may inhibit ovulation; copper IUD creates a sterile inflammatory reaction toxic to sperm and ova. Insertion: after sterile speculum exam, uterine sound, the IUD is placed via inserter tube; strings trimmed to 2-3 cm from the external cervical os. Best time: during menses (cervix slightly open, pregnancy excluded). Pain management: NSAIDs, para/paracervical block (for nulliparous, highly anxious). Efficacy: >99% (typical use failure rate <1%), same as tubal ligation and vasectomy. Contraindications: pregnancy, current PID, purulent cervicitis, Wilson disease (copper IUD), uterine anomaly, and unexplained vaginal bleeding. Complications: perforation (1:1000, usually at insertion), expulsion (2-10%, most in the first year), cramping, irregular bleeding (heavy menses with copper, spotting with hormonal), string problems (lost or retracted), and PID (primarily in the first 3 weeks post-insertion; higher risk with STI exposure). Return to fertility: immediate upon removal. Non-contraceptive benefits: reduces heavy menstrual bleeding (hormonal), endometrial cancer protection (hormonal), and emergency contraception (copper, up to 5 days after unprotected sex).

Mastopexy (Breast Lift Implant)

– A surgical procedure to lift and reshape sagging breasts (ptosis). Often combined with breast augmentation (implants) or reduction. Indications: involutional ptosis after pregnancy/breastfeeding, weight loss, aging. The NAC (nipple-areolar complex) is repositioned superiorly. The augmentation-mastopexy is a complex operation with a higher revision rate than augmentation alone.

Mechanical Heart Valve

– A prosthetic heart valve made of pyrolytic carbon (strong, thromboresistant, durable). The St. Jude Medical (now Abbott) bileaflet valve is the most common: two semicircular hinged leaflets that open centrally, creating three flow orifices with minimal obstruction. The Medtronic-Hall tilting disc valve (a single tilting disc suspended by a central strut) is less common. The Omnicarbon valve is another single-tilting disc. The Starr-Edwards ball-in-cage valve (caged-ball) is historical (no longer implanted but sometimes still seen in elderly patients). Advantage: excellent durability (>30 years).

Disadvantage: lifelong therapeutic anticoagulation with warfarin (INR 2.0-3.0 for aortic, 2.5-3.5 for mitral) due to thrombogenicity. Risk of thromboembolism (1-3%/year with adequate anticoagulation) and bleeding (1-3%/year). Indications: age <50-60 (especially in the mitral position), kidney disease (bioprosthetic valves degenerate faster), and patient preference (willing to take warfarin). Sound: a distinct clicking/ticking sound audible to the patient and sometimes to others.

Mid-Urethral Sling (MUS)

– A polypropylene mesh tape placed under the mid-urethra to treat stress urinary incontinence (SUI) by providing dynamic urethral support during increases in intra-abdominal pressure. Retropubic (TVT, tension-free vaginal tape): a monofilament polypropylene mesh tape inserted via a vaginal incision and passed through the retropubic space with trocars exiting the suprapubic skin (risk of bladder perforation, bowel injury). Transobturator (TOT, TVT-O): the tape is passed through the obturator foramen exiting the groin crease (less bladder injury, more groin pain). Single-incision mini-sling (SIMS, e.g., Altis, MiniArc): shorter, the tape is anchored directly to the obturator internus fascia through a single vaginal incision (less invasive, but higher failure rates for severe SUI). Indications: urodynamic stress incontinence (USI, SUI confirmed on urodynamic studies) with hypermobility of the urethra. Contraindications: pregnancy (future childbearing), active UTI, untreated UTI, and desire to void. Complications: mesh erosion into the vagina (3-5%), voiding dysfunction (retention, de novo urgency), groin/thigh pain (TOT), bladder perforation (TVT, 2-5%), mesh infection, and de novo urgency urinary incontinence. Success rate: 80-90% subjective cure at 5 years. The FDA 2011 transvaginal mesh safety communication specifically warned against mesh for POP repair; slings remain the standard of care for SUI.

Pacemaker (Cardiac Implantable Electronic Device CIED)

– An implantable device that delivers electrical pulses to the heart to maintain adequate heart rate. Single-chamber: VVI (RV lead, for rate support in AF). Dual-chamber: DDD (RA + RV leads, for AV block and sinus node dysfunction). Biventricular

(CRT-P): RV + LV (coronary sinus lead) for cardiac resynchronization in heart failure. Indications: symptomatic sinus node dysfunction (sick sinus syndrome, HR <40), third-degree (complete) AV block, Mobitz II second-degree AV block, bifascicular block with intermittent AV block, and chronotropic incompetence. Pacing modes (NBG code): first letter = chamber paced (A, V, D), second = chamber sensed, third = response (I, T, D), fourth = rate modulation (R). Rate-responsive (DDDR): uses an accelerometer or minute ventilation sensor to increase rate during exercise. MRI-conditional (most modern): labeled MR Conditional, safe under specified conditions. Endocardial leads: passive fixation (tines) or active fixation (screw-in helix), placed via subclavian or axillary venous access. Left subpectoral pocket is standard. Leadless pacemaker (Micra AV, Medtronic; Aveir, Abbott): all-in-one device implanted in the RV via a femoral approach (no pocket, no lead). Dual-chamber leadless pacing is emerging (Aveir DR). Generator replacement: every 6-12 years (CRT-P shorter). Remote monitoring: standard (MyCareLink, Merlin, Latitude) reduces clinic visits. Complications: infection (pocket, endocarditis, 1-2% for new implant, 5-7% for system revision), lead failure (fracture, insulation break, recall-prone), pneumothorax (subclavian puncture), pocket hematoma, and twiddler syndrome (patient rotates generator, dislodging leads).

Patent Ductus Arteriosus (PDA) Occlusion Device

– An implant for transcatheter closure of a patent ductus arteriosus, a congenital heart defect where the fetal ductus arteriosus fails to close after birth. The Amplatzer Duct Occluder II (Abbott) and the Cook detachable coil are the most common. The device is delivered through a 4-6 Fr sheath via the femoral vein or artery. The Amplatzer device is a self-expanding nitinol mesh with a retention disc on the aortic side and a plug on the pulmonary side. Indications: hemodynamically significant PDA (left-to-right shunt, enlarged left heart, continuous murmur). Closure is typically performed >6 months of age (weight >6 kg). Absolute contraindication: pulmonary vascular disease (Eisenmenger syndrome with right-to-left shunt, PDA-dependent pulmonary/systemic circulation). Complications:

device embolization (most common), residual shunt, hemolysis, and obstruction of the LPA or descending aorta.

Penile Prosthesis (Implant)

– A surgically implanted device for treating erectile dysfunction (ED) refractory to oral therapy (PDE5 inhibitors) and vacuum/ICI therapies. Malleable (semi-rigid) rods: AMS 600M/650M (Boston Scientific), Coloplast Genesis. These are always semirigid and can be bent downward for urination/intercourse; simpler and cheaper, but less natural. Inflatable prostheses (two-piece: AMS Ambicor; three-piece: AMS 700 (Boston Scientific) with LGX (length-expanding) or CX (controlled expansion) cylinders, Coloplast Titan with One-Touch Release): cylinders placed in the corpora cavernosa, a scrotal pump (in the scrotum), and a fluid reservoir (retropubic space, collapsible for Coloplast; pre-connected for AMS 700). Three-piece is the standard for the best results (natural erection and flaccidity). Indications: organic ED (diabetes, post-radical prostatectomy, Peyronie disease, severe vascular disease) refractory to medical therapy. Contraindications: active infection, untreated UTI, and severe penile fibrosis (scarring). Surgery: penoscrotal (most common) or infrapubic approach. Cylinder size is measured intraoperatively (dilatation with Hegar dilators, Furlow inserter). Complication rates: infection (1-3% in naive patients; higher in revision/revision, 5-15%), mechanical failure (5-10% at 5 years, higher for 3-piece), cylinder erosion, pump migration, and auto-inflation (Correction: the Coloplast Titan has a lock-out valve to prevent auto-inflation). Satisfaction rates: >90% (patient and partner). Antibiotic impregnation: InhibiZone (rifampin/minocycline) on AMS devices reduces infection.

Port-a-Cath (Implantable Venous Access Port)

– A fully implanted central venous access device consisting of a silicone catheter (inserted into the superior vena cava via the internal jugular or subclavian vein) connected to a titanium or plastic reservoir (port) placed in a subcutaneous pocket on the chest wall (typically 2-3 cm below the clavicle, over the pectoralis major fascia). Access is through the skin via a non-coring Huber needle (right-angle or straight). The power-injectable port

(e.g., Bard PowerPort, Cook Vital-Port) can handle CT contrast injection at up to 5 mL/sec. Indications: chemotherapy (most common), long-term IV antibiotics (osteomyelitis, endocarditis), TPN, frequent blood transfusions, and frequent blood draws (rare). Double-lumen ports are available for incompatible infusions. Placement: interventional radiology or surgeon, under ultrasound and fluoroscopic guidance. Tip position: cavoatrial junction. Flush: heparinized saline (100 U/mL, 5 mL) monthly when not in use, or saline-only ports (e.g., BD Q-Syte, neutral displacement). Complication rate: 5-15%. Immediate: pneumothorax, hemothorax, arterial puncture, air embolism. Short-term: pin-hole infection, catheter malposition. Long-term: catheter-related bloodstream infection (CRBSI, most common, 1-3 per 1000 catheter-days, treat with antibiotics + port removal if tunnel infection), catheter occlusion (thrombotic: alteplase), fibrin sheath formation (retraction of blood, resistant aspiration but easy flushing), venous thrombosis (upper extremity DVT, catheter-related thrombosis), and port erosion/exposure. Port longevity: indefinite (until no longer needed or complication occurs).

Responsive Neurostimulation (RNS System)

– An implantable closed-loop neurostimulation system for treating drug-resistant focal epilepsy. The NeuroPace RNS System is the only FDA-approved device. Components: a cranially implanted neurostimulator (placed in a skull defect, similar to a cranial bone flap), one or two depth or subdural strip electrodes placed at the seizure focus(es), and a wireless telemetry wand for programming and data download. The device continuously records electrocorticography (ECoG) data and delivers stimulation (brief electrical pulses) when it detects a pattern that matches a pre-programmed seizure-onset pattern (detection and stimulation cycles). It is a responsive, adaptive, closed-loop system (not continuous like DBS). Indications: adults with drug-resistant focal epilepsy (with 1-2 seizure foci) who are not candidates for resective surgery. Contraindications: multifocal epilepsy with >2 foci, generalized epilepsy, and MRI incompatibility (RNS is MRI-conditional). Efficacy: 50-70% median seizure reduction at 2

years, continues to improve over time (possibly due to neuromodulation effects). Advantages over VNS and DBS: delivers therapy only when needed, provides long-term ECoG monitoring for seizure tracking, and is adjustable without surgery. Complications: infection (5-10%, often requires device removal), implant site pain, hemorrhage, and lead fracture. Device battery: about 4-6 years.

Shunt (Ventriculoperitoneal VP Shunt)

– A device that diverts cerebrospinal fluid (CSF) from the cerebral ventricles to the peritoneal cavity for the treatment of hydrocephalus. Components: ventricular catheter (inserted through a frontal or occipital burr hole into the lateral ventricle, typically the right frontal horn), a valve (programmable: Codman Hakim, Medtronic Strata, Sophysa Polaris; or fixed-pressure: low/medium/high), and a peritoneal catheter (tunneled subcutaneously from the head to the upper abdomen, inserted into the peritoneal cavity). Programmable valves: adjusted externally with a magnetic tool (Codman Hakim: 30-200 mm H₂O; Medtronic Strata: 0.5-2.5; Aesculap Miethke proGAV 2.0: gravitational valve that changes with body position). Indications: congenital hydrocephalus, normal pressure hydrocephalus (NPH), post-hemorrhagic hydrocephalus (IVH, SAH), post-meningitic hydrocephalus, and obstructive hydrocephalus from tumors. Contraindications: active peritonitis, infected CSF (VP shunt), and presence of a ventriculostomy (EVD) that is infected. Complications: shunt obstruction (most common, 30-40% at 2 years, most frequent in the proximal catheter), infection (5-10%, most within 3 months, typically *Staphylococcus epidermidis*), overdrainage (subdural hematoma, slit ventricle syndrome, orthostatic headaches), underdrainage (persistent hydrocephalus), and shunt migration (peritoneal catheter can erode into the bowel, bladder, or through the skin). Overdrainage in NPH may lead to subdural hygromas/hematomas from negative pressure. Antibiotic-impregnated catheters (Bactiseal, Codman) reduce infection (OR 0.5-0.6).

Spinal Cord Stimulator (SCS)

– An implantable neuromodulation device for treating chronic neuropathic pain. Components: epidural leads (percutaneous cylindrical leads or sur-

gical paddle leads placed in the dorsal epidural space) and an implantable pulse generator (IPG, battery) placed in the lower back/buttock/subcostal pocket. Trial: temporary external system for 3-7 days to evaluate efficacy before permanent implantation (>50% pain reduction needed for proceeding). Indications: failed back surgery syndrome (FBSS, most common), complex regional pain syndrome (CRPS, type I and II), diabetic peripheral neuropathy, and refractory angina. Traditional SCS: paresthesia-based (tonic, 40-60 Hz) covers the painful area with a tingling sensation (paresthesia overlap). Newer waveforms: high-frequency (10 kHz, HF10 therapy) — paresthesia-free, superior for back pain; burst stimulation (40 Hz burst with 5 spikes) — targets affective component of pain; and closed-loop SCS (Abbott Proclaim, closed-loop feedback from evoked compound action potentials ECAPs) — maintains consistent activation and improves outcomes. Brands: Boston Scientific (Spectra WaveWriter, paresthesia-based + burst + combination), Abbott (Proclaim DRG, for SCS and dorsal root ganglion stimulation), Nevro (Senza HFX, high-frequency 10 kHz), and Medtronic (Intellis with differential target multiplexed programming). DRG stimulation (Abbott Axium): lead placed at the dorsal root ganglion in the epidural space at the L1-S2 levels for focal neuropathic pain (e.g., post-herniorrhaphy pain, CRPS of a limb) with better paresthesia coverage and positional stability. Complications: lead migration (most common, 5-15%), infection (2-5%, often IPG pocket), IPG site pain, lead fracture, dural puncture, and CSF leak.

Subdermal Contraceptive Implant (Nexplanon)

– A single-rod, non-biodegradable, etonogestrel-releasing implant (68 mg, released over 3 years) placed subdermally on the inner upper arm. The applicator is pre-loaded (loaded disposable inserter, changed from Implanon). Mechanism: inhibits ovulation (by suppressing LH surge), thickens cervical mucus, and suppresses endometrial proliferation. Insertion: after local anesthesia—the device is inserted subdermally at the medial aspect of the non-dominant arm, 8-10 cm above the medial epicondyle, in the sulcus between the biceps and triceps. The new Nexplanon uses a single-use, preloaded,

auto-disable applicator (prevents reinsertion). The device is radiopaque (barium sulfate added). Efficacy: >99% (Pearl Index 0.05). Duration: 3 years (FDA-approved), but evidence suggests it is effective up to 5 years. Advantages: long-acting reversible contraception (LARC), 100% reversible (returns to fertility immediately after removal), excellent for adolescents and women who cannot use estrogen. Disadvantages: irregular bleeding/spotting (most common side effect, 50% after 1 year), amenorrhea (20%), weight gain, breast tenderness, and acne. Contraindications: active VTE, liver disease, breast cancer, and unexplained abnormal vaginal bleeding.

Transcatheter Aortic Valve Replacement (TAVR Valve)

– A bioprosthetic valve crimped onto a catheter and delivered percutaneously to replace a stenotic aortic valve without open heart surgery. Two main platforms: balloon-expandable (Edwards SAPIEN 3 Ultra, SAPIEN 3 — bovine pericardial leaflets, cobalt-chromium stent frame) and self-expanding (Medtronic Evolut PRO+, PRO — porcine pericardial leaflets, nitinol frame with external pericardial wrap for sealing). Access: transfemoral (most common), transapical (left lateral thoracotomy, direct LV apex), transaortic (direct ascending aorta), transaxillary/subclavian, and transcarotid. Indications: symptomatic severe aortic stenosis (reduced survival if untreated) — currently approved for all risk categories (extreme, high, intermediate, and low risk). The PARTNER trials (Edwards) and CoreValve US trials (Medtronic) validated TAVR across risk strata. Pre-procedural CT: annulus sizing (perimeter, area), coronary height (risk of coronary occlusion), and iliofemoral access assessment. Annulus measurement is crucial: oversizing by 5-15% prevents paravalvular leak; severe oversizing risks annular rupture. Valve-in-valve: TAVR within a failed surgical bioprosthesis (viable TAVR) is safe and effective. Complications: paravalvular leak (PVL, 5-10% moderate or greater for new-generation valves, less with improved sealing skirts), permanent pacemaker requirement (PPM, 15-30% for self-expanding — due to conduction disturbances LBBB/AV block, 5-10% for balloon-expandable), stroke (2-5%, lowered with embolic protection devices like Sentinel CPS), vascular access complica-

tions (bleeding, pseudoaneurysm, dissection, 5-10%), coronary obstruction (rare but fatal if undetected), and annular rupture (rare).

Transjugular Intrahepatic Portosystemic Shunt (TIPS)—See TIPS in Surgery.

– See also Intrathecal Pump for CSF shunting.

Tympanostomy Tube (Grommet)

– A small ventilation tube inserted through the tympanic membrane (eardrum) to equalize pressure and drain middle ear fluid. Materials: silicone, fluoroplastic, and titanium; with or without antibiotic coating. Types: short-term (Paparella type 1, Armstrong, Shepard, Donaldson — extrude spontaneously in 6-18 months) and long-term (T-tube, Goode T-tube — stay in 2-4+ years, may require surgical removal). Indications: persistent otitis media with effusion (OME, >3 months in children with hearing loss >20 dB), recurrent acute otitis media (AOM, >3 episodes/6 months or >4/12 months), chronic eustachian tube dysfunction, and adult barotrauma (flyers, divers). Contraindications: active otorrhea, cholesteatoma, and prior history of TM perforation. Procedure: myringotomy (anterior-inferior quadrant, avoiding the chorda tympani nerve) with aspiration of effusion, then tube insertion. Follow-up: keep water out of ears (earplugs for swimming are controversial; generally recommended to avoid deep water diving but surface swimming is acceptable). Tubes extrude spontaneously as the TM regenerates. Complications: tube otorrhea (most common, 10-30%, treat with topical antibiotics), obstruction (crust, dried effusion), early extrusion, persistent TM perforation after tube extrusion (1-5%, higher with T-tubes), tympanosclerosis (TM scarring, 20-30%), and cholesteatoma.

Vagus Nerve Stimulator (VNS)

– An implantable neurostimulator that delivers intermittent electrical pulses to the left vagus nerve for the treatment of drug-resistant epilepsy and depression. The LivaNova VNS Therapy System (Demipulse, AspireHC) is the primary device. A spiral electrode is wrapped around the left vagus nerve in the carotid sheath (left is chosen to minimize cardiac effects, as the right vagus heavily innervates the SA node). The pulse generator is placed in a left infraclavicular subcutaneous pocket.

Stimulation parameters: output current (0.25-3.0 mA), frequency (20-30 Hz), pulse width (250-500 μ s), on-time (30 sec), and off-time (5 minutes). Indications: drug-resistant partial-onset epilepsy (≥ 12 years, FDA-approved 1997) and treatment-resistant depression (FDA-approved 2005). It is not for patients with prior left cervical vagotomy. Efficacy: 30-50% seizure reduction at 3 months, improving to 50-60% at 2 years. Magnets: patients/caregivers can swipe a magnet over the generator to trigger on-demand stimulation to abort seizures. Vagal nerve stimulation for depression: NIMH STAR*D post-hoc analysis showing benefit, but insurance approval varies. Complications: voice alteration/hoarseness (most common, 30-60%, due to stimulation of the laryngeal nerve, resolves when stimulator off), cough, dysphagia, paresthesias, infection, and device malfunction. It is MRI conditional. Battery life: 4-10 years.

Vascular Graft (Synthetic)

- A prosthetic conduit used to replace or bypass diseased arteries or veins. Materials: Dacron (polyethylene terephthalate PET, woven or knitted, used for large-diameter high-flow vessels: aorta, iliac) and ePTFE (expanded polytetrafluoroethylene, Gore-Tex, used for medium-diameter vessels: femoral, popliteal, AV grafts for dialysis). Heparin-bonded grafts (e.g., Gore Propaten, GORE-TEX with heparin bioactive surface) reduce early thrombosis. Linings: tissue-engineered and autologous endothelial cell-seeded grafts (experimental). Bifurcated grafts: for aortoiliac occlusion or AAA repair (body + left/right limbs). Ringed grafts: external ePTFE rings prevent kinking at the knee (fem-pop bypass). Biological grafts: autologous (saphenous vein — best patency for infrainguinal bypass, 60-80% at 5 years; internal mammary artery for CABG), allograft (cadaveric vein), and xenograft (bovine carotid artery, bovine mesenteric vein). Indications: peripheral arterial disease (aortobifemoral, femoropopliteal, femorotibial bypass), aortic aneurysm repair (open AAA repair or hybrid repair), and hemodialysis access (AV graft when native AV fistula is not feasible, e.g., basilic vein transposition, forearm loop). Complications: infection (most dreaded, especially if graft is in the groin, treatment includes excision and extra-

anatomic bypass), thrombosis (pseudointimal hyperplasia, especially at low-flow anastomoses), anastomotic pseudoaneurysm, and graft-enteric fistula (aortoduodenal fistula after AAA repair). Patency: aortobifemoral 80-90% at 5 years; femoropopliteal 50-70%.

Vena Cava Filter (IVC Filter)

- An endovascular device placed in the inferior vena cava to prevent pulmonary embolism (PE) in patients with venous thromboembolism (VTE) who cannot tolerate anticoagulation. The filter is a metal cage (cone-shaped, with struts and hooks) that traps emboli while allowing blood flow. The most commonly used is the Greenfield filter (stainless steel or titanium, 4-6 struts). Retrieval filters: Bard Denali (conical, retrievable, nitinol), Cook Celect (conical, retrievable, with timers), Cook Gunther Tulip (conical, retrievable), and Cordis OptEase (double-basket, retrievable). Permanent filters: Greenfield (stainless steel) and TrapEase. Indications: contraindication to anticoagulation (active bleeding, recent surgery, hemorrhagic stroke), failure of anticoagulation (recurrent PE despite therapeutic anticoagulation), and prophylactic in high-risk trauma (severe pelvic/long bone fractures, TBI). Contraindications: complete IVC thrombosis (no room to deploy), severe IVC stenosis, and uncorrectable coagulopathy. The ideal position is infrarenal IVC (below the renal veins, above the IVC bifurcation at L2-L3). The filter is placed under fluoroscopic guidance via the right femoral vein (most common) or right internal jugular vein. Complications: IVC penetration (struts through the IVC wall, estimated 15-40% in retrievable filters, often asymptomatic), filter migration (to the heart, pulmonary artery — can be fatal), IVC thrombosis (5-15%, causing phlegmasia, edema, DVT), retrieval failure (filter tilting, endothelialization, strut penetration, significant clot in filter, time since implant >1 year reduces likelihood of successful retrieval — 60-90% retrieval success in experienced centers). DVT at the insertion site (5-10%). The FDA in 2010 and 2014 recommended that retrievable filters be removed as soon as PE protection is no longer needed (ideally within 29-54 days). Long-term complications: filter fracture, systemic embolization, and chronic IVC occlusion.

Ventricular Assist Device (VAD/LVAD)

– A mechanical pump that supports the failing left ventricle. The HeartMate 3 (Abbott) is the current state-of-the-art LVAD: a fully magnetically levitated centrifugal pump with artificial pulse (designed to reduce pump thrombosis and shear stress). The HeartWare HVAD (Medtronic, previously HeartWare — withdrawn from market due to mortality/morbidity concern but still used in some patients) is a smaller centrifugal pump with a hybrid suspension. Impella (Abiomed): a microaxial percutaneous VAD placed via the femoral artery (Impella CP, Impella 5.5) for short-term support (up to 30 days for Impella 5.5). The TandemHeart (LivaNova) is a percutaneous left atrial-to-femoral artery bypass system. Indications: bridge to transplant (BTT, keep patient alive until a donor heart becomes available), bridge to candidacy (BTC, improve end-organ function to become transplant-eligible), destination therapy (DT, permanent support for patients ineligible for heart transplant), and bridge to recovery (BTR, support until the native heart recovers, e.g., myocarditis, post-cardiotomy). Surgery: median sternotomy or thoracotomy, inflow cannula in the LV apex, outflow graft to the ascending aorta (LVAD). A driveline exits the abdominal wall and connects to an external controller and batteries. Complications: pump thrombosis (reduced with HeartMate 3 full mag-lev design), stroke (ischemic and hemorrhagic, 10-20% at 1-2 years), driveline infection (15-30% at 1 year, 30-50% at 2 years), GI bleeding (30-50% from acquired von Willebrand syndrome type 2A, especially with axial flow HM II), right heart failure (20-30%), aortic insufficiency (from continuous flow, 20-30% at 2-3 years), and hemolysis. Life: HM3 is approved for up to 2 years as DT but is known to run much longer.

Chapter 19

Medical Instruments

Arthroscope

– A fiberoptic endoscope used to visualize the interior of a joint through small incisions (portals). Diameter: 2.7-4.0 mm with 30° or 70° lens angle. Introduced through a trocar/cannula system. Continuous saline irrigation distends the joint and clears debris. Common joints: knee (most common), shoulder, hip, wrist, ankle, and elbow. Diagnostic arthroscopy has been largely replaced by MRI; therapeutic arthroscopy is used for meniscectomy, ACL reconstruction, rotator cuff repair, and labral debridement.

Aspiration Needle

– A thin, hollow needle used to aspirate fluid or biopsy tissue. Types: fine needle aspiration (FNA, 22-25 gauge, for cytology), core needle (14-18 gauge, for histology), and aspiration for drainage (larger bore, for cysts, abscesses, and effusions). Ultrasound or CT guidance improves accuracy. Indications: thyroid nodules, breast masses, lymphadenopathy, liver lesions, pancreatic cysts, and pleural/peritoneal effusions. Complications: bleeding, infection, and pneumothorax (for chest procedures).

Auroscope (Otoscope)

– A handheld instrument with a light source and magnifying lens used to examine the external auditory canal and tympanic membrane. Speculum sizes: 2-5 mm (pediatric to adult). Features: pneumatic attachment for insufflation (assesses TM mobility, middle ear effusion), and cerumen removal loop. Normal TM: translucent, pearly gray, with visible landmarks (umbo, manubrium of malleus, light reflex). Abnormal: retraction, bulging, perforation, effusion (air-fluid level), cholesteatoma, and tympanosclerosis.

Bandage Scissors

– Scissors designed for cutting bandages and dress-

ings without injuring the skin. Blades: angled with a blunt probe tip on one blade that slides between the bandage and the patient. Types: Lister bandage scissors (most common, angled), trauma shears (heavy-duty, serrated blade for cutting through clothing, belts, and boots). Disposable or reusable (stainless steel). Essential in emergency departments and surgical wards. Not intended for suture removal or tissue dissection.

BiliLight (Phototherapy Unit)

– A device emitting blue light in the 460-490 nm wavelength range used to treat neonatal hyperbilirubinemia. Mechanism: converts unconjugated bilirubin to water-soluble isomers (photobilirubin) that can be excreted without conjugation. Types: conventional (overhead lamps), fiberoptic blanket (BiliBed, wrapped around infant), and LED phototherapy. Intensity: measured in $\mu\text{W}/\text{cm}^2/\text{nm}$ (target >30 for intensive therapy). Used with protective eye shields. Complications: loose stools, dehydration, and hyperthermia.

Bilirubinometer

– A handheld device that measures transcutaneous bilirubin (TcB) in neonates without blood sampling. Uses spectrophotometry to measure yellow color of subcutaneous tissue. Placed on the infant's forehead or sternum. Correlates well with serum bilirubin levels. Used as a screening tool; elevated values are confirmed with serum bilirubin measurement. Reduces the need for painful heel-stick blood draws. Affected by skin pigmentation and phototherapy exposure.

Biopsy Punch

– A cylindrical blade used to obtain a full-thickness skin sample for histopathology. Sizes: 2-8 mm diameter (4 mm most common for shave biopsy of inflammatory lesions, 6 mm for neoplasms). Technique:

local anesthesia, rotate punch through epidermis and dermis to subcutaneous fat, lift specimen with forceps, cut base with scissors. Closure depends on size: small (2-3 mm) heal by secondary intention; larger require suture (4-0 or 5-0 nylon). Indications: skin cancer diagnosis, inflammatory dermatoses, and nail bed biopsy.

Bougie

– A flexible or rigid instrument used to dilate strictures in the esophagus, urethra, or other hollow organs. Esophageal bougienage: Maloney (mercury-filled, flexible), Savary-Gilliard (wire-guided, polyvinyl, tapered tip), and balloon dilators. Urethral bougie: sounds for stricture dilation. Sizing: French (Fr) scale (circumference in mm = 3x diameter in mm). Indications: esophageal stricture (peptic, radiation-induced, caustic, eosinophilic esophagitis), urethral stricture.

BP Cuff (Sphygmomanometer)

– A device for non-invasive blood pressure measurement. Components: inflatable cuff, bulb/valve, and manometer (mercury, aneroid, or digital). Cuff size: bladder width 40% of arm circumference, length 80% (pediatric, adult, large adult, thigh). Technique: cuff at heart level, inflate 30 mmHg above palpable brachial pulse, deflate at 2-3 mmHg/sec. Systolic: first Korotkoff sound. Diastolic: disappearance (fifth phase). Automated oscillometric cuffs (Dinamap) are standard in hospitals.

Bronchoscope

– A flexible or rigid endoscope for examining the tracheobronchial tree. Flexible bronchoscope: fiberoptic or video, diameter 3.5-6.0 mm, working channel 2.0-3.2 mm for instruments (brush, biopsy forceps, needle). Allows BAL, transbronchial biopsy, endobronchial biopsy, and EBUS-TBNA. Rigid bronchoscope: metal tube, used for massive hemoptysis, large foreign body removal, and stent placement. Indications: lung mass/cancer diagnosis, persistent cough, hemoptysis, interstitial lung disease, and foreign body.

Cannula

– A flexible tube inserted into a vessel, duct, or body cavity for fluid delivery or drainage. IV cannula: sizes 14-26 gauge (larger gauge = smaller diameter), color-coded: gray (16G), green (18G), pink (20G), blue (22G), yellow (24G). Nasal cannula: delivers

1-6 L/min O₂ (24-44% FiO₂). Surgical cannula: used for cardiopulmonary bypass, liposuction, and arthroscopy. Complications: phlebitis, infection, infiltration, and air embolism.

Cardiac Monitor (Telemetry)

– Continuous real-time ECG monitoring for arrhythmia detection. Standard 3-lead or 5-lead configuration. Displays heart rate, rhythm, and ST segments. Alarms for bradycardia, tachycardia, asystole, and ventricular arrhythmias. Central monitoring station enables surveillance of multiple patients. Indications: acute coronary syndrome, post-MI, arrhythmia evaluation, post-cardiac surgery, and critically ill patients. Cannot replace 12-lead ECG for diagnosis; limited lead views.

Cardiopulmonary Bypass Machine

– A heart-lung machine used during open-heart surgery to temporarily replace cardiac and pulmonary function. Components: venous reservoir (receives deoxygenated blood), oxygenator (gas exchange), heat exchanger (temperature control), arterial pump (roller or centrifugal, delivers oxygenated blood to aorta), and cardioplegia delivery system (arrests heart with potassium-rich solution). Circuit primes 1.5-2 L. Cannulae placed in right atrium (venous) and ascending aorta (arterial). Complications: systemic inflammatory response, coagulopathy, hemolysis, and air embolism.

Catheter

– A thin, flexible tube for drainage, injection, or access. Urinary catheters: Foley (balloon retention, indwelling), straight (intermittent catheterization), and three-way (continuous bladder irrigation for hematuria). Sizes: 8-30 Fr (pediatric to adult male). Central venous catheters: internal jugular, subclavian, or femoral; used for CVP monitoring, vasopressors, TPN, and hemodialysis. PICC lines: peripherally inserted, tip in superior vena cava. Swan-Ganz catheter: pulmonary artery pressure monitoring. Complications: infection, thrombosis, and vessel injury.

Cautery (Electrocautery)

– A device that uses electrical current to cut tissue and coagulate blood vessels. Monopolar: current travels from active electrode (pen, spatula, needle) through the patient to a grounding pad (dispersive electrode). Bipolar: current flows between two tips

of the forceps (safer near delicate structures, less tissue damage). Modes: cut (continuous, higher voltage for vaporizing tissue), coag (pulsed, higher voltage for hemostasis), and blend. Uses: surgical dissection, hemostasis, and lesion ablation. Smoke plume contains toxic compounds.

Chest Tube (Thoracostomy Tube)

– A flexible plastic tube inserted into the pleural space to drain air, fluid, or blood. Sizes: 8-14 Fr (pneumothorax), 16-24 Fr (effusion, empyema), 28-40 Fr (hemothorax, postoperative). Insertion: triangle of safety (4th-5th intercostal space, midaxillary line), tunnel over the rib, directed apically (air) or basally (fluid). Connected to closed drainage system (water seal chamber, suction, collection chamber). Pleur-evac or Atrium systems. Indications: pneumothorax, hemothorax, empyema, pleural effusion, chylothorax, and postoperative thoracic surgery.

Colonoscope

– A flexible endoscope for examination of the entire large intestine (cecum to rectum). Length: 160-180 cm. Diameter: 12-13 mm. Features: tip controls (up/down, left/right angulation), working channel (3.2-4.2 mm for biopsy forceps, snare, polypectomy tools), water jet, and light source. Video colonoscope: CCD chip at the tip for high-resolution imaging. High-definition (HD) and narrow-band imaging (NBI) enhance mucosal detail. Used for CRC screening, polyp detection/removal, and diagnosis of colitis.

Colposcope

– A binocular microscope with a light source used to magnify the cervix, vagina, and vulva. Magnification: 5x-40x (most common 10-15x). Green filter enhances vascular patterns. Used after application of 5% acetic acid (aceto-white lesions indicate dysplasia) and Lugol iodine (Schiller test). Indications: abnormal Pap smear, abnormal vaginal bleeding, and cervical dysplasia surveillance. Allows targeted cervical biopsy. Digital colposcopy improves documentation and telemedicine consultation.

Cryotherapy Device

– A device that uses extreme cold to destroy abnormal tissue. Agents: liquid nitrogen (-196°C, spray or cotton-tip applicator), nitrous oxide (-89°C, cryoprobe via Joule-Thomson effect), and argon gas (-150°C, used in cryoablation for renal/liver tumors).

Mechanism: rapid freeze-slow thaw cycles cause intracellular ice crystal formation, cell lysis, and vascular thrombosis. Used for: skin lesions (warts, actinic keratosis, seborrheic keratosis, basal cell carcinoma), cervical dysplasia (cryocautery), and prostate cancer ablation.

Cystoscope

– An endoscope for examination of the urethra and bladder. Flexible cystoscope: 15-17 Fr, office-based with local anesthesia. Rigid cystoscope: 19-26 Fr, requires anesthesia, has larger working channels for instruments (biopsy forceps, stone baskets, resectoscope). Lens angles: 0°, 30°, 70°. Irrigation: saline (not water, which could cause hemolysis). Indications: hematuria evaluation, recurrent UTI, bladder tumor surveillance, ureteral stent placement/removal, and diagnosis of interstitial cystitis.

Defibrillator

– A device that delivers a controlled electrical shock to the heart to terminate ventricular fibrillation or pulseless ventricular tachycardia. External: biphasic waveform (150-200 J), self-adhesive pads placed anterolateral or anteroposterior. Automated external defibrillator (AED): analyzes rhythm automatically, voice prompts for CPR and shock delivery. Implantable cardioverter-defibrillator (ICD): transvenous or subcutaneous leads, detects VT/VF and delivers shock, anti-tachycardia pacing (ATP), or pacing. Indications: sudden cardiac arrest, ischemic and non-ischemic cardiomyopathy with low EF.

Dermatoscope (Dermoscope)

– A handheld magnifying instrument with a light source and polarized/non-polarized lenses for skin surface examination. Magnification: 10x (standard) to 100x. Uses: evaluation of pigmented skin lesions (melanoma vs. benign nevi vs. seborrheic keratosis), nailfold capillaroscopy (connective tissue disease), and assessment of hair and scalp disorders (trichoscopy). Enables visualization of structures below the stratum corneum (pigment network, dots, globules, streaks, regression structures, and blue-white veil). Uses the 2-step dermoscopy algorithm (melanocytic vs. non-melanocytic, benign vs. malignant). Improves melanoma diagnostic accuracy by 25-50% compared to naked eye.

Dialysis Machine (Hemodialysis)

– A device that filters blood when the kidneys fail. Components: blood pump (roller pump, 200-500 mL/min), dialyzer (hollow fiber artificial kidney with semipermeable membrane), dialysate delivery system (mixes concentrate with water at 37°C, rate 500-800 mL/min), and safety monitors (air detector, pressure monitors, blood leak detector). Water treatment: reverse osmosis removes contaminants. Vascular access: AV fistula (gold standard), AV graft, or tunneled dialysis catheter. Sessions: 3-4 hours, 3 times weekly. Removes urea, creatinine, potassium, phosphate, and excess fluid.

Doppler Probe

– A handheld device using the Doppler effect to detect blood flow. Continuous wave Doppler: emits and receives ultrasound continuously, detects velocity but not depth. Used for: ankle-brachial index, fetal heart rate detection (10 MHz), and peripheral vascular assessment. Pulsed wave Doppler: measures velocity at a specific depth. Spectral Doppler: waveform analysis. Color Doppler: color-encodes direction and velocity on ultrasound images. Indications: DVT, PAD, carotid stenosis, and fetal heart rate.

Duodenoscope

– A specialized side-viewing endoscope used for ERCP. Length: 124 cm, diameter: 12 mm. Side-viewing optics provide en face view of the ampulla of Vater. Features: elevator (a hinged bridge that deflects cannulas, guidewires, and stents), working channel (4.2 mm for 10 Fr stents). Indications: common bile duct stone extraction, biliary stent placement for malignant obstruction, sphincterotomy, and pancreatic duct drainage. High-level disinfection critical due to complex design and elevator mechanism (risk of CRE transmission).

ECG Machine (Electrocardiograph)

– A device that records the heart's electrical activity. Standard 12-lead: 10 electrodes (4 limb: RA, LA, RL, LL; 6 precordial: V1-V6). Filters: AC filter (60 Hz), muscle tremor, and baseline drift. Paper speed: 25 mm/sec (standard), 50 mm/sec (for tachycardia). Calibration: 10 mm/mV. Acquisition: simultaneous vs. sequential lead recording. Digital ECG machines provide computerized interpretation (Marquette, Glasgow, or Cabrera algorithms) with

storage and networking. Telemetry and portable devices (iPhone ECG, Holter) extend ambulatory monitoring.

Esophageal Stethoscope

– A flexible tube inserted into the esophagus with a microphone at the tip to monitor breath sounds and heart sounds during general anesthesia. Placed at 28-32 cm from the incisors. Provides continuous monitoring of ventilation (air entry, bronchospasm, breath holding) and cardiac activity (muffled heart sounds suggest hypovolemia). Largely replaced by capnography and pulse oximetry in modern anesthesia.

Eye Chart (Snellen Chart)

– A standardized chart for measuring visual acuity. Snellen: rows of progressively smaller letters (20/200 at top, 20/20 at bottom). Patient stands 20 feet (6 meters) from the chart. Visual acuity expressed as a fraction: 20/20 (normal), 20/40 (can read at 20 feet what normal sees at 40 feet). Legal blindness: 20/200 or worse in the better eye with correction. Tumbling E chart: for non-readers and children. Rosenbaum pocket chart: near vision at 14 inches. Pinhole occluder: distinguishes refractive error from organic disease.

Eye Speculum

– An instrument to hold the eyelids open during eye examination or surgery. Types: wire speculum (Lancaster, most common, self-retaining), solid blade speculum (for fornix exposure), and pediatric speculum. Used in: cataract surgery, corneal transplantation, vitrectomy, and laser procedures. Also used in cranial surgery for corneal protection. Must be placed carefully under the eyelids to avoid corneal abrasion or globe perforation.

Fetal Doppler

– A handheld ultrasound device (2-5 MHz) used to detect and auscultate fetal heart tones. Uses continuous wave Doppler with a transducer placed on the maternal abdomen with ultrasound gel. FHR detectable as early as 10-12 weeks (typically 12+). Normal: 110-160 bpm. Used in prenatal visits, labor triage, and home monitoring. Replaces fetoscope (Pinard horn). Cannot replace electronic fetal monitoring for high-risk pregnancies.

Forceps (Surgical)

– Instruments for grasping, holding, or extracting

tissue. Thumb forceps: pickups with spring action (1x2 teeth: tissue forceps; Adson: fine teeth for skin; DeBakey: atraumatic cardiovascular). Dressing forceps: non-toothed, for gauze and wound packing. Ring forceps: Kelly, Mosquito, Crile, Rochester-Pean (hemostatic clamps with ratchet lock). Hemostatic: curved or straight, sizes from delicate (fine ophthalmic) to large (obstetric). Used for clamping bleeding vessels, holding sutures, and blunt dissection.

Glucose Meter (Glucometer)

– A handheld device for measuring capillary blood glucose from a fingerstick. Uses glucose oxidase, glucose dehydrogenase, or hexokinase reaction on a test strip. Blood volume: 0.3-1.0 microliter. Results in 5-15 seconds. Normal fasting: 70-100 mg/dL. Diabetes management: pre-meal 80-130, postprandial <180. Continuous glucose monitor (CGM): subcutaneous sensor measures interstitial glucose every 5 minutes (Dexcom, Medtronic, Abbott Libre). Trend arrows predict direction of change. Alarms for hypo/hyperglycemia. Essential for intensive insulin therapy.

Handpiece (Dental)

– A powered instrument used in dentistry for cutting, grinding, and polishing teeth. High-speed handpiece: air-driven turbine, up to 400,000 rpm, used for cutting enamel and dentin (caries removal, crown preparation). Uses copious water spray to prevent heat generation. Low-speed handpiece: electric motor, <40,000 rpm, with contra-angle and straight attachments, for caries excavation, polishing, and rotary endodontics. Surgical handpiece: for implant placement, bone cutting. Maintenance: sterilization, lubrication, and regular inspection.

Headlamp (Surgical Headlight)

– A wearable light source worn on the surgeon's head to illuminate the operative field. Components: LED or xenon light source, fiberoptic cable connecting to a headband-mounted lens, or battery-powered LED on the headband. Coaxial: light beam aligned with the surgeon's line of sight. Battery packs provide 2-8 hours of operation. Indications: ENT surgery (tonsillectomy, mastoidectomy, sinus surgery), neurosurgery, urology, and any deep cavity surgery where overhead lights are inadequate.

Heart-Lung Machine

– See Cardiopulmonary Bypass Machine.

Heat Lamp

– An infrared lamp used to provide localized heat therapy to body surfaces. Mechanism: infrared radiation penetrates to warm subcutaneous tissues. Indications: muscle relaxation and pain relief (sprains, fibromyalgia), warming neonates (radiant warmer), and promoting wound healing (increase local blood flow). Contraindications: acute inflammation, bleeding, malignancy, and insensate skin (burn risk).

Infusion Pump

– An electronic device that delivers fluids, medications, or nutrients intravenously at controlled rates. Types: volumetric (large volume, mL/hr, for maintenance fluids, TPN), syringe pump (small volume, mL/min, for critical medications like vasopressors, insulin, heparin), and patient-controlled analgesia (PCA: patient self-administers preset bolus doses with lockout interval). Smart pumps: drug library with dose error reduction software (alerts for limits). Programming: rate, volume to be infused, dose (mcg/kg/min). Complications: infiltration, extravasation, infection, and air embolism.

Insulin Pen

– A reusable or disposable device for subcutaneous insulin injection. Contains a prefilled insulin cartridge (3 mL, 300 units) or may be fully disposable. Dial selects dose (1-60 units in 1-unit or 0.5-unit increments). Needle: 4-8 mm, 30-34 gauge (fine and short for comfort). Types: rapid-acting (NovoLog, Humalog, Apidra), short-acting (Novolin R), long-acting (Lantus, Levemir, Toujeo, Tresiba). Ease of use improves adherence compared to vial and syringe. Air shot before each injection to eliminate air bubbles.

Joint Aspiration Needle

– A sterile needle used for arthrocentesis (joint aspiration). Sizes: 18-22 gauge for larger joints (knee, shoulder), 22-25 gauge for smaller joints (wrist, ankle, elbow). Knee: medial or lateral approach with the joint slightly flexed. Synovial fluid analysis: cell count/differential, Gram stain, culture, and crystal analysis (urate vs. CPPD). Contraindications: overlying cellulitis (risk of septic arthritis from introduction), severe coagulopathy. Therapeutic drainage for symptomatic relief.

Laparoscope

– A rigid endoscope for minimally invasive (keyhole) abdominal surgery. Diameter: 5-10 mm, lens angle: 0° or 30°. High-definition video camera attached to the eyepiece. Fiberoptic cable delivers light from a xenon source. CO₂ insufflation (pressure 12-15 mmHg) creates working space (pneumoperitoneum). Access: Veress needle or Hasson open technique. Indications: cholecystectomy, appendectomy, hernia repair, colectomy, sleeve gastrectomy, diagnostic laparoscopy (abdominal pain, cancer staging). Advantages: reduced pain, shorter stay, faster recovery.

Laryngoscope

– An instrument used to visualize the larynx and vocal cords for endotracheal intubation. Direct laryngoscopy: Macintosh blade (curved, tip placed in vallecula, lifts epiglottis indirectly) or Miller blade (straight, lifts epiglottis directly). Video laryngoscopy: GlideScope, C-MAC, McGrath — camera on the blade shows glottic view on a screen, improving first-pass success. Indications: general anesthesia, emergency airway management, and difficult airway. Grades: Cormack-Lehane I (full view) to IV (no view).

Lithotripter

– A device that uses shock waves to fragment urinary tract stones. Extracorporeal shock wave lithotripsy (ESWL): focused, high-energy acoustic waves generated by an electrohydraulic, electromagnetic, or piezoelectric source, transmitted through water into the body. Indications: renal calculi <2 cm (upper and middle calyces) and proximal ureteral stones. Contraindications: pregnancy, coagulopathy, distal obstruction, and renal artery aneurysm. Intracorporeal: laser lithotripsy (holmium:YAG, thulium fiber), pneumatic (Swiss Lithoclast), and ultrasonic lithotripsy, used through a ureteroscope or nephroscope.

Loupe (Surgical Loupe)

– Binocular magnifying glasses worn by surgeons, dentists, and ENT specialists for enhanced visualization. Magnification: 2.5x-8x (most common 2.5x-3.5x for general surgery, 4x-8x for microsurgery). Types: through-the-lens (TTL, custom, most comfortable), flip-up (adjustable, modular). Features: Galilean vs. prismatic optics (prismatic provides wider field at higher magnification). Working dis-

tance: 340-500 mm. Used in: microvascular anastomosis, nerve repair, dental endodontics, and fine plastic surgery.

Mechanical Ventilator

– A machine that supports or replaces spontaneous breathing. Modes: volume control (set tidal volume, e.g., 6-8 mL/kg IBW), pressure control (set inspiratory pressure), pressure support (spontaneous breaths supported), SIMV (synchronized intermittent mandatory ventilation), and CPAP (continuous positive airway pressure). Settings: FiO₂ (21-100%), PEEP (5-20 cmH₂O), respiratory rate, I:E ratio (1:2 to 1:1). High-frequency oscillatory ventilation (HFOV) and airway pressure release ventilation (APRV) for refractory hypoxemia. Complications: VILI (ventilator-induced lung injury), VAP (ventilator-associated pneumonia), and hemodynamic compromise.

Medical Devices

– Instruments, apparatuses, implants, or software used for diagnosis, monitoring, treatment, or prevention of disease, ranging from simple tongue depressors to complex implantable defibrillators and robotic surgical systems. Classification by risk: Class I (low risk, e.g., bandages, stethoscopes), Class II (moderate risk, e.g., infusion pumps, glucose monitors, MRI machines), and Class III (high risk, e.g., pacemakers, prosthetic heart valves, breast implants). Key categories: cardiovascular (stents, defibrillators, pacemakers), orthopedic (joint replacements, plates/screws), neurologic (deep brain stimulators, cochlear implants), diagnostic imaging (CT, MRI, ultrasound), and wearable/remote monitoring devices (continuous glucose monitors, smartwatch ECG). Regulatory oversight (FDA, CE marking) ensures safety and efficacy through premarket approval or clearance (510(k)). Device-related complications include infection, malfunction, thrombosis, and foreign body reaction.

Microscope (Operating Microscope)

– A binocular microscope providing magnification and illumination for microsurgery. Magnification: 5x-40x adjustable, with oculars 12.5x or 10x and objective lens 200-400 mm. Coaxial illumination: light path aligned with the surgeon's line of sight. Foot pedal controls: zoom, focus, and positioning

(motorized stand). Used in: ophthalmic surgery (cataract, vitrectomy, corneal transplant), neurosurgery (tumor resection, aneurysm clipping, spinal surgery), ENT (stapedectomy, cochlear implant), microvascular surgery, and dental endodontics.

Nasogastric Tube

– A flexible tube inserted through the nose into the stomach. Sizes: 8-18 Fr. Types: Salem sump (double lumen: larger for drainage, smaller for air vent), Levin (single lumen), and feeding tubes (Dobhoff: small bore, weighted tip, for enteral nutrition). Indications: gastric decompression (ileus, obstruction), lavage (GI bleeding, overdose), enteral feeding (when oral intake is inadequate), and diagnostic (aspiration for analysis). Confirmation: X-ray (most reliable), pH testing (gastric pH <5), and auscultation (less reliable). Complications: sinusitis, trauma, aspiration, and tube malposition (lung placement).

Needle Holder

– A surgical instrument used to hold a suturing needle while passing it through tissue. Jaws: smooth or diamond-dusted (for microsurgery), cross-hatched or tungsten carbide inserts for grip. Lock: ratchet mechanism. Sizes: Mayo-Hegar (general, heavy), Crile-Wood (medium), Webster (fine, for ophthalmic/vascular), Castroviejo (spring-loaded, for microsurgery). Needle handling: hold at the junction of middle and distal third of the needle, perpendicular to the holder. The type of needle holder matches the needle size and tissue type.

Ophthalmoscope (Direct)

– A handheld instrument for examining the fundus (retina, optic disc, blood vessels). Lens wheel: +20 to -20 diopters (focus). Light source: halogen or LED, with filters (red-free for nerve fiber layer, cobalt blue for fluorescein). Technique: right-right eye-right hand, left-left-left. Normal: optic disc (pink, sharp margins, cup-to-disc ratio <0.5), retinal vessels (A:V ratio 2:3), macula (avascular, 2 disc diameters temporal to disc). Findings: papilledema, optic atrophy, diabetic retinopathy, hypertensive retinopathy, and glaucoma.

Oxygen Mask

– A device for delivering supplemental oxygen. Simple mask: 5-10 L/min, FiO₂ 35-55%. Non-rebreather: mask + reservoir bag + one-way valves; 10-15 L/min, FiO₂ 60-90%. Partial rebreather: simi-

lar without expiratory valve. Venturi mask: delivers precise FiO₂ (24%, 28%, 31%, 35%, 40%) via color-coded entrainment ports; used for COPD patients requiring controlled oxygen (avoid CO₂ retention). Nasal cannula: 1-6 L/min, FiO₂ 24-44%. High-flow nasal cannula: heated, humidified, up to 60 L/min, FiO₂ up to 100%, used in respiratory failure.

Pacemaker

– An implantable device that delivers electrical impulses to the heart to maintain adequate heart rate. Types: single chamber (ventricular VVI or atrial AAI), dual chamber (DDD, most physiologic), biventricular (CRT: cardiac resynchronization therapy for heart failure with wide QRS), and leadless (Micra, directly in RV). Indications: sick sinus syndrome, AV block (third-degree, symptomatic second-degree), and heart failure with reduced EF and LBBB. Pacing modes: NBG code (e.g., DDD = dual chamber paced/sensed, dual response). Complications: infection, lead dislodgement, and generator pocket hematoma.

Peak Flow Meter

– A handheld device used to measure peak expiratory flow rate (PEFR), the maximum speed of expiration after maximal inspiration. The patient takes a deep breath and blows as hard and fast as possible into the device. PEFR is measured in litres per minute. Used in asthma management: monitoring (diurnal variation, response to treatment), diagnosis (reversibility testing—improvement >20% after bronchodilator), and identification of exacerbations (PEFR <60% of personal best indicates severe exacerbation). Predicted PEFR values are based on age, sex, and height (normal healthy adult: 400–700 L/min). A zone system (green/yellow/red) is used for action plans: green (≥80% of personal best—well controlled), yellow (50–79%—caution, increased treatment may be needed), red (<50%—medical emergency). Limitations: effort-dependent, poor technique reduces reliability. Electronic peak flow meters are available with digital recording and Bluetooth connectivity.

Pulse Oximeter

– A non-invasive device measuring SpO₂ (peripheral oxygen saturation). Principle: spectrophotometry at 660 nm (red, deoxygenated hemoglobin) and 940 nm (infrared, oxygenated hemoglobin). Probe: fin-

ger, toe, earlobe, or forehead (for low perfusion). Normals: SpO₂ 95-100%. Desaturation: <90% (hypoxemia, PaO₂ 60 mmHg). Limitations: motion artifact, poor perfusion (cold, shock), dyshemoglobinemias (COHb: falsely high, metHb: tends toward 85%), dark nail polish, and ambient light interference. Essential for oxygen therapy titration and anesthesia monitoring.

Reflex

– An involuntary, stereotyped, rapid response to a specific stimulus, mediated by a reflex arc without conscious thought. In clinical medicine, reflexes are assessed as part of the neurological examination to localise lesions within the central and peripheral nervous system. Deep tendon reflexes (muscle stretch reflexes): elicited by tapping a tendon with a reflex hammer, activating muscle spindles, and causing a monosynaptic spinal reflex. Tested: biceps (C5–C6), brachioradialis (C5–C6), triceps (C7–C8), patellar (L3–L4), and ankle (S1). Graded 0–4+: 0 (absent), 1+ (diminished), 2+ (normal), 3+ (brisk, may be normal), 4+ (hyperactive, with clonus). Hyperreflexia (with clonus) suggests upper motor neuron lesion (stroke, spinal cord injury, multiple sclerosis). Hyporeflexia/areflexia suggests lower motor neuron lesion (peripheral neuropathy, radiculopathy, motor neuron disease). Superficial reflexes: abdominal (T8–T12), cremasteric (L1–L2), plantar (Babinski sign—L5–S1, normal is flexor; extensor/Babinski sign is abnormal after infancy, indicates upper motor neuron lesion). Primitive reflexes (frontal release signs): grasp, palmental, snout, glabellar—emerge with frontal lobe pathology. Hoffman sign (finger flexor reflex) and Tromner sign: hyperactive deep tendon reflexes suggesting upper motor neuron lesion.

Reflex Hammer

– A tool for testing deep tendon reflexes by striking a tendon. Types: Queen Square (most common, triangular rubber head), Troemner (circular head, weighted), Babinski (whip-like for plantar response). Scoring: 0 (absent), 1+ (hypoactive), 2+ (normal), 3+ (hyperactive), 4+ (clonus). Reflexes tested: biceps (C5-6), brachioradialis (C6), triceps (C7), patellar (L3-4), Achilles (S1). Hyperreflexia suggests upper motor neuron lesion; hyporeflexia suggests lower motor neuron lesion, neuropathy, or

neuromuscular junction disorder.

Retractor

– A surgical instrument used to hold back edges of tissue or organs to expose the operative field. Handheld: Army-Navy (small, versatile), Richardson (large abdominal), Deaver (deep abdominal), Senn (double-ended: rake and blade), and Roux (breast/thyroid). Self-retaining: Balfour (abdominal, blades retract laterally), Bookwalter (ring system with multiple retractor blades, for complex abdominal surgery), Gelpi (sharp points, for spinal or deep small incisions), Weitlaner (toothed, for superficial wounds), and O'Sullivan-O'Connor (obstetric, for cesarean section).

Rhinoscope

– An instrument for examining the nasal cavity. Anterior rhinoscopy: standard nasal speculum with a headlight, examines the anterior nasal cavity (inferior turbinate, septum, vestibule). Nasal endoscopy (rigid rhinoscope): 0°, 30°, or 45° Hopkins rod telescopes, 2.7-4.0 mm diameter. Provides detailed examination of the middle meatus, ostia of the sinuses, sphenoethmoidal recess, and posterior choana. Indications: sinusitis, nasal obstruction, epistaxis, polyps, and nasal masses. Used for office-based diagnosis and endoscopic sinus surgery.

Robot (Surgical Robot)

– A robotic system for minimally invasive surgery (da Vinci Surgical System). Components: surgeon console (3D high-definition view, wrist controls, foot pedals), patient-side cart (4 robotic arms with articulated EndoWrist instruments), and vision cart (dual 3D camera system). Advantages: 7 degrees of freedom, tremor filtration, motion scaling, and 3D magnified visualization. Uses: prostatectomy, hysterectomy, colectomy, cholecystectomy, thoracic surgery, and transoral robotic surgery (TORS). Cost and steep learning curve are limitations.

Scalpel

– A small, sharp blade used for surgical incisions. Handles: #3 (small, for #10, #11, #12, #15 blades), #4 (large, for #20, #21, #22, #23, #24 blades), #7 (long, delicate, for #15 blade). Blade shapes: #10 (curved, general incisions), #11 (pointed, stab incisions), #12 (curved, tonsil), #15 (small, precise, ophthalmic, plastic, hand), #20 (larger curved, abdominal). Disposable scalpel:

single-piece plastic handle with pre-attached blade. Safety handles: retractable blade for sharps prevention.

Sclerometer (Tonometer)

– An instrument for measuring intraocular pressure. Goldmann applanation tonometer: gold standard, mounted on a slit lamp, flattens a 3.06 mm diameter area of cornea, pressure reading in mmHg. Indentation tonometry (Schiotz): less accurate, portable. Non-contact (air puff): convenient for screening, less accurate. Normal IOP: 10-21 mmHg. Elevated: glaucoma (primary open angle, angle closure). Used for glaucoma screening, monitoring, and management.

Slit Lamp (Biomicroscope)

– A binocular microscope with an adjustable light source (slit beam) for examining the anterior and posterior segments of the eye. Magnification: 6x-40x. Slit beam width and height adjustable. Filters: cobalt blue (fluorescein examination), red-free. Uses: cornea (abrasion, ulcer, keratitis, dystrophy), anterior chamber (cells, flare, depth), iris (synechiae, neovascularization), lens (cataract), vitreous (hemorrhage, cells), and retina (limited view without fundus lens). Combined with tonometer and gonioscope lens.

Speculum (Vaginal)

– An instrument for opening the vaginal walls to examine the cervix and upper vagina. Types: Graves (most common, two blades, screw or ratchet adjustment, sizes: neonatal, pediatric, small, medium, large), Pederson (narrower blades, for nulliparous or narrow introitus), and Cusco (bivalve, self-retaining, used outpatient). Inserted at 45-degree angle, rotated to transverse, opened by turning the screw. Used for Pap smear collection, cervical culture, IUD insertion, and colposcopy. Lubricate sparingly (affects Pap cytology).

Sphygmomanometer

– See BP Cuff.

SpO2 Probe

– See Pulse Oximeter.

Stapler (Surgical Stapler)

– A device for placing rows of staples to close tissue, divide organs, or reconnect segments. Types: linear cutter (GIA: gastrointestinal anastomosis, fires two triple-staggered rows and cuts between), linear

stapler (TA: thoracic-abdominal, fires two rows, no knife), circular stapler (EEA: end-to-end anastomosis, for bowel and esophageal surgery), and skin stapler (disposable, rapid skin closure). Staples: titanium or stainless steel. Uses: lung resection, colectomy, gastrectomy, bowel anastomosis, and wound closure. Bioabsorbable and laparoscopic staplers available.

Steam Sterilizer (Autoclave)

– A device for sterilizing medical instruments and supplies with saturated steam under pressure. Conditions: 121°C at 15 psi for 30 minutes (gravity displacement) or 134°C at 30 psi for 3-15 minutes (prevacuum). Kills all microorganisms including spores. Indicators: chemical (autoclave tape, Bowie-Dick test) and biological (*Geobacillus stearothermophilus* spore vials). Flashing: short-cycle sterilization of unwrapped instruments for immediate use. Not for heat-sensitive items (use ethylene oxide or hydrogen peroxide plasma).

Stethoscope

– An acoustic device for auscultation of heart, lung, and bowel sounds. Components: chestpiece (bell for low-frequency sounds — heart murmurs; diaphragm for high-frequency sounds — breath sounds, normal heart sounds), tubing (Y-shaped, single- or dual-lumen), and earpieces (angled to match ear canal direction). Electronic stethoscope: amplifies sound (up to 40x), filters ambient noise, and can record/transmit sounds for telemedicine. Types: Littmann (Cardiology, Classic), Welch Allyn, and pediatric. Essential for physical diagnosis.

Suction Device

– A device that creates negative pressure to remove fluids, secretions, or debris from a surgical field or airway. Components: vacuum source (wall suction or portable pump), collection canister, tubing, and suction tips. Suction tips: Yankauer (tonsil tip, rigid, large-bore, for oral and surgical suction), Poole (abdominal, multi-perforated to prevent tissue grasping), Frazier (fine, flexible, for ENT/neurosurgery), and catheter suction (flexible, for endotracheal suction). Wall suction: 80-120 mmHg (low), 120-200 (high).

Surgical Drill

– A powered instrument for cutting bone and drilling holes for screws. Powered: pneumatic (nitrogen-

driven, high torque, used in orthopedic and neurosurgery) or electric (battery-powered, variable speed). Attachments: burr (round, acorn, for burr holes and shaping), reamer (for acetabular preparation in hip arthroplasty), and wire driver (for K-wire placement). Used in: craniotomy (burr holes), orthopedic surgery (joint replacement, fracture fixation, spinal fusion), and ENT (mastoidectomy, cochlear implant). Sterilization between uses.

Suture Material

– Thread used to approximate tissues. Absorbable: surgical gut (10-14 days), polyglactin 910 (Vicryl, 60-90 days), poliglecaprone (Monocryl, 90-120 days), polydioxanone (PDS, 180 days). Non-absorbable: nylon (Ethilon, permanent, monofilament), polypropylene (Prolene, permanent, monofilament), silk (braided, handles well, permanent but can degrade), polyester (Ethibond, braided, permanent). Sizes: 1-0 (large, orthopedic) to 12-0 (microvascular). Needle types: cutting (skin), reverse cutting, taper (soft tissue), blunt (liver). Coated vs. uncoated.

Syringe

– A device for injecting or withdrawing fluids. Parts: barrel (graduated), plunger (rubber-tipped), and tip (Luer-Lok for secure connection, Luer-Slip for friction fit). Sizes: 1 mL (tuberculin, insulin), 3 mL (most common), 5 mL, 10 mL, 20 mL, 50-60 mL (irrigation, tube feeding). Insulin syringe: 0.3-1.0 mL, 29-31 gauge needle, marked in units (U-100). Tuberculin syringe: 1 mL, for PPD, allergy testing. Safety syringes: retractable needle or shield to prevent needlestick injury. Needles: gauge (larger number = smaller diameter), length (3/8 to 3 inches).

Thermometer

– An instrument for measuring body temperature. Types: (1) Mercury-in-glass thermometer—traditional, accurate (0.1°C precision), but mercury is toxic; phased out in many countries (banned in EU since 2009). (2) Digital electronic thermometer—uses a thermistor or thermocouple, fast (10-60 seconds), accurate, disposable probe covers. (3) Infrared tympanic thermometer—measures infrared heat from the tympanic membrane, fast (1-2 seconds), approximates core temperature, widely used in emergency departments and outpatient settings. (4) Temporal

artery thermometer—infrared scan across the forehead, non-invasive, fast. (5) Liquid crystal forehead strip—least accurate, for screening only. (6) Indwelling temperature probes—esophageal, nasopharyngeal, bladder, rectal, pulmonary artery catheter (gold standard for core temperature monitoring in ICU/theatre). Normal temperature varies by site: rectal (36.6–38.0°C), oral (36.0–37.4°C), axillary (35.5–37.0°C), tympanic (35.8–38.0°C). Factors: diurnal variation, exercise, eating, age, and menstrual cycle. Clinically significant: fever (pyrexia) >38°C, hyperpyrexia >41.5°C, hypothermia <35°C.

Thoracentesis Kit

– A sterile tray containing instruments for pleural fluid aspiration. Components: 18-22 gauge thoracentesis needle/catheter, three-way stopcock, 50-60 mL syringe, extension tubing, specimen collection tubes (culture, chemistry, cytology, cell count), and sterile drape. Ultrasound guidance is standard of care (reduces pneumothorax). Insertion: at the superior aspect of the rib (to avoid intercostal neurovascular bundle), posteriorly (for effusion) or anteriorly (for pneumothorax). Maximum safe aspiration: 1-1.5 L (risk of re-expansion pulmonary edema).

Tongue Depressor

– A thin, flat wooden or plastic blade used to depress the tongue for examination of the oropharynx and oral cavity. Adult size: 15 cm x 2 cm. Indications: oropharyngeal examination for tonsillitis, pharyngitis, and oral ulcers. Also used as an emergency airway tool (simple jaw thrust in CPR) and for mixing dental materials. Disposable (single-use). Can be broken to create a sharp edge for emergency cricothyroidotomy.

Tourniquet

– A device that constricts blood flow to a limb. Types: surgical tourniquet (pneumatic cuff, controlled pressure, used in orthopedic surgery to create a bloodless field: upper arm 250 mmHg, thigh 300 mmHg, max time 1-2 hours), emergency tourniquet (CAT, SOFT-T: windlass mechanism for battlefield hemorrhage control), and venous tourniquet (elastic band for venipuncture). Complications of prolonged use: nerve injury, muscle ischemia, rhabdomyolysis, and compartment syndrome.

Tracheostomy Tube

– A curved tube inserted into the trachea through a

surgical tracheostomy. Parts: outer cannula (with flange and ties), inner cannula (removable for cleaning), and obturator (for insertion). Cuffed tube: balloon inflated for mechanical ventilation and aspiration prevention. Uncuffed: for patients with spontaneous breathing and low aspiration risk. Fenestrated tube: allows speech when capped. Sizes: 4-10 (inner diameter in mm). Shiley (most common), Portex, and Bivona brands. Indications: prolonged ventilation, upper airway obstruction, and severe secretions management.

Tuning Fork

– A metal two-pronged instrument that vibrates at a specific frequency when struck, used for hearing and vibration sensation testing. Frequencies: 128 Hz and 256 Hz (vibration sensation testing), 256 Hz and 512 Hz (hearing tests). Rinne test: tuning fork on mastoid (bone conduction) then next to ear (air conduction); normal: air > bone (Rinne positive). Conductive loss: bone > air (Rinne negative). Weber test: tuning fork on vertex; lateralizes to affected ear in conductive loss, to unaffected ear in sensorineural loss.

Ultrasound Machine

– A device using high-frequency sound waves (2-18 MHz) to create real-time images of internal structures. Components: transducer (piezoelectric crystals generate and receive sound waves), processing unit (converts echo signals to images), and display. Modes: B-mode (brightness, 2D grayscale), M-mode (motion, for cardiac function), Doppler (color, spectral, power for blood flow), and 3D/4D. Transducers: curvilinear (abdominal, obstetric, 2-5 MHz), linear (vascular, breast, MSK, 7-15 MHz), phased array (cardiac, 2-4 MHz), and endocavitary (TVUS, TRUS). Indications: abdominal, obstetric, cardiac, vascular, MSK, and emergency (FAST, POCUS).

Urinary Catheter

– See Catheter.

Ventilator

– See Mechanical Ventilator.

Wheelchair

– A chair with wheels for mobility-impaired patients. Types: manual (self-propelled or attendant-propelled: standard, transport, lightweight, sports), power/electric (joystick or sip-and-puff control, for patients unable to self-propel). Components: frame

(folding vs. rigid), seat and back cushion (pressure redistribution), armrests (full, half, or desk-length), footrests (swing-away, elevating leg rest), and wheels (24-inch rear with push rims, 8-inch front casters). Measurements: seat width (16-20 inches), seat depth, back height. Used for: spine cord injury, amputation, stroke, multiple sclerosis, and severe deconditioning.

Chapter 20

Medical Tests

Abdominal Aortic Aneurysm Screening

- Ultrasound screening for AAA recommended for men aged 65-75 with smoking history (USPSTF). A one-time abdominal ultrasound detects infrarenal aortic diameter ≥ 3 cm. Surveillance: 3.0-3.9 cm q3 years, 4.0-4.4 cm q12 months, 4.5-5.4 cm q6 months. Surgical referral at ≥ 5.5 cm or rapid enlargement (>1 cm/yr). Screening reduces AAA-related mortality by 50%.

Abdominal X-Ray

- Plain radiograph of the abdomen (KUB: kidneys, ureters, bladder). Indications: suspected bowel obstruction (air-fluid levels, dilated loops), perforation (free air under diaphragm), constipation, foreign body, and renal calculi (90% of stones are radiopaque). Sensitivity low for most intra-abdominal pathology. Uses: limited to specific clinical scenarios; CT is preferred for most acute abdominal conditions.

ABO Blood Typing

- Determination of a patient's ABO and Rh blood group prior to transfusion or organ transplantation. ABO system: A (A antigen, anti-B antibody), B (B antigen, anti-A antibody), AB (both antigens, no antibodies), O (no antigens, both antibodies). Rh: D antigen positive (85%) or negative (15%). Universal donor: O negative. Universal recipient: AB positive. Crossmatching confirms compatibility between donor and recipient.

Acid-Fast Bacillus (AFB) Smear

- Microscopic examination of sputum for acid-fast bacilli (*Mycobacterium tuberculosis*), using Ziehl-Neelsen or auramine-rhodamine stain. Positive smear indicates active pulmonary TB and correlates with infectiousness. Sensitivity: 50-80% in culture-positive TB. Three specimens collected on

consecutive mornings. Grading: negative, 1+ (1-9 per 100 fields), 2+ (1-9 per 10 fields), 3+ (1-9 per field), 4+ (>9 per field). Culture and NAAT are more sensitive.

AFP (Alpha-Fetoprotein)

- A tumor marker and prenatal screening analyte. Tumor marker: hepatocellular carcinoma (elevated in 60-80%, >400 ng/mL highly specific), yolk sac tumors (germ cell tumors). Non-specific: cirrhosis, hepatitis, pregnancy. Prenatal: elevated in neural tube defects (maternal serum AFP). Screening for HCC: AFP + ultrasound q6 months in high-risk patients (cirrhosis, chronic HBV/HCV). AFP-L3 (isoform) improves specificity.

Allergy Testing

- Identification of IgE-mediated allergic sensitization. Skin prick test (SPT): allergen extract applied to skin via lancet, read after 15 min (wheal >3 mm = positive). Intradermal test: more sensitive, used when SPT negative but suspicion remains. Specific IgE (formerly RAST): blood test measuring allergen-specific IgE levels; unaffected by antihistamines. Total IgE: elevated in atopic disease and parasitic infection. Indications: allergic rhinitis, asthma, food allergy, drug allergy, and anaphylaxis evaluation.

Alvarado Score

- Clinical scoring system for acute appendicitis. Components (MANTRELS): Migration of pain (1), Anorexia (1), Nausea/vomiting (1), Tenderness in RLQ (2), Rebound pain (1), Elevated temperature (1), Leukocytosis (2), Left shift (1). Scores: 1-4 (low probability, observe), 5-6 (moderate probability, CT or ultrasound), 7-10 (high probability, surgical consult). MASS (Modified Alvarado) removes left shift and uses 0-9.

Ammonia

- Measurement of serum ammonia (NH₃). Normal: 15-45 mcg/dL (9-33 micromol/L). Elevated in hepatic encephalopathy (monitoring and diagnosis), urea cycle disorders (very high, >200 in neonates), Reye syndrome, and valproate therapy. Timing: must be collected in pre-chilled tube on ice and processed within 20 minutes (falsely elevated by delayed processing, smoking, exercise, and hemolysis). Used in initial evaluation of altered mental status with liver disease and suspected metabolic disorders.

Amniocentesis

- Sampling of amniotic fluid for prenatal diagnosis. Typically performed at 15-20 weeks gestation. Indications: advanced maternal age (≥ 35), abnormal quad screen, family history of genetic disorders, and fetal lung maturity assessment. Analyzed for karyotype, FISH (aneuploidy of 13, 18, 21, X, Y), microarray, and AFP (neural tube defects). Procedure: ultrasound-guided needle aspiration of 15-20 mL of fluid. Risks: miscarriage (0.1-0.3%), infection, and fetal injury.

Amylase and Lipase

- Pancreatic enzymes, elevated in acute pancreatitis. Lipase is more specific (pancreas-only) and remains elevated longer than amylase. Normal: amylase 30-110 U/L, lipase 10-140 U/L. Diagnosis: elevation $>3\times$ upper limit of normal, with compatible clinical presentation (epigastric pain, nausea/vomiting). Amylase also elevated in salivary gland disease, intestinal obstruction, perforated ulcer, and ectopic pregnancy. Lipase is the preferred single test for pancreatitis.

Analysis of Urine

- See Urinalysis.

Angiography

- Invasive imaging of blood vessels by injecting contrast material under fluoroscopy. Coronary angiography (cardiac catheterization): assesses coronary artery stenosis, guides PCI. Cerebral angiography: evaluates aneurysms, AVMs, and vasculitis. Peripheral angiography: evaluates PAD and guides intervention. Requires arterial access (femoral, radial). Complications: bleeding, pseudoaneurysm, contrast nephropathy, atheroembolism, and dissection. CTA and MRA have largely replaced diagnostic angiography.

Angioplasty

- Percutaneous coronary intervention (PCI) to open stenotic coronary arteries. Balloon angioplasty: inflation of balloon at the lesion to compress plaque. Bare metal stent (BMS): metal scaffold, restenosis 20-30%. Drug-eluting stent (DES): elutes antiproliferative (sirolimus, paclitaxel, everolimus), restenosis 5-10%. Dual antiplatelet therapy (DAPT: aspirin + P2Y₁₂ inhibitor) required after stent placement. Indications: STEMI, NSTEMI, unstable angina, and stable angina refractory to medical therapy.

Ankle-Brachial Index

- Ratio of systolic BP at the ankle (dorsalis pedis or posterior tibial artery) to the brachial artery, measured with Doppler. Normal: 1.0-1.4. PAD: ABI ≤ 0.90 (mild 0.7-0.9, moderate 0.4-0.7, severe <0.4). Non-compressible vessels (ABI >1.4 , shows calcified vessels in diabetes). Uses: screening for PAD, wound healing assessment, and cardiovascular risk stratification. Toe-brachial index (TBI) if ABI unreliable.

Antibiogram

- A periodic summary of antimicrobial susceptibility patterns of bacterial isolates from a hospital or laboratory. Guides empiric antibiotic therapy by showing local resistance patterns (e.g., % of *E. coli* susceptible to TMP-SMX). Updates annually. Clinicians use antibiograms to select appropriate empiric antibiotics while awaiting culture results. Cumulative antibiograms report susceptibilities for the most common pathogens.

Anti-CCP Antibody

- Anti-cyclic citrullinated peptide antibody, a highly specific serologic marker for rheumatoid arthritis (specificity $>95\%$, sensitivity 70%). Positive anti-CCP is associated with more aggressive erosive RA. Appears early in disease and may precede clinical symptoms. Used in the ACR/EULAR classification criteria with RF and acute phase reactants. Testing recommended in any patient with unexplained inflammatory polyarthritis.

Anti-dsDNA Antibody

- Anti-double-stranded DNA antibody, highly specific for systemic lupus erythematosus (specificity 95%, sensitivity 60-70%). Elevated titers correlate with active disease, particularly lupus nephritis and systemic vasculitis. Serial monitoring used to assess disease activity and treatment response. In

the ACR classification criteria for SLE. Other autoantibodies in SLE: anti-Smith (specific but low sensitivity), anti-Ro/SSA, anti-La/SSB, anti-RNP.

Anti-Mullerian Hormone

– AMH is a glycoprotein produced by granulosa cells of ovarian follicles, reflecting the ovarian reserve (quantity of remaining oocytes). Uses: assessment of ovarian reserve in infertility evaluation, predicting response to ovarian stimulation in IVF, diagnosis of PCOS (elevated), and monitoring for granulosa cell tumors. AMH declines with age and is undetectable after menopause. Unlike FSH, AMH is cycle-independent and reliable any day of the menstrual cycle.

Antinuclear Antibody (ANA)

– A screening test for autoimmune connective tissue diseases. Positive in SLE (sensitivity 95%), Sjogren syndrome, systemic sclerosis, mixed connective tissue disease, and many other autoimmune conditions. Titer: 1:40 (low positive, common in healthy), 1:160 (clinically significant), 1:320 (strongly positive). Pattern: homogeneous (SLE, drug-induced), speckled (SLE, Sjogren, MCTD), nucleolar (scleroderma), centromere (limited scleroderma). Positive ANA requires further testing for specific autoantibodies.

Arterial Blood Gas (ABG)

– Direct measurement of arterial blood for pH, PaCO₂, PaO₂, HCO₃⁻, base excess, and oxygen saturation. Indications: respiratory failure assessment, acid-base disorder evaluation, ventilator management, and critical care. Normal values: pH 7.35-7.45, PaCO₂ 35-45 mmHg, PaO₂ 80-100 mmHg, HCO₃⁻ 22-26 mEq/L, SaO₂ 95-100%. Sample: radial artery (Allen test for collateral flow). Complications: hematoma, arterial spasm, thrombosis, and infection.

Arthrocentesis

– Aspiration of joint fluid for diagnostic or therapeutic purposes. Indications: septic arthritis (urgent, crystals), inflammatory arthritis (gout, pseudogout), hemorrhagic effusion (trauma, coagulopathy), and therapeutic drainage for symptomatic relief. Synovial fluid analysis: cell count/differential, Gram stain/culture, crystal analysis (polarized light microscopy: monosodium urate = needle-shaped, negatively birefringent; CPPD = rhomboid, weakly positively birefringent), and glucose/protein.

Audiometry

– Objective measurement of hearing thresholds across frequencies. Pure tone audiometry: air conduction (headphones) and bone conduction (mastoid oscillator) thresholds at 250-8000 Hz. Conductive hearing loss: abnormal air, normal bone (air-bone gap). Sensorineural: abnormal both. Speech audiometry: speech reception threshold (SRT) and word recognition score (WRS). Tympanometry: middle ear function (type A normal, B effusion, C negative pressure). Used for hearing loss diagnosis and hearing aid candidacy.

Barium

– A metallic element (atomic number 56, symbol Ba) whose sulfate salt (barium sulfate) is used as a radiocontrast agent due to its high atomic number, which effectively absorbs X-rays. Barium sulfate is insoluble and passes through the gastrointestinal tract without absorption, allowing radiographic visualization of the esophagus (barium swallow), stomach and duodenum (upper GI series), small bowel (barium follow-through), and colon (barium enema). Adverse effects include constipation and, rarely, barium impaction. Barium should not be used if perforation is suspected.

Barium Enema

– Fluoroscopic imaging of the large intestine after retrograde filling with barium contrast. Double-contrast (barium + air) provides better mucosal detail. Indications: colorectal cancer screening (historical, now CT colonography preferred), evaluation of colonic obstruction, diverticulosis, and postsurgical anatomy. Findings: filling defects (polyp, cancer), strictures, diverticula, and fistulas. Contraindications: suspected perforation (use water-soluble contrast). Largely replaced by colonoscopy.

Barium Swallow

– Fluoroscopic examination of the esophagus (pharynx to gastroesophageal junction) with barium contrast. Modified barium swallow: speech therapist evaluates oral and pharyngeal phases of swallowing. Indications: dysphagia, esophageal dysmotility (achalasia, diffuse esophageal spasm), hiatal hernia, GERD, stricture, and esophageal cancer. Findings: aspiration, cricopharyngeal bar, webs, rings (Schatzki), strictures, and diverticula (Zenker, epiphrenic).

Basic Metabolic Panel

– A panel of blood tests measuring serum glucose, sodium, potassium, chloride, bicarbonate, BUN, and creatinine. Also includes calcium in some institutions. Uses: assess hydration status, renal function, acid-base balance, and glucose control. Abnormalities suggest electrolyte disturbances, renal impairment, diabetes, or acid-base disorders. BMP is used for monitoring hospitalized patients and annual health screening.

BCG Vaccine

– Bacille Calmette-Guerin, a live attenuated vaccine derived from *Mycobacterium bovis*, used for TB prevention. Efficacy: 60-80% against disseminated TB and TB meningitis in children; variable efficacy against pulmonary TB. Indications: part of routine childhood immunization in high-TB-burden countries. Not routinely used in low-risk countries (interferes with TST/IGRA screening). Also used as intravesical immunotherapy for non-muscle invasive bladder cancer.

Biophysical Profile (BPP)

– Antepartum fetal assessment combining ultrasound and NST. Components (2 points each): NST reactivity (reactive), fetal breathing movements (≥ 1 episode of 30 seconds in 30 minutes), fetal movement (≥ 3 discrete movements in 30 minutes), fetal tone (≥ 1 episode of extension/flexion), and amniotic fluid volume (AFI ≥ 5 cm). Score: 8-10 (normal), 6 (equivocal, deliver if term, repeat if preterm), 4 (suspect asphyxia, deliver), 0-2 (probable asphyxia, deliver). Modified BPP: NST + AFI.

Biopsy

– Sampling of tissue for histopathologic examination. Types: needle biopsy (core needle: breast, liver, kidney, prostate; fine needle: thyroid, lymph node), excisional biopsy (entire lesion removal), incisional biopsy (partial sampling), endoscopic biopsy (GI, bronchoscopic), punch biopsy (skin), shave biopsy (skin), and stereotactic biopsy (breast guided by mammography). Essential for distinguishing benign from malignant, staging, and identifying inflammatory or infectious pathology.

Blood Alcohol Level

– Measurement of ethanol concentration in blood. Legal limit for driving: 0.08 g/dL (80 mg/dL) in most US states. Impaired: 0.04-0.08 g/dL. Severe in-

toxication: 0.15-0.30 g/dL. Potentially fatal: >0.30 g/dL. With chronic alcoholism: marked tolerance (may appear functional at 0.30+). Elimination rate: 15-25 mg/dL/hour. Uses: legal (DUI assessment), medical (alcohol intoxication, withdrawal management), and screening. Serum: whole blood ratio approximately 1.18:1.

Blood Culture

– Inoculation of blood into culture media to detect bacteremia or fungemia. Two sets (two bottles each: aerobic + anaerobic) from separate venipuncture sites, 20-30 mL total. Indications: fever of unknown origin, suspected sepsis, infective endocarditis, and immunocompromised with fever. Positive cultures with identification and susceptibility (MIC) guide targeted antibiotic therapy. Negative cultures do not rule out infection (especially with prior antibiotics, fastidious organisms, or intracellular pathogens).

Blood Gas (Venous)

– Sampling of venous blood (typically from a peripheral vein or central line) for pH, PvCO₂, HCO₃, and base excess. Less painful than ABG, avoids arterial puncture risks. Limitations: no PaO₂ or SpO₂ data; peripheral venous gases in shock may not reflect arterial pH. VBG pH is typically 0.03-0.05 lower than ABG; PvCO₂ is 3-8 mmHg higher. Used for acid-base assessment and CO₂ monitoring when oxygenation is not the primary concern.

Bone Marrow Aspiration and Biopsy

– Sampling of bone marrow, typically from the posterior iliac crest. Aspiration: liquid marrow for cytology (differential, morphology), flow cytometry, cytogenetics, and MRD. Biopsy: core of bone for cellularity, architecture, fibrosis, and infiltrative disease (lymphoma, metastatic cancer, granulomas). Indications: unexplained cytopenias, leukemia, lymphoma, multiple myeloma, myelodysplasia, myelofibrosis, and staging of certain malignancies. Contraindication: severe coagulopathy.

Bone Scan (Nuclear Scintigraphy)

– Nuclear medicine imaging using Tc-99m MDP (methylene diphosphonate) that accumulates in areas of increased bone turnover. Three phases: perfusion (immediate), blood pool (5 min), and delayed (2-3 hours). Indications: occult fracture, metastatic

disease (breast, prostate, lung), osteomyelitis, complex regional pain syndrome (CRPS), avascular necrosis, and Paget disease. Findings: increased uptake in osteoblastic activity. Limitations: poor specificity (cannot distinguish tumor from infection or fracture). Used with SPECT for better localization.

Brain Natriuretic Peptide (BNP)

– A cardiac neurohormone released from the ventricles in response to volume overload and wall stress. BNP <100 pg/mL makes heart failure unlikely; >400 pg/mL suggests heart failure. NT-proBNP: <125 pg/mL (<75 years) or <450 pg/mL (>75 years) excluding HF. Also prognostic: rising levels indicate worsening HF and higher mortality. Elevated in HF (systolic and diastolic), pulmonary embolism, CKD, and sepsis. Used for diagnosis, severity assessment, and monitoring therapy.

Breast MRI

– Magnetic resonance imaging of the breast with IV gadolinium contrast. Indications: screening high-risk women (BRCA mutation, lifetime risk >20%, prior chest radiation), evaluating extent of disease after breast cancer diagnosis, assessing response to neoadjuvant chemotherapy, implant evaluation, and problem-solving for equivocal mammogram/ultrasound. High sensitivity (>90%) but lower specificity, leading to false positives. BI-RADS lexicon: kinetics (wash-in, washout) and morphology.

Breast Ultrasound

– Ultrasound imaging of the breast. Indications: evaluating palpable masses (distinguishing solid vs. cystic), characterizing mammographic abnormalities, guiding biopsy (core needle, fine needle, or vacuum-assisted), evaluating implant integrity, and imaging young/dense breast tissue. BI-RADS US classification: simple cyst (benign), complicated cyst, complex cystic and solid, and solid mass (assessed by shape, margins, orientation, echogenicity, and posterior features). Used with mammography for comprehensive breast evaluation.

Bronchoscopy

– Endoscopic examination of the tracheobronchial tree. Flexible bronchoscopy: most common, for diagnosis (lung mass, persistent cough, hemoptysis, suspected infection, ILD) and therapy (foreign body

removal, bronchial washing, biopsy, BAL). Rigid bronchoscopy: for massive hemoptysis, large foreign bodies, and stent placement. Samples: BAL (bronchoalveolar lavage: cell count, culture, cytology), transbronchial biopsy (lung parenchyma), endobronchial biopsy (visible lesions), and EBUS-TBNA (mediastinal lymph node sampling).

CA-125

– Cancer antigen 125, a tumor marker most commonly used for ovarian cancer. Elevated in 80% of epithelial ovarian cancers (less in mucinous). Non-specific: elevated in endometriosis, PID, pregnancy, fibroids, pancreatitis, cirrhosis, and other malignancies (pancreatic, breast, lung, endometrial). Normal: <35 U/mL. Uses: monitoring treatment response in known ovarian cancer, detecting recurrence, and differential diagnosis of pelvic mass (with Risk of Malignancy Index). Not recommended for screening (low specificity, high false positives).

CA 19-9

– A tumor marker for pancreatic cancer. Normal: <37 U/mL. Sensitivity: 70-80% for pancreatic cancer (lower for early-stage). Specificity: limited (elevated in cholangitis, pancreatitis, cholecystitis, biliary obstruction, cirrhosis, and other GI malignancies). Uses: monitoring treatment response in known pancreatic cancer, detecting recurrence, and prognosis. Not recommended for screening (low sensitivity/specificity). Non-secretor phenotype (Lewis a-b-, 5-10% of population) cannot produce CA 19-9, limiting its use.

Capsule Endoscopy

– A wireless, ingestible camera capsule (11 x 26 mm) that takes 50,000+ images as it traverses the GI tract. Used to visualize the small intestine (beyond reach of standard endoscopy). Indications: obscure GI bleeding, Crohn disease (small bowel involvement), suspected small bowel tumors, and surveillance in familial polyposis. Images transmitted to a data recorder worn on a belt, downloaded for review (3-4 hour study). Limitations: cannot biopsy or treat, capsule retention (1-2% risk, higher in Crohn strictures), and poor visualization of the stomach and colon. PillCam (Given Imaging) and EndoCapsule (Olympus) are common systems.

Cardiac Catheterization

– Invasive procedure to evaluate cardiac anatomy,

hemodynamics, and coronary arteries. Right heart catheterization: Swan-Ganz catheter measures RA, RV, PA pressures, PCWP, cardiac output (thermodilution), and SVR/PVR. Left heart catheterization: coronary angiography and ventriculography. Indications: CAD evaluation (stable angina with high-risk features, positive stress test, acute coronary syndromes), valvular disease (assess severity), cardiomyopathy, and pre-transplant evaluation. Complications: hematoma, bleeding, CVA, MI, arrhythmia.

Cardiac Stress Test

– Evaluation of cardiac function and ischemia under increased cardiac workload. Exercise stress test (treadmill, Bruce protocol): ECG monitoring for ST-segment changes, symptoms, BP response, and arrhythmias. Sensitivity 65-75% for CAD. Pharmacologic stress test: dobutamine (inotrope/chronotrope), regadenoson/adenosine/dipyridamole (vasodilator) — used for patients unable to exercise. Imaging: stress echo (wall motion), nuclear perfusion (SPECT, PET), and stress MRI.

Cardiopulmonary Exercise Testing (CPET)

– Comprehensive exercise test with breath-by-breath analysis of respiratory gases (VO_2 , VCO_2 , VE). Indications: unexplained dyspnea, pre-operative risk assessment (lung resection, cardiac surgery), evaluation of exercise tolerance in heart failure (peak VO_2 predicts prognosis and guides transplant listing), and differentiating cardiac vs. pulmonary limitation. Key parameters: peak VO_2 (normal >80% predicted), anaerobic threshold (AT), VE/ VCO_2 slope (<30 normal, >34 poor prognosis in HF), and oxygen pulse (VO_2/HR). Maximum exercise test with 12-lead ECG and BP monitoring.

Cardioversion (Synchronized)

– Delivery of a low-energy electrical shock synchronized to the QRS complex to terminate arrhythmias. Synchronization: shock delivered on the R wave (not T wave, which induces VF). Energy: atrial fibrillation (100-200 J biphasic), atrial flutter (50-100 J), SVT (50-100 J), stable VT (100 J). Success: 70-90% for AF, >95% for atrial flutter. Pre-treatment: anticoagulation for >3 weeks or TEE-guided to exclude LA thrombus (for AF >48 hours). Complications:

thromboembolism, skin burns, arrhythmias, and sedation risks.

Caries Risk Assessment

– Systematic evaluation of an individual's likelihood of developing dental caries. Low risk: no active caries, good oral hygiene, regular fluoride exposure. Moderate risk: one or more active lesions in past 3 years, fair oral hygiene. High risk: multiple active lesions, poor oral hygiene, frequent sugar intake, low fluoride, xerostomia, smoking, or special healthcare needs. Based on clinical exam (caries, restorations), radiographs (incipient lesions), plaque assessment, and dietary/medical history. Guides recall interval (3-12 months) and preventive interventions.

Cariogram

– A computer-based program that illustrates the interaction of caries-related factors and provides an overall caries risk assessment. Factors: diet (content, frequency), bacteria (mutans streptococci, lactobacilli), fluoride exposure, saliva (flow rate, buffering capacity), plaque amount, and clinical/social history. Output: pie chart showing the relative weight of different etiological factors and the probability of avoiding new caries. Used for patient education and preventive planning.

Carotid Duplex Ultrasound

– Ultrasound evaluation of the carotid arteries for atherosclerotic plaque and stenosis. Measures peak systolic velocity (PSV) and end-diastolic velocity (EDV) in the internal carotid artery (ICA). Criteria: normal (<50% stenosis: PSV <125 cm/s), 50-69% (PSV 125-230, EDV 40-100), 70-99% (PSV >230, EDV >100), and occlusion (no detectable flow). Indications: TIA/stroke evaluation, asymptomatic bruit, pre-CABG screening, and surveillance of known stenosis. Plaque morphology: echolucent (high risk) vs. calcified.

Carpal Tunnel Syndrome Tests

– Provocative tests for diagnosing carpal tunnel syndrome. Tinel sign: percuss over median nerve at the carpal tunnel → tingling in median distribution. Phalen sign: hold wrists in full flexion for 60 seconds → reproduces symptoms. Durkan test (carpal compression): direct compression over carpal tunnel for 30 seconds → paresthesias. Thenar atrophy suggests advanced disease. Confirmatory: nerve conduction studies show prolonged distal latencies

and decreased conduction velocity across the carpal tunnel.

Catecholamines (Urine/Plasma)

– Measurement of catecholamines (epinephrine, norepinephrine, dopamine) and their metabolites (metanephrines, VMA) for diagnosis of pheochromocytoma and paraganglioma. Plasma free metanephrines: sensitivity 96-100%. 24-hour urinary fractionated metanephrines: sensitivity 90-95%. Elevated levels require tumor localization (CT/MRI, MIBG scan). False positives: stress, exercise, smoking, tricyclic antidepressants, MAOIs, and levodopa.

CD4 Count

– Absolute count of CD4+ T-helper lymphocytes, essential for monitoring HIV disease progression and treatment response. Normal: 500-1500 cells/uL. HIV staging: >500 (asymptomatic, start ART regardless), 200-500 (consider prophylaxis for some OIs), <200 (AIDS-defining: start PCP prophylaxis, TB screening, high risk of OIs). <100: risk of CMV, MAC, toxoplasmosis, cryptococcosis. Used with HIV viral load (HIV RNA) to guide ART initiation and monitor response (goal: undetectable viral load, CD4 recovery).

CEA (Carcinoembryonic Antigen)

– A tumor marker primarily for colorectal cancer. Normal: <3 ng/mL (non-smokers), <5 ng/mL (smokers). Uses: monitoring treatment response in metastatic colorectal cancer, surveillance for recurrence after curative resection (q3-6 months for 2 years, then q6-12 months for 5 years), and prognosis (preoperative level). Non-specific elevations: smoking, pancreatitis, IBD, cirrhosis, hepatitis, and other malignancies (lung, gastric, pancreatic, breast). Not recommended for screening.

Central Line Placement

– Insertion of a catheter into a central vein (internal jugular, subclavian, or femoral), with the tip in the superior (or inferior) vena cava. Ultrasound guidance is standard. Indications: administration of vasopressors, TPN, chemotherapy, long-term antibiotics, central venous pressure monitoring, hemodialysis, and plasmapheresis. Complications: arterial puncture, pneumothorax (subclavian > IJ), hemothorax, air embolism, catheter-related bloodstream infection, thrombosis, and malposition. Confirm

position with chest X-ray (tip at SVC-RA junction, 2-3 cm above RA). Suture and sterile dressing.

Cerebrospinal Fluid Analysis

– Laboratory examination of CSF obtained via lumbar puncture. Indications: meningitis, encephalitis, subarachnoid hemorrhage, demyelinating disease (MS: oligoclonal bands, elevated IgG index), and carcinomatous meningitis. Components: opening pressure (normal 10-20 cmH₂O), appearance (clear vs. cloudy vs. bloody), cell count/differential (normal <5 WBC, all monocytes; neutrophils in bacterial), glucose (CSF:serum ratio >0.6), protein (normal 15-45 mg/dL), Gram stain, culture, and PCR.

Cervical Screening (Pap Smear)

– Screening for cervical cancer by collecting cells from the transformation zone of the cervix. Liquid-based cytology (ThinPrep) or conventional Pap smear. HPV co-testing (high-risk HPV 16, 18, others) improves sensitivity. Screening guidelines: start at age 21; ages 21-29: Pap q3 years; ages 30-65: Pap + HPV q5 years or Pap q3 years; over 65: discontinue if adequate prior negative screening. Results: ASCUS, LSIL, HSIL, AGC, and carcinoma. Management per ASCCP risk-based guidelines.

Chest Tube Thoracostomy

– Insertion of a tube into the pleural space to drain air, fluid, or blood. Indications: pneumothorax (large, tension, or on mechanical ventilation), hemothorax, pleural effusion (empyema, malignant, transudative), and postoperative (cardiac, thoracic surgery). Tube sizes: small (8-14F for air), medium (16-24F for effusion), large (28-40F for hemothorax/empyema). Placement: triangle of safety (4th-5th intercostal space, midaxillary line). Complications: bleeding, infection, lung laceration, and re-expansion pulmonary edema.

Chorionic Villus Sampling

– Prenatal diagnostic test at 10-13 weeks gestation, earlier than amniocentesis. Transabdominal or transcervical biopsy of chorionic villi (placental tissue). Indications: advanced maternal age, abnormal first-trimester screen, carrier screening, or family history of genetic disorders. Analyzed for karyotype, FISH, and microarray. Advantages: earlier diagnosis than amniocentesis (allows earlier termination if desired). Risks: miscarriage (0.5-1%, slightly higher than

amniocentesis) and limb defects if performed <10 weeks. Does not detect neural tube defects (requires AFP at 16-18 weeks).

Coagulation Profile

– Panel of tests assessing the coagulation cascade. PT (prothrombin time, 11-14 sec): measures extrinsic and common pathways; elevated in vitamin K deficiency, warfarin, liver disease, DIC. INR standardizes PT for warfarin monitoring. PTT (partial thromboplastin time, 25-35 sec): measures intrinsic and common pathways; elevated in hemophilia A/B, heparin, lupus anticoagulant, factor deficiencies. Fibrinogen (200-400 mg/dL): acute phase reactant; low in DIC, liver disease. Mixing studies: corrects in factor deficiency, does not correct in inhibitor.

Colonoscopy

– Endoscopic examination of the entire colon from cecum to rectum. Indications: colorectal cancer screening (starting age 45 for average risk), surveillance (polyps: q3-5y; cancer: q1y; IBD: q1-2y for dysplasia), diagnostic (hematochezia, chronic diarrhea, iron deficiency anemia, change in bowel habits), and therapeutic (polypectomy, hemostasis, stricture dilation, stent placement). Requires full bowel preparation (polyethylene glycol, split-dose). Complications: perforation (0.03-0.3%), bleeding (0.1-1%), and sedation-related.

Colorectal Cancer Screening

– See Colonoscopy, FIT, FIT-DNA, CT Colonography.

Colorectal Cancer Screening Tests

– Multiple screening modalities. Stool-based: fecal immunochemical test (FIT, annual), high-sensitivity guaiac FOBT (annual), and multitarget stool DNA (FIT-DNA/Cologuard, q3y). Direct visualization: colonoscopy (q10y preferred), CT colonography (q5y), flexible sigmoidoscopy (q5-10y), and capsule colonoscopy (q5y). Guidelines: average risk start at age 45; stop at age 75 if adequate prior screening and negative; age 76-85: individual decision based on life expectancy and comorbidities. FIT is the most cost-effective option.

Colposcopy

– Magnified visualization of the cervix, vagina, and vulva after application of acetic acid. Indication: abnormal Pap smear (ASCUS with high-risk HPV,

LSIL, HSIL, AGC). Acetic acid causes acetowhite lesions in dysplastic epithelium. Lugol iodine (Schiller test): normal glycogenated epithelium stains brown; abnormal epithelium does not. Targeted biopsy (punch biopsies and endocervical curettage) of abnormal areas to confirm CIN (cervical intraepithelial neoplasia). Grading: CIN 1 (mild), CIN 2 (moderate), CIN 3 (severe/carcinoma in situ).

Complete Blood Count (CBC)

– A panel of blood tests evaluating cellular components: WBC (leukocytes: normal 4.5-11.0 K/uL), RBC (erythrocytes: male 4.5-5.9, female 4.1-5.1 M/uL), hemoglobin (male 13.5-17.5, female 12.0-16.0 g/dL), hematocrit (male 41-53%, female 36-46%), platelets (150-450 K/uL), RBC indices (MCV, MCH, MCHC), and differential (neutrophils, lymphocytes, monocytes, eosinophils, basophils). Uses: anemia, infection, bleeding, inflammation, and hematologic malignancy screening.

Comprehensive Metabolic Panel

– Extended version of BMP including albumin, total protein, alkaline phosphatase, ALT, AST, and bilirubin (total and direct). Evaluates liver function, kidney function, electrolytes, glucose, calcium, and protein status. Uses: preoperative assessment, medication monitoring, and liver/kidney disease evaluation. Flags acute and chronic conditions: transaminitis (hepatitis, NAFLD), elevated ALP (obstruction, bone disease), low albumin (cirrhosis, malnutrition).

Coronary Calcium Score

– Non-contrast CT measurement of coronary artery calcium (Agatston score). Score 0: no plaque, very low event risk (near 0% over 5 years). 1-100: mild plaque, moderate risk. 101-400: moderate plaque, increased risk. >400: extensive plaque, high risk. Used in ASCVD risk assessment for intermediate-risk patients when risk-based decision is uncertain. Independent predictor of cardiovascular events beyond traditional risk factors. Zero calcium score is an excellent negative predictor.

COVID-19 Test (SARS-CoV-2)

– Detection of SARS-CoV-2. NAAT (RT-PCR): gold standard, nasopharyngeal/nasal swab, highly sensitive/specific, results in 1-48 hours. Rapid antigen test: lateral flow, results in 15 minutes, sensitive in high viral load (early symptomatic), less sensi-

tive in asymptomatic. Serology: anti-S and anti-N antibodies, indicates prior infection or vaccination, not used for acute diagnosis. Used for diagnosis, infection control, and public health surveillance. Antiviral therapy (nirmatrelvir/ritonavir, remdesivir) for high-risk patients.

C-Reactive Protein (CRP)

– An acute-phase reactant produced by the liver in response to inflammation (IL-6). CRP rises within 4-6 hours of inflammatory stimulus and peaks at 36-50 hours. Uses: monitoring inflammatory disease activity (RA, vasculitis), detecting infection postoperatively, and cardiovascular risk stratification (hs-CRP: high-sensitivity). CRP >10 mg/L suggests significant inflammation or infection. More sensitive than ESR for acute changes.

Creatine Kinase (CK)

– An enzyme found in muscle, brain, and heart. CK-MB: cardiac isoenzyme (used historically for MI diagnosis, largely replaced by troponin). CK-MM: skeletal muscle (elevated in rhabdomyolysis, trauma, statins, myopathy). Total CK: elevated in muscle injury, myocardial infarction, seizures, hypothyroidism, and statin myopathy. Strikingly elevated in rhabdomyolysis (>5000-100,000 U/L). Used to monitor rhabdomyolysis (risk of AKI) and inflammatory myopathies.

Cryoglobulins

– Immunoglobulins that precipitate at cold temperatures (<37°C) and redissolve on warming. Types: Type I (monoclonal IgM, in MGUS, Waldenstrom, myeloma), Type II (mixed: monoclonal + polyclonal, in HCV infection), Type III (mixed polyclonal, in autoimmune disease). Presents with palpable purpura, arthralgias, neuropathy, and glomerulonephritis (membranoproliferative). Diagnosis: serum collected and transported at 37°C, cold-precipitated, measured as cryocrit. Treatment: address underlying cause (HCV: DAAs), immunosuppression.

CT Angiography (CTA)

– CT imaging with IV contrast timed to visualize arteries. Coronary CTA: assesses coronary artery stenosis and plaque, calcium scoring (Agatston). CTA chest: pulmonary embolism (PE protocol), aortic dissection. CTA head/neck: stroke evaluation, aneurysm, dissection, and vasculitis. CTA

abdomen: mesenteric ischemia, renal artery stenosis, and AAA. 64-slice or better scanners required. Advantages: non-invasive, three-dimensional reconstruction, and rapid acquisition. Disadvantage: radiation and contrast exposure.

CT Colonography (Virtual Colonoscopy)

– CT imaging of the colon after bowel preparation and air insufflation. Indications: colorectal cancer screening (alternative to colonoscopy), incomplete colonoscopy due to obstructing mass, and patients unable to undergo colonoscopy. Sensitivity >90% for polyps >10mm. Requires same bowel prep as colonoscopy. Limitations: cannot biopsy or remove polyps; positive findings require optical colonoscopy. No sedation required.

CT Scan (Computed Tomography)

– Cross-sectional imaging using X-rays and computer reconstruction. Non-contrast: evaluate hemorrhage, stones, and bone. IV contrast (iodinated): evaluate inflammation, infection, tumor, and vascular structures. Oral contrast: opacify bowel. Window settings: bone (fractures, calcifications), soft tissue (organs, masses), lung (pulmonary parenchyma), and brain (gray-white differentiation). Radiation dose varies (2-8 mSv for head, 5-15 mSv for body). Hounsfield units quantify tissue density.

Culture and Sensitivity

– Microbiological culture of a clinical specimen (blood, urine, sputum, wound swab, CSF) to identify pathogens and determine antimicrobial susceptibility. Culture media: blood agar (most bacteria), MacConkey (Gram-negative), chocolate agar (fastidious: *N. gonorrhoeae*, *H. influenzae*), and selective media. Automated systems (VITEK, MALDI-TOF) speed identification. MIC (minimum inhibitory concentration) reported as susceptible, intermediate, or resistant per CLSI breakpoints. Guides targeted antimicrobial therapy.

Cystoscopy

– Endoscopic examination of the urethra, bladder, and ureteral orifices. Flexible cystoscopy: office-based, local anesthesia. Rigid cystoscopy: OR, allows larger instruments for interventions. Indications: hematuria (gross or microscopic), recurrent UTIs, bladder tumor surveillance, lower urinary tract symptoms (obstruction), ureteral stent place-

ment/removal, and foreign body removal. Findings: tumors, stones, strictures, trabeculation, diverticula, and inflammation. Complications: infection, hematuria, and perforation.

Cytogenetics (Karyotype)

– Visualization of chromosomes under light microscopy from dividing cells (bone marrow, blood, amniotic fluid, tissue). Staining: G-banding (Giemsa, light and dark bands). Resolution: 400-550 bands per haploid genome. Detects: aneuploidy (trisomy 21, 18, 13, Turner, Klinefelter), structural abnormalities (translocations, deletions, inversions, duplications), and marker chromosomes. Essential in: prenatal diagnosis, hematologic malignancy (t(9;22) BCR-ABL in CML, t(15;17) PML-RARA in APL, t(8;14) MYC in Burkitt), and constitutional genetic disorders.

D-Dimer

– A fibrin degradation product, elevated in thrombosis (PE, DVT, DIC). High sensitivity but low specificity. D-dimer <500 ng/mL (ELISA) has high negative predictive value for VTE; used to rule out PE/DVT in patients with low or moderate pretest probability (Wells criteria). Age-adjusted D-dimer (>50 years: age x 0.1 mg/L) improves specificity in older patients. Also elevated in infection, inflammation, surgery, trauma, pregnancy, and malignancy.

Deep Vein Thrombosis Ultrasound

– Venous duplex ultrasound for DVT diagnosis. Complete compression ultrasound (CUS): venous segments are compressed; non-compressible = DVT (96% sensitivity for proximal DVT). Whole-leg ultrasound (proximal + distal): for symptomatic patients. Findings: intraluminal thrombus, absent flow, lack of compressibility, and abnormal Doppler signals. Distal DVT (calf) is less clinically significant; management varies.

Dental Radiographs

– Imaging for dental diagnosis. Intraoral: periapical (tooth root and surrounding bone), bitewing (interproximal caries detection, crestal bone level), and occlusal (larger area, localization). Panoramic (extraoral): wide view of jaws, teeth, sinuses, and TMJ; used for impacted teeth, fractures, pathology (cysts, tumors), and implant planning. CBCT (cone-beam CT): 3D imaging for implant planning and complex surgical cases. Frequency based on caries risk.

Direct Coombs Test (DAT)

– Direct antiglobulin test: detects antibodies or complement (C3) bound to the surface of RBCs in vivo. Positive in: autoimmune hemolytic anemia (warm: IgG, cold: C3), drug-induced hemolytic anemia, hemolytic transfusion reaction, and hemolytic disease of the newborn (HDN). Grading: 1+ to 4+. Used with indirect Coombs test (antibody screen for transfusion).

Doppler Ultrasound

– Ultrasound technique using the Doppler effect to evaluate blood flow. Color Doppler: direction and velocity of flow (red = toward transducer, blue = away). Spectral Doppler: waveform analysis (arterial: pulsatile; venous: continuous). Pulsed-wave: measures flow at a specific depth. Continuous-wave: measures high velocities (valvular stenosis). Uses: assessment of DVT, carotid stenosis, PAD, renal artery stenosis, valvular heart disease, and pregnancy (fetal umbilical artery, middle cerebral artery).

DXA Scan (Dual-Energy X-ray Absorptiometry)

– The gold standard for measuring bone mineral density (BMD) and diagnosing osteoporosis. Measures at the lumbar spine, total hip, and femoral neck. T-score: normal (≥ -1.0), osteopenia (-1.0 to -2.5), osteoporosis (≤ -2.5). Z-score (compared to age-matched) used in premenopausal women and men <50. Indications: women ≥ 65 , men ≥ 70 , younger adults with risk factors (prior fragility fracture, steroid use, hypogonadism, malabsorption). FRAX calculates 10-year fracture risk. Used for monitoring treatment response (repeat q2y).

Echocardiography

– Ultrasound imaging of the heart. Transthoracic (TTE): standard, assesses LV/RV function, wall motion, valves (stenosis, regurgitation), pericardium (effusion), and chamber sizes. Transesophageal (TEE): higher resolution of valves (mitral, aortic), left atrial appendage, and for endocarditis evaluation. Stress echo: images before and after stress (exercise or dobutamine) for inducible wall motion abnormalities (ischemia). Doppler: measures blood flow velocities across valves (pressure gradients) and estimates pulmonary artery pressure.

Electrocardiogram (ECG / EKG)

– A recording of the heart's electrical activity from 12 leads (I, II, III, aVR, aVL, aVF, V1-V6). P wave: atrial depolarization. PR interval (120-200 ms): conduction through AV node. QRS (80-110 ms): ventricular depolarization. ST segment: early repolarization. T wave: ventricular repolarization. QT interval: corrected for heart rate (QTc, normal <450 ms in men, <460 ms in women). Uses: chest pain (ischemia/infarction), arrhythmia diagnosis, syncope, palpitations, and pre-surgical evaluation.

Electroencephalogram (EEG)

– Recording of the brain's electrical activity from scalp electrodes. Background rhythms: alpha (8-13 Hz, relaxed, eyes closed, occipital), beta (13-30 Hz, alert/active), theta (4-8 Hz, drowsy/light sleep, pathological in awake adults), delta (<4 Hz, deep sleep, pathological in awake). Uses: seizure diagnosis and classification, epilepsy monitoring, altered mental status, brain death determination, and sleep disorders. Activation: hyperventilation, photic stimulation, and sleep deprivation.

Electrophysiology Study (EPS)

– Invasive cardiac catheterization with multielectrode catheters placed in the heart to map the cardiac conduction system. Measures: sinus node function (SNRT, SACT), AV node function (AH interval, HV interval), and inducibility of arrhythmias (programmed electrical stimulation). Indications: evaluation of syncope, sustained palpitations, wide-complex tachycardia, supraventricular tachycardia (AVNRT, AVRT, atrial flutter), ventricular tachycardia, and risk stratification in Brugada syndrome or hypertrophic cardiomyopathy. Often followed by catheter ablation.

Endoscopic Retrograde Cholangiopancreatography

– Endoscopic cannulation of the ampulla of Vater for retrograde injection of contrast into the biliary and pancreatic ducts. Combined diagnostic and therapeutic: ERCP with sphincterotomy, stone extraction, stent placement, and brush cytology. Indications: choledocholithiasis (common bile duct stones), malignant biliary obstruction (palliative stenting), biliary stricture, and sphincter of Oddi dysfunction. Risks: pancreatitis (5-10%), cholangitis, perforation, and bleeding post-sphincterotomy.

Endoscopic Ultrasound (EUS)

– Combined endoscopy and ultrasound for high-resolution imaging of the GI wall and adjacent structures. Linear echoendoscope: allows FNA of mediastinal, pancreatic, and peripancreatic lesions. Radial echoendoscope: 360-degree view for staging GI cancers (TNM staging). Indications: pancreatic cancer staging, mediastinal lymph node sampling (EBUS-TBNA or EUS-FNA), subepithelial GI lesions, choledocholithiasis, and celiac plexus neurolysis for pain. Complications: perforation (0.03%), pancreatitis (from pancreatic FNA), and infection.

Erythrocyte Sedimentation Rate (ESR)

– A non-specific inflammatory marker measuring the rate at which erythrocytes settle in 1 hour. Normals: males age/2, females (age+10)/2. Markedly elevated >100 mm/hr: suggests infection (endocarditis), autoimmune (giant cell arteritis, polymyalgia rheumatica, SLE, RA), malignancy (multiple myeloma), and chronic kidney disease. Faster in anemia (rouleaux formation). Slower in polycythemia and spherocytosis. Uses: monitoring disease activity in inflammatory conditions. Less sensitive than CRP for acute changes.

Esophageal Manometry

– Measurement of esophageal pressures at rest and during swallows. Components: upper esophageal sphincter (UES), esophageal body (amplitude, peristalsis), and lower esophageal sphincter (LES, resting pressure and relaxation). High-resolution manometry (HRM) with Chicago Classification: diagnoses achalasia (incomplete LES relaxation, absent peristalsis), esophagogastric junction outflow obstruction, distal esophageal spasm, hypercontractile (jackhammer) esophagus, and ineffective esophageal motility. Indications: dysphagia, non-cardiac chest pain, and pre-operative evaluation for anti-reflux surgery.

Esophageal pH Monitoring

– 24-hour ambulatory monitoring of esophageal acid exposure. Catheter-based (transnasal pH probe placed 5 cm above LES) or wireless (Bravo capsule endoscopically attached to esophageal mucosa). Measures: % time pH <4 (total, upright, supine), DeMeester score (>14.7 abnormal), and symptom-reflux correlation. Indications: refractory GERD, atypical GERD symptoms (chest pain,

cough, asthma), pre-operative evaluation for anti-reflux surgery, and monitoring of therapy. Off acid suppression for diagnostic testing.

Esophagogastroduodenoscopy (EGD)

– Upper endoscopy: flexible endoscopic examination of the esophagus, stomach, and duodenum. Indications: dysphagia, GERD (surveillance of Barrett esophagus), dyspepsia (alarm symptoms: age >60, weight loss, anemia, dysphagia, bleeding), upper GI bleeding (variceal and non-variceal: ulcers, Mallory-Weiss tears), and surveillance for polyps (FAP, gastric intestinal metaplasia). Therapeutic: hemostasis (cautery, clips, sclerotherapy), polypectomy, dilation (strictures), and PEG tube placement.

Evoked Potentials (VEP, BAER, SSEP)

– Electrophysiologic tests measuring the CNS electrical response to specific sensory stimuli. Visual evoked potentials (VEP): checkboard pattern reversal, measures P100 latency; delayed in optic neuritis/MS. Brainstem auditory evoked responses (BAER): click stimuli, waves I-V; delayed in acoustic neuroma, MS, brainstem stroke. Somatosensory evoked potentials (SSEP): electrical stimulation of peripheral nerves (median, tibial); used intraoperatively for spinal cord monitoring (scoliosis surgery) and prognostic in spinal cord injury and hypoxic-ischemic encephalopathy.

Exercise Stress Test

– Treadmill exercise with ECG monitoring using the Bruce protocol (3-minute stages increasing speed and grade). Indications: diagnosis of CAD (chest pain evaluation), functional capacity assessment, and prognosis after MI. Contraindications: acute MI (within 2 days), unstable angina, decompensated heart failure, severe aortic stenosis, and uncontrolled arrhythmias. Positive test: ≥ 1 mm horizontal or downsloping ST depression at 80 ms after the J point. Duke Treadmill Score (DTS) provides prognostic information (duration, ST deviation, angina).

Extraocular Muscle Function Testing

– Assessment of the six extraocular muscles innervated by CN III (medial rectus: adduction; superior rectus: elevation; inferior rectus: depression; infe-

rior oblique: extorsion), CN IV (superior oblique: intorsion and depression), and CN VI (lateral rectus: abduction). Tested by asking the patient to follow a target in the six cardinal directions of gaze. Abnormalities: strabismus (misalignment), diplopia (double vision), and palsy. Cover-uncover test and alternate cover test identify phoria vs. tropia.

Fecal Calprotectin

– A protein released by neutrophils in the stool, a marker of intestinal inflammation. Normal: <50 mcg/g. Elevated in IBD (>150-200 mcg/g for active Crohn, ulcerative colitis). Distinguishes IBD from IBS (IBS: normal). Monitoring: correlates with endoscopic disease activity; reduction indicates treatment response. Also elevated in: NSAID enteropathy, infectious colitis, and colorectal cancer. False negatives: skip lesions in Crohn. Used to avoid unnecessary colonoscopies and guide treatment escalation.

Fecal Immunochemical Test (FIT)

– A stool-based screening test for colorectal cancer that detects human hemoglobin in a single stool sample using antibodies. Annual screening. Sensitivity: 74-80% for cancer, 25-30% for advanced adenomas. Specificity: 94-96%. No dietary restrictions required. Positive test requires follow-up colonoscopy. More specific than guaiac FOBT. Cost-effective and non-invasive. Compared to colonoscopy: lower sensitivity but more accessible and less invasive.

FeNO (Fractional Exhaled Nitric Oxide)

– A non-invasive biomarker of type 2 airway inflammation (eosinophilic). Normal: <25 ppb (adults), <35 ppb (children). Elevated (>50 ppb): eosinophilic asthma, good response to inhaled corticosteroids. Low (<25 ppb): non-eosinophilic asthma, neutrophilic inflammation. Used to: diagnose asthma (when spirometry is equivocal), predict steroid responsiveness, monitor adherence to ICS, and guide treatment (adjust ICS dose to normalize FeNO). Affected by smoking (falsely low), atopy, and certain foods.

Ferritin

– Intracellular iron storage protein reflecting total body iron stores. Low ferritin: iron deficiency anemia (<30 ng/mL, absolute; <100 can be consistent with iron deficiency in inflammation). High ferritin:

iron overload (hemochromatosis, repeated transfusions), inflammation (acute phase reactant), liver disease, malignancy, and hemophagocytic lymphohistiocytosis (HLH). Used with serum iron, TIBC, and transferrin saturation for complete iron studies. Transferrin saturation $>45\%$ suggests iron overload.

Fetal Ultrasound

- Ultrasound imaging during pregnancy. First trimester (6-12 weeks): confirm pregnancy, gestational age (crown-rump length), number of fetuses, viability (heart activity), nuchal translucency (screening for aneuploidy at 11-13 weeks). Second trimester (18-22 weeks): anatomy survey (fetal head, chest, heart, abdomen, spine, extremities, placenta, amniotic fluid), gender determination. Third trimester: growth assessment (biometric parameters: BPD, HC, AC, FL), fetal weight estimation, placental location, amniotic fluid index, and biophysical profile. Doppler: umbilical artery, middle cerebral artery.

FISH (Fluorescence In Situ Hybridization)

- A molecular cytogenetic technique using fluorescent DNA probes that hybridize to specific chromosomal regions. Faster than karyotype (24-48 hours, vs. 7-14 days). Indications: rapid prenatal aneuploidy testing (trisomy 13, 18, 21, X, Y), detection of microdeletion syndromes (22q11.2 DiGeorge, TP53 in CLL), gene rearrangements in cancer (BCR-ABL, PML-RARA, MLL rearrangements, MYC, IGH), and HER2 amplification in breast cancer. Can be performed on interphase nuclei (does not require dividing cells). Higher resolution than karyotype.

Flexible Sigmoidoscopy

- Endoscopic examination of the rectum and sigmoid colon (up to 60 cm). Indications: colorectal cancer screening (q5-10 years, combined with FIT), evaluation of rectal bleeding, chronic diarrhea, and surveillance of known distal colonic disease (ulcerative colitis). Advantages over colonoscopy: no sedation required in most cases, less bowel prep (enema only), lower cost and risk. Limitations: cannot visualize the proximal colon; positive findings require full colonoscopy. Largely replaced by colonoscopy for screening in the US.

Flow Cytometry

- Technique that measures physical and chemical

characteristics of cells or particles in a fluid stream, using laser-based detection. Commonly used in hematology: immunophenotyping of leukemia and lymphoma (CD markers: CD3, CD19, CD20, CD34, CD33, CD13), detection of minimal residual disease, and evaluation of immunodeficiency disorders. Analysis of DNA content (ploidy) in neoplasms. Also used in stem cell enumeration (CD34+) for transplant.

Fluoroscopy

- Real-time X-ray imaging used to visualize dynamic processes. Common applications: upper GI series (barium swallow, barium meal), lower GI series (barium enema), voiding cystourethrogram (VCUG for VUR), hysterosalpingography (tubal patency), angiography, and interventional procedures (ERCP, PICC line placement, joint injection, pacemaker implantation, and catheterization). Utilizes continuous or pulsed X-ray beam. Radiation exposure is a concern for both patients and operators.

Genetic Testing (Sequencing)

- Analysis of DNA to identify pathogenic variants associated with genetic disorders. Sanger sequencing: gold standard for single-gene testing (CFTR for cystic fibrosis, BRCA1/2 for hereditary breast/ovarian cancer). Next-generation sequencing (NGS): massively parallel sequencing enabling panel testing (multiple genes), exome sequencing (all exons, 1-2% of genome), and genome sequencing (whole genome). Detects SNPs, indels, and copy number variants. Indications: confirm a suspected genetic diagnosis, carrier screening, prenatal diagnosis, pharmacogenomics, and cancer genomics. Variant interpretation: pathogenic, likely pathogenic, VUS (variant of uncertain significance), likely benign, benign.

Glucose Tolerance Test

- Testing for diabetes mellitus and gestational diabetes. 75g OGTT (oral glucose tolerance test): measure plasma glucose at 0, 60, and 120 minutes. Diagnostic: fasting ≥ 126 mg/dL, 2-hour ≥ 200 mg/dL. Gestational diabetes screening: 50g glucose challenge test (GCT) at 24-28 weeks; if >140 mg/dL at 1 hour, proceed to 100g 3-hour OGTT. Carpenter-Coustan criteria: ≥ 2 values elevated (fasting >95 , 1h >180 , 2h >155 , 3h >140). Glucose tolerance categories: normal, impaired fasting glucose (IFG 100-125), impaired glucose tolerance (IGT 140-199),

and diabetes.

Gram Stain

– A differential staining technique that classifies bacteria as Gram-positive (purple, thick peptidoglycan) or Gram-negative (pink/red, thin peptidoglycan + outer membrane). Also reports morphology (cocci, rods, spirals) and arrangement (clusters, chains, pairs). Used to guide empiric antibiotic therapy while awaiting culture. Quality: epithelial cells suggest contamination; polymorphonuclear leukocytes suggest true infection. Foundational in microbiology.

Haptoglobin

– An alpha-2 globulin that binds free hemoglobin, preventing oxidative damage and renal excretion. Low/undetectable: acute hemolysis (intravascular and extravascular), liver disease (decreased production), and hereditary deficiency. Elevated: acute phase reaction (inflammation, infection, malignancy). Used with LDH and bilirubin to confirm hemolytic anemia. Normal: 30-200 mg/dL.

hCG (Human Chorionic Gonadotropin)

– A glycoprotein hormone produced by the placenta, detected in urine and serum for pregnancy diagnosis. Qualitative: positive ≥ 25 mIU/mL (urine). Quantitative: serum hCG levels — < 5 mIU/mL (negative), 5-25 (indeterminate), > 25 (positive). In early pregnancy: hCG doubles every 48-72 hours until 8-10 weeks. Abnormal levels: ectopic pregnancy (slow rise), miscarriage (declining), or molar pregnancy (very high). Also a tumor marker for gestational trophoblastic disease and germ cell tumors.

Hemoglobin A1c

– Glycated hemoglobin reflecting average blood glucose over the preceding 2-3 months. Normal: $< 5.7\%$. Prediabetes: 5.7-6.4%. Diabetes: $\geq 6.5\%$ (diagnostic, confirmed with repeat). Targets: generally $< 7\%$ for most adults with diabetes (individualized: $< 6.5\%$ for some, $< 8\%$ for frail/elderly). Used for diabetes diagnosis and monitoring glycemic control. Factors affecting accuracy: hemoglobinopathies, anemia, renal failure, pregnancy, and recent transfusions.

Hemoglobin Electrophoresis

– Separation of hemoglobin variants by electrophore-

sis or HPLC. Normal adult: HbA (95-98%), HbA2 (2-3%), HbF ($< 1\%$). Sickle cell disease (HbSS): HbS only, no HbA. Sickle cell trait (HbAS): HbA $>$ HbS. Thalassemia: elevated HbA2 or HbF. Beta thalassemia trait: HbA2 3.5-7%. HbF elevated in beta thalassemia, sickle cell disease, HPFH, and juvenile myelomonocytic leukemia. Used for diagnosis of hemoglobinopathies.

Hepatitis Serology

– Panel of serologic markers for hepatitis A, B, C, and E. HAV: anti-HAV IgM (acute), anti-HAV IgG (past infection/vaccination). HBV: HBsAg (active infection), anti-HBs (immunity/vaccination), anti-HBc IgM (acute), anti-HBc IgG (past), HBeAg (high replication), anti-HBe (low replication). HBV DNA: quantifies viral load. HCV: anti-HCV (screening, past or present), HCV RNA (active infection, viral load). HEV: anti-HEV IgM/IgG. Used for diagnosis, determination of phase/chronicity, and treatment monitoring.

HIV Test

– Screening and confirmatory testing for HIV. Fourth-generation HIV antigen/antibody combo test (p24 antigen + HIV-1/2 antibodies): window period 2-4 weeks. Positive screening requires confirmatory HIV-1/2 antibody differentiation assay. Rapid point-of-care tests (fingerstick, oral swab): results in 20 minutes. Nucleic acid amplification test (HIV RNA): detects virus as early as 10 days post-infection. Recommended: annual screening for sexually active individuals, all pregnant women, and high-risk populations.

Holter Monitor

– Continuous ECG recording for 24-48 hours to detect arrhythmias, quantify burden (atrial fibrillation, PVCs, PACs), and correlate symptoms with rhythm. Patient diary logs symptoms. Indications: palpitations, syncope, presyncope, and assessment of arrhythmia control. Reveals paroxysmal arrhythmias not captured on standard 12-lead ECG. Extended monitoring (event recorder, loop recorder, mobile cardiac telemetry) for up to 30 days for infrequent symptoms. Implantable loop recorder (Reveal) for annual monitoring.

Hydrogen Breath Test

– Non-invasive test for carbohydrate malabsorption (lactose, fructose) and small intestinal bacterial over-

growth (SIBO). Patient ingests a substrate (lactose, glucose, or lactulose). Breath hydrogen is measured at baseline and q15-30 minutes for 2-3 hours. Rise in H₂ >20 ppm from baseline: positive (bacterial fermentation). Lactose intolerance: elevated H₂ after lactose challenge, with symptoms. SIBO: early peak (within 60-90 minutes) after glucose or lactulose. False positives: recent antibiotics, colonic fermentation (rapid transit). Antibiotics, colonoscopy prep, and dietary restrictions required before testing.

Hysterosalpingography (HSG)

– Fluoroscopic imaging after injection of iodinated contrast into the uterine cavity through a cervical cannula. Used for infertility evaluation: assesses tubal patency (normal: contrast spills freely into peritoneal cavity), uterine cavity shape (fibroids, polyps, synechiae, Mullerian anomalies), and proximal/distal tubal occlusion. Performed in the follicular phase (days 7-10). Contraindications: pregnancy, active PID, and contrast allergy. Complications: pain, vasovagal reaction, and infection.

IGRA (Interferon-Gamma Release Assay)

– Blood test for *Mycobacterium tuberculosis* infection (latent or active). T-SPOT.TB (ELISPOT) or QuantiFERON-TB Gold Plus (ELISA). Measures IFN-gamma released by T cells after exposure to MTB-specific antigens (ESAT-6, CFP-10, TB7.7). Advantages over PPD: no cross-reactivity with BCG or most nontuberculous mycobacteria, single patient visit, no booster phenomenon. Preferred for BCG-vaccinated individuals and serial testing. Cannot distinguish latent from active TB.

Immunohistochemistry

– Technique using antibodies to detect specific antigens in tissue sections. Uses: tumor classification and subtyping (Carcinoma: CK7, CK20; Lymphoma: CD markers; Melanoma: S100, HMB45, MelanA; Sarcoma: vimentin, desmin, CD34), determination of tumor origin (CK7+/CK20-: lung, breast; CK7-/CK20+: colorectal), assessment of prognostic markers (ER/PR, HER2 in breast cancer), and identification of infectious agents. Essential in modern pathology for diagnosis and treatment planning.

Influenza Test

– Detection of influenza A and B viruses. Rapid anti-

gen test: nasal/throat swab, results in 15 minutes, specificity >95%, sensitivity 50-70% (high false negative rate). RT-PCR: gold standard, highly sensitive and specific, results in 1-4 hours, distinguishes influenza A subtypes (H1N1, H3N2). Used during influenza season for patients with ILI (fever + cough/sore throat). Antiviral therapy (oseltamivir, baloxavir) is most effective when started within 48 hours.

Intravenous Pyelogram (IVP)

– Radiographic imaging of the urinary tract after IV contrast administration. Used to evaluate the kidneys, ureters, and bladder for obstruction, stones, tumors, and anatomic abnormalities. Sequential films show nephrogram (renal parenchyma), pyelogram (collecting system), and ureterogram (ureters). Largely replaced by CT urography and MR urography, which provide better anatomic detail and sensitivity.

IV Fluids

– Intravenous fluid therapy for volume resuscitation and maintenance. Crystalloids: normal saline (0.9% NaCl, increases chloride, risk of hyperchloremic metabolic acidosis), lactated Ringer (balanced, contains K⁺, Ca²⁺, lactate buffer, safer in large volumes), Plasma-Lyte (balanced, closest to plasma). Colloids: albumin (5%, 25%), hydroxyethyl starch (HES, nephrotoxic, no longer recommended). Resuscitation: 30 mL/kg bolus for sepsis, hemorrhage. Maintenance: 1.5-2.5 L/day with D5 1/2NS + 20 mEq KCl.

Lactate

– A product of anaerobic metabolism, elevated in tissue hypoperfusion and hypoxia. Normal: <2.0 mmol/L. Lactate >2.0: hyperlactatemia. Lactate >4.0: severe sepsis/septic shock (associated with increased mortality). Types: type A (tissue hypoxia: shock, sepsis, hypoperfusion, seizures, exercise) and type B (no hypoxia: liver disease, thiamine deficiency, metformin, mitochondrial dysfunction, malignancy). Used for sepsis screening (qSOFA), monitoring resuscitation response, and prognostication in critical illness.

Lactic Acid

– See Lactate.

Lactose Tolerance Test

– See Hydrogen Breath Test.

Lipid Panel

– Measurement of total cholesterol, LDL-C, HDL-C, and triglycerides. Fasting (9-12 hours) or non-fasting acceptable for screening. Desirable levels: total cholesterol <200 mg/dL, LDL <100 mg/dL (<70 for very high risk), HDL >40 (men) or >50 (women) mg/dL, triglycerides <150 mg/dL. Used for ASCVD risk assessment (Pooled Cohort Equations), guiding statin therapy, and monitoring treatment. Non-HDL cholesterol (total minus HDL) provides additional risk information.

Liver Function Tests

– A panel of blood tests that assess the health and function of the liver, used to screen for, diagnose, and monitor liver disease and to monitor response to treatment with hepatotoxic drugs. The typical LFT panel includes: (1) Alanine aminotransferase (ALT): a cytosolic enzyme found predominantly in the liver, released into the bloodstream when hepatocytes are damaged. Elevated in: viral hepatitis (all types), alcoholic hepatitis, non-alcoholic fatty liver disease (NAFLD), drug-induced liver injury (DILI), and ischemic hepatitis. ALT is more specific for liver injury than AST (aspartate aminotransferase). AST is present in the liver, heart, muscle, kidney, and brain. The AST/ALT ratio helps distinguish etiology: alcoholic hepatitis (AST:ALT >1.5, usually 2:1), viral hepatitis (AST:ALT <1), and cirrhosis (AST:ALT >1). (2) Alkaline phosphatase (ALP): an enzyme found in bile ducts (canalicular membrane), bone (osteoblasts), placenta, and intestine. Elevated in: cholestatic liver disease (obstructive jaundice, primary biliary cholangitis, primary sclerosing cholangitis), bone disease (Paget, metastasis, fracture, healing), infiltrative disease (sarcoidosis, amyloidosis), and third trimester of pregnancy. Gamma-glutamyl transferase (GGT) is often measured with ALP to distinguish hepatic (GGT elevated) from bone (GGT normal) sources. GGT is induced by alcohol and medications (phenytoin, carbamazepine). (3) Bilirubin: total, conjugated (direct) and unconjugated (indirect). See Jaundice. (4) Albumin: synthesised exclusively by the liver, half-life 20 days. Decreased in chronic liver disease (cirrhosis) indicating impaired synthetic function, nephrotic syndrome, and malnutrition. (5) Prothrombin time (PT) and international normalised

ratio (INR): vitamin K-dependent clotting factors (II, VII, IX, X) are synthesised in the liver. PT/INR is prolonged in severe liver disease (hepatic synthetic dysfunction) and vitamin K deficiency. PT/INR is the most sensitive acute measure of liver function in acute liver failure. (6) Total protein: decreased in chronic liver disease, increased in monoclonal gammopathies and chronic inflammation.

Liver Function Tests (LFTs)

– A panel of blood tests assessing liver health: ALT (alanine aminotransferase, primarily hepatocyte injury), AST (aspartate aminotransferase, also released by muscle/heart), ALP (alkaline phosphatase, biliary obstruction, bile duct injury), GGT (gamma-glutamyl transferase, confirms hepatobiliary source of elevated ALP), total and direct bilirubin (jaundice, conjugation/excretion), albumin (synthetic function), and PT/INR (clotting factor synthesis). Patterns: hepatocellular (ALT/AST high), cholestatic (ALP/GGT/bilirubin high), and mixed.

Lumbar Puncture

– See Spinal Tap.

Lumbar Puncture (Spinal Tap)

– Insertion of a needle into the subarachnoid space at L3-L4 or L4-L5 to obtain CSF. Indications: suspected meningitis/encephalitis, subarachnoid hemorrhage, demyelinating disease, and intrathecal therapy. Contraindications: increased intracranial pressure (papilledema, mass lesion on CT), coagulopathy, and infection at the puncture site. Opening pressure: normal 10-20 cm H₂O. Complications: post-dural puncture headache (volume depletion, caffeine, blood patch), infection, and bleeding.

Mammography

– X-ray imaging of the breast for cancer screening and diagnosis. Screening mammography: annual for women ≥40 (USPSTF: biennial 50-74). Views: CC (craniocaudal) and MLO (mediolateral oblique). Digital mammography with CAD (computer-aided detection) improves sensitivity. Tomosynthesis (3D): reduces tissue overlap, improves cancer detection and recall rates. BI-RADS classification: 0 (incomplete), 1 (negative), 2 (benign), 3 (probably benign, short interval), 4 (suspicious, biopsy), 5 (highly suggestive of malignancy), 6 (known biopsy-proven malignancy).

Medical Tests

– Diagnostic procedures used to screen for, confirm, or monitor disease through analysis of biologic specimens, imaging, physiologic measurements, or genetic material. Categories: laboratory tests (complete blood count, comprehensive metabolic panel, cardiac biomarkers, thyroid function, HbA1c, cultures, PCR), imaging studies (X-ray, CT, MRI, ultrasound, PET, nuclear scintigraphy), physiologic testing (ECG, Holter monitor, pulmonary function tests, echocardiography), endoscopic procedures (colonoscopy, esophagogastroduodenoscopy, bronchoscopy, cystoscopy), and genetic/molecular testing (karyotype, microarray, NGS panels). Interpretation requires understanding of sensitivity, specificity, positive/negative predictive values, and reference ranges adjusted for age, sex, and comorbidities. Appropriate use reduces overdiagnosis and incidentalomas; shared decision-making about testing is recommended.

Methacholine Challenge Test

– A bronchoprovocation test for diagnosing asthma when spirometry is normal. Inhaled methacholine (a cholinergic agonist) induces bronchoconstriction. Spirometry is repeated after each escalating dose. Positive: $\geq 20\%$ fall in FEV1 (PC20) at ≤ 16 mg/mL. Sensitivity $>90\%$ for asthma. Contraindications: FEV1 $<50\%$ predicted, recent MI, uncontrolled hypertension, and pregnancy. Bronchodilator reversibility and asthma treatment affect results.

Monospot (EBV Heterophile Antibody)

– Rapid test for infectious mononucleosis caused by Epstein-Barr virus. Detects heterophile antibodies (IgM) that agglutinate horse or sheep red blood cells. Sensitivity: 70-95% in symptomatic patients. False negative in early disease (<1 week) and children <5 . False positive in autoimmune disease, HIV, lymphoma, and other viral infections. Positive: confirms EBV infection. Negative with high suspicion: order EBV-specific serology (VCA IgM, VCA IgG, EBNA IgG).

MRCP (Magnetic Resonance Cholangiopancreatography)

– Non-invasive MRI of the biliary and pancreatic ducts using heavily T2-weighted sequences that highlight static fluid. Used for: choledocholithiasis (CBD stones), biliary strictures, primary scleros-

ing cholangitis, pancreatic duct anatomy, and congenital biliary anomalies. Advantages over ERCP: non-invasive, no contrast, no radiation, no pancreatitis risk. Limitations: lower spatial resolution than ERCP, cannot treat (stone removal, stenting). Sensitivity for CBD stones: $>90\%$.

MRI (Magnetic Resonance Imaging)

– Imaging using strong magnetic fields and radiofrequency pulses to generate detailed cross-sectional images. No ionizing radiation. Superior soft-tissue contrast compared to CT. Sequences: T1-weighted (anatomy, fat bright), T2-weighted (pathology, water bright), FLAIR (suppresses CSF, for brain lesions), DWI (acute stroke, abscess, cellular tumors), and STIR (suppresses fat). Gadolinium contrast: highlights inflammation, infection, and tumors. Contraindications: ferromagnetic implants (some pacemakers, aneurysm clips, metal fragments).

MRV (Magnetic Resonance Venography)

– MRI technique to visualize veins, using time-of-flight (TOF) or contrast-enhanced sequences. Indications: cerebral venous sinus thrombosis, dural sinus stenosis, abdominal/pelvic venous thrombosis, portal vein thrombosis, and renal vein thrombosis. Differentiates acute vs. chronic thrombus. Non-invasive alternative to conventional venography.

MUGA Scan (Multigated Acquisition Scan)

– Radionuclide ventriculography using Tc-99m-labeled RBCs to assess left ventricular function. ECG-gated acquisition synchronized to the QRS complex. Measures: LVEF (most accurate non-invasive method), wall motion, and ventricular volumes. Gold standard for LVEF assessment prior to cardiotoxic chemotherapy (doxorubicin, trastuzumab). Normal LVEF $>55\%$. Decline $>10\%$ to $<50\%$ indicates cardiotoxicity. Also used for pre-operative risk assessment and heart failure evaluation.

Multiplex PCR (BioFire, FilmArray)

– A rapid molecular diagnostic system using nested multiplex PCR to detect multiple pathogens from

a single sample. Panels: respiratory (adenovirus, coronavirus, hMPV, influenza, parainfluenza, RSV, rhinovirus, Bordetella, Chlamydia, Mycoplasma), GI (Campylobacter, Salmonella, Shigella, E. coli, norovirus, rotavirus, etc.), blood culture ID, and meningitis/encephalitis. Results in 45-60 minutes. Sensitivity 90-100%. Guides early targeted therapy and reduces unnecessary antibiotics.

Nerve Conduction Studies

– Measurement of the speed and amplitude of electrical impulses along peripheral nerves. Sensory NCS: stimulate at one point, record distally. Motor NCS: stimulate at two or more points along the nerve, record from muscle. Parameters: conduction velocity (m/s), amplitude (microvolts/millivolts), and distal latency. Abnormalities: axonal loss (low amplitude, normal velocity), demyelination (slow velocity, prolonged latency, conduction block). Used with EMG to diagnose neuropathy, radiculopathy, and myopathy.

Newborn Hearing Screen

– Universal screening for congenital hearing loss, performed before hospital discharge. Two-step protocol: otoacoustic emissions (OAE: measures cochlear outer hair cell response to click stimulus) and automated auditory brainstem response (AABR: measures neural response from the cochlea to the brainstem). Pass/refer. Refer: requires outpatient diagnostic audiology (full ABR) by 3 months. Early intervention by 6 months improves language outcomes. Risk factors for late-onset/progressive HL: NICU stay >5 days, congenital CMV, family history, and certain syndromes.

Newborn Screening

– A public health program testing newborns for treatable genetic, metabolic, and endocrine disorders 24-48 hours after birth. Blood spot (heel stick) on filter paper (Guthrie card). Conditions vary by state (Recommended Uniform Screening Panel: 35 core conditions). Common: phenylketonuria (PKU), congenital hypothyroidism, cystic fibrosis, sickle cell disease, medium-chain acyl-CoA dehydrogenase (MCAD) deficiency, galactosemia, biotinidase deficiency, congenital adrenal hyperplasia, and hearing loss (by otoacoustic emissions). Positive screens require confirmatory testing and prompt specialist referral. Early treatment prevents morbidity and

mortality.

Non-Stress Test (NST)

– Antepartum fetal monitoring assessing fetal heart rate reactivity. Reactive NST: ≥ 2 accelerations of 15 bpm for 15 seconds (≥ 32 weeks) or 10 bpm for 10 seconds (< 32 weeks) within 20 minutes. Non-reactive: insufficient accelerations after 40 minutes (may indicate fetal sleep, acidosis, or CNS depression). False positive rate high. Used for fetal well-being assessment in high-risk pregnancies (preeclampsia, IUGR, diabetes, postterm, decreased fetal movement). Often combined with AFI (biophysical profile).

Pancreatic Elastase

– Measurement of fecal elastase-1 (FE-1) as a non-invasive test for pancreatic exocrine insufficiency. Values: > 200 mcg/g (normal), 100-200 (mild-moderate insufficiency), < 100 mcg/g (severe insufficiency). Unaffected by pancreatic enzyme replacement therapy (does not cross-react with porcine enzymes). More sensitive and stable than fecal fat quantification. False positives: watery stool (dilution effect). Used to diagnose chronic pancreatitis, cystic fibrosis, and pancreatic insufficiency.

Paracentesis

– Aspiration of fluid from the peritoneal cavity (ascites). Indications: diagnostic (evaluate new ascites: SAAG, cell count, culture, cytology, albumin, total protein; rule out SBP: PMN > 250) and therapeutic (relief of tense ascites, 4-6 L). Site: left lower quadrant (avascular zone), lateral to rectus sheath, ultrasound-guided. Contraindications: overlying cellulitis, severe coagulopathy, and pregnancy. Serum-ascites albumin gradient (SAAG): > 1.1 g/dL (portal hypertension: cirrhosis, heart failure), < 1.1 g/dL (peritoneal disease: malignancy, TB, pancreatitis, nephrotic). Large-volume paracentesis requires albumin infusion (6-8 g/L removed) to prevent post-paracentesis circulatory dysfunction.

PEG Tube (Percutaneous Endoscopic Gastrostomy)

– Endoscopic placement of a feeding tube through the abdominal wall directly into the stomach. Indications: long-term enteral feeding (> 4 weeks) for dysphagia (stroke, ALS, dementia, head/neck cancer) and malnutrition. Contraindications: gastric outlet obstruction, severe ascites, coagulopathy, gastric cancer, and inability to transilluminate the abdomi-

nal wall. Procedure: EGD with transillumination, needle puncture under direct endoscopic visualization, wire passage, and tube placement (Pull or Push technique). Replacements: 8-12 months later (balloon or button type). Complications: aspiration, infection (peristomal cellulitis), bleeding, perforation, and tube dislodgement. Buried bumper syndrome: overgrowth of gastric mucosa over the internal bumper.

Pericardiocentesis

– Aspiration of pericardial fluid using a needle inserted through the subxiphoid or apical approach, under echocardiographic or fluoroscopic guidance. Indications: cardiac tamponade (therapeutic emergency), diagnostic evaluation of pericardial effusion (malignancy, infection, autoimmune). Complications: myocardial puncture/laceration, coronary artery injury, pneumothorax, arrhythmia, and infection. A small catheter can be left in place for continuous drainage. Fluid analysis: cell count, cytology, culture, TB PCR/ culture, and rheumatologic studies. High-risk procedure; should be performed with surgical backup.

Periodontal Probing

– Measurement of the depth of the gingival sulcus/pocket using a periodontal probe with millimeter markings. Normal: 1-3 mm. Periodontal pockets: ≥ 4 mm (indicates attachment loss and periodontitis). Full-mouth probing at 6 sites per tooth: mesio-buccal, mid-buccal, disto-buccal, mesio-lingual, mid-lingual, disto-lingual. Bleeding on probing (BOP): sign of active inflammation. Clinical attachment level (CAL): distance from CEJ to base of pocket. Used for periodontal disease diagnosis, staging (Stage I-IV), and monitoring treatment response.

Peripheral Blood Smear

– Microscopic examination of a stained blood smear (Wright-Giemsa stain). Evaluates: RBC morphology (size: macrocytic, microcytic; shape: spherocytes, sickle cells, schistocytes, target cells, elliptocytes; color: hypochromic, polychromasia; inclusions: basophilic stippling, Howell-Jolly bodies, Pappenheimer bodies), WBC morphology (blast cells, band forms, toxic granulation, Doehle bodies, smudge cells, Auer rods), and platelet morphology (size, granules). Performed when automated CBC

shows abnormalities.

PET Scan (Positron Emission Tomography)

– Nuclear medicine imaging using radioactive tracers (most commonly FDG, a glucose analog) to detect metabolically active tissues. Indications: cancer staging and restaging (lung, lymphoma, melanoma, breast, colon), evaluation of solitary pulmonary nodule, myocardial viability (FDG uptake in hibernating myocardium), and neurologic (Alzheimer disease: hypometabolism; epilepsy: seizure focus). Standardized uptake value (SUV) quantifies tracer activity. Combined PET/CT provides anatomic localization. False positives in infection/inflammation.

Polysomnography (Sleep Study)

– Overnight monitoring for sleep-disordered breathing. Parameters: EEG (sleep staging: N1, N2, N3, REM), EOG (eye movements), EMG (chin and leg movements), airflow (nasal pressure, thermistor), respiratory effort (chest/abdomen belts), snore microphone, body position, oximetry (SpO₂), and ECG. Calculates AHI (apnea-hypopnea index): normal < 5 , mild 5-15, moderate 15-30, severe > 30 . Used to diagnose obstructive sleep apnea, central sleep apnea, periodic limb movement disorder, and narcolepsy (MSLT following PSG).

Pregnancy Test

– See hCG (Human Chorionic Gonadotropin).

Preoperative Evaluation

– Medical assessment before elective surgery to optimize outcomes and minimize perioperative risk. Components: history and physical (comorbidities: CAD, CHF, COPD, diabetes, CKD), medications (anticoagulants, antiplatelets, antihyperglycemics), functional status (METs), and cardiac risk assessment (RCRI: Revised Cardiac Risk Index, NSQIP MICA risk calculator). Testing per RCRI and age/symptoms: ECG (age > 65 , cardiac risk factors, known CAD), CBC, BMP, coagulation studies, type and screen (for planned transfusions), CXR (age > 70 , cardiac/pulmonary disease), and PFTs (lung resection, COPD exacerbation). Nothing routine; testing guided by specific risk factors and surgical severity.

Procalcitonin

– A biomarker for bacterial infection and sepsis, produced by thyroid C-cells and peripheral tissues in

response to bacterial toxins. Levels: <0.1 ng/mL (normal), 0.1-0.25 (unlikely bacterial), 0.25-0.5 (possible), >0.5 (probable bacterial infection), >2.0 (severe sepsis/septic shock). More specific for bacterial infection than CRP. Used to guide antibiotic initiation and discontinuation (procalcitonin algorithms reduce antibiotic duration). Elevated in bacterial pneumonia, meningitis, UTI. Not elevated in viral infections or non-infectious inflammation.

PSA (Prostate-Specific Antigen)

– A serine protease produced by the prostate, used for prostate cancer screening. Normal: <4.0 ng/mL, but age-specific ranges exist. PSA >10 ng/mL: high probability of cancer. PSA 4-10: gray zone; percent free PSA (<25% suggests cancer) and PSA density help. Screening controversy: reduces prostate cancer mortality (1.3 per 1000) but leads to overdiagnosis/overtreatment. Shared decision-making for men 55-69. Annual screening recommended for high-risk (African American, family history).

Pulmonary Function Tests

– Spirometry: FVC (forced vital capacity), FEV1 (forced expiratory volume in 1 second), FEV1/FVC ratio. Obstructive pattern: FEV1/FVC <0.7 (asthma, COPD). Restrictive pattern: FVC <80% with normal or increased FEV1/FVC (pulmonary fibrosis, chest wall disorders). Lung volumes: TLC (total lung capacity), RV (residual volume). Diffusion capacity (DLCO): measures gas transfer across the alveolar-capillary membrane. Indications: dyspnea evaluation, COPD staging (GOLD), pre-operative assessment, and monitoring lung disease progression.

Quad Screen (Maternal Serum Screening)

– Second-trimester prenatal screening (15-22 weeks) for fetal aneuploidy and neural tube defects. Measures 4 markers: AFP (alpha-fetoprotein: elevated in NTD, low in Down syndrome), hCG (elevated in Down syndrome), uE3 (unconjugated estriol: low in Down syndrome), and inhibin A (elevated in Down syndrome). Detection rates: trisomy 21 (80%), trisomy 18 (60-70%), NTD (80%). Replaced in many settings by cell-free DNA (cfDNA, NIPT) with higher detection rates.

Rapid Strep Test

– Immunoassay for Group A Streptococcus (Strepto-

coccus pyogenes) from throat swab. Results: 5-10 minutes. Specificity: >95%. Sensitivity: 80-90% compared to culture. Positive: treat. Negative: confirm with throat culture (especially in children). Used for diagnosis of GAS pharyngitis to guide antibiotic therapy (prevents unnecessary antibiotics for viral pharyngitis). First-line treatment for confirmed GAS: penicillin or amoxicillin.

Reticulocyte Count

– Percentage of young RBCs in the peripheral blood, reflecting bone marrow erythroid activity. Normal: 0.5-2.5% (absolute 25-100 K/uL). Reticulocyte production index (RPI) corrects for anemia severity: $RPI = \text{reticulocyte \%} \times (\text{Hct}/45) / \text{maturation correction factor}$. High RPI (>2-3): bone marrow responding appropriately (hemolysis, acute blood loss). Low RPI (<2): bone marrow not responding (iron deficiency, aplastic anemia, marrow infiltration). Used to classify anemia as hyperproliferative vs. hypoproliferative.

Rheumatoid Factor (RF)

– An autoantibody directed against the Fc portion of IgG, positive in 70-80% of rheumatoid arthritis patients. Also positive in other autoimmune diseases (SLE, Sjogren, mixed cryoglobulinemia), chronic infections (TB, endocarditis, hepatitis C), and 5% of healthy elderly. Low sensitivity (may be negative in seronegative RA) and moderate specificity. Used in ACR/EULAR classification criteria for RA with anti-CCP. Serial monitoring is not useful. Higher titers associated with more severe, erosive disease.

RPR/VDRL (Syphilis Serology)

– Non-treponemal screening tests for syphilis. Non-treponemal: RPR (rapid plasma reagin) or VDRL (venereal disease research laboratory). Positive in primary syphilis (1-4 weeks after chancre), secondary (100% positive), and early latent. Quantitative: titer correlates with disease activity and treatment response (fourfold decline indicates successful treatment). False positives: pregnancy, SLE, TB, IV drug use, hepatitis, HIV. Positive screening requires confirmatory treponemal test (FTA-ABS, TP-PA, EIA). Titer monitoring after treatment.

Serum Protein Electrophoresis (SPEP)

– Separation of serum proteins by electrophoresis into 5 fractions: albumin, alpha-1, alpha-2, beta,

and gamma. Monoclonal gammopathy: M-spike in gamma region (multiple myeloma, MGUS, Waldenstrom macroglobulinemia). Immunofixation: identifies heavy chain (IgG, IgA, IgM, IgD, IgE) and light chain (kappa, lambda) isotype. Serum free light chain assay: kappa/lambda ratio (abnormal in light chain myeloma, AL amyloidosis). Used to screen for, diagnose, and monitor plasma cell dyscrasias.

SPECT Scan (Single Photon Emission CT)

– Nuclear medicine imaging using gamma-emitting radioisotopes (Tc-99m, Tl-201, I-123) with a rotating gamma camera to create 3D images. Indications: myocardial perfusion imaging (MPI with sestamibi, dobutamine or regadenosone stress), bone scan (metastases, stress fracture, osteomyelitis), brain perfusion (dementia, seizure focus), and VQ scan (Tc-99m MAA for perfusion, Xe-133 or Tc-DTPA for ventilation). Combined with CT (SPECT/CT) improves anatomic localization.

Sweat Chloride Test

– The gold standard diagnostic test for cystic fibrosis. Measures chloride concentration in sweat after pilocarpine iontophoresis. Normal: <30 mmol/L. Intermediate: 30-59. Positive: ≥60 mmol/L. False positives: malnutrition, adrenal insufficiency, hypothyroidism, and ectodermal dysplasia. False negatives: rare CFTR mutations with normal sweat chloride. Requires adequate sweat collection (>75 mg). Part of CF diagnostic algorithm with clinical features and CFTR genetic testing.

Thyroid Function Tests

– Measurement of TSH (most sensitive screening test), free T4, and free T3. TSH high, T4 low → primary hypothyroidism. TSH low, T4 high → primary hyperthyroidism. TSH low, T4 normal → subclinical hyperthyroidism or T3-toxicosis (measure T3). TSH high, T4 normal → subclinical hypothyroidism. TSH normal, T4 low → central hypothyroidism (pituitary/hypothalamic). Anti-TPO antibodies: positive in Hashimoto thyroiditis. TSH receptor antibodies (TRAb): positive in Graves disease.

Tilt Table Test

– Evaluation of unexplained syncope by reproducing orthostatic stress. Patient is strapped to a motorized table tilted from supine to 60-80 degrees for

20-45 minutes. Positive: reproduction of symptoms with hypotension and/or bradycardia (vasovagal syncope, delayed orthostatic hypotension). Also assesses for postural orthostatic tachycardia syndrome (POTS: HR increase >30 bpm without hypotension). Isoproterenol or nitroglycerin provocation increases sensitivity. Used when initial evaluation for syncope is inconclusive.

TORCH Panel

– Serologic screening for congenital infections: Toxoplasma, Rubella, CMV, Herpes simplex (and others: syphilis, parvovirus B19, VZV, Zika). IgM: indicates recent/active infection (maternal or fetal). IgG: past infection or passive immunity. Paired maternal and neonatal testing. Indications: pregnancy with febrile illness or rash, fetal abnormalities on ultrasound (hydrops, microcephaly, calcifications), and neonatal evaluation for congenital infection. Management depends on the specific pathogen identified.

Troponin

– Cardiac-specific troponin I and T, the preferred biomarkers for myocardial injury (MI). Highly sensitive and specific. Rise 2-4 hours after symptom onset, peak at 12-24 hours, remain elevated for 7-10 days. High-sensitivity troponin (hs-cTn) allows earlier detection (1-2 hours). Fourth Universal Definition: detection of a rise/fall of troponin with at least one value above the 99th percentile upper reference limit, plus clinical evidence of myocardial ischemia. Used for diagnosis of NSTEMI, risk stratification in ACS, and prognosis in many cardiac conditions.

Tuberculin Skin Test (PPD)

– Intradermal injection of 0.1 mL of purified protein derivative (PPD) on the forearm (Mantoux method). Read at 48-72 hours measuring induration (not erythema). Positive thresholds: ≥5 mm (HIV, close contacts, transplant, immunosuppressed), ≥10 mm (recent immigrants, IV drug users, healthcare workers, children <4, high-risk settings), ≥15 mm (no risk factors). Does not differentiate latent from active TB. False positives: BCG vaccination, nontuberculous mycobacteria. Positive test requires chest X-ray and symptom evaluation.

Ultrasonography

– See Ultrasound (Ultrasonography).

Ultrasound

– Imaging using high-frequency sound waves (2-18 MHz). No ionizing radiation. Right upper quadrant (RUQ): gallbladder (gallstones, cholecystitis), liver (steatosis, cysts), kidneys, and pancreas. Pelvic: uterus, ovaries, adnexa. Renal: hydronephrosis, stones, cysts, tumors. Scrotal: testicular torsion, epididymitis, varicocele, hydrocele. Thyroid: nodules (TI-RADS classification), goiter. Soft tissue: abscess, cellulitis, hematoma, lipoma. Vascular: DVT, carotid stenosis, AAA. Point-of-care (POCUS): FAST, cardiac, lung.

Umbilical Cord Blood Gas

– Analysis of arterial and venous cord blood collected immediately after delivery. Umbilical artery (UA): reflects fetal (baby's) acid-base status. Normal UA pH >7.20 , base excess < -10 . Umbilical vein (UV): reflects maternal/placental status. Indications: suspected fetal distress, low Apgar scores, and medicolegal documentation of birth asphyxia. Fetal acidosis: pH <7.0 (severe) or pH 7.0-7.19 (moderate). Mixed acidosis (respiratory + metabolic component) indicates prolonged hypoxic event.

Upper Endoscopy

– See Esophagogastroduodenoscopy (EGD).

Upper GI Series

– Fluoroscopic examination of the esophagus, stomach, and duodenum after oral barium contrast. Single-contrast: looks for gross abnormalities (obstruction, masses). Double-contrast (barium + gas): better mucosal detail for ulcers, erosions, and early malignancies. Indications: dysphagia, dyspepsia, nausea/vomiting, weight loss, and GI bleeding. Can assess for hiatal hernia, ulcers, gastric cancer, and outlet obstruction. Largely replaced by EGD.

Urinalysis

– Analysis of urine. Dipstick: specific gravity, pH, leukocyte esterase (WBCs), nitrite (bacteria), protein, glucose, ketones, bilirubin, urobilinogen, blood, and hemoglobin. Microscopy: RBCs, WBCs, casts (hyaline, granular, RBC, WBC), crystals (calcium oxalate, uric acid, triple phosphate), bacteria, yeast, squamous cells, and epithelial cells. Indications: UTI, hematuria, renal disease (proteinuria, casts), and screening. Clean-catch midstream specimen for culture reduces contamination.

Urine Drug Screen

– Immunoassay-based screening for common drugs of abuse in urine. Detects: amphetamines, benzodiazepines, cocaine (benzoylecgonine), opiates (morphine, codeine, heroin), oxycodone, methadone, fentanyl, barbiturates, PCP, THC (cannabinoids), and alcohol. Pros: rapid (minutes at POC), inexpensive. Cons: false positives (poppy seeds $\rightarrow$ opiates, certain antihistamines $\rightarrow$ PCP, NSAIDs $\rightarrow$ barbiturates), false negatives (synthetic cannabinoids/spice, synthetic cathinones/bath salts, LSD). Positive screen requires confirmatory GC-MS or LC-MS/MS.

Urine hCG (Pregnancy Test)

– Rapid point-of-care test detecting human chorionic gonadotropin in urine. Sensitivity: detects as low as 25 mIU/mL. Positive as early as 12-14 days after conception (before missed period). Results in 3-5 minutes. False negative: dilute urine, very early pregnancy, ectopic pregnancy. False positive: recent pregnancy, hCG-producing tumors (GTN, germ cell), or rarely due to cross-reacting substances. Most sensitive and specific when performed on first morning urine specimen.

Venesection (Phlebotomy)

– The controlled removal of blood from a vein for therapeutic or diagnostic purposes. Therapeutic phlebotomy: treatment for haemochromatosis (removal of excess iron by reducing red cell mass and stimulating erythropoiesis, which mobilises iron stores), polycythaemia vera, and porphyria cutanea tarda; typical removal of 450-500 mL per session, frequency determined by haematocrit or ferritin levels. Diagnostic phlebotomy: blood collection (venepuncture) for laboratory testing, using evacuated tube system (Vacutainer) with appropriate anticoagulant or additive tubes (EDTA for hematology, citrate for coagulation studies, SST/gel for chemistry, fluoride oxalate for glucose). Site: median cubital vein (antecubital fossa) most common. Complications: haematoma, nerve injury (rare), infection, vasovagal syncope, and excessive bleeding in coagulopathic patients.

Venipuncture

– Puncture of a vein to obtain blood specimens or administer IV therapy. Common sites: median cubital vein (most common), cephalic vein, basilic vein, and dorsal hand veins. Steps: tourniquet application

(30-60 seconds), vein palpation, skin antisepsis (alcohol, chlorhexidine), needle insertion at 15-30 degree angle, blood collection into appropriate tubes (order of draw: culture first, then serum, then citrate, then heparin, then EDTA, then tubes with additives), and proper needle disposal. Complications: hematoma, hemolysis, nerve injury, infection, and needlestick injury.

Viral Load (HIV RNA)

– Quantitative measurement of HIV-1 RNA in plasma by RT-PCR (Roche COBAS, Abbott Real-Time). Normal: undetectable (<20-40 copies/mL). Treatment goal: undetectable viral load (U=U: Undetectable = Untransmittable). Initiation: start ART regardless of viral load or CD4. Monitoring: at baseline, 4-6 weeks after ART start, then q3-6 months. Virologic failure: persistently detectable or rebound >200 copies/mL. Resistance testing before ART switch.

Vitamin B12

– Cobalamin, essential for DNA synthesis, red blood cell production, and neurologic function. Normal: 200-900 pg/mL. Deficiency: <200 pg/mL (but borderline 200-300 may still be symptomatic). Causes: pernicious anemia (autoimmune, most common), gastrectomy, Crohn disease, ileal resection, strict vegan diet, proton pump inhibitors, and metformin. Symptoms: megaloblastic anemia, neuropathy (paresthesias, ataxia), cognitive decline, and glossitis. Methylmalonic acid and homocysteine are more sensitive markers for B12 deficiency.

Vitamin D

– 25-hydroxyvitamin D, the storage form of vitamin D. Normal: >30 ng/mL (75 nmol/L). Insufficiency: 20-30 ng/mL. Deficiency: <20 ng/mL (<50 nmol/L). Extremely deficient: <10 ng/mL (high risk of osteomalacia/rickets). Sources: sun exposure (80%), diet, and supplements. Deficiency causes secondary hyperparathyroidism, increased bone turnover, osteoporosis, and increased fall/fracture risk. Associated with autoimmune disease, cardiovascular disease, and cancer (causal role unproven). Supplementation: 800-2000 IU/day for deficiency.

Voiding Cystourethrogram (VCUG)

– Fluoroscopic imaging of the bladder and urethra during voiding, after filling the bladder with

contrast via a catheter. Indications: evaluation of vesicoureteral reflux (VUR) in children with recurrent UTIs, posterior urethral valves in males, and post-surgical assessment of the bladder/urethra. Grading of VUR: I (ureter only), II (ureter and pelvis, no dilation), III (mild dilation), IV (moderate dilation, tortuous ureter), V (severe dilation, tortuous ureter, intrarenal reflux). Also evaluates bladder capacity, wall thickness, and post-void residual.

X-Ray (Plain Radiography)

– The most common form of medical imaging, using X-rays to create a 2D projection image. Uses: chest (pneumonia, pneumothorax, effusion, cardiomegaly, mass), abdomen (obstruction, perforation, stones), musculoskeletal (fractures, dislocation, arthritis, osteomyelitis), and spine (fracture, alignment, degeneration). Views: PA (posteroanterior) and lateral chest, AP and lateral for spine, AP and frog-leg for hips. Density: air (black), fat (dark gray), soft tissue/water (gray), calcium/bone (white), metal (bright white).

X-Rays (Röntgen Rays)

– See X-Ray (Plain Radiography).

Chapter 21

Microbiology

Adenovirus

– A non-enveloped DNA virus that causes respiratory infections, conjunctivitis, gastroenteritis, and cystitis. Adenoviruses are highly stable in the environment and can cause outbreaks in closed populations. The virus has over 50 serotypes with different tissue tropisms. Diagnosis is made by PCR, antigen detection, or viral culture. There is no specific antiviral treatment, and management is supportive. Severe disseminated infection can occur in immunocompromised patients. Adenoviruses are used as vectors in gene therapy and vaccine development due to their ability to efficiently deliver DNA to target cells.

Agar

– A gelatinous polysaccharide from red algae used to solidify culture media. Melting near 85°C and solidifying at 35–40°C, it remains solid at incubation temperatures and is largely undegraded by bacteria, enabling isolation of pure colonies on media such as blood, MacConkey, and Sabouraud agars.

Airborne precautions

– Infection control measures used for pathogens transmitted through airborne droplet nuclei. Precautions include negative pressure rooms, N95 respirators, and restricted access. Airborne precautions are used for tuberculosis, measles, varicella, and disseminated herpes zoster. The duration of precautions depends on the pathogen and clinical situation. Understanding airborne precautions is essential for preventing transmission of airborne infections in healthcare settings.

Antibiotic resistance genes

– Genes that encode mechanisms conferring resistance to antibiotics. These genes can be located on chromosomes, plasmids, or transposons. Major resistance genes include *mecA* (methicillin resistance

in *S. aureus*), *vanA/vanB* (vancomycin resistance in *Enterococcus*), and *blaKPC* (carbapenem resistance). Resistance genes can be spread between bacteria through horizontal gene transfer. The acquisition of resistance genes is a major public health concern. Understanding resistance genes is essential for developing effective treatment strategies and infection control policies, and for guiding antimicrobial stewardship programmes.

Antibodies

– Immunoglobulin proteins produced by B cells that bind to specific antigens. There are five classes: IgG (most abundant), IgM (first produced), IgA (mucosal immunity), IgE (allergic responses), and IgD. Antibodies neutralise pathogens, opsonise for phagocytosis, activate complement, and mediate antibody-dependent cellular cytotoxicity. Monoclonal antibodies are engineered antibodies used as therapeutics. Antibody testing is used to diagnose infections and assess immune status. Understanding antibody structure and function is fundamental to immunology, vaccine development, and the design of monoclonal antibody therapies.

Antifungal drug classes

– Major classes of antifungal agents include polyenes (amphotericin B), azoles (fluconazole, voriconazole), echinocandins (caspofungin, micafungin), and allylamines (terbinafine). Polyenes bind to ergosterol in fungal cell membranes. Azoles inhibit ergosterol synthesis. Echinocandins inhibit cell wall synthesis. Allylamines inhibit ergosterol synthesis at a different step. The choice of antifungal depends on the fungus, site of infection, and patient factors. Understanding antifungal drug classes is essential for selecting appropriate therapy, managing resistance, and optimising treatment outcomes in patients with

invasive fungal infections.

Antifungal prophylaxis

- The use of antifungal agents to prevent invasive fungal infections in high-risk patients. Common indications include prolonged neutropenia, hematopoietic stem cell transplantation, and advanced HIV infection. Fluconazole, posaconazole, and micafungin are used for prophylaxis. Understanding antifungal prophylaxis is essential for preventing invasive fungal infections in immunocompromised patients. The decision to use prophylaxis should be based on individual risk assessment.

Antifungal resistance

- The ability of fungi to withstand the effects of antifungal agents. Resistance can be intrinsic or acquired. Azole resistance occurs through efflux pumps and target mutations. Echinocandin resistance occurs through FKS gene mutations. Amphotericin B resistance is rare. *Candida auris* is a multidrug-resistant species causing healthcare-associated outbreaks. *Aspergillus fumigatus* azole resistance is emerging, partly due to environmental azole use. Understanding antifungal resistance is essential for guiding treatment decisions, implementing antifungal stewardship, and developing new antifungal agents.

Antigenic Drift

- The gradual accumulation of point mutations in viral surface antigens (hemagglutinin, neuraminidase) during replication, allowing influenza viruses to evade pre-existing antibodies and cause recurrent seasonal epidemics. Drift is continuous and selected by host immunity; it is why the seasonal vaccine is updated annually. Contrast with antigenic shift—a major, abrupt reassortment change causing pandemics.

Antigenic Shift

- A major, abrupt change in the antigenic structure of a virus (especially influenza A) resulting from genetic reassortment between different strains (e.g., human and avian viruses) infecting the same cell. Produces a novel hemagglutinin (HA) and/or neuraminidase (NA) to which most of the population has no immunity, potentially causing pandemics (1918, 1957, 1968, 2009). Contrast with antigenic drift—accumulation of point mutations causing gradual change and seasonal epidemics.

Antigenic variation

- The process by which pathogens change their surface proteins to evade immune recognition. Antigenic drift: gradual changes in surface proteins. Antigenic shift: major changes through reassortment of genome segments. Influenza virus demonstrates both mechanisms. Trypanosomes and *Plasmodium* also use antigenic variation. Understanding antigenic variation is essential for developing effective vaccines and predicting epidemic patterns.

Antimicrobial adverse effects

- Side effects associated with antimicrobial agents. Beta-lactams can cause allergic reactions. Fluoroquinolones can cause tendon rupture and QT prolongation. Aminoglycosides can cause nephrotoxicity and ototoxicity. Azole antifungals can cause hepatotoxicity. Understanding adverse effects is essential for monitoring patients and preventing harm. The benefits of antimicrobial therapy must be weighed against the risks.

Antimicrobial dosing optimization

- Strategies to ensure antimicrobial agents achieve therapeutic concentrations at the site of infection. Optimization includes appropriate drug selection, dosing interval, route of administration, and duration of therapy. Extended or continuous infusion of beta-lactams may improve outcomes. Weight-based dosing is important for many agents. Understanding dosing optimization is essential for maximizing efficacy and minimizing toxicity.

Antimicrobial drug interactions

- Interactions between antimicrobial agents and other medications. Fluoroquinolones chelate divalent cations. Macrolides inhibit CYP3A4. Rifampin is a potent enzyme inducer. Azole antifungals inhibit CYP3A4. Understanding drug interactions is essential for safe prescribing and preventing adverse effects. Careful review of concomitant medications is essential when prescribing antimicrobials.

Antimicrobial pharmacodynamics

- The relationship between antimicrobial drug concentrations and their effect on microorganisms. Time-dependent antibiotics (beta-lactams) are most effective when concentrations remain above the MIC. Concentration-dependent antibiotics (aminoglycosides) are most effective with high peak concentrations. Understanding pharmacodynamics is es-

essential for optimizing dosing regimens and improving clinical outcomes. Pharmacodynamic principles guide antimicrobial dosing strategies.

Antimicrobial pharmacokinetics

- The absorption, distribution, metabolism, and elimination of antimicrobial agents. Pharmacokinetics varies by drug class, patient factors, and disease state. Renal impairment affects elimination of many antibiotics. Hepatic impairment affects metabolism of many antifungals. Understanding pharmacokinetics is essential for dosing optimization in special populations including critically ill patients and those with organ dysfunction.

Antimicrobial resistance surveillance

- The systematic monitoring of antimicrobial resistance patterns in clinical isolates. Surveillance programmes track resistance rates over time and guide empiric therapy. National and international networks share resistance data. Understanding resistance surveillance is essential for effective antimicrobial stewardship and infection control. Surveillance data inform treatment guidelines and public health interventions.

Antimicrobial susceptibility testing

- Laboratory methods used to determine the susceptibility of microorganisms to antimicrobial agents. Methods include disk diffusion, broth microdilution, and automated systems. MIC (minimum inhibitory concentration) is the gold standard measure. Results guide antimicrobial therapy and are interpreted using standardised breakpoints. Resistance testing is essential for managing infections caused by multidrug-resistant organisms. Understanding susceptibility testing is essential for appropriate antimicrobial prescribing and for monitoring resistance trends at local, national, and global levels.

Antiretroviral therapy

- Treatment of HIV infection with combinations of antiretroviral agents. ART targets multiple steps in the viral life cycle including entry, reverse transcription, integration, and maturation. Combination ART suppresses viral replication and restores immune function. ART is lifelong therapy. Understanding ART is essential for managing HIV infection and preventing transmission. ART has transformed HIV from a fatal disease to a chronic

manageable condition.

Antiseptics

- Chemical agents applied to living tissue to reduce microbial load. Antiseptics are used for hand hygiene, skin preparation before procedures, and wound care. Common antiseptics include alcohols, chlorhexidine, povidone-iodine, and hydrogen peroxide. Antiseptics have lower efficacy than disinfectants due to toxicity concerns. The choice of antiseptic depends on the application and microbial spectrum. Hand hygiene with alcohol-based rubs is the most effective way to prevent healthcare-associated infections and is the cornerstone of infection control programmes worldwide.

Antiviral drug classes

- Major classes of antiviral agents include nucleoside analogues (acyclovir, tenofovir), protease inhibitors (ritonavir, atazanavir), reverse transcriptase inhibitors (efavirenz, sofosbuvir), and neuraminidase inhibitors (oseltamivir). Each class targets a specific step in the viral replication cycle. Understanding antiviral drug classes is essential for selecting appropriate therapy and managing drug resistance. Combination therapy is often used to prevent resistance.

Aseptic Technique

- A set of laboratory practices preventing contamination of sterile sites, cultures, and specimens by unwanted microorganisms. Key elements include hand hygiene, sterile fields and instruments, surface disinfection, and minimal exposure of sterile items to air and touch, forming the basis of reliable clinical and culture work.

Bacterial adherence

- The process by which bacteria attach to host cell surfaces, a critical first step in colonisation and infection. Adherence is mediated by adhesins, which are surface structures that bind to specific receptors on host cells. Adhesins include pili, fimbriae, outer membrane proteins, and capsules. The specificity of adhesin-receptor interactions determines the tissue tropism of bacterial pathogens. For example, uropathogenic *E. coli* express adhesins that bind to uroepithelial cells. Anti-adhesion strategies, including competitive inhibitors of adhesin-receptor binding, are being investigated as novel therapeutic approaches to prevent bacterial colonisation.

Bacterial biofilms

– Structured communities of bacteria attached to surfaces and embedded in a self-produced matrix of extracellular polymeric substances. Biofilms are a major cause of chronic infections, particularly on medical devices including catheters, prosthetic joints, and heart valves. Bacteria in biofilms are more resistant to antibiotics (up to 1000-fold) and host immune responses. The biofilm matrix consists of polysaccharides, proteins, and extracellular DNA. Quorum sensing regulates biofilm formation and dispersal, making it a potential target for anti-biofilm therapies.

Bacterial capsule

– A polysaccharide layer surrounding the bacterial cell wall that protects against phagocytosis and complement-mediated killing. Capsules are major virulence factors for many pathogens including *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Klebsiella pneumoniae*. The capsule inhibits opsonisation and prevents engulfment by immune cells. Anti-capsular antibodies are protective and form the basis of conjugate vaccines. Capsule production can be demonstrated by the quellung reaction, which shows capsular swelling when specific antibodies bind to the capsule.

Bacterial cell wall

– The rigid outer layer of bacteria that provides structural integrity and determines cell shape. The cell wall is composed primarily of peptidoglycan, a polymer of sugars cross-linked by short peptides. Gram-positive bacteria have a thick peptidoglycan layer (20-80 nm) while gram-negative bacteria have a thin layer (5-10 nm) surrounded by an outer membrane. The cell wall is essential for bacterial survival and is the target of many antibiotics including beta-lactams and vancomycin. The unique structure of the bacterial cell wall, particularly peptidoglycan synthesis enzymes, provides an excellent target for antimicrobial drugs that have minimal toxicity to human cells.

Bacterial classification

– The organisation of bacteria into taxonomic groups based on genetic, phenotypic, and evolutionary relationships. Bacteria are classified using a hierarchical system: domain, phylum, class, order, family, genus, and species. Classification methods include pheno-

typic characterisation (morphology, staining, biochemical tests) and genotypic methods (16S rRNA sequencing, DNA-DNA hybridisation). The 16S rRNA gene is the primary marker for bacterial phylogenetics. Modern classification emphasises molecular phylogenetic approaches, particularly whole-genome sequencing, which provides more accurate taxonomic resolution than traditional methods.

Bacterial conjugation

– The transfer of genetic material between bacteria through direct cell-to-cell contact via a pilus. Conjugation is mediated by conjugative plasmids that encode the genes for transfer. The donor cell (F+) forms a conjugative pilus that attaches to the recipient cell (F-). A single strand of plasmid DNA is transferred through the pilus, and both cells synthesise the complementary strand. Conjugation is the most efficient mechanism of horizontal gene transfer and can spread antibiotic resistance genes across bacterial species and genera, contributing to the rapid emergence of multidrug-resistant pathogens.

Bacterial dormancy

– A state of reduced metabolic activity that allows bacteria to survive unfavourable conditions. Dormant forms include spores, persisters, and viable but non-culturable cells. Spores are highly resistant structures formed by *Bacillus* and *Clostridium*. Persisters are phenotypic variants that are tolerant to antibiotics. Understanding dormancy is essential for treating chronic infections and developing new antimicrobial strategies.

Bacterial endospores

– Highly resistant dormant structures formed by certain gram-positive bacteria including *Bacillus* and *Clostridium* species. Endospores form during nutrient deprivation and can survive for decades. They are resistant to heat, radiation, chemicals, and desiccation. Sporulation involves asymmetric cell division, engulfment of the forespore, cortex formation, and coat assembly. Germination occurs when conditions improve, with the spore returning to vegetative growth. Endospore formation is a significant challenge for infection control because spores resist standard disinfection methods and can survive for extended periods in the healthcare environment.

Bacterial flagella

– Thread-like appendages composed of flagellin pro-

tein that provide motility to bacteria. Flagella are composed of three parts: the filament, hook, and basal body. The basal body is embedded in the cell wall and functions as a rotary motor. Bacteria are classified by flagellar arrangement: monotrichous (single flagellum), lophotrichous (tuft at one pole), amphitrichous (flagella at both poles), and peritrichous (flagella distributed over entire surface). Flagella are important for chemotaxis, allowing bacteria to move towards nutrients and away from harmful substances, and they also contribute to pathogenesis by enabling bacteria to reach host tissues.

Bacterial genetics

– The study of genes and genetic processes in bacteria. Bacteria have a single circular chromosome and may contain plasmids, which are extrachromosomal DNA elements. Bacterial genes are organized into operons, which are clusters of genes regulated as a unit. Genetic variation occurs through mutation, transformation, transduction, and conjugation. Horizontal gene transfer allows rapid spread of antibiotic resistance and virulence factors. The bacterial genome is compact with little non-coding DNA, and its analysis provides insights into metabolic capabilities, virulence potential, and evolutionary relationships between strains.

Bacterial growth phases

– The stages of bacterial growth in culture. The lag phase is when bacteria adapt to their environment. The log (exponential) phase is when bacteria multiply at their maximum rate. The stationary phase is when nutrient depletion and waste accumulation limit growth. The death phase is when bacteria die. Understanding growth phases is essential for antimicrobial susceptibility testing and understanding pathogenesis. Many antibiotics are most effective during the log phase.

Bacterial metabolism

– The chemical processes that occur within bacteria to maintain life. Bacteria have diverse metabolic capabilities including aerobic and anaerobic respiration, fermentation, and photosynthesis. Metabolic pathways are targets for antimicrobial drugs. Understanding bacterial metabolism is essential for developing new antibiotics and understanding pathogenesis. Metabolic flexibility allows bacteria to survive in diverse environments.

Bacterial morphology

– The shape and arrangement of bacteria as observed under microscopy. Basic shapes include cocci (spheres), bacilli (rods), and spirilla (spirals). Cocci can be arranged in pairs (diplococci), chains (streptococci), clusters (staphylococci), or tetrads. Bacilli can be single, paired, or arranged in chains. Spiral bacteria include vibrios (curved), spirilla (rigid spirals), and spirochetes (flexible spirals). Morphology is a fundamental characteristic for bacterial identification. The size of bacteria typically ranges from 0.5 to 5 micrometres, making them significantly smaller than eukaryotic cells.

Bacterial pathogenesis

– The mechanisms by which bacteria cause disease. Pathogenesis involves adhesion, invasion, toxin production, and immune evasion. Adhesins mediate attachment to host cells. Invasins allow penetration of tissues. Toxins damage host cells. Immune evasion mechanisms include capsules, biofilms, and intracellular survival. Understanding pathogenesis is essential for developing new antimicrobial therapies and vaccines. The study of pathogenesis has identified virulence factors that are targets for drug development, including anti-virulence therapies that disarm pathogens without killing them, potentially reducing selective pressure for resistance.

Bacterial pili

– Hair-like appendages on the bacterial surface composed of pilin protein. Pili are shorter and thicker than flagella. Type I pili mediate adherence to host cells and are important virulence factors. Type IV pili are involved in twitching motility and DNA uptake during transformation. F-pili (sex pili) facilitate conjugation between bacteria. Pili are antigenic (K antigens) and can stimulate immune responses. They are too thin to be visible with light microscopy. Pili are essential for colonisation and biofilm formation, making them important targets for vaccine development and anti-adhesion therapies.

Bacterial toxins

– Substances produced by bacteria that cause damage to host cells. There are two major categories: exotoxins and endotoxins. Exotoxins are proteins secreted by bacteria that have specific toxic effects. Endotoxins are lipopolysaccharide components of gram-negative bacterial outer membranes

released during cell lysis. Exotoxins are classified into types based on mechanism of action: A-B toxins, membrane-disrupting toxins, and superantigens. Endotoxin causes fever, hypotension, and disseminated intravascular coagulation through activation of the innate immune system, and is a key mediator of septic shock in gram-negative bacterial infections.

Bacterial transduction

- The transfer of bacterial DNA from one bacterium to another through bacteriophages (bacterial viruses). There are two types: generalized transduction, which occurs during the lytic cycle when random bacterial DNA is packaged into phage particles, and specialized transduction, which occurs during the lysogenic cycle when specific genes adjacent to the prophage are transferred. Transduction is an important mechanism of horizontal gene transfer and can spread antibiotic resistance genes and virulence factors between bacterial strains, contributing to the evolution of pathogenic bacteria.

Bacterial transformation

- The uptake of free DNA from the environment by competent bacteria. Transformation occurs naturally in some bacterial species including *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Neisseria*. Competence is the ability to take up DNA and is regulated by specific genes. The DNA can be incorporated into the bacterial chromosome through homologous recombination. Transformation is an important mechanism of horizontal gene transfer and can spread antibiotic resistance genes. Artificial transformation is widely used in molecular biology to introduce engineered plasmids into bacteria for research and industrial applications.

Bacterial virulence factors

- Molecules produced by bacteria that contribute to their ability to cause disease. Virulence factors include adhesins, invasins, toxins, capsules, and enzymes. Adhesins mediate attachment to host cells. Toxins damage host cells directly. Capsules protect against phagocytosis. Enzymes degrade host tissues. Understanding virulence factors is essential for developing new antimicrobial therapies and vaccines. Virulence factors are potential targets for drug and vaccine development.

Bactericide

- An agent that kills bacteria rather than merely

inhibiting their growth (bacteriostatic). Bactericidal antibiotics include beta-lactams (penicillins, cephalosporins, carbapenems), aminoglycosides, fluoroquinolones, metronidazole, and vancomycin. The distinction is concentration-dependent and organism-specific; some drugs are bactericidal for certain organisms and bacteriostatic for others. Bactericidal activity is preferred for endocarditis, meningitis, and neutropenic fever.

Bacteriology

- The branch of microbiology concerned with the study of bacteria, including their morphology, genetics, physiology, ecology, and clinical significance. Encompasses bacterial taxonomy, identification methods (Gram stain, culture, biochemical tests, MALDI-TOF, 16S rRNA sequencing), pathogenesis mechanisms, antibiotic susceptibility testing, and the role of bacteria in health (microbiome) and disease. Foundational to clinical infectious disease practice and infection control.

Bacteriophage

- A virus that infects and replicates within bacteria. Types: virulent (lytic) phages cause cell lysis (e.g., T4); temperate phages integrate into the host genome as prophage (lysogeny) and may confer new traits (lysogenic conversion—toxin production by *Corynebacterium diphtheriae*, *Clostridium botulinum*, *Vibrio cholerae*; transduction—horizontal gene transfer). Phage typing identifies bacteria by susceptibility; phages are explored as therapy (phage therapy) for antibiotic-resistant infections. Widely used in molecular biology as cloning vectors.

Bacteriophages

- Viruses that specifically infect and replicate within bacteria, also known as phages. Each phage type typically infects a narrow range of bacterial strains. Phages attach to bacterial surface receptors and inject their genome, hijacking bacterial machinery to produce progeny phages that lyse the host cell. Phage therapy, using lytic phages to treat multidrug-resistant bacterial infections, is a re-emerging antimicrobial strategy. Phages are also essential tools in molecular biology (lambda, M13, T4).

Bacterium

- A unicellular prokaryote lacking a nucleus and membrane-bound organelles, possessing a single circular chromosome and typically a peptidoglycan

cell wall. Bacteria reproduce by binary fission and are classified by Gram reaction, morphology, oxygen requirement, and metabolism, ranging from commensals to pathogens such as *Mycobacterium tuberculosis* and *Escherichia coli*.

Bioburden

- The number and type of viable microorganisms contaminating a surface, medical device, tissue, or pharmaceutical product; a measure of contamination. Bioburden testing assesses the level of microbial contamination (total viable count) before sterilization or in quality control. High bioburden increases the risk of infection and the demands on sterilization processes; sterility assurance relies on achieving a defined log reduction from the initial bioburden.

Biofilm

- An organized community of microorganisms attached to a surface and embedded in a self-produced extracellular polymeric matrix (polysaccharides, proteins, DNA). Biofilms form on medical devices (catheters, prosthetic valves, implants) and in nature; bacteria within biofilms are less susceptible to antibiotics and host defenses, causing persistent and recurrent infections (e.g., *Pseudomonas* in cystic fibrosis, catheter-associated UTI, infective endocarditis). Resistance mechanisms: reduced penetration, slow growth, persister cells, and quorum sensing. Eradication often requires device removal.

Biofilm-associated infections

- Infections caused by bacteria growing in biofilms on medical devices or tissues. Biofilms are structured communities of bacteria embedded in extracellular polymeric substances. Bacteria in biofilms are more resistant to antibiotics and host immune responses. Common biofilm-associated infections include catheter-associated urinary tract infections, ventilator-associated pneumonia, and prosthetic joint infections. Prevention through anti-biofilm strategies and device management is essential. Understanding biofilm-associated infections is essential for developing effective prevention and treatment strategies, including antimicrobial lock therapy and biofilm-disrupting agents.

C. difficile

- *Clostridioides difficile*, a gram-positive, spore-forming bacterium that causes antibiotic-associated

diarrhea and colitis. *C. difficile* produces toxins A and B that cause colonic inflammation. Risk factors include antibiotic exposure, proton pump inhibitor use, and advanced age. Treatment includes vancomycin or fidaxomicin. Recurrence occurs in approximately 25% of cases. fecal microbiota transplantation is highly effective for multiply recurrent infections. Prevention through antibiotic stewardship, environmental cleaning with sporicidal agents, and isolation of affected patients is essential to control *C. difficile* transmission in healthcare settings.

Chikungunya virus

- A positive-sense RNA virus belonging to the *Togaviridae* family that causes fever and severe joint pain. The virus is transmitted by *Aedes* mosquitoes. Symptoms include fever, rash, and polyarthralgia that can be debilitating. Most patients recover fully, but some develop chronic joint pain lasting months to years. Diagnosis is made by PCR or serology. Treatment is supportive with pain management. There is no specific antiviral treatment. Prevention through mosquito control is important. The virus continues to cause outbreaks in tropical and subtropical regions where vector control is inadequate, and travellers returning from endemic areas may import the disease.

***Clostridioides difficile* pathogenesis**

- The mechanisms by which *C. difficile* causes disease. The organism produces toxins A and B that damage the colonic mucosa. Antibiotic disruption of normal gut flora allows *C. difficile* to colonize and produce toxins. The organism forms spores that are resistant to disinfectants and can persist in the environment. Understanding *C. difficile* pathogenesis is essential for developing new treatments and prevention strategies. The organism is a major cause of healthcare-associated diarrhea.

Clostridium botulinum

- A gram-positive, spore-forming, anaerobic rod that produces botulinum toxin, the most potent toxin known. The toxin causes flaccid paralysis by blocking acetylcholine release at neuromuscular junctions. Infant botulism occurs from ingestion of spores in honey or soil. Wound botulism occurs from injection of contaminated heroin. Food-borne botulism occurs from ingestion of preformed toxin in improperly preserved food. Diagnosis is clinical with toxin de-

tection. Treatment includes botulinum antitoxin to neutralise circulating toxin and intensive supportive care, including mechanical ventilation if respiratory muscle paralysis occurs.

Clostridium perfringens

- A gram-positive, spore-forming, anaerobic rod that causes gas gangrene (clostridial myonecrosis) and food poisoning. The organism produces alpha-toxin, which causes tissue necrosis. Gas gangrene presents with crepitus, tissue necrosis, and systemic toxicity. Food poisoning presents with acute onset of diarrhea and abdominal cramps. Diagnosis involves culture and toxin detection. Treatment includes surgical debridement, hyperbaric oxygen, and penicillin. The organism is part of the normal gastrointestinal flora in some individuals, but when introduced into deep tissues through trauma or surgery, it can cause rapidly progressive necrotising infection.

Clostridium tetani

- A gram-positive, spore-forming, anaerobic rod that causes tetanus. The organism produces tetanospasmin, a neurotoxin that causes spastic paralysis. Spores are found in soil and enter through wound contamination. The toxin blocks inhibitory neurotransmitters causing uncontrolled muscle contractions. Symptoms include trismus (lockjaw), opisthotonus, and respiratory failure. Diagnosis is clinical. Treatment includes metronidazole, tetanus immune globulin, and supportive care. Prevention through vaccination with tetanus toxoid and appropriate wound management is highly effective.

Colony-Forming Unit (CFU)

- A unit used to estimate the number of viable microorganisms in a sample, derived from counting colonies grown on agar after plating a diluted sample. Each colony is assumed to arise from a single viable microorganism (or a cluster); results are reported as CFU/mL or CFU/g. Used in quantitative cultures (urine, quantitative sputum), environmental monitoring, water/food testing, and assessing antimicrobial efficacy.

Community Acquired Infection

- An infection present or incubating at hospital admission, or developing within 48 hours of admission without recent healthcare exposure. Common examples include pneumonia, urinary tract infection, and meningitis caused by organisms such as *Strep-*

tococcus pneumoniae and *Escherichia coli*, generally susceptible to narrow-spectrum antibiotics.

Contact precautions

- Infection control measures used for patients colonised or infected with multidrug-resistant organisms. Precautions include gown and glove use, patient placement in single rooms, and dedicated equipment. Contact precautions are used for MRSA, VRE, CRE, and other resistant organisms. Hand hygiene remains essential in addition to contact precautions. The duration of precautions depends on the organism and clinical situation. Understanding contact precautions is essential for preventing transmission of multidrug-resistant organisms in health-care settings and reducing the burden of healthcare-associated infections.

Coxiella burnetii

- An obligate intracellular bacterium that causes Q fever, a zoonotic infection transmitted from animals to humans. The organism is transmitted through inhalation of contaminated aerosols or ingestion of contaminated dairy products. Acute Q fever presents with fever, headache, and pneumonia. Chronic Q fever can cause endocarditis. Diagnosis involves serology and PCR. Treatment includes doxycycline for acute disease and doxycycline with hydroxychloroquine for chronic endocarditis. Prevention through pasteurisation of dairy products, protective measures for abattoir workers and veterinarians, and awareness of the disease in endemic regions is essential for reducing transmission.

CRE

- Carbapenem-resistant Enterobacteriaceae, resistant to carbapenem antibiotics through production of carbapenemases including KPC, NDM, and OXA-48-like enzymes. CRE are a major public health threat due to limited treatment options. Infections are associated with high mortality rates. Treatment options include ceftazidime-avibactam, meropenem-vaborbactam, and aminoglycosides. Infection prevention and antimicrobial stewardship are essential to control spread. Active surveillance may be necessary in high-risk settings such as intensive care units to detect colonised patients and implement timely infection control measures.

Culture Media

- Nutrient preparations used to grow microorgan-

isms in the laboratory, classified by composition and purpose. Types: liquid (broth), solid (agar plates, slants); enriched (blood agar—fastidious organisms), selective (inhibit unwanted organisms—MacConkey, bile esculin), differential (distinguish species by appearance—blood agar hemolysis, MacConkey lactose), and special (selective for specific pathogens—TCBS for *Vibrio*, Löwenstein-Jensen for *M. tuberculosis*). Choice depends on the suspected organism, source, and clinical question.

Cytomegalovirus

– A herpesvirus that causes significant disease in immunocompromised patients including transplant recipients and HIV-infected individuals. CMV infects a wide range of cell types and establishes latent infections in myeloid progenitor cells. Primary infection is usually asymptomatic in immunocompetent individuals. Reactivation can cause retinitis, colitis, oesophagitis, and pneumonitis in immunocompromised patients. Congenital CMV infection is the most common viral cause of birth defects. Diagnosis involves PCR, antigen detection, viral culture, and serology, with treatment including ganciclovir, valganciclovir, or foscarnet for active disease in immunocompromised patients.

Dengue virus

– A positive-sense RNA virus belonging to the Flaviviridae family that causes dengue fever. The virus has four serotypes, and infection with one serotype provides lifelong immunity to that serotype but only temporary cross-protection against others. Secondary infection with a different serotype can cause severe dengue hemorrhagic fever or dengue shock syndrome due to antibody-dependent enhancement. The virus is transmitted by *Aedes* mosquitoes. Diagnosis is made by PCR or antigen detection. Treatment is supportive with careful fluid management and avoidance of non-steroidal anti-inflammatory drugs due to the risk of bleeding complications.

Diagnostic microbiology

– The laboratory identification of microorganisms causing disease. Methods include microscopy, culture, biochemical testing, serology, and molecular methods. Rapid diagnostic tests provide same-day results. MALDI-TOF mass spectrometry revolutionized bacterial identification. PCR and nucleic acid amplification tests are essential for diagnos-

ing infections caused by fastidious organisms. Understanding diagnostic microbiology is essential for appropriate antimicrobial therapy.

Dysbiosis

– An alteration in microbiome composition, diversity, or function relative to a healthy state, permitting overgrowth of pathobionts or loss of beneficial microbes. Causes include antibiotics, dietary change, stress, and infection. It is associated with inflammatory bowel disease, obesity, allergy, and *Clostridioides difficile* colitis.

Disinfection

– The elimination of most pathogenic microorganisms on inanimate surfaces. Disinfection does not eliminate all forms of microbial life, particularly spores. High-level disinfection eliminates all microorganisms except spores. Intermediate-level disinfection eliminates mycobacteria, most viruses, and bacteria. Low-level disinfection eliminates most bacteria and some viruses. Chemical disinfectants include alcohols, bleach, quaternary ammonium compounds, and phenolics. The level of disinfection required depends on the intended use of the medical device, with critical items requiring sterilisation, semi-critical items requiring high-level disinfection, and non-critical items requiring intermediate or low-level disinfection.

Droplet precautions

– Infection control measures used for pathogens transmitted through respiratory droplets. Precautions include surgical masks, patient placement in single rooms, and spatial separation. Droplet precautions are used for influenza, pertussis, and meningococcal infections. The distance for spatial separation is typically 3-6 feet. Understanding droplet precautions is essential for preventing transmission of respiratory infections in healthcare settings.

Ebola virus

– A filovirus that causes Ebola virus disease, a severe hemorrhagic fever. The virus is transmitted through contact with infected body fluids. The incubation period is 2-21 days. Symptoms include fever, headache, myalgia, and hemorrhage. Diagnosis is made by PCR and antigen detection. Treatment is supportive with rehydration and management of complications. The rVSV-ZEBOV vaccine is available. Outbreaks have occurred primarily in Africa

with significant public health impact. Prevention through infection control measures, including isolation of affected patients, use of personal protective equipment, and safe burial practices, is critical to containing Ebola outbreaks.

Echinococcus granulosus

– A tapeworm that causes hydatid disease (cystic echinococcosis). The adult worm infects dogs, and humans are accidental intermediate hosts. Infection occurs through ingestion of eggs from dog feces. Larval cysts form in the liver and lungs, causing space-occupying lesions. Diagnosis involves imaging showing characteristic cysts and serology. Treatment includes surgical removal or percutaneous aspiration with albendazole coverage. Puncture of cysts can cause anaphylaxis. Prevention through regular deworming of dogs and proper disposal of dog feces is essential in endemic areas to break the transmission cycle.

Ehrlichia and Anaplasma

– Obligate intracellular bacteria transmitted by ticks that cause ehrlichiosis and anaplasmosis. Ehrlichia chaffeensis causes human monocytic ehrlichiosis. Anaplasma phagocytophilum causes human granulocytic anaplasmosis. The organisms infect white blood cells (Ehrlichia) or granulocytes (Anaplasma). Symptoms include fever, headache, and myalgia. Diagnosis involves PCR and serology. Treatment includes doxycycline. Prevention through tick avoidance is essential. These infections can be severe in immunocompromised patients and may require prolonged antibiotic therapy to prevent relapse.

Endemic fungi

– Fungi that are found in specific geographic regions and cause systemic infections in immunocompetent individuals. Endemic fungi include Histoplasma capsulatum (Ohio and Mississippi River valleys), Blastomyces dermatitidis (Great Lakes region), Coccidioides immitis (southwestern United States), and Paracoccidioides brasiliensis (Central and South America). These fungi are dimorphic, existing as moulds in the environment and yeasts in tissue. Infections are acquired through inhalation of spores. Diagnosis involves culture, histopathology, and antigen detection in tissue specimens, with treatment including azole antifungals or amphotericin B depending on the species and severity.

Endotoxin

– Lipopolysaccharide (LPS) located in the outer membrane of gram-negative bacteria, released on cell lysis or death; the classic pyrogen. Composed of lipid A (active/toxic component), core polysaccharide, and O antigen. Effects: fever, hypotension, shock, disseminated intravascular coagulation, and multi-organ failure via TLR4-mediated cytokine release (TNF, IL-1, IL-6). Endotoxin is heat-stable (survives autoclaving) and measured by the limulus amoebocyte lysate (LAL) test. Contrast with exotoxin—heat-labile secreted protein toxins.

Endotoxins

– Lipopolysaccharide components of gram-negative bacterial outer membranes released during cell lysis or bacterial growth. Endotoxin is composed of lipid A (the toxic component), core oligosaccharide, and O-antigen. It activates macrophages through toll-like receptor 4, leading to cytokine release. Clinical effects include fever, hypotension, and disseminated intravascular coagulation. Endotoxin is heat-stable and difficult to remove. All gram-negative bacteria contain endotoxin, but potency varies between species, with Neisseria meningitidis and Escherichia coli producing particularly potent endotoxin.

Entamoeba histolytica

– A protozoan parasite that causes amoebiasis, a gastrointestinal and extra-intestinal infection transmitted via the fecal-oral route. The organism exists in two forms: the infectious cyst (transmitted in contaminated food or water) and the invasive trophozoite. Trophozoites colonise the large intestine, where they can adhere to colonic epithelium via a galactose-binding lectin and cause tissue invasion, often producing characteristic flask-shaped ulcers. In most cases, infection is asymptomatic; however, invasive disease can cause amoebic dysentery (bloody diarrhea with mucus, abdominal pain, and tenesmus). Extraintestinal spread most commonly results in amoebic liver abscess. Diagnosis involves microscopy demonstrating trophozoites with ingested red blood cells, antigen detection, PCR, and serology for extra-intestinal disease. Treatment includes tinidazole or metronidazole followed by a luminal agent (paromomycin or diloxanide furoate) to eradicate cyst carriage.

Enterotoxin

- A toxin acting on the intestinal tract to cause diarrhea and vomiting by altering epithelial fluid secretion. Examples include cholera toxin, enterotoxigenic *Escherichia coli* toxins, and *Staphylococcus aureus* enterotoxins causing food poisoning; some, such as enterotoxin B, also function as superantigens.

Epstein-Barr virus

- A herpesvirus that causes infectious mononucleosis and is associated with several malignancies including Burkitt lymphoma, nasopharyngeal carcinoma, and Hodgkin lymphoma. EBV infects B cells and establishes latent infections. The virus encodes several oncoproteins including LMP1 and EBNA2. Primary infection is often asymptomatic in childhood but can cause mononucleosis in adolescents and adults. Diagnosis is confirmed by heterophile antibody test or EBV-specific serology. There is no specific antiviral treatment for EBV, and management of infectious mononucleosis is supportive, with corticosteroids reserved for airway compromise or severe complications.

ESBL

- Extended-spectrum beta-lactamase, enzymes that hydrolyse penicillins, cephalosporins, and monobactams. ESBLs are common in Enterobacteriaceae, particularly *Klebsiella pneumoniae* and *E. coli*. ESBL production confers resistance to most beta-lactam antibiotics except carbapenems. Infections are associated with increased morbidity and mortality. Treatment typically requires carbapenems or other agents active against ESBL-producing organisms. Stewardship strategies are essential to limit the spread of ESBL-producing organisms and preserve the efficacy of remaining treatment options.

Escherichia coli

- A gram-negative rod that is part of the normal intestinal flora but can cause various infections. Uropathogenic *E. coli* causes urinary tract infections. Enterotoxigenic *E. coli* causes traveller's diarrhea. Enterohemorrhagic *E. coli* (O157:H7) causes bloody diarrhea and hemolytic uremic syndrome. ESBL-producing *E. coli* is an increasing cause of healthcare-associated infections. The organism is identified by lactose fermentation and biochemical tests. Treatment depends on the infection site and susceptibility profile, with increasing resistance to

commonly used antibiotics necessitating tailored therapy based on local resistance patterns.

Exotoxin

- A heat-labile, protein toxin secreted or released by bacteria (mostly gram-positive; also some gram-negative), often encoded on plasmids or phages, that acts at distant sites. Highly potent with specific mechanisms: neurotoxins (botulinum, tetanus), enterotoxins (cholera toxin—ADP-ribosylates Gs; ETEC), cytotoxins (diphtheria—inhibits protein synthesis via EF-2 ADP-ribosylation; Shiga toxin), superantigens (staphylococcal TSST, streptococcal pyrogenic exotoxins—massive cytokine release). May be converted to toxoids for vaccines (tetanus, diphtheria). Contrast with endotoxin.

Exotoxins

- Proteins secreted by bacteria that have specific toxic effects on host cells. Exotoxins are generally more potent than endotoxins and have specific mechanisms of action. A-B toxins consist of an active (A) component and a binding (B) component. Examples include diphtheria toxin, cholera toxin, and botulinum toxin. Membrane-disrupting toxins include haemolysins and leukocidins that damage cell membranes. Superantigens including toxic shock syndrome toxin-1 cause non-specific T cell activation. Exotoxins are a major focus of vaccine development, as demonstrated by toxoid vaccines for diphtheria and tetanus, and they are also used in biomedical research for their specific cellular targets.

Extracellular pathogens

- Microorganisms that survive and replicate outside host cells. Extracellular bacteria include *Streptococcus*, *Staphylococcus*, and *Escherichia coli*. These pathogens are typically killed by antibodies and complement. They produce toxins and enzymes to damage host tissues. Understanding extracellular pathogenesis is essential for developing vaccines that generate protective antibodies. Extracellular pathogens are typically susceptible to antibiotics that can reach high concentrations in extracellular fluids and are effectively cleared by antibody-mediated immune mechanisms.

Filariasis

- A group of nematode infections transmitted by mosquitoes and other vectors. The major species causing lymphatic filariasis are *Wuchereria ban-*

crofti, *Brugia malayi*, and *Brugia timori*. Adult worms reside in lymphatic vessels causing lymphoedema and elephantiasis. Diagnosis involves microscopy of blood collected at night when microfilariae are circulating. Treatment includes diethylcarbamazine (DEC). Prevention through mosquito control is essential. Onchocerciasis (river blindness) is caused by *Onchocerca volvulus*, transmitted by black flies, and is treated with ivermectin.

Filoviruses

- A family of negative-sense RNA viruses that includes Ebola and Marburg viruses. These viruses cause severe hemorrhagic fever with high mortality rates. The virus is transmitted through contact with infected body fluids. The incubation period is 2-21 days. Symptoms include fever, headache, myalgia, and hemorrhage. Diagnosis is made by PCR and antigen detection. Treatment is supportive with rehydration and management of complications. The rVSV-ZEBOV vaccine is available for Ebola virus. Prevention through infection control measures, including isolation and barrier nursing, is essential for managing filovirus outbreaks in healthcare settings.

Fomite

- An inanimate object or surface capable of transmitting infectious agents (viruses, bacteria, fungi) between people (e.g., doorknobs, towels, medical equipment, toys, needles). Transmission occurs when contaminated fomites contact mucous membranes or skin, or are involved in procedures. Cleaning, disinfection, and hand hygiene break fomite transmission; important in healthcare-associated infections and respiratory/gastrointestinal virus spread (norovirus, influenza, SARS-CoV-2).

Francisella tularensis

- A gram-negative coccobacillus that causes tularemia, a zoonotic infection transmitted by ticks, deer flies, or direct contact with infected animals. The organism can be acquired through the skin, respiratory tract, or gastrointestinal tract. Ulceroglandular tularemia presents with skin ulcer and regional lymphadenopathy. Pneumonic tularemia can be severe. Diagnosis involves serology and culture (requires special media). Treatment includes streptomycin or gentamicin. Tularemia is a rare infection that is considered a potential bioterrorism agent due to its low infectious dose and ease of

aerosolisation.

Fungal pathogenesis

- The mechanisms by which fungi cause disease. Fungal pathogenesis involves adhesion, invasion, and evasion of host defences. Adhesins mediate attachment to host cells. Invasive hyphae penetrate tissues. Capsules and melanin protect against immune responses. Biofilm formation provides protection against antifungal agents. Immunocompromised individuals are at increased risk for invasive fungal infections. Understanding fungal pathogenesis is essential for developing new antifungal therapies and vaccines, particularly given the increasing population of immunocompromised patients at risk for invasive fungal disease.

Fungus

- A eukaryotic microorganism with a chitin cell wall and ergosterol-containing membrane, classified as yeasts, moulds, or dimorphic fungi. Reproducing by spores, fungi cause superficial, mucosal, subcutaneous, and systemic infections, especially in immunocompromised hosts. Antifungal targets include ergosterol (polyenes, azoles) and glucan synthesis (echinocandins).

Germ

- A colloquial term for a microorganism that causes disease.

Germ Theory of Disease

- The scientific principle that specific microorganisms cause specific infectious diseases; established in the late 19th century by Koch (postulates—organism present in all cases, isolated in pure culture, reproduces disease when inoculated, re-isolated) and promoted by Pasteur and Lister. Foundation of modern microbiology, infection control, sterilization, vaccination, and antibiotics. Koch's postulates have limitations (non-cultivable organisms, asymptomatic carriage, some viruses) addressed by molecular criteria.

Giardia lamblia

- A protozoan parasite that causes giardiasis, a diarrhoeal illness transmitted through the fecal-oral route. The organism has a trophozoite and cyst stage. Infection occurs through ingestion of cysts in contaminated water. Symptoms include foul-smelling diarrhea, abdominal cramps, and bloating. Diagnosis involves stool microscopy showing tropho-

zoites or cysts, and antigen detection. Treatment includes metronidazole or tinidazole. Prevention through water treatment and sanitation is essential. *Giardia lamblia* is a common cause of waterborne outbreaks and is highly prevalent in areas with poor sanitation and inadequate water treatment.

Giemsa Stain

– A Romanowsky-type stain of methylene blue and eosin dyes used to visualise blood cells and microorganisms in smears and tissue sections. In microbiology it stains *Plasmodium*, *Babesia*, *Trypanosoma*, *Leishmania*, *Borrelia*, and intracellular cytomegalovirus inclusions, supporting rapid diagnosis of blood-borne parasitic and other infections.

Gram Negative Bacilli

– Rod-shaped gram-negative bacteria appearing pink on Gram stain owing to a thin peptidoglycan layer and lipopolysaccharide outer membrane. Clinically important genera include *Enterobacteriaceae*, *Pseudomonas*, and *Bacteroides*, causing urinary, respiratory, and intra-abdominal infections; many produce beta-lactamases conferring antibiotic resistance.

Gram-Negative Bacteria

– Bacteria that do not retain crystal violet in the Gram stain (appear pink/red), characterized by a thin peptidoglycan layer and an outer membrane containing lipopolysaccharide (endotoxin). Examples: *Enterobacteriaceae* (*E. coli*, *Klebsiella*, *Salmonella*, *Shigella*, *Proteus*), *Pseudomonas*, *Acinetobacter*, *Neisseria* (meningitidis, gonorrhoeae), *Haemophilus*, *Legionella*, *Helicobacter pylori*, *Bacteroides*, *Vibrio*. Common causes of sepsis, UTIs, pneumonia (especially healthcare-associated), meningitis, and intra-abdominal infections. Inherent resistance to many antibiotics (efflux pumps, beta-lactamases, porin changes); ESBL/CRE producing strains pose treatment challenges.

Gram-Positive Bacteria

– Bacteria that retain crystal violet in the Gram stain (appear purple/blue), characterized by a thick peptidoglycan cell wall and no outer membrane. Examples: *Staphylococcus* (*aureus*—causes skin infections, pneumonia, sepsis, endocarditis, osteomyelitis; coagulase-negative—device infections), *Streptococcus* (*pyogenes*—pharyngitis, cellulitis, rheumatic fever; *pneumoniae*—pneumonia, meningitis; *agalac-*

tiae—neonatal sepsis), *Enterococcus* (UTIs, endocarditis; VRE concern), *Bacillus* (anthracis, *cereus*), *Clostridium* (*botulinum*, tetani, *difficile*, *perfringens*—gas gangrene), *Listeria* (neonatal, pregnant, immunocompromised), and *Corynebacteria*. Antibiotic coverage includes beta-lactams, vancomycin; gram-positive cocci in clusters vs. chains guide empiric therapy.

Gram Positive Cocci

– Spherical gram-positive bacteria staining purple owing to a thick peptidoglycan layer and absent outer membrane. Clinically important genera include *Staphylococcus*, *Streptococcus*, and *Enterococcus*, identifiable by arrangement (clusters, chains, pairs) and hemolysis, and causing skin, pharyngeal, respiratory, and bloodstream infections.

Gram stain

– A differential staining technique that classifies bacteria into two major groups based on cell wall structure. The procedure involves crystal violet staining, iodine mordant, alcohol decolorisation, and safranin counterstain. Gram-positive bacteria retain the crystal violet-iodine complex due to their thick peptidoglycan layer and appear purple. Gram-negative bacteria lose the crystal violet and take up the counterstain, appearing pink or red. The Gram stain is the most important initial step in bacterial identification and provides critical information for guiding empiric antimicrobial therapy while cultures are pending.

Growth Medium

– A nutrient preparation supporting microbial multiplication in vitro, supplying carbon, nitrogen, minerals, and growth factors in liquid or solid form. Media are classified as defined or complex and by function as general-purpose, enriched, selective, or differential, exemplified by MacConkey agar and Löwenstein-Jensen medium for particular organisms.

Haemophilus influenzae

– A gram-negative coccobacillus that causes meningitis, epiglottitis, pneumonia, and other infections. The encapsulated type b (Hib) strain was the most virulent, causing invasive disease in children. The Hib conjugate vaccine has dramatically reduced the incidence of invasive Hib disease. Non-typeable strains cause otitis media, sinusitis, and exacerbations.

tions of chronic bronchitis. The organism requires X factor (haemin) and V factor (NAD) for growth. Diagnosis involves culture on chocolate agar. Treatment includes broad-spectrum antibiotics such as third-generation cephalosporins, and prevention of invasive Hib disease has been achieved through routine childhood vaccination.

Hand hygiene

- The most effective measure for preventing healthcare-associated infections. Hand hygiene includes handwashing with soap and water and hand rubbing with alcohol-based rubs. Alcohol-based rubs are preferred for routine hand hygiene as they are faster and more effective than soap and water. Soap and water should be used when hands are visibly soiled or when caring for patients with *C. difficile*. The WHO has established five moments for hand hygiene in healthcare settings. Hand hygiene compliance is monitored in healthcare settings as a key quality indicator, and improvement strategies include education, feedback, and the availability of alcohol-based hand rub at the point of care.

Healthcare Associated Infection

- An infection developing as a consequence of healthcare delivery, typically beyond 48 hours after admission or within 30 days of a procedure. Major categories include central line, catheter, ventilator, and surgical site infections, often caused by resistant organisms such as MRSA, VRE, and *Candida*, prevented by hand hygiene and device bundles.

Helminths

- Parasitic worms that cause disease in humans. The major groups are nematodes (roundworms), cestodes (tapeworms), and trematodes (flukes). Helminths have complex life cycles often involving intermediate hosts. Infection occurs through ingestion of eggs or larvae, penetration of skin, or insect vectors. Diagnosis involves stool microscopy for eggs and larvae, serology, and imaging. Treatment includes anthelmintic agents such as albendazole, mebendazole, and praziquantel. Helminth infections are a major cause of morbidity in tropical and subtropical regions, contributing to malnutrition, anemia, and impaired cognitive development in children.

Herpes simplex virus

- A double-stranded DNA virus belonging to the

Herpesviridae family that causes oral and genital herpes. HSV has two serotypes: HSV-1, which typically causes oral herpes, and HSV-2, which typically causes genital herpes. The virus establishes latent infections in sensory ganglia and can reactivate periodically. Primary infection is often asymptomatic. Reactivation causes recurrent outbreaks of vesicular lesions. Antiviral treatment with acyclovir, valacyclovir, or famciclovir can reduce the frequency and severity of recurrent episodes and is recommended for patients with frequent or severe outbreaks.

Hookworms

- Nematodes including *Ancylostoma duodenale* and *Necator americanus* that cause hookworm infection. Infection occurs through skin penetration by filariform larvae, typically when walking barefoot on contaminated soil. Adult worms attach to the intestinal mucosa and feed on blood, causing iron deficiency anemia. Diagnosis involves stool microscopy for eggs. Treatment includes albendazole or mebendazole. Prevention through sanitation, wearing shoes, and avoiding soil contact is essential. Hookworm infection remains a significant public health problem in resource-limited settings, particularly among children and agricultural workers in tropical regions.

Horizontal gene transfer

- The transfer of genetic material between bacteria through mechanisms other than parent-to-offspring transmission. The three mechanisms are transformation (uptake of free DNA), transduction (transfer via bacteriophages), and conjugation (direct cell-to-cell transfer). Horizontal gene transfer allows rapid spread of antibiotic resistance genes and virulence factors. Understanding this process is essential for tracking the spread of resistance and developing strategies to combat it.

Hospital-acquired infections

- Infections that develop during or after hospitalisation. Major types include central line-associated bloodstream infections, catheter-associated urinary tract infections, ventilator-associated pneumonia, and surgical site infections. Risk factors include invasive devices, prolonged hospitalisation, and antimicrobial use. Prevention through infection control measures including hand hygiene, device bundles, and antimicrobial stewardship is essential. Hospital-acquired infections are associated with in-

creased morbidity, mortality, length of stay, and healthcare costs, and represent a major patient safety concern.

Human immunodeficiency virus

– A retrovirus belonging to the Lentivirus genus that causes acquired immunodeficiency syndrome (AIDS). HIV has two species: HIV-1 and HIV-2. The virus targets CD4+ T cells, macrophages, and dendritic cells. HIV has a complex genome encoding structural proteins, enzymes (reverse transcriptase, integrase, protease), and regulatory proteins. The virus integrates into the host genome as a provirus and can establish latent reservoirs. Without treatment, HIV infection leads to progressive CD4+ T cell depletion, increasing susceptibility to opportunistic infections and malignancies, and ultimately resulting in AIDS and death.

Human microbiome

– The collection of microorganisms that live on and in the human body. The microbiome includes bacteria, viruses, fungi, and archaea. The gut microbiome is the most studied and plays a role in digestion, immune function, and disease. Dysbiosis (alteration of the microbiome) is associated with inflammatory bowel disease, obesity, and infections. Understanding the microbiome is essential for developing new therapeutic approaches including fecal microbiota transplantation and probiotics.

Immunodeficiency and infections

– Immunocompromised individuals are at increased risk for opportunistic infections. Primary immunodeficiencies are genetic disorders affecting immune function. Secondary immunodeficiencies include HIV/AIDS, organ transplantation, chemotherapy, and corticosteroid use. Common opportunistic infections include *Pneumocystis jirovecii*, CMV, *Aspergillus*, and *Cryptococcus*. Prevention through antimicrobial prophylaxis and vaccination is essential. Early diagnosis and treatment of opportunistic infections is critical for improving outcomes in immunocompromised patients, and prophylactic antimicrobial therapy should be tailored to the specific immune defect.

Immunofluorescence

– A technique using fluorescently labeled antibodies to detect specific antigens in tissues, cells, or microorganisms; visualized by fluorescence microscopy.

Direct immunofluorescence (DIF): labeled antibody binds antigen directly—used for autoimmune skin diseases (pemphigus, bullous pemphigoid), renal biopsy (lupus nephritis, anti-GBM), and tissue infections. Indirect immunofluorescence (IIF): patient serum antibodies detected using labeled anti-human immunoglobulin—used for ANA, ANCA, anti-desmoglein, and serological diagnosis of infections. Methods include antibody staining of microorganisms (e.g., DFA for respiratory viruses, rabies, *Legionella*).

Incubator

– A controlled-environment chamber culturing microorganisms, cells, or tissues at defined temperature, humidity, and atmospheric composition. Standard bacterial incubation is 35–37°C; CO₂ incubators support fastidious organisms and cell culture, while anaerobic jars or chambers cultivate *Bacteroides* and *Clostridium* for accurate recovery and susceptibility testing.

Influenza virus

– A segmented, negative-sense RNA virus belonging to the Orthomyxoviridae family. Influenza causes seasonal epidemics and occasional pandemics of respiratory illness. The virus has two surface glycoproteins: hemagglutinin (HA), which mediates attachment, and neuraminidase (NA), which facilitates release. Influenza A infects humans, birds, and other animals, while influenza B infects only humans. Antigenic drift (point mutations in HA and NA) causes seasonal epidemics, while antigenic shift (reassortment of genome segments) can generate novel pandemic strains to which the population has little pre-existing immunity.

Innate immune evasion

– Mechanisms by which pathogens evade the innate immune system. Strategies include capsules that prevent phagocytosis, biofilms that protect against immune cells, and intracellular survival within macrophages. Some bacteria produce enzymes that degrade complement components. Others modify their surface molecules to avoid recognition. Understanding immune evasion is essential for developing new therapeutic approaches and vaccines. Pathogens that evade innate immunity can establish infections before adaptive immune responses are mounted, making early recognition and rapid

diagnosis critical for effective treatment.

Inoculation

- The introduction of microorganisms or clinical material into a culture medium, host, or sterile site to initiate growth, infection, or immune response. In the laboratory, loops, needles, or pipettes transfer specimens onto agar, broth, or slants; aseptic technique during inoculation prevents contamination and ensures valid culture results.

Integrans

- Genetic elements that capture and express gene cassettes through site-specific recombination. Integrans contain an integrase gene and a recombination site for gene cassette insertion. They are important vehicles for the spread of antibiotic resistance genes, particularly in gram-negative bacteria. Class 1 integrans are the most clinically significant and are associated with multidrug resistance. Gene cassettes can contain multiple resistance genes, allowing accumulation of resistance. Integrans play a key role in the dissemination of antibiotic resistance in clinical settings, particularly among gram-negative pathogens where they contribute to the emergence of multidrug-resistant strains.

Intracellular pathogens

- Microorganisms that survive and replicate within host cells. Intracellular bacteria include *Mycobacterium*, *Listeria*, and *Chlamydia*. Viruses are obligate intracellular pathogens. Intracellular survival protects pathogens from antibiotics and immune responses. Strategies for intracellular survival include avoiding lysosomal fusion and surviving within phagosomes. Understanding intracellular pathogenesis is essential for developing new therapeutic approaches. Intracellular pathogens require treatment with antimicrobial agents that can penetrate host cell membranes, such as macrolides, tetracyclines, and fluoroquinolones, and often require prolonged therapy to achieve eradication.

Lactose Fermentation

- The ability of bacteria to ferment lactose to acid (and gas), a key differential characteristic on MacConkey agar. Lactose-fermenting enteric gram-negative bacteria produce pink/red colonies (*E. coli*, *Klebsiella*, *Enterobacter*, *Citrobacter*); non-lactose fermenters form colorless colonies (*Salmonella*, *Shigella*, *Proteus*, *Pseudomonas*). Part of the bio-

chemical identification scheme; also used in carbohydrate utilization tests (e.g., bile esculin for group D enterococci).

Legionella pneumophila

- A gram-negative rod that causes Legionnaires' disease, a severe pneumonia, and Pontiac fever, a milder illness. The organism is found in aquatic environments and is transmitted through inhalation of contaminated water droplets. Risk factors include age, smoking, and immunosuppression. Diagnosis involves urine antigen testing and culture on BCYE agar. Treatment includes fluoroquinolones or azithromycin. Prevention through water system management is essential. *Legionella* can colonise building water systems, including cooling towers, hot water tanks, and decorative fountains, and outbreaks require identification and decontamination of the environmental source.

Leishmania donovani

- A protozoan parasite that causes visceral leishmaniasis (kala-azar), transmitted by the bite of infected female phlebotomine sandflies. The organism exists as flagellated promastigotes in the sandfly gut and as non-flagellated amastigotes within human macrophages. After inoculation, promastigotes are phagocytosed by macrophages and transform into amastigotes, which multiply intracellularly and disseminate throughout the reticuloendothelial system. Visceral leishmaniasis presents with fever, hepatosplenomegaly, pancytopenia, weight loss, and hypergammaglobulinaemia; it is fatal if untreated. Cutaneous leishmaniasis is caused by other *Leishmania* species (*L. major*, *L. tropica*, *L. mexicana*), presenting as skin ulcers. Diagnosis involves microscopy of tissue smears (amastigotes in macrophages), culture, and PCR. Treatment includes liposomal amphotericin B and miltefosine.

Listeria monocytogenes

- A gram-positive, facultatively anaerobic rod that causes listeriosis, a foodborne infection. The organism is transmitted through contaminated food, particularly deli meats, soft cheeses, and ready-to-eat foods. It can grow at refrigeration temperatures. Listeriosis is most severe in pregnant women, neonates, and immunocompromised patients. The organism crosses the intestinal barrier and can cross the placenta. Diagnosis involves culture and molec-

ular methods. Treatment includes ampicillin or trimethoprim-sulfamethoxazole, and prompt therapy is critical given the high mortality rate of invasive listeriosis, particularly in neonates and immunocompromised patients.

Lysogenic Conversion

– The acquisition of new properties (genes) by a bacterium when a temperate bacteriophage integrates its genome as a prophage and expresses phage-encoded genes. Classic examples: toxin production by *Corynebacterium diphtheriae* (diphtheria toxin), *Clostridium botulinum* (botulinum toxin), *Vibrio cholerae* (cholera toxin), and enteric toxin production by *E. coli* O157:H7 (Shiga toxin); also *Streptococcus pyogenes* (erythrogenic toxins). Phage-encoded factors can increase virulence and are critical to disease pathogenesis. Contrast with transduction as a genetic transfer mechanism.

MacConkey Agar

– A selective and differential medium for culturing gram-negative bacilli. Selectivity: bile salts and crystal violet inhibit gram-positive organisms. Differential: lactose (with neutral red pH indicator)—lactose fermenters produce pink/red colonies (*E. coli*, *Klebsiella*); non-lactose fermenters are colorless (*Salmonella*, *Shigella*, *Proteus*, *Pseudomonas*). Used for stool cultures, urine cultures, and identification of enteric pathogens.

Measles virus

– A negative-sense RNA virus that causes measles, a highly contagious respiratory illness. The virus is transmitted by respiratory droplets and is one of the most infectious pathogens known. Symptoms include fever, cough, coryza, conjunctivitis, and rash. Complications include pneumonia, encephalitis, and subacute sclerosing panencephalitis (SSPE). Diagnosis involves serology and PCR. Treatment is supportive. Prevention through vaccination with MMR vaccine is highly effective. Measles elimination remains a global health goal, but outbreaks continue to occur in communities with suboptimal vaccination coverage, highlighting the importance of maintaining high immunisation rates.

Microbiome

– The collection of microorganisms (bacteria, archaea, fungi, viruses—the microbiota) and their genetic material inhabiting a host's body surfaces, partic-

ularly the gastrointestinal tract. Functions: digestion (fiber fermentation, short-chain fatty acids), vitamin synthesis, immune development and regulation, colonization resistance against pathogens, and metabolic effects. Dysbiosis (microbial imbalance) is associated with obesity, inflammatory bowel disease, *Clostridioides difficile* infection, allergies, and neuropsychiatric conditions. Studied via metagenomic sequencing; therapeutic modulation includes probiotics, fecal microbiota transplantation (FMT).

Mobile genetic elements

– Genetic elements that can move within and between genomes. These include plasmids, transposons, and integrons. Mobile genetic elements can carry antibiotic resistance genes and virulence factors. They facilitate horizontal gene transfer and contribute to the rapid evolution of bacteria. Understanding mobile genetic elements is essential for tracking the spread of resistance and developing new antimicrobial strategies.

MRSA

– Methicillin-resistant *Staphylococcus aureus*, resistant to beta-lactam antibiotics through acquisition of the *mecA* gene encoding PBP2a. MRSA is a major cause of healthcare-associated and community-associated infections. Treatment options include vancomycin, daptomycin, and linezolid. MRSA infections are associated with increased morbidity and mortality. Infection prevention includes hand hygiene, contact precautions, and decolonization protocols. The prevalence of MRSA varies by healthcare setting and geographic region, with some areas reporting endemic levels requiring ongoing surveillance and control efforts.

MRSA decolonization

– Strategies to eliminate MRSA carriage from the nares and skin of colonized individuals. Decolonization reduces the risk of infection and transmission. The most common regimen is intranasal mupirocin for 5 days. Chlorhexidine bathing is used for body decolonization. Decolonization is recommended for preoperative patients, those with recurrent infections, and during outbreaks. Eradication is not always successful, and recolonization can occur. Understanding decolonisation strategies is essential for reducing MRSA infection rates in high-risk populations and for preventing surgical site infections in

colonised patients.

Mucormycosis

– A life-threatening fungal infection caused by Mucorales order fungi including Rhizopus, Mucor, and Rhizomucor species. The infection primarily affects immunocompromised patients, particularly those with uncontrolled diabetes mellitus and hematologic malignancies. The fungi invade blood vessels causing thrombosis and tissue infarction. Rhino-orbital-cerebral mucormycosis is the most common form. Diagnosis involves culture and microscopy showing broad, ribbon-like, pauciseptate hyphae. Treatment involves surgical debridement of necrotic tissue and antifungal therapy with amphotericin B or posaconazole, with early intervention critical for survival given the high mortality rate.

Mumps virus

– A paramyxovirus that causes mumps, a contagious respiratory illness. The virus is transmitted by respiratory droplets. Symptoms include fever, headache, and parotitis. Complications include orchitis, oophoritis, meningitis, and deafness. Diagnosis involves serology and PCR. Treatment is supportive. Prevention through vaccination with MMR vaccine is highly effective. Mumps outbreaks can occur in vaccinated populations, particularly in close-contact settings.

Mycobacterium avium complex

– A group of slowly growing mycobacteria that cause pulmonary disease and disseminated infection in immunocompromised patients. MAC is the most common nontuberculous mycobacterium causing pulmonary disease. Treatment for pulmonary MAC requires a macrolide (azithromycin or clarithromycin) combined with ethambutol and a rifamycin. Disseminated MAC in HIV patients requires macrolide therapy with antiretroviral therapy. The organism is ubiquitous in the environment. Diagnosis requires isolation of MAC from respiratory or tissue specimens, with molecular methods providing faster identification and susceptibility testing guiding treatment selection.

Mycobacterium leprae

– An acid-fast bacillus that causes leprosy (Hansen's disease), a chronic infection affecting the skin and peripheral nerves. The organism is transmitted through respiratory droplets, though the exact mech-

anism is not fully understood. The incubation period is long (2-5 years). Tuberculoid leprosy presents with few, well-defined skin lesions. Lepromatous leprosy presents with widespread skin involvement and nerve damage. Diagnosis involves skin biopsy showing acid-fast bacilli. Treatment includes a multi-drug regimen of dapsone, rifampicin, and clofazimine, with therapy duration ranging from 6 months for paucibacillary disease to 12 months or longer for multibacillary disease.

Mycobacterium tuberculosis

– An acid-fast bacillus that causes tuberculosis, a chronic respiratory infection. The organism is transmitted by respiratory droplets and primarily affects the lungs but can disseminate to other organs. Latent TB infection is asymptomatic and non-transmissible. Active TB presents with cough, haemoptysis, fever, and weight loss. Diagnosis involves sputum smear for acid-fast bacilli, culture, and nucleic acid amplification testing. Treatment requires multi-drug therapy for 6-9 months. Isoniazid, rifampicin, pyrazinamide, and ethambutol are used in the intensive phase, followed by isoniazid and rifampicin in the continuation phase, though the emergence of multidrug-resistant TB requires alternative regimens.

Mycology

– The branch of microbiology that studies fungi, including yeasts, moulds, and mushrooms. Medical mycology focuses on fungal pathogens that cause disease in humans. Fungal infections (mycoses) are classified as superficial, cutaneous, subcutaneous, or systemic. Immunocompromised individuals are at increased risk for invasive fungal infections. Common fungal pathogens include Candida, Aspergillus, Cryptococcus, and endemic fungi. Diagnosis involves culture, microscopy, antigen detection, and molecular methods, with rapid molecular tests improving time to diagnosis and facilitating early targeted therapy.

Neisseria gonorrhoeae

– A gram-negative diplococcus that causes gonorrhea, a sexually transmitted infection. The organism has developed resistance to many antibiotics including fluoroquinolones and macrolides. Current treatment recommendations include dual therapy with ceftriaxone and azithromycin, though monotherapy

with ceftriaxone is now preferred in some guidelines. The organism colonises mucous membranes of the genitourinary tract, pharynx, and rectum. Complications include pelvic inflammatory disease, infertility, ectopic pregnancy, and disseminated infection, and antimicrobial resistance continues to threaten treatment efficacy.

Neisseria meningitidis

– A gram-negative diplococcus that causes meningitis and meningococemia. The organism has a polysaccharide capsule that is the target of conjugate vaccines. Serogroups A, B, C, W, X, and Y cause most disease. Meningitis presents with fever, headache, neck stiffness, and altered mental status. Meningococemia presents with petechial rash and septic shock. Diagnosis involves blood culture and PCR. Treatment includes ceftriaxone or penicillin. Close contacts require prophylaxis with rifampicin, ciprofloxacin, or ceftriaxone to prevent secondary cases following exposure to invasive meningococcal disease.

Normal Flora

– The resident microorganisms (commensals) colonizing body surfaces—skin, oropharynx, gastrointestinal tract, genitourinary tract—without causing disease under normal conditions. They provide protection (colonization resistance, immune priming), synthesis of vitamins, and nutrient metabolism. They can cause disease when displaced (translocation—*Enterococcus*/*E. coli* in peritonitis), in immunocompromised hosts, or via catheters (*Staphylococcus epidermidis*). Sterile sites are normally free of flora (blood, CSF). Disruption by antibiotics leads to superinfection (*C. difficile*).

Norovirus

– A single-stranded RNA virus that is the leading cause of gastroenteritis outbreaks worldwide. The virus is highly contagious and can cause large outbreaks in closed settings including hospitals, cruise ships, and nursing homes. Norovirus causes acute onset of vomiting and diarrhea. Diagnosis is made by PCR or antigen detection in stool. Treatment is supportive with rehydration. The virus is highly stable in the environment and resistant to many disinfectants. There is no vaccine or specific antiviral treatment for norovirus, and management focuses on preventing dehydration through oral or

intravenous rehydration.

Nosocomial Infection

– A hospital-acquired infection developing during or after hospitalization that was not present or incubating at admission, classically defined by onset beyond 48 hours. Common sites are bloodstream, urinary tract, lungs, and surgical wounds; causative organisms are frequently multidrug-resistant, prevented by hand hygiene and stewardship.

Onchocerca volvulus

– A filarial nematode that causes onchocerciasis (river blindness), transmitted by repeated bites of infected blackflies (*Simulium* species) breeding near fast-flowing rivers. Adult worms reside in subcutaneous nodules (onchocercomata), where they can survive for years, producing microfilariae that migrate through the skin and eyes. The host inflammatory response to dying microfilariae causes the pathological manifestations: intense pruritus, dermatitis, depigmentation (leopard skin), lichenification, and, most importantly, progressive ocular damage leading to blindness (keratitis, iridocyclitis, chorioretinitis, optic atrophy). Diagnosis involves skin snip biopsy (microfilariae emerge when skin is placed in saline), slit-lamp examination of the cornea, and PCR. Treatment with ivermectin (annual or semi-annual mass drug administration) kills microfilariae but not adult worms. No safe, effective macrofilaricide currently exists.

Parasitology

– The branch of microbiology that studies parasites, including protozoa, helminths, and ectoparasites. Parasitic infections are a major global health problem, particularly in tropical and subtropical regions. Protozoan parasites include *Plasmodium* (malaria), *Trypanosoma* (sleeping sickness, Chagas disease), and *Leishmania* (leishmaniasis). Helminths include roundworms, tapeworms, and flukes. Diagnosis involves microscopy, serology, and molecular methods. Treatment depends on the parasite and includes antiparasitic agents such as metronidazole, praziquantel, and ivermectin, with prevention focusing on vector control, sanitation, and health education.

Pasteurization

– A heat treatment reducing microbial load in liquids by heating below boiling point to inactivate vegetative pathogens and spoilage organisms while

preserving quality. Methods include LTLT (63°C, 30 min) and HTST (72°C, 15 s), controlling *Mycobacterium tuberculosis*, *Brucella*, *Coxiella*, *Salmonella*, and *Listeria*; heat-resistant spores may survive.

Pathogen

– A microorganism (bacterium, virus, fungus, parasite, prion) capable of causing disease. Classification by site: extracellular (*Streptococcus*, *E. coli*—resisted by antibodies, phagocytes, complement), intracellular (*Mycobacterium*, *Listeria*, viruses—cell-mediated immunity), and facultative/obligate. Virulence depends on adhesins, toxins, capsules, and immune evasion. Opportunistic pathogens (*Candida*, *Pseudomonas*) cause disease in immunocompromised hosts. The outcome of infection reflects the balance between pathogen virulence and host defenses.

PCR (Polymerase Chain Reaction)

– A molecular technique that exponentially amplifies a specific DNA sequence, enabling detection of tiny amounts of nucleic acid. Components: template DNA, two primers, DNA polymerase (Taq), nucleotides, buffer; cycles of denaturation, annealing, extension. Variants: RT-PCR (RNA detection via reverse transcription), real-time/qPCR (quantitative, with fluorescent probes), multiplex PCR, nested PCR. Clinical uses: diagnosis of infections (HIV, hepatitis C, SARS-CoV-2, tuberculosis, viral load), genetic testing, oncology (minimal residual disease), and forensic DNA analysis. Highly sensitive and specific.

Plaque Assay

– A method for quantifying viruses: serial dilutions of a viral suspension are added to a monolayer of host cells, forming zones of cell destruction (plaques), each plaque representing one infectious unit; results expressed as plaque-forming units per mL (PFU/mL). Used to titer viruses, measure neutralizing antibodies (plaque reduction neutralization test—PRNT), and assess antiviral agents. Similar colony counting principles apply to bacterial plaques on lawns.

Plasmids

– Small, circular, extrachromosomal DNA elements that replicate independently of the bacterial chromosome. Plasmids carry non-essential genes that provide selective advantages including antibiotic

resistance, virulence factors, and metabolic capabilities. R-plasmids carry antibiotic resistance genes and can spread resistance between bacteria. F-plasmids carry genes for conjugation. Plasmids are transferred between bacteria through conjugation, transformation, and transduction. They are important vehicles for the dissemination of antibiotic resistance in bacterial populations and are key targets for molecular surveillance of resistance mechanisms.

Poliovirus

– An enterovirus that causes poliomyelitis, a paralytic illness. The virus is transmitted by the fecal-oral route. Most infections are asymptomatic, but a small percentage cause acute flaccid paralysis. The virus attacks motor neurons in the spinal cord. Diagnosis involves stool culture and PCR. There is no specific treatment. Prevention through vaccination with inactivated (Salk) or oral (Sabin) polio vaccine is highly effective. Polio has been eliminated from most countries through vaccination efforts, but transmission continues in Afghanistan and Pakistan, and importation into polio-free areas remains a risk.

Polymicrobial infections

– Infections caused by multiple microbial species. Polymicrobial infections are common in wound infections, intra-abdominal infections, and respiratory infections. The interactions between organisms can be synergistic or antagonistic. Understanding polymicrobial infections is essential for selecting appropriate antimicrobial therapy. Culture and identification of all organisms in a polymicrobial infection can be challenging.

Post-exposure prophylaxis

– The administration of antimicrobial agents after exposure to a pathogen to prevent infection. PEP is used for HIV, hepatitis B, hepatitis C, rabies, and other infections. The timing of PEP is critical, with early administration being most effective. Understanding PEP is essential for managing occupational exposures and outbreaks. PEP guidelines vary by pathogen and exposure type.

Post-Exposure Prophylaxis (PEP)

– The administration of drugs after exposure to a pathogen to prevent infection. Examples: HIV PEP (high-risk sexual, needlestick—tenofovir-based triple therapy started within 72 h, 28-day course), hepatitis B PEP (HBIG + vaccine after exposure), rabies

PEP (vaccine $\pm$ rabies immunoglobulin), tetanus PEP (vaccine $\pm$ TIG), and meningococcal/pertussis prophylaxis. Timing is critical—early initiation maximizes efficacy. Managed in occupational health, sexual health, and travel/emergency settings.

Prion

- An infectious agent composed solely of misfolded protein (PrP^{Sc}) that propagates by converting normal cellular prion protein (PrP^C) into the abnormal conformation; contains no nucleic acid, resistant to standard sterilization (heat, radiation, formaldehyde). Causes transmissible spongiform encephalopathies: Creutzfeldt-Jakob disease (sporadic, genetic, iatrogenic), variant CJD (BSE/mad cow), kuru, Gerstmann-Sträussler-Scheinker, and fatal familial insomnia. Features: rapidly progressive dementia, myoclonus, ataxia; diagnosis: MRI (cortical ribboning), CSF 14-3-3/real-time quaking-induced conversion, brain biopsy. No cure; universally fatal.

Probiotic

- Live microorganisms administered in adequate amounts to confer a health benefit by modulating the microbiome and immune responses. Common organisms include *Lactobacillus*, *Bifidobacterium*, and *Saccharomyces boulardii*, used for prevention of antibiotic-associated and *Clostridioides difficile* diarrhea; effects are strain-specific and generally safe in immunocompetent individuals.

Protozoa

- Single-celled eukaryotes lacking a cell wall, classified by locomotion into amoebae, flagellates, ciliates, and sporozoa. Most exhibit trophozoite and cyst stages, transmitting via water, food, or vectors and causing malaria, toxoplasmosis, leishmaniasis, trypanosomiasis, and amoebiasis, diagnosed by microscopy, antigen tests, serology, and PCR.

Quorum Sensing

- Cell-density-dependent bacterial communication system in which bacteria produce and detect small signaling molecules (autoinducers—acyl-homoserine lactones in gram-negative, autoinducing peptides in gram-positive, AI-2 inter-species) to coordinate population-wide behaviors. Regulates biofilm formation, virulence factor production, bioluminescence, sporulation, and conjugation. When threshold density is reached, target genes are expressed synchronously. Target for novel antimicrobials

(quorum-quenching).

Rabies

- A fatal viral encephalitis caused by rabies virus, transmitted through the bite of infected animals. After inoculation, the virus travels to the CNS via peripheral nerves. Symptoms include hydrophobia, aerophobia, and progressive neurological deterioration. Diagnosis is made by direct fluorescent antibody testing of brain tissue. Post-exposure prophylaxis with rabies vaccine and immunoglobulin is highly effective if administered promptly. There is no specific treatment once symptoms develop. Prevention through pre-exposure vaccination of at-risk individuals and animal control programmes, including vaccination of domestic dogs, is essential for reducing the global burden of rabies.

Respiratory viruses

- Viruses that cause respiratory tract infections. Major respiratory viruses include influenza, respiratory syncytial virus (RSV), parainfluenza virus, adenovirus, and human metapneumovirus. SARS-CoV-2 causes COVID-19. Symptoms range from mild upper respiratory illness to severe pneumonia. Diagnosis involves PCR, rapid antigen testing, and viral culture. Treatment is supportive with antiviral agents available for influenza and SARS-CoV-2. Prevention through vaccination and hygiene is essential. Respiratory viruses are responsible for significant morbidity and mortality worldwide, particularly in young children, older adults, and immunocompromised individuals.

Retrovirus

- An RNA virus that replicates by reverse transcribing its RNA genome into DNA, which is then integrated into the host cell genome. Family Retroviridae. Key enzyme: reverse transcriptase (RNA-dependent DNA polymerase) converts viral RNA into double-stranded DNA; integrase inserts the viral DNA (provirus) into the host chromosome. The provirus is replicated with the host cell genome and transcribed into new viral RNA and proteins. Genera: Lentivirus (HIV-1, HIV-2, SIV), Deltaretrovirus (HTLV-1, HTLV-2), Gammaretrovirus (murine leukemia virus), and Spumavirus (foamy viruses). Clinical significance: HIV causes AIDS (depletion of CD4⁺ T cells, opportunistic infections, malignancies). HTLV-1 causes adult T-

cell leukemia/lymphoma and tropical spastic paraparesis (HAM/TSP). Antiretroviral therapy targets reverse transcriptase (NRTIs, NNRTIs), protease, integrase (integrase strand transfer inhibitors, INSTIs), and entry/fusion. Retroviruses are also used as gene therapy vectors (lentiviral vectors) due to their ability to stably integrate into the host genome.

Rhinovirus

– A genus of non-enveloped, single-stranded positive-sense RNA viruses in the Picornaviridae family, the most common cause of the common cold. Rhinoviruses have >160 identified serotypes, each with distinct surface proteins (viral capsid proteins VP1–VP4) that determine antigenicity and host immune response. Transmission: respiratory droplets and direct contact (contaminated hands, fomites). Incubation: 2–3 days. Clinical: nasal congestion, rhinorrhoea, sore throat, cough, sneezing, headache, and mild malaise—symptoms peak at 2–3 days and resolve in 7–10 days. Rhinoviruses replicate optimally at 33–35°C (cooler temperature of the nasal passages) and bind to ICAM-1 (intercellular adhesion molecule 1—major receptor for most serotypes) or LDL receptor (minor group). Immunity is serotype-specific and short-lived, explaining recurrent infections throughout life. Complications: acute sinusitis, acute otitis media (especially in children), exacerbation of asthma and COPD, and pneumonia (in immunocompromised patients). Diagnosis is clinical; PCR or viral culture is rarely needed. Treatment: supportive (rest, hydration, decongestants, NSAIDs, antihistamines). No specific antiviral is approved; pleconaril (viral capsid binder) is investigational. Prevention: hand hygiene, avoiding close contact with infected individuals.

Rickettsia

– A genus of obligate intracellular Gram-negative coccobacillary bacteria transmitted by arthropod vectors (ticks, fleas, lice, mites). Rickettsia are the causative agents of the spotted fever group (SFG) and typhus group (TG) rickettsioses. SFG: *Rickettsia rickettsii* (Rocky Mountain spotted fever—most severe, mortality 20–30% untreated), *R. conorii* (Mediterranean spotted fever, Boutonneuse fever), *R. akari* (rickettsialpox). TG: *R. prowazekii* (epidemic typhus—louse-borne, associated with war and poverty, mortality 10–60% untreated), *R. ty-*

phi (murine/endemic typhus—flea-borne, milder). Pathophysiology: *Rickettsia* invade vascular endothelial cells, causing systemic vasculitis, increased vascular permeability, and microthrombi. Clinical: fever, severe headache, myalgia, and a characteristic rash (maculopapular, petechial, or eschar at the bite site—tache noire in SFG; centripetal spread in Rocky Mountain spotted fever; macular rash on the trunk spreading centrifugally in typhus). Diagnosis: serology (IFA—gold standard, Weil–Felix test—obsolete), PCR on skin biopsy or blood, immunohistochemistry of skin biopsy. Treatment: doxycycline 100 mg BD for 7–14 days (first-line for all rickettsioses, including children—short course does not cause tooth staining). Chloramphenicol is an alternative (pregnancy, doxycycline allergy). Prevention: tick avoidance, protective clothing, insect repellent (DEET), and prompt tick removal. No vaccine is available for most rickettsioses.

Rotavirus

– A double-stranded RNA virus that is the leading cause of severe gastroenteritis in children worldwide. The virus has a segmented genome and infects enterocytes of the small intestine. Rotavirus causes profuse watery diarrhea, vomiting, and dehydration. Diagnosis is made by antigen detection in stool. Treatment is supportive with oral rehydration. Vaccination is available and recommended for infants. The virus is highly stable in the environment and transmitted through the fecal-oral route, with vaccination being the most effective preventive measure against severe disease.

Rubella virus

– A togavirus that causes rubella (German measles), a mild febrile illness with rash. The virus is transmitted by respiratory droplets. Rubella is most dangerous during pregnancy, causing congenital rubella syndrome (CRS) with deafness, cataracts, and cardiac defects. Diagnosis involves serology. Treatment is supportive. Prevention through vaccination with MMR vaccine is highly effective. Rubella has been eliminated from the Americas through vaccination. Congenital rubella syndrome is a devastating but preventable consequence of maternal rubella infection, and maintaining high vaccination coverage is essential for elimination.

Salmonella

- See Salmonella in Infectious Diseases.

Sarcoptes scabiei

- A mite that causes scabies, a contagious skin infestation transmitted by prolonged skin-to-skin contact. The female mite burrows into the stratum corneum, laying eggs along the burrow, which appears as a greyish, serpiginous line. The life cycle from egg to adult takes approximately 10-14 days. The host immune response to the mites, their eggs, and their feces (scybala) causes intense pruritus, particularly at night. The typical distribution includes interdigital finger webs, wrists, elbows, axillae, waist, and genitalia, sparing the face in adults. Crusted (Norwegian) scabies is a hyperinfestation form occurring in immunocompromised patients, characterized by thick crusted plaques containing thousands of mites. Diagnosis is clinical, confirmed by microscopy of skin scrapings from burrows (identification of mites, eggs, or scybala). Treatment involves permethrin 5% cream or oral ivermectin.

SARS-CoV-2

- A coronavirus belonging to the Coronaviridae family that causes COVID-19. SARS-CoV-2 has a positive-sense single-stranded RNA genome and a spike glycoprotein that mediates attachment to ACE2 receptors. The virus replicates in the cytoplasm using its own RNA-dependent RNA polymerase. Transmission occurs through respiratory droplets and aerosols. The disease ranges from mild respiratory symptoms to severe pneumonia and multi-organ failure. Vaccines targeting the spike protein have been developed and deployed globally, with mRNA, viral vector, and protein subunit platforms demonstrating high efficacy against severe disease. The rapid emergence of variants of concern necessitates ongoing vaccine updates and booster strategies.

Serotype

- A group within a species of microorganisms (or viruses) distinguished by antigenic differences, usually surface antigens (capsular polysaccharides, O/H antigens, viral surface proteins). Examples: pneumococcal serotypes (23 in vaccine), Salmonella serotypes (Typhi, Enteritidis), group A streptococcal M types, influenza hemagglutinin/neuraminidase subtypes, rotavirus G/P types. Serotyping aids epidemiology, outbreak investigation, and vaccine

development; antibody-based typing (agglutination, latex, molecular) is used.

SMART Goals for Antibiotic Stewardship

- Structured, measurable objectives for antimicrobial stewardship programs to optimize antibiotic use and reduce resistance: Specific (target a defined outcome, e.g., reducing fluoroquinolone use), Measurable (quantifiable metrics—defined daily doses, use rates), Achievable (realistic within resources), Relevant (addresses local resistance/audit findings), and Time-bound (deadline for achievement). Part of programs promoting appropriate selection, dosing, duration, de-escalation, and review of antimicrobials.

Spirochete

- A thin, coiled gram-negative bacterium with internal periplasmic flagella conferring corkscrew motility, requiring darkfield or special stains. Pathogenic genera include Treponema (syphilis), Borrelia (Lyme disease, relapsing fever), and Leptospira (leptospirosis), diagnosed mainly by serology and darkfield microscopy.

Spore

- A highly resistant, dormant form of certain bacteria (Bacillus, Clostridium) and fungi, enabling survival under adverse conditions. Bacterial endospores resist heat, desiccation, chemicals, and radiation; germination occurs in favorable conditions. Clinically important: Clostridium difficile, C. botulinum, C. tetani, C. perfringens, Bacillus anthracis. Spore resistance requires specific sterilization methods (autoclaving, ethylene oxide) and explains disease transmission (contaminated soil, food poisoning). Fungal spores are reproductive units causing allergies and opportunistic infection.

Staining

- A laboratory technique applying dyes to microbial smears or tissue sections to visualise microorganisms and reveal structural characteristics. Major methods include Gram, acid-fast, Giemsa, and fluorescent stains, providing rapid presumptive identification from clinical specimens and guiding initial empiric therapy.

Staphylococcus aureus

- A gram-positive, catalase-positive, coagulase-positive coccus that causes a wide range of infections

including skin infections, pneumonia, endocarditis, and osteomyelitis. *S. aureus* produces numerous virulence factors including toxins, enzymes, and surface proteins. MRSA strains carry the *mecA* gene encoding PBP2a. The organism is part of the normal nasal flora. Diagnosis involves culture and coagulase testing. Treatment depends on susceptibility and includes beta-lactams for methicillin-susceptible strains and vancomycin, daptomycin, or linezolid for MRSA, with the choice guided by local epidemiology and patient factors.

Streptococcus agalactiae

- A gram-positive, beta-hemolytic streptococcus (Group B Streptococcus) that is a leading cause of neonatal sepsis, meningitis, and pneumonia. The organism colonises the gastrointestinal and genital tracts. Transmission occurs during birth. Risk factors include prematurity, prolonged rupture of membranes, and maternal colonisation. Screening and intrapartum antibiotic prophylaxis have reduced the incidence of early-onset GBS disease. The organism is identified by Lancefield Group B antigen and hippurate hydrolysis testing, and intrapartum antibiotic prophylaxis has been highly effective in preventing vertical transmission during labour.

Streptococcus pyogenes

- A gram-positive, beta-hemolytic streptococcus (Group A Streptococcus) that causes pharyngitis, skin infections, and post-infectious complications including rheumatic fever and glomerulonephritis. The organism produces streptolysins, erythrogenic toxin, and streptokinase. It is identified by bacitracin sensitivity and Lancefield Group A antigen. Pharyngitis presents with fever, sore throat, and exudates. Skin infections include impetigo and cellulitis. Severe invasive infections include necrotising fasciitis and streptococcal toxic shock syndrome, which require prompt recognition, aggressive surgical debridement, and appropriate antimicrobial therapy.

Sterilization

- A process eliminating all microbial life including spores, achieving a sterility assurance level of at least 10^{-6} . Methods include moist heat autoclaving, dry heat, ethylene oxide, hydrogen peroxide plasma, ionizing radiation, and filtration, essential for critical instruments, implants, pharmaceuticals,

and culture media, and verified by biological and chemical indicators.

Subculture

- The transfer of microorganisms from one culture to fresh culture medium, used to maintain pure cultures, isolate colonies, increase viability, prepare standardized inocula, and perform identification/susceptibility testing. On solid media, subculture aims to obtain isolated single colonies from a mixed or stock culture. Also refers to passage of cell cultures. Serial subculture can cause attenuation of organisms (e.g., live vaccine development).

Superantigen

- A protein that bypasses antigen processing and non-specifically activates large T-cell populations by binding MHC class II and the T-cell receptor V β region, triggering massive cytokine release. Staphylococcal TSST-1 and enterotoxins, and streptococcal pyrogenic exotoxins, cause toxic shock and scarlet fever.

Susceptibility Testing

- Laboratory tests determining the sensitivity of a bacterial isolate to antimicrobials to guide therapy. Methods: disk diffusion (Kirby-Bauer—zone sizes), broth dilution (MIC—minimum inhibitory concentration, MBC—minimum bactericidal concentration), E-test (gradient strips), and automated systems (VITEK). Results reported as susceptible (S), intermediate (I), or resistant (R), interpreted per CLSI/EUCAST breakpoints. Used for clinically significant isolates, especially when resistance is suspected (MRSA, ESBL, VRE, carbapenem-resistant).

Syndrome Surveillance

- The public health monitoring of pre-diagnostic clinical indicators (symptoms, syndromes—fever, rash, GI illness, influenza-like illness) in real time to detect outbreaks, bioterrorism, or emerging infections earlier than laboratory confirmation. Uses data sources: emergency department visits, pharmacy sales, school absenteeism, poison control. Signals trigger investigation and response. Strengths: early warning; limitations: lower specificity, false alarms, and privacy concerns. Complementary to traditional notifiable-disease surveillance.

Toxin

- A biological poison produced by a microorganism,

plant, or animal that damages host tissues at low concentrations. Microbial toxins include bacterial exotoxins (botulinum, tetanus, diphtheria, cholera), gram-negative endotoxin (lipopolysaccharide), and mycotoxins, acting via protein synthesis inhibition, signaling disruption, membrane injury, or immune dysregulation.

Toxoplasma gondii

– An obligate intracellular protozoan parasite that causes toxoplasmosis. The definitive host is the cat (family Felidae), which sheds environmentally resistant oocysts in feces. Humans are intermediate hosts, acquiring infection through ingestion of undercooked meat containing tissue cysts, ingestion of oocysts from contaminated soil or cat litter, or transplacentally from mother to fetus. In immunocompetent individuals, infection is usually asymptomatic or causes a mild flu-like illness with lymphadenopathy. Immunocompromised patients (HIV/AIDS, transplant recipients) are at risk of severe disease, most commonly toxoplasma encephalitis presenting with brain abscesses. Congenital toxoplasmosis can cause chorioretinitis, intracranial calcifications, hydrocephalus, and developmental delay. Diagnosis relies on serology (IgM, IgG) and PCR. Treatment involves pyrimethamine with sulfadiazine and folinic acid.

Transposons

– Mobile genetic elements that can move between different locations within the bacterial genome or between the chromosome and plasmids. Transposons carry genes including antibiotic resistance genes and can facilitate the spread of resistance. They are sometimes called "jumping genes." Transposons insert into DNA through a cut-and-paste or copy-and-paste mechanism. They can inactivate genes by inserting into coding regions. Composite transposons consist of insertion sequences flanking antibiotic resistance genes and facilitate their movement between replicons, contributing to the assembly of multidrug-resistant plasmids.

Travel medicine

– The branch of medicine dealing with health problems associated with international travel. Pre-travel consultation includes vaccinations, malaria prophylaxis, and travel advice. Common travel-related illnesses include traveller's diarrhea, malaria, and

hepatitis A. High-risk destinations require specific vaccinations including yellow fever, typhoid, and Japanese encephalitis. Post-travel evaluation should consider tropical infections in returning travellers. Understanding travel medicine is essential for providing appropriate pre-travel advice, recognising imported diseases, and preventing the international spread of infectious diseases.

Treponema pallidum

– A spirochete that causes syphilis, a sexually transmitted infection. The organism is transmitted through sexual contact or transplacentally (congenital syphilis). Primary syphilis presents with a painless genital ulcer (chancre). Secondary syphilis presents with rash, mucous patches, and condylomata lata. Tertiary syphilis can involve the cardiovascular system, CNS, and skin. Diagnosis involves serology (RPR, FTA-ABS) and darkfield microscopy. Treatment includes penicillin G. Congenital syphilis remains a preventable cause of stillbirth and neonatal morbidity, and routine antenatal screening and treatment of maternal infection are essential for prevention.

Trypanosoma brucei

– A protozoan parasite that causes African trypanosomiasis (sleeping sickness), transmitted by the bite of the tsetse fly (*Glossina* species). Two subspecies cause human disease: *T. b. gambiense* (West African form, chronic, accounting for over 95% of reported cases) and *T. b. rhodesiense* (East African form, acute). The parasite is inoculated during a tsetse fly blood meal, multiplies in the blood and lymphatics (haemolymphatic stage), and eventually crosses the blood-brain barrier to invade the central nervous system (meningoencephalitic stage). The haemolymphatic stage presents with intermittent fever, headache, lymphadenopathy (classic Winterbottom sign – enlarged posterior cervical nodes), and chancre at the bite site. The meningoencephalitic stage causes progressive neurological deterioration, daytime somnolence with nighttime insomnia, ataxia, and coma. Diagnosis involves microscopy of blood and CSF, serology, and PCR. Treatment depends on stage: pentamidine or suramin for early disease; eflornithine or melarsoprol for late-stage CNS involvement.

Vaccine

– A biological preparation that induces protective immunity against a specific pathogen, administered before exposure (prophylactic) or therapeutically (e.g., rabies, some cancer vaccines). Types: live-attenuated (MMR, varicella, rotavirus—strongest, contraindicated in immunocompromised/pregnancy), inactivated (IPV, hepatitis A), subunit (HBV, HPV, acellular pertussis), toxoid (tetanus, diphtheria), conjugate (Hib, pneumococcal), mRNA (COVID-19), and vector-based (J&J, AstraZeneca). Herd immunity protects the unvaccinated. Adjuvants (aluminum salts) enhance immunogenicity; contraindications and adverse events (anaphylaxis, febrile seizures) are monitored.

Varicella-zoster virus

– A herpesvirus that causes chickenpox (varicella) and shingles (herpes zoster). VZV establishes latent infections in dorsal root ganglia and can reactivate decades later. Chickenpox is highly contagious and typically occurs in childhood. Reactivation as shingles causes painful dermatomal vesicular rash. Complications include postherpetic neuralgia and disseminated infection in immunocompromised patients. Antiviral treatment with acyclovir or valacyclovir is effective. Vaccination is available for varicella (chickenpox) and herpes zoster (shingles), with live attenuated vaccines recommended for immunocompetent individuals and recombinant zoster vaccine recommended for adults aged 50 years and older.

Vector-borne diseases

– Diseases transmitted by arthropod vectors including mosquitoes, ticks, fleas, and sandflies. Major vector-borne diseases include malaria, dengue, Zika, chikungunya, Lyme disease, and leishmaniasis. Prevention through vector control, personal protection, and chemoprophylaxis is essential. Climate change is affecting the distribution of vectors and vector-borne diseases. Understanding vector biology is essential for developing control strategies. Vector-borne diseases are a major global health problem, accounting for more than 17% of all infectious diseases and causing over 700,000 deaths annually worldwide, with the burden falling disproportionately on tropical and subtropical regions.

Vibrio cholerae

– A gram-negative, curved rod that causes cholera,

a severe diarrhoeal illness. The organism produces cholera toxin, which causes profuse watery diarrhea (rice-water stools). Transmission occurs through contaminated water and food. The infectious dose varies depending on stomach acidity. Diagnosis involves stool culture on selective media (TCBS agar). Treatment is aggressive fluid replacement with oral rehydration solution or intravenous fluids. Antibiotics (doxycycline, azithromycin) reduce the duration and volume of diarrhea and should be given in moderate to severe cases alongside aggressive fluid resuscitation.

Viral assembly

– The process of packaging newly synthesised viral genomes and proteins into complete virions. Assembly typically occurs in the nucleus or cytoplasm, depending on the virus type. The process involves self-assembly of capsid proteins around the viral genome. Enveloped viruses acquire their envelope from host cell membranes during assembly or release. The efficiency of assembly varies by virus type and can be affected by cellular factors. Assembly is a potential target for antiviral drugs. Understanding viral assembly mechanisms provides opportunities for developing antiviral drugs that disrupt capsid formation or packaging of the viral genome.

Viral attachment

– The initial step in viral infection where viral surface proteins bind to specific receptors on host cells. Attachment determines viral tropism and host range. The viral attachment protein is called the ligand, and the host cell receptor is typically a protein or glycan. Examples include HIV gp120 binding to CD4 receptors, influenza hemagglutinin binding to sialic acid, and SARS-CoV-2 spike protein binding to ACE2 receptors. Attachment can be blocked by neutralising antibodies or receptor antagonists, making viral attachment a key target for vaccines and antiviral therapies.

Viral culture

– The growth of viruses in cell culture for identification and characterisation. Viral culture remains the gold standard for many viral infections. The technique involves inoculating cell lines with clinical specimens and observing for cytopathic effects. Shell vial culture uses centrifugation to enhance viral adsorption and provides faster results. Viral

culture is more sensitive than antigen detection but less sensitive than PCR. Culture is essential for antiviral susceptibility testing. Understanding viral culture techniques remains important for virology laboratories, particularly for antiviral susceptibility testing and the isolation of novel viruses.

Viral cytopathic effects

– Observable changes in host cells caused by viral infection. CPE include cell rounding, detachment, syncytia formation (fusion of infected cells), inclusion bodies, and cell lysis. CPE are used in viral diagnosis and can be observed by light microscopy. Some viruses cause rapid cell lysis while others cause chronic infection without obvious CPE. The mechanism of CPE varies by virus type and can involve viral protein expression, host cell shutoff, or immune-mediated damage. CPE are important for viral diagnosis and quantification, and the pattern of CPE can provide clues to the identity of the infecting virus.

Viral entry

– The process by which viruses cross the host cell membrane to deliver their genome into the cytoplasm. Entry occurs through membrane fusion (enveloped viruses) or endocytosis (enveloped and non-enveloped viruses). For membrane fusion, viral fusion proteins mediate merger of the viral envelope with the host cell membrane. For endocytosis, the virus is internalised in vesicles and then escapes into the cytoplasm. The mechanism of entry varies by virus type. Entry can be blocked by fusion inhibitors such as enfuvirtide for HIV, making viral entry an important target for antiviral drug development.

Viral gastroenteritis

– Gastrointestinal inflammation caused by viral infections. The major causes include rotavirus, norovirus, adenovirus, and astrovirus. Symptoms include watery diarrhea, vomiting, and abdominal cramps. Diagnosis is made by antigen detection or PCR in stool. Treatment is supportive with rehydration. Prevention through vaccination (rotavirus) and hygiene is essential. Viral gastroenteritis is the most common cause of diarrhoeal illness worldwide. Most cases are self-limited but can cause severe dehydration in young children, older adults, and immunocompromised patients, requiring prompt oral or intravenous rehydration therapy.

Viral hepatitis

– Inflammation of the liver caused by viral infections. The major hepatitis viruses include A, B, C, D, and E. Hepatitis A and E are transmitted through the fecal-oral route and cause acute, self-limited infections. Hepatitis B and C are transmitted through blood and sexual contact and can cause chronic infections leading to cirrhosis and hepatocellular carcinoma. Hepatitis D requires hepatitis B for replication. Diagnosis involves serology and viral load testing. Prevention through vaccination is available for hepatitis A and B, and antiviral therapy can effectively control hepatitis B and C, though access to treatment remains limited in many resource-constrained settings.

Viral immune evasion

– Mechanisms by which viruses evade host immune responses. Strategies include antigenic variation, inhibition of interferon signalling, downregulation of MHC molecules, and encoding viral homologues of cytokines. Understanding viral immune evasion is essential for developing effective vaccines and antiviral therapies. Viruses that evade immune responses can establish persistent infections.

Viral latency

– A state in which viral genomes persist in host cells without producing infectious particles. Latent viruses can reactivate under certain conditions including immunosuppression. Herpesviruses establish latent infections in specific cell types (HSV in neurons, EBV in B cells, CMV in myeloid cells). HIV integrates into the host genome as a provirus and can establish latent reservoirs. Latency is a major barrier to viral eradication. Reactivation can cause disease years after initial infection. Understanding viral latency is critical for developing curative therapies for chronic viral infections, as eradication of latent reservoirs remains one of the greatest challenges in virology.

Viral latency mechanisms

– The strategies by which viruses establish and maintain latent infections. Herpesviruses maintain their genomes as episomes in the nucleus. HIV integrates into the host genome as a provirus. Latent viruses express minimal proteins to avoid immune detection. Reactivation can be triggered by immunosuppression, stress, or other stimuli. Understanding latency

mechanisms is essential for developing strategies to cure chronic viral infections. Reactivation can cause disease years after initial infection, and novel therapeutic approaches including latency-reversing agents are being investigated to eliminate persistent viral reservoirs.

Viral pathogenesis

- The mechanisms by which viruses cause disease. Pathogenesis involves attachment, entry, replication, and spread within the host. Viral damage can be direct (cytopathic effects) or indirect (immune-mediated). Direct effects include cell death, altered cell function, and cell transformation. Indirect effects include inflammation, autoimmunity, and cytokine storm. The incubation period, viral load, and host immune response determine disease severity. Some viruses cause acute infections (influenza, norovirus) that are cleared by the immune system, while others establish persistent or latent infections (HIV, HBV, herpesviruses) that require long-term management.

Viral release

- The process by which newly assembled virions exit the host cell to infect other cells. Release occurs through budding (enveloped viruses) or cell lysis (non-enveloped viruses). Budding allows the virus to acquire an envelope from host cell membranes without killing the cell. Cell lysis releases large numbers of virions but destroys the host cell. Neuraminidase inhibitors block release of influenza viruses. Understanding release mechanisms is important for developing antiviral drugs that target the final stages of the viral life cycle, such as neuraminidase inhibitors for influenza and HIV protease inhibitors.

Viral replication

- The process of synthesising new viral genomes and proteins within host cells. The mechanism varies by virus type. DNA viruses typically replicate in the nucleus using host cell DNA polymerases (except poxviruses). RNA viruses typically replicate in the cytoplasm using viral RNA-dependent RNA polymerase. Retroviruses use reverse transcriptase to convert RNA to DNA, which integrates into the host genome. The replication strategy determines susceptibility to antiviral drugs. Viral replication requires exploitation of host cell machinery, and the

specific replication strategy of each virus determines its susceptibility to antiviral agents and its capacity for genetic variation.

Viral replication cycle

- The series of steps by which viruses reproduce within host cells. The cycle includes attachment to host cell receptors, entry through membrane fusion or endocytosis, uncoating of the viral genome, replication of viral nucleic acids, transcription and translation of viral proteins, assembly of new virions, and release by budding or cell lysis. The replication cycle varies by virus type and can take hours to days. Some viruses integrate into the host genome (proviruses) and can establish latent infections that persist for the lifetime of the host, requiring lifelong suppressive therapy.

Viral structure

- The basic components of viral particles (virions). Viruses consist of a nucleic acid genome (DNA or RNA) surrounded by a protein coat called a capsid. Some viruses have an outer lipid envelope derived from host cell membranes. The capsid is composed of structural units called capsomeres. Viral genomes can be single-stranded or double-stranded, linear or circular. Enveloped viruses include influenza, HIV, and hepatitis B. Non-enveloped viruses include adenoviruses, noroviruses, and papillomaviruses, and are generally more resistant to environmental inactivation and disinfectants than enveloped viruses.

Viral uncoating

- The process by which the viral capsid is disassembled to release the viral genome into the host cell cytoplasm. Uncoating occurs after entry and before replication. The mechanism varies by virus type and can involve pH-dependent conformational changes, proteolytic cleavage, or disassembly of capsid proteins. For some viruses, uncoating is triggered by the acidic environment of endosomes. For others, uncoating occurs at the cell surface or in the cytoplasm. Uncoating is essential for viral genome release and is a potential target for antiviral drugs that prevent capsid disassembly.

Virology

- The branch of microbiology concerned with viruses: structure, classification (DNA/RNA, enveloped/nonenveloped, Baltimore scheme), replication, pathogenesis, epidemiology, diagnosis, treat-

ment, and prevention. Diagnostic methods: cell culture, antigen detection, nucleic acid amplification (PCR), and serology (IgM/IgG). Clinical virology addresses infections (respiratory, hepatitis, herpesvirus, HIV, arboviruses, emerging viruses) and their management (antivirals—acyclovir, tenofovir, oseltamivir; vaccines). Fundamental to pandemic response and emerging infectious disease.

Virulence Factor

– A microbial product or trait that enhances pathogenicity and ability to cause disease. Examples: adhesins (pili, fimbriae—*E. coli*, *Neisseria*), toxins (exotoxins, endotoxin), capsules (antiphagocytic—*S. pneumoniae*, *N. meningitidis*, *H. influenzae*), enzymes (coagulase, hyaluronidase, collagenase, IgA protease), iron-acquisition systems (siderophores), immune evasion (antigenic variation—*Neisseria*, influenza), and secretion systems (type III—*Shigella*, *Salmonella*). Virulence factors determine clinical manifestations and are vaccine/therapeutic targets.

VRE

– Vancomycin-resistant *Enterococcus*, resistant to vancomycin through acquisition of *vanA* or *vanB* gene clusters. VRE is a significant cause of healthcare-associated infections, particularly in immunocompromised patients. Treatment options include linezolid, daptomycin, and quinupristin-dalfopristin (for *E. faecium* only). VRE infections are associated with increased mortality and healthcare costs. Infection prevention includes hand hygiene, contact precautions, and environmental cleaning.

Yeast

– Unicellular fungi that reproduce by budding (blastoconidia formation) or fission. The clinically most important yeasts are *Candida* species (*Candida albicans*, *C. glabrata*, *C. parapsilosis*, *C. tropicalis*, *C. krusei*, *C. auris*) and *Cryptococcus* species (*C. neoformans*, *C. gattii*). *Candida albicans* is a commensal of the human gastrointestinal tract, oral cavity, and vagina, but causes opportunistic infections in immunocompromised patients: oral thrush (white, curd-like plaques on the oral mucosa that scrape off, leaving an erythematous base), vulvovaginal candidiasis (vaginal itching, burning, thick white discharge), esophageal candidiasis (dysphagia,

odynophagia, seen in HIV/AIDS with CD4 <100), cutaneous candidiasis (intertrigo in skin folds), and invasive candidiasis/candidaemia (fever, sepsis in ICU patients, neutropenic patients, post-surgery, associated with central venous catheters, treated with echinocandins — caspofungin, micafungin, anidulafungin — or fluconazole for susceptible strains). *Cryptococcus neoformans* is an encapsulated yeast that causes cryptococcal meningitis in immunocompromised patients (HIV/AIDS with CD4 <100, organ transplant recipients). *Saccharomyces cerevisiae* (baker's/brewer's yeast) is rarely pathogenic but can cause fungemia in immunocompromised patients. *Malassezia* species are lipophilic yeasts associated with seborrheic dermatitis, pityriasis versicolor, and folliculitis. Diagnosis: KOH preparation (wet mount of clinical specimen shows budding yeasts with or without pseudohyphae), culture (Sabouraud dextrose agar, CHROMagar *Candida* for species identification), and biochemical tests (germ tube test for *C. albicans*, API 20C, MALDI-TOF). Treatment: topical (clotrimazole, miconazole, nystatin) and systemic (fluconazole, voriconazole, echinocandins, amphotericin B) antifungals, depending on species, site of infection, and susceptibility.

Yersinia pestis

– A gram-negative rod that causes plague, a severe and potentially fatal infection. The organism is transmitted by flea bites or direct contact with infected animals. Bubonic plague presents with painful lymphadenopathy (buboes). Pneumonic plague involves the lungs and is transmitted by respiratory droplets. Septicemic plague causes widespread dissemination. Diagnosis involves culture and PCR. Treatment includes streptomycin, gentamicin, or doxycycline. Plague is a rare but serious infection, with natural reservoirs in rodent populations in various parts of the world, and it remains a public health concern due to its epidemic potential and use as a bioterrorism agent.

Ziehl-Neelsen Stain

– An acid-fast stain retaining carbol fuchsin in waxy mycolic-acid cell walls despite acid-alcohol decolorization, with methylene blue counterstain rendering acid-fast organisms red. Clinically important for *Mycobacterium tuberculosis*, *M. leprae*, *Nocardia*, and *Cryptosporidium* oocysts, it is a rapid initial

sputum test for tuberculosis.

Zika virus

- A positive-sense RNA virus belonging to the Flaviviridae family that causes mild febrile illness. Zika virus is transmitted by Aedes mosquitoes and can also be transmitted sexually. Infection during pregnancy can cause congenital Zika syndrome including microcephaly. Most infections are asymptomatic or mild. Diagnosis is made by PCR or serology. There is no specific treatment or vaccine. Prevention through mosquito control and avoiding travel to endemic areas during pregnancy is important. The virus caused a major epidemic in the Americas in 2015-2016, and surveillance continues to monitor its spread and the risk of congenital infections.

Zoonotic infections

- Infections that are naturally transmitted between animals and humans. Major zoonotic infections include rabies, brucellosis, leptospirosis, and psittacosis. The animal reservoir can be domestic or wild animals. Transmission occurs through direct contact, ingestion, or vectors. Prevention through animal vaccination, food safety, and avoiding animal contact is essential. Zoonotic infections are a significant public health problem worldwide. Understanding zoonotic transmission is essential for preventing emerging infectious diseases, as the majority of newly identified pathogens originate from animal reservoirs.

Chapter 22

Nephrology

Acid-Base Disorder

– Disturbance of the body's acid-base balance, classified by primary disturbance and compensation. Respiratory acidosis: hypoventilation, high PaCO_2 , low pH. Respiratory alkalosis: hyperventilation, low PaCO_2 , high pH. Metabolic acidosis: low HCO_3 , low pH; with high AG (DKA, lactic acidosis, renal failure, toxins) or normal AG (diarrhea, RTA). Metabolic alkalosis: high HCO_3 , high pH; from vomiting, diuretics, or hyperaldosteronism. Mixed disorders: two or more primary disturbances simultaneously. Diagnosis: ABG + electrolytes, using Winters formula for appropriate compensation. Management: treat the underlying cause.

Acute Interstitial Nephritis

– Inflammatory infiltrate in the renal interstitium and tubules most commonly caused by drug reactions including NSAIDs, antibiotics particularly penicillins and cephalosporins, proton pump inhibitors, and diuretics. Also caused by infections and autoimmune diseases. Presents with AKI, low-grade fever, rash, and eosinophilia though the classic triad is present in less than one third of cases. Urinalysis shows white blood cell casts, sterile pyuria, and eosinophiluria. Diagnosis requires renal biopsy showing interstitial inflammation with eosinophils. Management includes discontinuation of the offending drug and supportive care; corticosteroids may accelerate recovery in severe cases.

Acute Kidney Injury

– Rapid decline in renal function over hours to days. KDIGO criteria define AKI as creatinine increase by 0.3 mg/dL within 48 hours, 1.5 times baseline within 7 days, or urine output less than 0.5 mL/kg/hr for 6 hours. Classified into stages 1 through 3. Causes include prerenal, intrinsic renal, and postrenal etiolo-

gies. Early recognition and treatment of reversible causes is essential to prevent permanent kidney damage.

Acute Tubular Necrosis

– Most common cause of intrinsic AKI resulting from ischemic or nephrotoxic injury to tubular epithelial cells. Ischemic ATN develops from prolonged prerenal states. Nephrotoxic ATN results from direct injury by aminoglycosides, amphotericin B, cisplatin, contrast, and myoglobin. Histology shows tubular cell flattening, brush border loss, and intratubular casts. Oliguric phase may be followed by polyuric phase during tubular regeneration. Recovery takes one to three weeks but may be prolonged in severe cases with comorbidities and advanced age.

Alkalosis

– A metabolic (elevated bicarbonate) or respiratory (low PaCO_2) disturbance that raises arterial pH above 7.45. Metabolic alkalosis: vomiting/NG suction (HCl loss), diuretics, mineralocorticoid excess, hypokalemia, and alkali ingestion—compensated by hypoventilation; chloride-responsive vs. chloride-resistant distinguishes causes. Respiratory alkalosis: hyperventilation (anxiety, hypoxia, sepsis, PE, salicylates, pregnancy). Consequences: hypokalemia, hypocalcemia symptoms, arrhythmias, and impaired O_2 delivery (Bohr). Diagnosis: ABG and electrolytes. Management: correct the underlying cause, replace chloride/potassium, avoid over-correction.

Alport Syndrome

– Hereditary nephritis caused by mutations in type four collagen genes leading to progressive sensorineural hearing loss, ocular anomalies, and renal failure. X-linked form from COL4A5 mutations is the most common. Autosomal recessive and dominant forms exist. Kidney biopsy shows characteristic thinning

and lamellation of the glomerular basement membrane on electron microscopy. Hearing loss is bilateral sensorineural and progressive. Ocular findings include anterior lenticonus and retinal flecks. There is no specific cure; management includes ACE inhibitors or angiotensin receptor blockers to reduce proteinuria and slow progression to end-stage renal disease. Hearing aids for hearing loss and genetic counseling are important.

ANCA-Associated Vasculitis

- Small vessel vasculitis with antineutrophil cytoplasmic antibodies causing pauci-immune crescentic GN. GPA features PR3-ANCA with granulomatous inflammation. MPA features MPO-ANCA without granulomas. EGPA features MPO-ANCA with asthma and eosinophilia. Treatment with corticosteroids and rituximab or cyclophosphamide for induction followed by rituximab maintenance.

Anti-GBM Disease

- Autoimmune disease with antibodies against alpha-3 chain of type IV collagen in glomerular and alveolar basement membranes. Presents with crescentic GN and pulmonary hemorrhage (Goodpasture syndrome). Linear IgG deposits on immunofluorescence. Treatment requires emergent plasmapheresis, cyclophosphamide, and corticosteroids. Dramatically improved outcomes compared to near-uniform fatality before these treatments.

Anuria

- Absence of urine output (<100 mL/day). Classification by cause: prerenal (severe hypovolaemia, shock, renal artery occlusion), renal (acute tubular necrosis, acute cortical necrosis, rapidly progressive glomerulonephritis, bilateral renal artery occlusion), and postrenal (bilateral ureteric obstruction, bladder outlet obstruction, urethral obstruction). Anuria is a medical emergency requiring urgent investigation: renal ultrasound to exclude obstruction, bladder catheterisation, urinalysis, serum creatinine, and renal biopsy if indicated. Management: treat underlying cause (fluid resuscitation for prerenal, relief of obstruction for postrenal, dialysis for severe renal failure). Complications: hyperkalaemia, volume overload, uraemia, and metabolic acidosis.

Apparent Mineralocorticoid Excess

- Rare autosomal recessive disorder caused by deficiency of 11-beta-hydroxysteroid dehydrogenase

type 2 normally converting cortisol to cortisone in the collecting duct. Cortisol activates mineralocorticoid receptors causing severe hypertension, hypokalemia, metabolic alkalosis, and low renin with low aldosterone. Presents in childhood with growth retardation. Exogenous liquorice and carbenoxolone inhibit the same enzyme causing an acquired form. Treatment is spironolactone and dexamethasone to suppress ACTH and reduce cortisol production.

ARBs

- Block angiotensin II AT1 receptors providing renoprotection similar to ACE inhibitors. Alternative for ACE inhibitor cough. Do not combine ACE inhibitor and ARB due to increased adverse effects without benefit. Similar renoprotective effects to ACE inhibitors.

Arteriovenous Fistula

- Surgical anastomosis between artery and vein for hemodialysis. Preferred access due to lower infection and thrombosis rates. Radiocephalic at wrist or brachiocephalic at elbow. Takes 6 to 8 weeks to mature. Failure to mature occurs in 30%.

Arteriovenous Graft

- Synthetic conduit connecting artery to vein for dialysis. Used when veins inadequate for fistula. Thrombosis and infection more common than AVF. Can be used earlier than fistula. Dec clotting with thrombectomy or angioplasty.

Atheroembolic Renal Disease

- Cholesterol crystal embolization to kidneys after vascular procedures. AKI with livedo reticularis and peripheral eosinophilia. Renal biopsy shows cholesterol clefts. Poor prognosis with progressive renal failure.

Autosomal Dominant PKD

- Most common hereditary kidney disease affecting 1 in 400 to 1000. PKD1 chromosome 16 more severe with earlier ESRD than PKD2 chromosome 4. Progressive cyst growth causes hypertension, pain, hematuria, infections, and eventually ESRD. Screen family members with ultrasound. Tolvaptan may slow cyst growth. Transplant may require native nephrectomy if very large.

Autosomal Recessive PKD

- Rare childhood disorder from PKHD1 mutation. Bilateral enlarged kidneys with fusiform dilation of collecting ducts. Associated with congenital hepatic

fibrosis. Severe forms cause pulmonary hypoplasia in utero. Variable severity from perinatal lethal to presentation in childhood or adolescence. Management is supportive with treatment of complications.

Bartter Syndrome

– Inherited autosomal recessive disorder of the thick ascending limb of the loop of Henle causing salt wasting, hypokalemic metabolic alkalosis, and hypercalciuria. Results from mutations in genes encoding the NKCC2 transporter or its regulatory subunits. Presents in childhood with failure to thrive, polyuria, and polydipsia. Distinguished from Gitelman syndrome by normal or elevated urinary calcium. Complications include nephrocalcinosis and chronic kidney disease. Treatment includes indomethacin to reduce prostaglandin-mediated salt wasting, and potassium and magnesium supplementation as needed.

Benign Prostatic Hyperplasia (BPH)

– Benign prostatic hyperplasia is a noncancerous enlargement of the prostate gland that commonly affects aging men, compressing the urethra and obstructing urine flow. Symptoms include urinary frequency, urgency, hesitancy, weak stream, and nocturia. Management ranges from watchful waiting and alpha-blockers or 5-alpha-reductase inhibitors to minimally invasive procedures and surgery.

Berger Disease

– Historical name for IgA nephropathy named after Jean Berger who first characterized mesangial IgA deposition in 1968. Characterized by recurrent gross hematuria triggered by mucosal infections with intervals of microscopic hematuria and proteinuria. Generally benign course in most patients but subset progresses to CKD. Complement activation through alternative and lectin pathways plays important pathogenic role leading to investigation of complement-targeted therapies.

BK Virus Nephropathy

– Polyomavirus infection in transplant recipients. Viral cytopathic changes on biopsy. Reduce immunosuppression as primary treatment. Can lead to graft loss. Monitor viral loads in blood for early detection.

Blood Urea Nitrogen

– BUN: serum urea, the end product of protein catabolism, filtered and partially reabsorbed by the tubules. Used with creatinine to assess renal function and volume status. BUN-to-creatinine ratio: high ratio (>20) suggests prerenal azotemia (dehydration, heart failure, GI bleed—blood is protein load) or catabolic states; low ratio suggests intrinsic renal disease, liver disease, or low protein intake. BUN rises with impaired GFR; interpreted with creatinine because urea depends on protein intake and hydration. Not specific to renal disease alone.

Bowman Capsule

– Double-walled epithelial cup surrounding the glomerular capillaries forming the beginning of the nephron. The visceral layer is composed of podocytes whose foot processes interdigitate to form filtration slits. The parietal layer is composed of simple squamous epithelium. Between the layers is Bowman space which collects the glomerular ultrafiltrate. The urinary pole of Bowman capsule is continuous with the proximal tubule. Injury to the podocyte layer results in proteinuria, while damage to the epithelial cells of the parietal layer can contribute to crescent formation in rapidly progressive glomerulonephritis.

Calciophylaxis

– Calcific uremic arteriolopathy causing painful skin necrosis in CKD. Risk factors include warfarin use, elevated calcium-phosphorus product, and obesity. High mortality rate. Treat with sodium thiosulfate, wound care, and discontinuation of warfarin. Avoid calcium-based binders.

Calcitriol and Analogues

– Active vitamin D forms suppressing PTH. Calcitriol, paricalcitol, doxercalciferol. Monitor calcium and phosphorus to avoid hypercalcemia and hyperphosphatemia. Part of CKD-MBD management.

Calcium Stones

– Most common kidney stone type composed of calcium oxalate or calcium phosphate. Risk factors include hypercalciuria, hyperoxaluria, hypocitraturia, and low urine volume. Treat with thiazides for hypercalciuria, dietary modification, and hydration. Potassium citrate for hypocitraturia. Avoid excessive dietary calcium restriction as it increases oxalate absorption.

Central Venous Catheter

- Temporary or tunneled catheter for dialysis. Internal jugular or femoral placement. Tunneled preferred for long-term with lower infection risk. Last resort access with highest complication rates.

Cerebral Salt Wasting

- Renal sodium wasting causing hyponatremia and volume depletion occurring after intracranial surgery or in setting of intracranial disease. Distinguished from SIADH by the presence of volume depletion with negative sodium balance and compensatory elevation of renin and aldosterone. Results from release of natriuretic peptides in response to intracranial disease. Treatment is saline replacement and fludrocortisone to promote sodium retention. Distinguishing from SIADH is critical because fluid restriction is harmful in cerebral salt wasting and may worsen hypovolaemia.

Chronic Allograft Nephropathy

- Progressive transplant kidney function decline over months to years. Interstitial fibrosis and tubular atrophy on histology. Can be immunologic or non-immunologic. Optimize immunosuppression and manage risk factors including hypertension and recurrent disease.

Chronic Kidney Disease

- Progressive loss of kidney function over months to years, defined by $\text{GFR} < 60 \text{ mL/min/1.73 m}^2$ or markers of kidney damage for ≥ 3 months. Stages 1-5 based on GFR. Leading causes: diabetes mellitus (diabetic nephropathy) and hypertension. Complications: anemia, mineral bone disorder, metabolic acidosis, hyperkalemia, cardiovascular disease, and uremia. Management: blood pressure control (ACEi/ARB), glycemic control, dietary protein restriction, phosphate binders, vitamin D analogs, erythropoiesis-stimulating agents, and preparation for renal replacement therapy (dialysis or transplant).

Chronic Kidney Disease (CKD)

- Chronic kidney disease is the progressive loss of kidney function over months to years, typically from diabetes, hypertension, or glomerular diseases. It is staged by estimated glomerular filtration rate and albuminuria, with end-stage renal disease requiring dialysis or transplantation. Early detection and management of underlying causes, blood pressure control, and dietary modifications slow progression.

CKD

- Abbreviation for Chronic Kidney Disease: a progressive loss of kidney function over months to years, defined by a glomerular filtration rate (GFR) less than $60 \text{ mL/min/1.73 m}^2$ or markers of kidney damage (albuminuria, haematuria, structural abnormalities) persisting for at least 3 months. CKD is staged by GFR (G1-G5) and albuminuria category (A1-A3). Major causes include diabetes mellitus and hypertension. Complications: anemia, metabolic acidosis, hyperphosphataemia, hypocalcaemia, secondary hyperparathyroidism, hypertension, and cardiovascular disease. Management: blood pressure control (ACEi/ARB), glycaemic control, dietary protein restriction, phosphate binders, erythropoiesis-stimulating agents, and vitamin D analogues. Progression leads to end-stage renal disease requiring renal replacement therapy (dialysis or transplantation).

CKD-Mineral Bone Disorder

- Systemic disorder of mineral and bone metabolism in CKD. Includes calcium, phosphorus, PTH, and vitamin D abnormalities with vascular calcification and bone disease. Renal osteodystrophy encompasses osteitis fibrosa, osteomalacia, adynamic bone disease, and mixed uremic osteodystrophy. Management includes phosphate binders, active vitamin D analogues, and calcimimetics.

Collecting Duct

- Final segment of the nephron where fine-tuning of urine concentration and composition occurs. Principal cells respond to antidiuretic hormone by inserting aquaporin-2 water channels into the luminal membrane, enabling water reabsorption and urine concentration. Aldosterone acts on principal cells to promote sodium reabsorption and potassium secretion through ENaC channels. Intercalated cells regulate acid-base balance through hydrogen ion secretion and bicarbonate reabsorption. The collecting duct is the site of action of aldosterone, vasopressin, and loop diuretics, and is critical in the regulation of blood pressure, electrolyte balance, and acid-base homeostasis.

Contrast-Induced Nephropathy

- AKI following iodinated contrast. Risk factors include CKD, diabetes, dehydration. Prevent with IV saline hydration. Monitor creatinine 48 to 72

hours post-contrast. Hold metformin in high-risk patients.

Creatinine

– A breakdown product of muscle creatine phosphate produced at a constant rate, filtered by the glomerulus and minimally reabsorbed; serum creatinine is the most used marker of kidney function. Elevated levels indicate reduced GFR (renal impairment), but are affected by muscle mass (low in elderly/malnourished), diet, and drugs (cimetidine, trimethoprim block tubular secretion). Used to estimate GFR (CKD-EPI, Cockcroft-Gault) and stage CKD. Rapid rise indicates acute kidney injury; baseline values aid interpretation. Not sensitive to early GFR loss.

Cystine Stones

– Rare stones from inherited cystinuria with defective cystine transport. Hexagonal crystals on urine microscopy. Difficult to dissolve. Treat with aggressive hydration, urine alkalization to pH greater than 7.5, and thiol agents including tiopronin and D-penicillamine that form soluble complexes with cystine.

Diabetic Nephropathy

– Kidney disease caused by diabetes mellitus, the leading cause of ESRD worldwide. Pathophysiology: hyperglycemia-induced glomerular hyperfiltration, basement membrane thickening, mesangial expansion, and glomerulosclerosis. Presents with progressive albuminuria (microalbuminuria → macroalbuminuria) and declining GFR. Often accompanied by diabetic retinopathy. Screening: annual urine albumin-to-creatinine ratio and serum creatinine in all diabetic patients. Treatment: strict glycemic control, ACE inhibitors or ARBs (renoprotective independent of blood pressure), blood pressure control, and SGLT2 inhibitors for additional renoprotection.

Dialysis Disequilibrium Syndrome

– Neurological complications during hemodialysis in severely uremic patients. Headache, nausea, confusion, seizures, and coma. Results from rapid solute removal causing cerebral edema. Prevent with gradual dialysis initiation and shorter initial sessions.

Distal Tubule

– Segment of the nephron extending from the thick ascending limb of the loop of Henle to the collecting duct. The early distal tubule reabsorbs sodium

and chloride through the NCC cotransporter, which is the target of thiazide diuretics. The late distal tubule and connecting tubule contain principal cells that respond to aldosterone for sodium reabsorption and potassium secretion, and intercalated cells that regulate acid-base balance. The macula densa cells at the junction with the thick ascending limb, where it forms the juxtaglomerular apparatus that regulates renin release, glomerular filtration rate, and renal blood flow through tubuloglomerular feedback.

DMSA Scan

– Nuclear medicine scan evaluating renal cortical function and scarring. Gold standard for detecting pyelonephritis and renal scars in children. Shows photopenic areas corresponding to cortical damage. Important for long-term follow-up of childhood UTI.

Electrolyte Imbalance

– Abnormal serum concentration of electrolytes (sodium, potassium, calcium, magnesium, phosphate, chloride). Hyponatremia (<135 mEq/L): most common electrolyte disorder; causes include SIADH, heart failure, hypovolemia, and polydipsia. Hypernatremia (>145 mEq/L): free water deficit from poor intake, diabetes insipidus, or diuretics. Hypokalemia (<3.5 mEq/L): diuretics, vomiting, diarrhea, hyperaldosteronism. Hyperkalemia (>5.0 mEq/L): renal failure, ACEi, K-sparing diuretics. Hypocalcemia, hypercalcemia, hypomagnesemia, and hypermagnesemia each have specific causes and clinical presentations. Management: correct the underlying cause and replace/remove electrolyte as needed, with careful monitoring to avoid rapid shifts.

End-Stage Renal Disease

– The final stage of chronic kidney disease (CKD stage 5), defined by $\text{GFR} < 15 \text{ mL/min/1.73 m}^2$ or the need for renal replacement therapy. Uremia develops with accumulation of toxins causing nausea, anorexia, pruritus, pericarditis, encephalopathy, and bleeding diathesis. Life-sustaining treatments: hemodialysis, peritoneal dialysis, or kidney transplantation. Management also includes anemia correction, phosphate binding, vitamin D analogs, and blood pressure control.

Erythropoiesis-Stimulating Agents

– Epoetin alfa and darbepoetin alfa stimulate red blood cell production in CKD anemia. Target

hemoglobin 10 to 11.5 g/dL. Avoid exceeding 13 g/dL due to increased cardiovascular risk. Ensure adequate iron stores before initiating therapy.

ESKD

- End-stage kidney disease defined as GFR less than 15 or need for dialysis. Medicare eligibility at GFR less than 15 or on dialysis. Palliative care option for those not wanting renal replacement therapy. Comprehensive advance care planning essential.

Fanconi Syndrome

- Generalized proximal tubular dysfunction with impaired reabsorption of glucose, amino acids, phosphate, uric acid, and bicarbonate. Causes glycosuria, aminoaciduria, phosphaturia, and metabolic acidosis. Associated with proximal RTA. Causes include myeloma, heavy metal toxicity, Wilson disease, and genetic disorders. Treatment addresses underlying cause and replaces depleted substances.

Fibromuscular Dysplasia

- Non-atherosclerotic arterial disease affecting renal arteries. Causes renovascular hypertension in young women. String-of-beads on angiography from medial fibroplasia. Treated with angioplasty alone which is highly effective. Renal function normalizes after successful procedure.

Fluid Overload

- Excess total body fluid due to impaired renal sodium/water excretion or excessive intake, leading to edema, weight gain, hypertension, and pulmonary congestion. Causes: heart failure, renal failure (acute/chronic), nephrotic syndrome, cirrhosis, iatrogenic (IV fluids), and hypoalbuminemia. Features: peripheral/pitting edema, pulmonary edema (dyspnea, crackles), JVP elevation, ascites, effusions, hypertension. Diagnosis: clinical, BNP, chest X-ray (cardiomegaly, congestion), and assessment of volume status. Management: sodium/fluid restriction, diuretics (loop), treat the underlying cause; dialysis for refractory renal overload.

Focal Segmental Glomerulosclerosis

- Pattern of glomerular injury with sclerosis in some focal glomeruli and segments. Can be primary idiopathic or secondary to HIV, obesity, heroin use, or adaptive responses to nephron loss. Histology shows segmental sclerosis with hyalinosis. Less responsive to steroids than minimal change with approximately

50% achieving remission. Secondary FSGS treated by addressing underlying cause. Progressive disease leads to ESRD. Recurrence after transplantation occurs in approximately 30%.

Focal Segmental Glomerulosclerosis (FSGS)

- The most common cause of nephrotic syndrome in African American adults and Hispanic populations. Associated with HIV infection (HIV-associated nephropathy), heroin use, sickle cell disease, massive obesity, interferon therapy, and renal hyperfiltration (solitary kidney). Pathophysiology: podocyte effacement and segmental sclerosis of glomeruli on light microscopy; immunofluorescence is non-specific (IgM/C3 in sclerotic areas). Electron microscopy shows extensive foot process effacement. Clinical features: heavy proteinuria (> 3.5 g/24h), edema, hypoalbuminemia, hypertension, and progressive renal insufficiency. Primary FSGS managed with high-dose oral corticosteroids and immunosuppressants (calcineurin inhibitors). High rate of recurrence after renal transplantation (up to 30-50%).

Frequency

- Increased daytime micturition, typically more than seven episodes per day, distinguished from polyuria (high urine volume) and nocturia (nighttime voiding). Common causes include urinary tract infection, benign prostatic hyperplasia, overactive bladder, and diabetes mellitus. Evaluation comprises urinalysis, post-void residual, and targeted imaging; management is directed at the underlying cause.

Gitelman Syndrome

- Inherited autosomal recessive disorder of the distal convoluted tubule caused by mutations in the NCC sodium-chloride cotransporter gene. Milder than Bartter syndrome typically presenting in adolescence or adulthood. Characterized by hypokalemic metabolic alkalosis, hypomagnesemia, and hypocalcemia distinguishing it from Bartter syndrome. Patients may have muscle cramps, fatigue, and chondrocalcinosis from hypomagnesemia. Treatment includes magnesium and potassium supplementation and NSAIDs or eplerenone for symptom management.

Glomerular Filtration Rate

- Volume of plasma filtered by the glomeruli per

unit time normally ninety to one hundred twenty milliliters per minute per one point seven three square meters body surface area. Estimated by the CKD-EPI equation using serum creatinine, age, sex, and race. Key determinants include renal plasma flow, hydrostatic pressure across the glomerular capillary, and the ultrafiltration coefficient reflecting glomerular permeability and surface area. GFR is the single best indicator of kidney function and decreases progressively with age and nephron loss. The slope of eGFR decline over time is a key prognostic indicator in chronic kidney disease progression.

Glomerulonephritis

- Inflammation of the glomeruli, classified by clinical presentation (nephritic vs. nephrotic syndrome) and histopathology (e.g., IgA nephropathy, post-streptococcal, membranoproliferative, crescentic). Presents with hematuria, proteinuria, hypertension, and reduced GFR. Diagnosis: urinalysis, complement levels, autoantibodies (ANA, ANCA, anti-GBM), and renal biopsy. Treatment depends on etiology: immunosuppression for immune-mediated forms, blood pressure control, and supportive care.

Glomerulus

- Network of capillaries enclosed within Bowman's capsule in the renal corpuscle. Blood is filtered through the glomerular filtration barrier consisting of fenestrated endothelium, glomerular basement membrane, and podocytes with their interdigitating foot processes. The filtration barrier is selectively permeable based on size and charge, normally preventing passage of large proteins and blood cells while allowing free filtration of water, electrolytes, and small solutes. Injury to any component of the filtration barrier results in proteinuria, haematuria, and progressive loss of renal function.

Goodpasture Syndrome

- Anti-GBM disease affecting both kidneys and lungs. Pulmonary hemorrhage with hemoptysis and crescentic GN. Linear IgG deposits on renal biopsy. Emergent plasmapheresis, cyclophosphamide, and steroids. Early treatment essential to prevent irreversible renal and pulmonary damage.

Granular Casts

- Degenerated cellular debris within tubular lumen appearing as coarse or fine-grained structures. Coarse casts represent more acute process, fine casts

indicate chronic degenerative process. Common in acute tubular necrosis reflecting tubular epithelial cell damage. Also seen in chronic kidney disease, nephrotic syndrome, and hypertension. Nonspecific finding of tubular injury.

Hemodialysis

- Extracorporeal blood purification using semipermeable membrane. Three sessions per week for 3 to 4 hours. Requires vascular access with AV fistula preferred. Adequacy assessed by Kt/V greater than 1.4. Complications include hypotension, access infection, and dialyzer reactions.

Hyaline Casts

- Transparent colorless cylindrical structures composed primarily of Tamm-Horsfall protein secreted by the thick ascending limb. Most common type of urine cast. Normal in concentrated urine and after exercise. Increased in dehydration, prerenal states, and volume depletion. Generally benign reflecting increased Tamm-Horsfall concentration or mild tubular dysfunction.

Hydronephrosis

- Dilation of renal collecting system proximal to obstruction. Causes include stones, strictures, malignancy, and BPH. Graded on ultrasound from mild to severe. Prolonged obstruction leads to cortical thinning and renal failure. Bilateral more clinically significant. Urgent decompression required for obstructive uropathy with infection.

Hyperkalemia

- Elevated serum potassium >5.0 mEq/L, a potentially life-threatening electrolyte abnormality. Causes: renal failure (most common), medications (ACE inhibitors, ARBs, potassium-sparing diuretics, NSAIDs), adrenal insufficiency, metabolic acidosis (shift), massive tissue breakdown (rhabdomyolysis, tumor lysis), and excessive intake. ECG changes: peaked T waves, widened QRS, loss of P wave, sine wave pattern leading to VFib/asystole. Management: stabilize myocardium (IV calcium gluconate or chloride), shift K^+ intracellularly (insulin + glucose, albuterol, sodium bicarbonate if acidotic), and remove K^+ (loop diuretics, patiromer, hemodialysis for severe or refractory cases).

Hyperphosphatemia

- Serum phosphate above normal range (>4.5 mg/dL), usually due to impaired renal excretion

(CKD—most common), hypoparathyroidism, tumor lysis syndrome, rhabdomyolysis, or excessive intake/absorbable laxatives. Consequences: secondary hyperparathyroidism, vascular/metastatic calcification, and when combined with hypocalcemia, tetany. Features are mostly from the associated hypocalcemia. Management: dietary phosphate restriction, phosphate binders (calcium, sevelamer, lanthanum), treat the cause; in severe/tumor lysis, consider dialysis. Chronic control is central in CKD-MBD.

Hypertensive Nephropathy

– Kidney damage caused by chronic hypertension, leading to nephrosclerosis (arteriolar hyalinosis and glomerulosclerosis). Presents with slowly progressive proteinuria (usually subnephrotic), hypertension, and gradual decline in kidney function. More common in African American patients. Diagnosis of exclusion. Prevention and treatment: strict blood pressure control, ACE inhibitors/ARBs are renoprotective.

Hypertensive Nephrosclerosis

– Kidney damage from chronic hypertension. Benign form with hyaline arteriolosclerosis. Malignant form with hyperplastic arteriolosclerosis and onion-skinning. Second leading cause of ESRD after diabetes. Tight BP control with ACE inhibitors or ARBs essential to slow progression.

Hypokalemia

– Serum potassium less than 3.5 mEq/L. Causes include gastrointestinal losses from vomiting and diarrhea, renal losses from diuretics, RTA, and hyperaldosteronism, intracellular shift from alkalosis and insulin, and inadequate intake. Clinical manifestations include muscle weakness, cramps, cardiac arrhythmias with characteristic ECG changes including U waves, flattened T waves, and ST depression, and rhabdomyolysis in severe cases. Treatment depends on severity and symptoms ranging from oral potassium supplementation to IV potassium replacement at rates not exceeding ten milliequivalents per hour through a peripheral line or twenty milliequivalents per hour through central access, with continuous ECG monitoring during IV replacement.

IgA Nephropathy

– The most common primary glomerulonephritis

worldwide, characterized by mesangial IgA deposition. Presents with hematuria (macroscopic with mucosal infections, especially upper respiratory), proteinuria, and hypertension. Most common in young adults, with male predominance. Diagnosis: renal biopsy showing mesangial IgA deposits with mesangial proliferation on light microscopy and electron-dense deposits. Prognosis: 30-40% progress to ESRD over 20 years. Risk factors: hypertension, proteinuria >1g/day, impaired GFR, and biopsy findings of fibrosis. Treatment: BP control with ACEi/ARB; fish oil; corticosteroids for progressive disease; immunosuppression reserved for crescentic IgA.

Immunosuppression in Transplant

– Medications to prevent rejection. Induction with thymoglobulin or basiliximab. Maintenance with tacrolimus, mycophenolate, and prednisone. Monitor drug levels and renal function. Calcineurin inhibitor nephrotoxicity is major concern requiring dose optimization.

Intravenous pyelogram

– Also known as IVP or excretory urography, a radiographic imaging study of the urinary tract following intravenous administration of iodinated contrast material. The contrast is filtered by the glomeruli and excreted through the collecting system, allowing sequential imaging of the renal parenchyma, calyces, renal pelvis, ureters, and bladder. Indications include evaluation of hematuria, suspected ureteral obstruction (stones, strictures, tumors), congenital anomalies of the urinary tract, and pre-operative assessment of ureteral anatomy. CT urography has largely replaced IVP in modern practice due to superior sensitivity for small masses and stones without the need for compression.

Intrinsic Renal AKI

– AKI caused by damage to renal parenchyma. Major categories include acute tubular necrosis from ischemic or nephrotoxic injury, acute interstitial nephritis from drug reactions, glomerulonephritis, and vascular causes including thrombotic microangiopathy. FENa typically greater than 2% indicating tubular dysfunction. Urine sediment findings help differentiate specific causes: muddy brown granular casts in ATN, WBC casts in AIN, RBC casts in glomerulonephritis.

Juxtaglomerular Apparatus

– Specialized structure located at the vascular pole of the glomerulus where the distal tubule comes into contact with the afferent arteriole. Composed of macula densa cells in the tubular wall, juxtaglomerular cells in the afferent arteriolar wall that produce renin, and extraglomerular mesangial cells. Senses sodium and chloride delivery through the macula densa and renal perfusion pressure through the juxtaglomerular cells. Regulates renin secretion initiating the renin-angiotensin-aldosterone system and thereby blood pressure, fluid volume, and electrolyte homeostasis.

Kidney and Urinary Health

– Kidney and urinary health encompasses the function of the kidneys, ureters, bladder, and urethra in filtering waste, regulating fluid/electrolyte balance, and eliminating urine. Chronic kidney disease (CKD)—defined by reduced glomerular filtration rate ($\text{GFR} < 60 \text{ mL/min/1.73 m}^2$) or kidney damage for >3 months—affects approximately 15% of adults and is most commonly caused by diabetes and hypertension. Urinary tract infections (UTIs) are bacterial infections (usually *Escherichia coli*) of the bladder (cystitis) or kidney (pyelonephritis) presenting with dysuria, frequency, urgency, and flank pain. Diagnostic evaluation includes serum creatinine/eGFR, urinalysis, urine culture, renal ultrasound, and urodynamic studies. Management emphasizes blood pressure control, glucose management, dietary sodium/protein restriction, avoidance of nephrotoxins, and pharmacotherapy (ACE inhibitors, SGLT2 inhibitors for CKD; antibiotics for UTIs).

Kidney Failure

– The inability of the kidneys to maintain fluid, electrolyte, and acid-base homeostasis and to excrete metabolic wastes. Acute kidney injury (AKI): sudden decline in GFR over hours-days—prerenal (hypoperfusion), intrinsic (acute tubular necrosis, glomerulonephritis, interstitial nephritis), postrenal (obstruction). Chronic kidney disease (CKD): progressive loss >3 months from diabetes, hypertension, glomerulonephritis, polycystic disease; staged by GFR (1-5). Features of uremia: fatigue, pruritus, edema, nausea, anemia, metabolic acidosis, hyperkalemia. Management: treat cause, control

BP/glycemia, RAAS blockade, dietary restriction; dialysis or transplantation in stage 5.

Kidney stones

– Also known as nephrolithiasis or renal calculi, crystalline mineral deposits that form within the renal pelvis or collecting system, affecting approximately 10 percent of the population over a lifetime, with a male-to-female ratio of 2:1 and peak incidence in the 4th-6th decades. Stone types and causes: calcium oxalate stones (most common, 60-70 percent, associated with hypercalciuria, hyperoxaluria, hyperuricosuria, hypocitraturia, and low urine volume), calcium phosphate stones (10-15 percent, associated with renal tubular acidosis, hyperparathyroidism, and urinary tract infections with urease-producing organisms), struvite stones (15-20 percent, associated with urease-producing bacteria such as *Proteus mirabilis*, forming staghorn calculi), uric acid stones (5-10 percent, radiolucent, forming in acidic urine pH less than 5.5, associated with gout, high purine intake, and chronic diarrhea), and cystine stones (1-2 percent, from cystinuria, hexagonal crystals).

Kidney Transplantation

– Best treatment for ESRD with improved survival over dialysis. Living donor superior to deceased donor. Lifelong immunosuppression required. Rejection types include hyperacute, acute, and chronic. Complications include rejection, infection, vascular complications, and recurrent disease.

Kimmelstiel-Wilson Nodules

– Characteristic round eosinophilic nodular mesangial expansions in diabetic nephropathy. Represent advanced mesangial matrix accumulation. Found in peripheral mesangium associated with diffuse mesangial expansion, GBM thickening, and arteriolar hyalinosis. Indicate advanced diabetic nephropathy correlating with heavy proteinuria and declining GFR.

Kt/V

– Dialysis adequacy measure representing the fractional clearance of urea. K is dialyzer clearance, t is treatment time, V is volume of distribution of urea. Target Kt/V greater than 1.4 for thrice-weekly hemodialysis. Urea reduction ratio greater than 70% is alternative adequacy measure.

Liddle Syndrome

– Autosomal dominant condition caused by gain-of-

function mutations in the ENaC sodium channel subunits leading to constitutive sodium reabsorption and potassium secretion in the collecting duct. Presents with severe hypertension, hypokalemia, and metabolic alkalosis occurring in childhood or young adulthood. Aldosterone levels are suppressed reflecting volume expansion. Unlike primary hyperaldosteronism, the hypertension is resistant to spironolactone because the ENaC mutation is constitutively active. Diagnosis is by low aldosterone and low renin levels, which distinguishes it from primary hyperaldosteronism. Treatment is with amiloride or triamterene, which directly block the ENaC channel.

Loop of Henle

- U-shaped tubular segment consisting of a thin descending limb, thin ascending limb, and thick ascending limb. The descending limb is permeable to water but not solutes, allowing water reabsorption into the hypertonic medullary interstitium. The thick ascending limb actively transports sodium, potassium, and chloride through the NKCC2 transporter, which is the target of loop diuretics, and is impermeable to water creating the dilute tubular fluid essential for the countercurrent multiplication system that generates the medullary osmotic gradient essential for urine concentration.

MAG3 Renal Scan

- Nuclear medicine scan evaluating renal function and obstruction. Differential function between kidneys. Non-obstructive dilation does not show delayed excretion. Useful for assessing split renal function and planning surgical interventions.

Malignant Hypertension

- Severely elevated BP greater than 180/120 with end-organ damage. Renal findings include hyperplastic arteriolosclerosis with onion-skinning and fibrinoid necrosis. Treat with IV antihypertensives. Poor prognosis if untreated. May cause AKI, encephalopathy, and retinopathy.

May-Thurner Syndrome

- Compression of left common iliac vein by right common iliac artery causing left lower extremity DVT. Stenting is mainstay of treatment.

Medullary Sponge Kidney

- Congenital malformation characterized by cystic dilatation of the collecting ducts in the renal papillae

predisposing to nephrolithiasis and nephrocalcinosis. Presents with recurrent kidney stones, hematuria, and urinary tract infections. Diagnosis is by CT urogram showing dilated collecting ducts in the renal papillae with or without nephrocalcinosis. Usually bilateral. Treatment is preventive with increased fluid intake and thiazide diuretics for calcium stone prevention. Most patients have no reduction in life expectancy.

Membranoproliferative Glomerulonephritis

- Pattern of glomerular injury with mesangial proliferation and capillary wall thickening creating tram-track appearance on silver stain. Hepatitis C is common cause of immune complex MPGN. C3 glomerulopathy represents complement-mediated disease. Associated with monoclonal gammopathies. Treatment addresses underlying cause with antiviral therapy for hepatitis C and immunosuppression for immune-mediated forms.

Membranous Nephropathy

- A common cause of nephrotic syndrome in adults, characterized by immune complex deposition in the subepithelial space of the glomerular basement membrane. Primary (idiopathic, 75%): associated with anti-PLA2R antibodies (diagnostic). Secondary: infections (hepatitis B, syphilis), autoimmune (SLE), drugs (NSAIDs, penicillamine), and malignancy (lung, colon). Presents with nephrotic-range proteinuria, edema, and normal renal function initially. Diagnosis: renal biopsy with granular IgG staining along capillary loops; anti-PLA2R antibody testing. Treatment: aggressive BP control, RAAS blockade; immunosuppression (cyclophosphamide + steroids, rituximab, or calcineurin inhibitors) for high-risk progressive disease.

Microalbuminuria

- Excretion of 30 to 300 mg of albumin daily undetectable by standard dipstick. Earliest marker of diabetic nephropathy and cardiovascular risk predictor. Detected by urine albumin-to-creatinine ratio on spot specimen. Normal less than 30 mg/g creatinine. Signals early glomerular damage in diabetes warranting RAAS blockade initiation. Screen all diabetics beginning 5 years after type 1 or at diagnosis of type 2 diabetes.

Mineralocorticoid Receptor Antag-

onists

- Spironolactone and eplerenone block aldosterone receptors. Antifibrotic effects in CKD. Finerenone is non-steroidal MRA with cardiovascular and renal benefits in diabetic CKD. Monitor for hyperkalemia especially when combined with RAAS inhibitors.

Minimal Change Disease

- Most common cause of nephrotic syndrome in children accounting for approximately 80%. Glomeruli appear normal on light microscopy but podocyte foot processes are diffusely effaced on electron microscopy. Circulating factors from dysregulated T cells may increase glomerular permeability. Presents with sudden onset nephrotic syndrome. Responds excellently to corticosteroids with complete remission in over 90% of children. Relapse is common but long-term prognosis is excellent.

Myeloma Cast Nephropathy

- Light chain cast formation in tubules causing AKI in multiple myeloma. Friable waxy casts with giant cells. Bence Jones proteinuria. Treat myeloma and consider plasmapheresis to reduce light chain burden.

Nephritic Syndrome

- Characterized by hematuria with dysmorphic RBCs and RBC casts, oliguria, hypertension, and mild proteinuria less than 3.5 g/day. Results from glomerular inflammation increasing permeability to cells and reducing GFR. Hypertension from sodium and water retention. Caused by post-streptococcal GN, IgA nephropathy, lupus nephritis, and anti-GBM disease. Management includes blood pressure control, diuretics, and immunosuppression when indicated.

Nephron

- Functional unit of the kidney comprising the glomerulus, proximal tubule, loop of Henle, distal tubule, and collecting duct. Each kidney contains approximately one million nephrons responsible for filtering blood, reabsorbing solutes and water, and excreting waste to form urine. Nephron loss is irreversible and leads to compensatory hypertrophy of remaining nephrons, which may eventually contribute to progressive kidney disease through glomerular hyperfiltration and hypertension. The juxtamedullary nephrons with long loops of Henle are essential for producing concentrated urine.

Nephrotic Range Proteinuria

- Protein excretion greater than 3.5 g/day or urine protein-to-creatinine ratio greater than 3.5 g/g. Reflects severe glomerular damage with significant protein loss. Degree correlates with severity of injury and risk of complications including thromboembolism, infection, and progression to ESRD. Causes include minimal change disease, FSGS, membranous nephropathy, diabetic nephropathy, and amyloidosis.

Nephrotic Syndrome

- Clinical constellation of heavy proteinuria greater than 3.5 g/day, hypoalbuminemia less than 3.0 g/dL, generalized edema, hyperlipidemia, and lipiduria. Results from increased glomerular permeability to albumin. Reduced oncotic pressure causes fluid extravasation. Hepatic lipoprotein synthesis increases causing hyperlipidemia. Loss of antithrombin III increases thromboembolic risk. Treatment addresses underlying cause with diuretics for edema and RAAS blockade to reduce proteinuria.

Nutcracker Syndrome

- Compression of left renal vein between aorta and SMA causing hematuria and flank pain. Managed conservatively. Stenting or surgery for severe cases.

Oliguria

- Reduced urine output, defined as <400 mL/day or <0.5 mL/kg/hour in adults. Oliguria is an important sign of acute kidney injury (AKI) and prerenal azotaemia. Causes: prerenal (hypovolaemia—hemorrhage, dehydration, sepsis, heart failure, cirrhosis, nephrotic syndrome), renal (acute tubular necrosis—ischemic or nephrotoxic, acute interstitial nephritis, glomerulonephritis, hemolytic uraemic syndrome), and postrenal (obstruction—benign prostatic hyperplasia, stones, tumors, retroperitoneal fibrosis). Assessment: urine output monitoring (hourly in ICU), urinalysis, urine sodium and osmolality, fractional excretion of sodium (FENa <1% suggests prerenal, >2% suggests ATN), serum creatinine and BUN, renal ultrasound (rule out obstruction). Management: treat underlying cause; fluid challenge for prerenal causes, diuretics once volume replete, renal replacement therapy for refractory oliguric AKI with hyperkalemia, acidosis, or uraemia. Anuria (<100 mL/day) suggests complete obstruction, bilateral renal cortical necrosis, or rapidly progressive glomeru-

lonephritis.

Osmotic Demyelination Syndrome

– Demyelinating process affecting the pons and extrapontine regions caused by overly rapid correction of chronic hyponatremia. The brain adapts to chronic hyponatremia by extruding osmoles and when sodium is corrected too quickly water shifts out of brain cells causing osmotic injury to oligodendrocytes. Classically presents with quadriparesis, dysarthria, dysphagia, and locked-in syndrome. Risk increases when sodium correction exceeds ten milliequivalents per liter in twenty-four hours. Prevention is the most important strategy, with a target rate of correction not exceeding eight milliequivalents per litre per day in high-risk patients.

Overactive Bladder

– A clinical syndrome of urinary urgency, usually with frequency and nocturia, with or without urge incontinence, due to detrusor overactivity during filling. Causes: idiopathic (most), neurogenic (stroke, spinal injury, MS, Parkinson), bladder outlet obstruction, and aging; worsened by caffeine and diuretics. Diagnosis: history, urinalysis, voiding diary, urodynamics in refractory cases. Management: bladder training, timed voiding, pelvic floor exercises, antimuscarinics (oxybutynin, tolterodine), beta-3 agonist (mirabegron), and interventional (botulinum toxin, neuromodulation) for refractory disease.

Parathyroidectomy

– Surgical removal of parathyroid glands for refractory secondary hyperparathyroidism unresponsive to medical therapy. Indicated when calcium-phosphorus product persistently elevated despite maximal medical management, symptomatic bone disease, or calciphylaxis. Subtotal or total parathyroidectomy with autotransplantation.

Percutaneous Nephrolithotomy

– Minimally invasive procedure for removal of large renal stones through a nephrostomy tract created in the flank. A tract is created from the skin to the collecting system under fluoroscopic guidance and dilated to allow passage of a nephroscope. Stones are fragmented and removed using ultrasonic lithotripsy, pneumatic lithotripsy, or laser lithotripsy. Preferred for stones greater than two centimeters or staghorn calculi. Success rates exceed ninety percent. Com-

plications include bleeding requiring transfusion, pneumothorax, and infection, which are less common with experienced operators.

Peritoneal Dialysis

– Dialysis using peritoneum as semipermeable membrane. CAPD with four manual exchanges daily or APD using cycler overnight. Advantages include home-based therapy and hemodynamic stability. Complications include peritonitis and catheter infection. Tenckhoff catheter is standard access.

Peritonitis in PD

– Most common complication of peritoneal dialysis. Cloudy effluent, abdominal pain, and fever. Diagnosis by effluent cell count with neutrophils greater than 50/mm³. Treat with intraperitoneal antibiotics. Recurrent peritonitis may require catheter removal.

Phosphate Binders

– Calcium acetate, sevelamer, lanthanum. Bind dietary phosphate in GI tract. Target normal serum phosphorus in CKD-MBD. Avoid calcium-based binders in patients with vascular calcification.

Polyarteritis Nodosa

– Systemic necrotizing vasculitis affecting medium-sized arteries without glomerular involvement or ANCA positivity. Causes aneurysms, stenosis, and occlusion leading to organ ischemia. Renal involvement causes renovascular hypertension. Other manifestations include mononeuritis multiplex and mesenteric ischemia. Angiography shows microaneurysms. Treatment with corticosteroids and cyclophosphamide.

Polycystic Kidney Disease

– Inherited disorder with progressive renal cyst formation. ADPKD most common from PKD1 or PKD2 mutations. Bilateral enlarged kidneys with countless cysts. PKD1 more severe with earlier ESRD. Extrarenal manifestations include hepatic cysts and berry aneurysms. Screen family members. ARPKD is rare childhood disorder from PKHD1 mutation with congenital hepatic fibrosis.

Polycystic Liver Disease

– Dominant polycystic liver disease is an autosomal dominant condition characterized by multiple hepatic cysts that may cause massive hepatomegaly, abdominal pain, and compressive symptoms. Usually associated with autosomal dominant polycystic

kidney disease. Liver function is preserved even with extensive cyst involvement. Diagnosis is by imaging showing multiple hepatic cysts. Treatment of symptoms includes cyst fenestration or liver transplantation for severe cases. Somatostatin analogues may reduce cyst volume and symptoms in selected patients.

Polyuria

– Excessive urine output, defined as >3 L/day in adults. Causes are divided into water diuresis and solute diuresis. Water diuresis: central diabetes insipidus (ADH deficiency), nephrogenic diabetes insipidus (ADH resistance from lithium, hypercalcemia, hypokalemia, genetic causes), and primary polydipsia (psychogenic or dipsogenic). Solute diuresis: hyperglycemia (diabetes mellitus, the most common cause), excess salt intake (IV saline, tube feeding), urea diuresis (high-protein feeding, post-obstruction), and mannitol. Evaluation: 24-hour urine volume, serum and urine osmolality, and water deprivation test. Treatment: address underlying cause; desmopressin (DDAVP) for central DI, thiazides for nephrogenic DI.

Postrenal AKI

– AKI caused by obstruction of urinary outflow at any level from renal tubules to urethra. Causes include BPH, nephrolithiasis, malignancy, retroperitoneal fibrosis, and neurogenic bladder. Bilateral ureteral obstruction or unilateral in a solitary kidney is required for significant impairment. Early diagnosis with renal ultrasound showing hydronephrosis is essential. Prompt decompression with stenting or nephrostomy can restore renal function if initiated before permanent damage.

Post-Streptococcal Glomerulonephritis

– Immune-mediated glomerulonephritis following infection with nephritogenic strains of group A streptococcus typically 1 to 3 weeks after pharyngitis or 3 to 6 weeks after skin infection. Subepithelial humps on electron microscopy representing immune complex deposits. Presents with nephritic syndrome including hematuria, edema, hypertension, and oliguria. Low complement levels (C3) that normalize within 6 to 8 weeks. Supportive management with most patients recovering completely.

Potassium Binders

– Sodium zirconium cyclosilicate and patiromer. Exchange potassium in GI tract for sodium or calcium. Treat chronic hyperkalemia allowing continued RAAS inhibitor use in CKD.

Prerenal Azotemia

– Most common cause of AKI resulting from decreased effective circulating volume. Causes include dehydration, hemorrhage, heart failure, sepsis, and hepatorenal syndrome. Tubular function is intact with urine sodium less than 20 mEq/L and FENa less than 1%. Urine osmolality greater than 500 reflects avid water reabsorption. BUN-to-creatinine ratio typically greater than 20:1. Usually rapidly reversible with restoration of adequate renal perfusion.

Proteinuria

– Excretion of more than 150 mg of protein in urine daily. Causes include glomerular disease, tubulointerstitial disease, overflow proteinuria from multiple myeloma, and functional proteinuria from fever or exercise. Quantification by 24-hour urine or spot protein-to-creatinine ratio. Significant proteinuria warrants evaluation to identify underlying cause and assess for nephrotic syndrome.

Proximal Tubule

– Segment of the nephron extending from Bowman capsule to the loop of Henle with a convoluted proximal straight tubule and convoluted proximal tubule. Responsible for reabsorbing approximately sixty-five percent of filtered sodium, water, bicarbonate, glucose, amino acids, and phosphate through an extensive brush border. Also secretes organic anions, drugs, and toxins. The high metabolic activity of proximal tubular cells makes them particularly vulnerable to ischemic and toxic injury, which is why proximal tubular injury predominates in ischemic acute tubular necrosis. The proximal tubule is also the primary site for renal drug elimination and plays a key role in drug-induced nephrotoxicity.

Pruritus in CKD

– Severe itching in dialysis patients from uremic toxin accumulation, elevated calcium-phosphorus product, and secondary hyperparathyroidism. Difficult to treat. Include phosphate binders, dialysis optimization, gabapentin, and UV phototherapy.

Rapidly Progressive Glomeru-

lonephritis

- Rapid renal function loss over days to weeks with crescent formation on biopsy. Type I anti-GBM with linear deposits. Type II immune complex with granular deposits. Type III pauci-immune with ANCA vasculitis. Requires aggressive immunosuppression. Without treatment progresses rapidly to ESRD.

Rasburicase

- Recombinant urate oxidase enzyme that converts uric acid to allantoin which is more soluble and easily excreted. Highly effective for prevention and treatment of hyperuricemia in tumor lysis syndrome. More effective than allopurinol for established hyperuricemia. Contraindicated in G6PD deficiency due to risk of hemolytic anemia from oxidative stress. Reduces need for dialysis in tumor lysis syndrome.

Renal Anemia

- Normocytic normochromic anemia in CKD from decreased erythropoietin production. Hemoglobin less than 10 g/dL usually requires treatment with ESAs and iron supplementation. Target hemoglobin 10 to 11.5 g/dL. HIF-PHI prolyl hydroxylase inhibitors are newer oral agents for CKD anemia.

Renal Artery Aneurysm

- Dilatation of renal artery, most common visceral artery aneurysm. Usually asymptomatic. Risk of rupture if greater than 2 cm or symptomatic. Treat with surgical or endovascular repair. Higher rupture risk in pregnant women.

Renal Artery Embolism

- Acute occlusion of renal artery from cardiac emboli typically from atrial fibrillation or mural thrombus. Presents with acute flank pain and hematuria. CT angiography shows filling defect. Treat with anticoagulation and possibly thrombolysis or embolectomy if caught early.

Renal Artery Stenosis

- Narrowing of renal artery causing renovascular hypertension. Atherosclerotic most common in elderly at ostium. Fibromuscular dysplasia in young women causing mid-distal stenosis with string-of-beads appearance. Flash pulmonary edema and declining function on ACE inhibitors indicate intervention. Treatment with angioplasty and stenting for atherosclerotic disease.

Renal Biopsy

- Percutaneous needle biopsy for histological diagnosis. Indicated for unexplained AKI, nephrotic syndrome, hematuria with renal involvement, and transplant dysfunction. Ultrasound-guided for accuracy. Complications include bleeding, arteriovenous fistula, and rarely loss of kidney.

Renal Calculi (Kidney Stones)

- See Kidney Stones.

Renal Colic

- Severe, paroxysmal flank pain caused by ureteral obstruction, typically by a kidney stone, with radiation to the groin; often the worst pain experienced. Features: sudden onset, colicky waves, nausea/vomiting, hematuria, urinary urgency/frequency; pain location reflects stone level (upper: flank; mid: lower abdomen; lower: suprapubic/groin). Diagnosis: non-contrast CT (gold standard), ultrasound (hydronephrosis), urinalysis (hematuria). Management: analgesia (NSAIDs first-line), hydration, alpha-blockers (tamsulosin) for distal stones, and urologic intervention (shock wave lithotripsy, ureteroscopy) for large (>10 mm), refractory, or complicated stones; treat infection/obstruction urgently.

Renal Failure

- Decline in kidney function leading to accumulation of waste products (azotemia) and electrolyte abnormalities. Acute kidney injury (AKI): rapid decline over hours to days, potentially reversible. Chronic kidney disease (CKD): progressive decline over months to years. Uremic symptoms: nausea, fatigue, pruritus, confusion, and pericarditis. Management: treat underlying cause, dialysis for severe acute or chronic renal failure, and kidney transplant evaluation.

Renal Leukemia Infiltration

- Kidney involvement by chronic lymphocytic leukemia or other hematological malignancies causing bilateral renomegaly and renal dysfunction. Leukemic cells infiltrate the interstitium and peritubular capillaries. May cause AKI from compression of tubules and vessels or chronic kidney disease. Diagnosis is by renal biopsy showing leukemic infiltrates or non-invasive imaging showing renomegaly. Treatment is directed at the underlying hematological malignancy with chemotherapy.

Renal Osteodystrophy

- Bone disease in CKD including osteitis fibrosa, osteomalacia, adynamic bone disease, and osteoporosis. Results from calcium-phosphate imbalance, secondary hyperparathyroidism, and vitamin D deficiency. Manage with phosphate binders, vitamin D analogues, and parathyroidectomy for refractory hyperparathyroidism.

Renal Tubular Acidosis

- Group of disorders with normal anion gap metabolic acidosis from impaired renal acid excretion or bicarbonate reabsorption. Type 1 distal with impaired H⁺ secretion and urine pH greater than 5.5. Type 2 proximal with impaired bicarbonate reabsorption. Type 4 hyperkalemic from aldosterone deficiency or resistance. Each type has distinct pathophysiology and treatment approach.

Renal Ultrasound

- Noninvasive imaging evaluating kidney size, structure, and hydronephrosis. First-line imaging for CKD evaluation. Shows cortical thickness, echogenicity, and cysts. Resistive index estimates vascular resistance. Essential for evaluating AKI to exclude obstruction.

Rhabdomyolysis and AKI

- Muscle breakdown releases myoglobin causing tubular obstruction and AKI. Elevated CK and dark urine. Aggressive IV hydration is key prevention and treatment. Alkalinize urine to increase myoglobin solubility.

Secondary Hyperparathyroidism

- Compensatory PTH increase in CKD from decreased phosphate excretion, low calcitriol, and hypocalcemia. Leads to renal osteodystrophy and vascular calcification. Managed with dietary phosphorus restriction, phosphate binders, active vitamin D, and calcimimetics. Refractory cases may require parathyroidectomy.

SIADH

- Syndrome of Inappropriate Antidiuretic Hormone secretion characterized by hyponatremia (dilutional) with inappropriately concentrated urine (>100 mOsm/kg) and elevated urine sodium (>40 mEq/L). Euvolemic hyponatremia. Causes: CNS disorders (meningitis, stroke, tumors), pulmonary disorders (pneumonia, TB, small cell lung cancer), medications (SSRIs, carbamazepine, vincristine), and post-operative state. Diagnosis: euvolemia, hypona-

tremia, low BUN/uric acid, normal TSH/cortisol. Treatment: fluid restriction (first-line), demeclocycline, vaptans (tolvaptan), and IV hypertonic saline for severe symptomatic hyponatremia with risk of osmotic demyelination.

Sodium Bicarbonate Therapy

- Alkalinizing agent for metabolic acidosis in CKD. Target serum bicarbonate greater than 22 mEq/L. Slows CKD progression and improves muscle wasting. Dose titrated to serum levels.

Specific Gravity

- Ratio of urine density to water density reflecting solute concentration. Normal 1.005 to 1.030. Less precise than osmolality but faster to measure. Elevated in dehydration, glycosuria, proteinuria, and contrast. Decreased in diabetes insipidus and fluid overload. Affected by molecular weight of dissolved substances and influenced by glucose and protein in urine.

Staghorn Calculus

- A large renal stone that occupies the renal pelvis and extends into at least two calyces, creating a cast of the collecting system. Composition: struvite (magnesium ammonium phosphate), associated with urease-producing bacteria (*Proteus mirabilis*, *Klebsiella*, *Pseudomonas*) causing urinary tract infection. More common in women and patients with recurrent UTIs, neurogenic bladder, or urinary diversion. Presents with recurrent UTIs, flank pain, hematuria, and can lead to renal failure if untreated. Diagnosis: CT demonstrates branching stone filling the collecting system. Treatment: PCNL (percutaneous nephrolithotomy) is the gold standard; complete stone clearance essential to prevent recurrence; antibiotics for concurrent infection.

Struvite Stones

- Infection stones composed of magnesium ammonium phosphate. Form in alkaline urine with urease-producing organisms including *Proteus* and *Klebsiella*. Staghorn calculi fill renal pelvis almost exclusively from *Proteus*. Treatment requires complete stone removal with antibiotics and urinary acidification. High recurrence if infection persists.

Thrombotic Microangiopathy

- Endothelial damage with platelet-rich microthrombi causing MAHA with schistocytes, thrombocytopenia, and organ ischemia. TTP from

ADAMTS13 deficiency treated with plasmapheresis. HUS from Shiga toxin managed supportively. Atypical HUS from complement dysregulation responds to eculizumab.

Tram-Track Appearance

- Histological finding on silver stain of MPGN representing GBM duplication. Results from mesangial cell interposition into capillary wall with new basement membrane formation. Creates double-contour pattern on Jones methenamine silver stain. Indicates chronic glomerular injury with capillary wall remodeling seen in immune complex-mediated and complement-mediated glomerulonephritis.

Uraemia

- The clinical syndrome resulting from accumulation of urea and other nitrogenous waste products in the blood in advanced chronic kidney disease (CKD stage 4-5) and acute kidney injury. Uraemia is characterized by nausea, vomiting, anorexia, fatigue, pruritus, insomnia, hiccups, muscle cramps, neuropathy (restless legs, peripheral neuropathy), pericarditis, platelet dysfunction (prolonged bleeding time, easy bruising), metabolic acidosis, hyperkalemia, hyperphosphatemia, and encephalopathy (lethargy, confusion, asterixis, coma). The uraemic syndrome results from accumulation of many organic waste compounds (middle molecules such as beta-2-microglobulin, advanced glycation end-products, p-cresol). Dialysis reverses most symptoms. Uraemic pericarditis is an indication for urgent dialysis. Uraemic fetor is the characteristic ammonia-like odour of the breath.

Uremia

- The clinical syndrome of advanced renal failure resulting from the accumulation of nitrogenous waste products and toxins (urea, creatinine, others), usually with GFR <15-20 mL/min (CKD stage 5). Features: fatigue, anorexia, nausea/vomiting, pruritus, peripheral neuropathy, restless legs, mental status changes (encephalopathy), pericarditis, bleeding diathesis (platelet dysfunction), and asterixis. Indications for dialysis: uremic symptoms, refractory fluid overload, hyperkalemia, metabolic acidosis, pericarditis, or neuropathy. Managed by renal replacement therapy (hemodialysis, peritoneal dialysis, transplantation).

Uremic Encephalopathy

- Neurological syndrome in severe renal failure. Confusion, asterixis, seizures, coma. Results from uremic toxin accumulation. Diagnosis is clinical in context of advanced renal failure. Emergent dialysis indicated with rapid neurological improvement typically.

Uremic Frost

- Urea crystallization on skin in severe untreated uremia. Rare finding indicating extremely advanced uremia. White crystalline deposits on skin. Indicates immediate need for dialysis. Extremely rare in developed countries due to early detection.

Uremic Pericarditis

- Pericardial inflammation in advanced uremia. Pleuritic chest pain, friction rub, diffuse ST elevation. Indicates need for emergent dialysis. Does not respond to anti-inflammatory therapy. Complications include tamponade. Emergent hemodialysis produces resolution within 2 to 3 weeks.

Uremic Platelet Dysfunction

- Impaired platelet adhesion and aggregation in uremia causing bleeding tendency. Easy bruising, epistaxis, GI bleeding. Improves with dialysis and desmopressin. Cryoprecipitate provides temporary benefit before procedures.

Ureterolithiasis

- The presence of kidney stones (calculi) within the ureter, causing ureteral obstruction and renal colic. Stones form from calcium oxalate/phosphate (most), uric acid, struvite (infection), and cystine. Features: acute severe flank pain radiating to the groin, hematuria, nausea, and vomiting; complications: hydronephrosis, infection (obstructive pyelonephritis—emergency), and renal damage. Diagnosis: non-contrast CT, ultrasound, urinalysis. Management: analgesics (NSAIDs), hydration, alpha-blockers for passage, lithotripsy or ureteroscopy for large/impacted stones; prevention by hydration, diet, and metabolic evaluation for recurrence.

Urethritis

- Inflammation of the urethra, most commonly caused by sexually transmitted infections (*Chlamydia trachomatis*, *Neisseria gonorrhoeae*) or non-infectious causes. Presents with dysuria, urethral discharge, and meatal itching. Diagnosis: urine nucleic acid amplification testing (NAAT). Treatment: empiric antibiotics covering gonorrhea and

chlamydia; partner treatment essential. Complications: epididymitis, prostatitis, pelvic inflammatory disease.

Urgency

– A sudden, compelling desire to urinate that is difficult to defer—a lower urinary tract symptom. Causes: overactive bladder (detrusor overactivity, often idiopathic), urinary tract infection (urgency + dysuria), bladder outlet obstruction (BPH), neurogenic bladder, interstitial cystitis, and pelvic floor disorders. May be accompanied by frequency, nocturia, and urge incontinence. Evaluation: history, urinalysis, voiding diary, urodynamics if refractory. Management: behavioral (bladder training, pelvic floor therapy), antimuscarinics or beta-3 agonists (mirabegron), treat infection, and assess for outlet obstruction.

Uric Acid Nephropathy

– Acute kidney injury from uric acid crystal precipitation in tubules. Occurs in tumor lysis syndrome and severe hyperuricemia. Prevent with hydration and rasburicase. Alkalinization of urine may be harmful as uric acid precipitates at alkaline pH unlike other stone types.

Uric Acid Stones

– 5 to 10% of kidney stones. Form in acidic urine with pH less than 5.5 and hyperuricosuria. Risk factors include gout, high purine diet, and chronic diarrhea. Radiolucent but visible on CT. Treat with urine alkalinization with potassium citrate and allopurinol. May dissolve with alkalinization which is unique among stone types.

Urine Osmolality

– Concentration of urine relative to plasma normally 50 to 1200 mOsm/kg. High greater than 500 in prerenal states reflecting intact concentrating ability. Low less than 350 indicates impaired concentrating ability in diabetes insipidus, chronic kidney disease, and excessive fluid intake. More precise than specific gravity. In prerenal azotemia, intact ADH action produces concentrated urine while damaged tubules cannot concentrate effectively.

Urine Sediment

– Microscopic examination of centrifuged urine providing diagnostic information about renal pathology. Normal findings include few RBCs, WBCs, and hyaline casts. Abnormal findings include RBC casts

indicating glomerulonephritis, WBC casts indicating pyelonephritis or interstitial nephritis, granular casts in ATN, waxy casts in advanced CKD, and oval fat bodies in nephrotic syndrome. Essential component of AKI and proteinuria evaluation.

Urine Sodium

– Concentration of sodium in urine measured in mEq/L. Low less than 20 in prerenal states reflecting avid tubular reabsorption. High greater than 40 in intrinsic renal disease, diuretic use, and salt-wasting nephropathies. Should be interpreted in context of volume status, medications, and concurrent therapies. Key component in differentiating prerenal from intrinsic causes of AKI.

Vitamin D Deficiency

– Serum 25-hydroxyvitamin D less than 20 ng/mL. Causes osteomalacia, secondary hyperparathyroidism, and increased fracture risk. Supplement with cholecalciferol and monitor levels. Important in CKD management as part of mineral bone disorder treatment.

Water Intoxication

– A potentially life-threatening condition of hyponatremia (low serum sodium) caused by excessive water intake exceeding the kidneys' maximal free water excretion capacity (0.7-1 L/hour in healthy adults). Water intoxication dilutes extracellular sodium, causing an osmotic shift of water into cells, particularly dangerous in the brain (cerebral edema). Causes: primary polydipsia (psychogenic polydipsia in psychiatric patients, especially schizophrenia), iatrogenic (excessive hypotonic IV fluids, postoperative, use of hypotonic irrigating solutions during TURP or hysteroscopy → TURP syndrome), infant water intoxication (overdiluted formula, forced water ingestion), exercise-associated hyponatremia (marathon runners, endurance athletes who overhydrate with plain water), and MDMA/ecstasy use (increased thirst + SIADH-like effect). Symptoms: mild (nausea, headache, confusion, lethargy), moderate (vomiting, disorientation, muscle cramps), severe (seizures, coma, brainstem herniation, respiratory arrest). Diagnosis: low serum sodium (<135 mEq/L), low serum osmolality (<275 mOsm/kg), and high urine osmolality. Treatment: mild-moderate — water restriction, observation. Severe: hypertonic saline (3% NaCl, 1-2

mL/kg IV bolus, repeat q10min until symptoms resolve or sodium reaches 120-125 mEq/L). Goal is to raise sodium by 4-6 mEq/L to reverse cerebral edema, avoiding overly rapid correction (>8-10 mEq/L in 24 hours) which risks osmotic demyelination syndrome (central pontine myelinolysis).

Waxy Casts

- Broad refractile cylindrical structures with smooth appearance indicating severe chronic kidney disease. Form from degeneration of granular casts in dilated tubules. Broad diameter reflects formation in dilated collecting ducts. Relatively specific for advanced CKD with significant tubular atrophy. Along with broad casts represent end-stage tubular dysfunction.

Wilms Tumor

- Most common renal malignancy in children. Large abdominal mass. Associated with WAGR, Beckwith-Wiedemann, and hemihypertrophy. Treat with surgery and chemotherapy. Excellent prognosis exceeding 90%.

Chapter 23

Neurology

23.1 Cerebrovascular & Stroke Medicine

Agenesis of the Corpus Callosum

– Complete or partial absence of the corpus callosum, the major commissural fiber bundle connecting the cerebral hemispheres. May be isolated or associated with other CNS anomalies (Dandy-Walker, Chiari, heterotopias) and genetic syndromes (Aicardi, Andermann, acrocallosal syndromes). Presents with a variable phenotype ranging from asymptomatic to developmental delay, intellectual disability, seizures, and impaired interhemispheric transfer. Diagnosis by prenatal or postnatal MRI (coronal and sagittal views show absent cingulate gyrus, colpocephaly, and radial orientation of medial sulci). No specific treatment; management addresses associated conditions.

ALS

– Amyotrophic lateral sclerosis (motor neuron disease, Lou Gehrig disease): a progressive neurodegenerative disease of upper and lower motor neurons, causing muscle weakness, atrophy, fasciculations, spasticity, and eventually respiratory failure. Features: asymmetric limb weakness, dysarthria, dysphagia, hyperreflexia, Babinski sign; sparing of sensation and extraocular movements. Diagnosis: clinical, EMG/NCS (denervation, fasciculations), exclusion of mimics; 5-10 percent familial (SOD1, C9orf72). Management: riluzole (small survival benefit), edaravone, multidisciplinary care, noninvasive ventilation, feeding tube, and symptom control. Median survival 2-5 years from onset.

Amyotrophic Lateral Sclerosis

– Progressive neurodegenerative disorder affecting both upper and lower motor neurons, causing weak-

ness, atrophy, fasciculations, and eventually respiratory failure. Most cases are sporadic (90 percent); 10 percent are familial. Average age of onset 55-60 years. Presents with asymmetric limb weakness (limb-onset) or bulbar symptoms (bulbar-onset: dysarthria, dysphagia). Upper motor neuron signs: spasticity, hyperreflexia, extensor plantar responses. Lower motor neuron signs: weakness, atrophy, fasciculations (visible muscle twitching), and cramps. Diagnosis is clinical (El Escorial criteria) with supportive electrodiagnostic studies (EMG showing active denervation and chronic reinnervation in multiple regions), neuroimaging to exclude mimics, and genetic testing for familial cases. Riluzole, a glutamate antagonist, prolongs survival by approximately 2-3 months by reducing excitotoxicity. Edaravone, a free radical scavenger, may slow functional decline in some patients. Multidisciplinary care including respiratory support (non-invasive ventilation for respiratory insufficiency), nutritional support (percutaneous endoscopic gastrostomy for dysphagia), speech therapy, and palliative care is essential for optimising quality of life. Median survival is 3-5 years from symptom onset, with respiratory failure as the most common cause of death.

Aphasia

– Impairment of language comprehension or production resulting from brain damage, most commonly from stroke affecting the left hemisphere (dominant) language areas. Types: Broca (expressive) aphasia from left inferior frontal gyrus damage—non-fluent speech, intact comprehension, frustration with communication; Wernicke (receptive) aphasia from left superior temporal gyrus damage—fluent but nonsensical speech, impaired comprehension, poor repetition; global aphasia from large left hemisphere stroke involving both anterior and posterior cir-
